

Patrick Connelly

Concern: Catastrophic events have occurred in the past IE: Alaska Bay with the S.S. Valdez oil spill then again in the Gulf of Mexico with the oil spill that contaminated the shoreline as well as the oil that remained in the Gulf of Mexico. Both of these events were caused by human error.

This plant will require to have onsite several material components to manufacture the final product that must be shipped to its customