## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Julia Larsen

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Richard Johnson

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Dan Schneider

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Kim Olson

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Daniel Henling

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Abby Wagman

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Cheryl Speer

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Susan Palmen

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Audrey Meade

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Ethel Renner

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats. WITH ALL WE KNOW ABOUT HUMAN DESTRUCTION OF OUR ECOSYSTEMS HOW CAN THERE BE SUPPORT FOR THIS IGNORANT PRACTICE?

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre.???!!! But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species.

As experts have stated,

there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the

unmonitored

spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or

conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law,

not cave to the shellfish industry

and allow it to kill valuable species just to grow more commercial shellfish.

I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Gail Barton

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Mark Porter

## Protect Wildlife in Willapa Bay from Imazamox and all other chemicals

Dear Washington Department of Ecology:

The Washington State Department of Ecology (DOE) is complicit in the destruction of our marine waters, in Willapa Bay, Grays Harbor and Puget Sound, by allowing the shellfish industry to spray herbicides for clam and oyster operations as well as allowing 7 miles of PVC plastics per acre into the tidelands for geoduck operations. Whoever is holding hands with the shellfish industry at DOE should be relieved of their duties.

As a shoreline resident of the Puget Sound, we know first hand of the destructions of our bays and marine waters. The shellfish industry is tiny compared to the recreational industry. With the decline of orcas and salmon, it is imperative that all our wildlife and their habitats be protected. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats. Any thought of spraying herbicides into Puget Sound waters should not be considered.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Cheryl Zoe Dailey

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

John Leaver

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Maria Mata

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Terri Inge

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

Adding more poison to the already struggling ecosystem just so that there is more room for one commercial species to grow is totally unacceptable in these times of environmental fragility and ecosystem collapse. Completely irresponsible. The practice must be stopped in favor of other, life- and ecosystem-supportive solutions.

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill critical eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). ## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Beverly Gilyeart

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Cecilia Alvarez

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Jack Stansfield

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Tom Wiitala

Protect Wildlife in Willapa Bay from Imazamox

To the Washington Department of Ecology:

I am a resident of the Pacific Northwest. Our bays and marine waters and the wildlife they support are part of my everyday life; they are vital to me. Their health is my health.

The Department of Ecology simply must not allow the spraying of dangerous herbicides into Puget Sound waters such as Willapa Bay and Grays Harbor.

Washington waterways are home to many rare and special creatures, including salmon and other species of fish, orcas and other unique mammals, and countless other sea creatures, birds and plants. The eelgrass habitats in Willapa Bay and Grays Harbor shelter and feed these Northwest natives. They purify, nourish and stabilize the water flow in those areas so heavily dependent upon a healthy Puget Sound. You know that

For five years, your department has allowed the unmonitored spraying of eelgrass with the herbicide imazamox. This should stop now. Over 60% of Willapa Bay's tidelands are currently used for commercial shellfish aquaculture. Your organization and other state agencies should be monitoring and restricting the impacts to the area from this intensive shellfish cultivation. You should not be allowing synthetic herbicide use to further decimate the protective eelgrass beds.

Pesticides do not belong in Willapa Bay and Grays Harbor. Your department has a duty to protect the environment and water quality under state and federal laws. Do so. Do not allow imazamox or other toxins on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Ann Brock

The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Lynne Roberson

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Robert Burns

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Eric Zimdars

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Carol Stevens

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Kathryn Godwin

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Steven Duke

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

William Custis

Please Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Please Protect Wildlife in Willapa Bay from Imazamox!

Thank you,

Barbara DelGiudice

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Mary DeVany

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Jessie Dameron

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Dean Webb

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

j. eggers

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Patti Harter

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Nancy Kilgore

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Sidney Cohen

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Sandra Wilson

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Monica Miklova

DO NOT allow continued use of Imazamox in Willapa Bay

The use of Imazamox in Willapa Bay MUST stop! It has gone on far too long already and it is absolutely critical for this ecosystem that this practice be ended.

Until recently, I was a homeowner in Pacific County near Tokeland on Willapa Harbor. As such, I have watched with growing concern while DOE allowed the industry to blanket the bay with herbicides in this folly of a fight against Spartina.

The Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to continue.

As you are fully aware, eelgrass of all kinds provide essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. This is absolutely not acceptable. In addition, new research has shown that the tidal flushing of Willapa Bay is not nearly as rapid as previously thought. This means that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species.

Experts have testified that there is NO sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds.

For 5 years, DOE has allowed this reckless spraying of eelgrass with the herbicide imazamox. THIS NEEDS TO STOP NOW!

Pesticides do not belong in Willapa Bay and Grays Harbor. Further, DOE failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying.

I shouldn't have to remind you, but it is your RESPONSIBILITY to protect the environment and water quality under state and federal law, not cater to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish.

It is absolutely critical that Ecology NOT move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor. Please quit doing the industry's bidding and DO YOUR JOB for the citizens of Washington.

Thank you for considering my comments.

Thank you,

Hal Enerson

These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Joyce Lewis

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Billie Mann

Please Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

Everything, the fish, wildlife, humans, water, the entire ecosystem in the Pacific Northwest is being poisoned by spraying herbicides. As a resident of the Pacific Northwest, our bays and marine waters, the wildlife, the water, all of it, matter a great deal to me. This is why I am asking the Department of Ecology to not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. ## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Tim Shannon

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Michael McGinnis

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Hannah Alex-Glasser

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Nancy Gilbert

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Kjersten Gmeiner

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Robert Sanford

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Bonnie Roemer

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Myrna Lipman

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

George Morgan

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

P. Willis

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Mary Jo Wilkins

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Beth Call

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

denese Burrell

Protect Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a Pacific Northwest resident, I know how important our bays, marine waters, and the wildlife they support are. That is why the DOE must forbid spraying dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, orcas, and numerous other fish, birds, and invertebrates. These species and their prey rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But eelgrass, introduced and native, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The DOE acknowledges this but is still proceeding with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this poorly-considered plan should not move forward.

For five years, DOE has allowed the unmonitored spraying of eelgrass with the herbicide Imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed Imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, DOE and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Ecology has a duty to protect the environment and water quality under state and federal law, rather than caving to the shellfish industry and allowing it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for Imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Karen Leifker

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

People live here on the southwest Washington coast and visit here (helping our local economy) because of our pristine nature and natural beauty. Don't destroy our environment for the greed of a few shellfish farmers, who only consider themselves and no one else. The Department of Ecology needs to ban the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

The natural world keeps us alive! We have got to stop casually destroying the natural world every time it is just convenient or just for selfish greed, and start taking care of the natural world before it dies -- and us too. WAKE UP!

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. Ecology means protecting the natural web of life, not destroying it for greed. No more poison spray permits for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Cheryl Peterson

Where are the baseline studies? With what looks like little if any monitoring, how can ecology know how well and with how much herbicide works? There has to be an alternative to herbicide use like mechanical methods. With climate crisis upon us we have to stop our easy fix of just spraying poison! Cancel the permit immediately!

With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Janet Hurd

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

John Dunn

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Tom Hemken

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Ursula Mass

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Phil Pennock

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

THOMAS JOHNSON

Sandra Smith

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

We are in climate breakdown. And still you insist on withdrawing protections for water and species - and humans.

I was born and raised and live In Pacific Northwest. Our bays and marine waters and the wildlife they support are essential for all of us humans. The delicate balance of nature they create is what makes this planet livable for humans

Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor. Such spraying endangers the habitats of endangered species which depend on these waters.

Washington is home to the salmon, the orcas and numerous other fish, birds, and invertebrates, all of which rely on eelgrass habitats in Willapa Bay and Grays Harbor.

Newscience shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will remain in the Bay far longer and with greater potential to impact native eelgrass and other species.

I am calling for a stop to unmonitored spraying of eelgrass with the herbicide imazamox.

Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts.

With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation.

It is time to seriously examine use synthetic herbicide which is decimating eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying.

Ecology has a duty to protect the environment and water quality under both state and federal law.

Do not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish.

I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Catherine Caron

And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

William Shanks

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. PLEASE Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

It is frustrating that our bays and marine waters and the wildlife they support are being destroyed by shellfish farmers in Willapa Bay. These waters are very important to our state and should not be allowed to be poisoned by the shellfish industry. Killing off the eelgrass that many marine species depend on, all to keep the shellfish industry happy is wrong on so many levels and is extremely harmful to this marine ecosystem.

Therefore, I urge the Department of Ecology to not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Who would want to eat a clam that has been sprayed by an herbicide anyway? An idiot maybe. Shellfish are water filterers.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Pamela Rains

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Laura Huddleston

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Doris Raspa

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Nadine Wallace

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Randy Shoemaker

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Diane Smith

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Arlene Roth

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Noel Orr

PLEASE Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

The Department of Ecology MUST NOT allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats. As a Washington resident, I am VERY AWARE of the many threats to our precious environment through the use of herbicides for commercial gain. WHY is the Department of Ecology going forward with unmonitored spraying of eelgrass beds, which provide essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation? SHAME ON YOU!

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. YOU MUST NOT move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Gary Albright

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. ## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

One of the most overlooked, yet critically important issues facing us today is the inadequate protections around our fresh water supplies. As industry polluters contaminate fresh water supplies with relative impunity, as our plumbing infrastructure collapses and as the planet slides toward desertification due to the climate crisis. Americans will find it more and more Americans will find. Water supplies to be more contaminated, more expensive, and there will be even more communities than left without any dependable fresh water supply. Water, is far more vital than oil! As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Rachel Nostrom

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Kristy kriner

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Brenda Michaels

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Linda Thompsen

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Jean Vavrek

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Willapa Bay: nolmazamox

Dear Washington Department of Ecology:

As a native Washingtonian who took a Native Plant Society trip to Willapa Bay, I know the oyster harvest has been variable & regulated by the state. Do NOT allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Eelgrass in Willapa Bay and Grays Harbor are part of the web supporting salmon & orcas, but shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed so they can grow more clams per acre. That hurts the eelgrass functions of nutrient cycling and climate change mitigation.

Don't allow spray eelgrass beds. Experts state there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, use of the herbicide imazamox should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Under state and federal law Ecology must protect

the waters. Since you did not evaluate the effects of imazamox for the last 5 years, deny the permit for Willapa Bay/Grays Harbor. Do the science. Get a handle on what's happening.

Thank you,

Carol Ellis

Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Dorothy Lipsky

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Bethany Eldred

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Toni Lugar

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

## Protect Wildlife in Willapa Bay from Imazamox

Dear Washington Department of Ecology:

As a resident of the Pacific Northwest, our bays and marine waters and the wildlife they support are very important to me. That is why the Department of Ecology must not allow the spraying of dangerous herbicides into Willapa Bay and Grays Harbor to kill valuable eelgrass habitats.

Washington is home to many iconic and endangered species like salmon, the orcas that rely on them, and numerous other fish, birds, and invertebrates. These species, and their prey, rely on eelgrass habitats in Willapa Bay and Grays Harbor (also home to two National Wildlife Refuges). Despite the decline of eelgrass and other seagrasses across the world, as well as the call for eelgrass restoration throughout Washington, shellfish growers successfully got eelgrass (*Z. japonica*) classified as a noxious weed just so they can grow more clams per acre. But introduced eelgrass, like native eelgrass, also provides essential ecosystem functions, like food, shelter, and habitat stabilization for numerous species, as well as nutrient cycling and climate change mitigation. The Department of Ecology acknowledges this, but is still going forward with unmonitored spraying of eelgrass beds. And new science shows that the tidal flushing of Willapa Bay is not nearly as quick as previously assumed, meaning that herbicides sprayed on shellfish beds will stick around in the Bay for longer with greater potential to impact native eelgrass and other species. As experts have stated, there is no sound reason to allow the direct spraying of any native eelgrass, including on commercial clam beds. Given the benefits of introduced eelgrass, the impacts of herbicides to the Bay and other species, and the significant data gaps, this under-studied plan should not move forward.

For five years, Ecology has allowed the unmonitored spraying of eelgrass with the herbicide imazamox, but this should stop now. Because of the permit buffer rules, growers who sprayed imazamox were not required to monitor impacts to eelgrass outside of their plots, so thousands of acres were sprayed over the last five years without any monitoring of off-site impacts. With over 60% of Willapa Bay's tidelands used for commercial shellfish aquaculture for decades, Ecology and other state agencies should be evaluating the impacts to eelgrass from years of this intensive shellfish cultivation, not allowing synthetic herbicide use to further decimate eelgrass.

Pesticides do not belong in Willapa Bay and Grays Harbor, and Ecology failed to evaluate any alternatives that are more environmentally protective than spraying herbicides to kill eelgrass or conduct any review of the impacts on the ground after five years of spraying. Simply put, Ecology has a duty to protect the environment and water quality under state and federal law, not cave to the shellfish industry and allow it to kill valuable species just to grow more commercial shellfish. I urge Ecology not to move forward with a spray permit for imazamox on shellfish beds in Willapa Bay/Grays Harbor.

Thank you,

Gay Thompson
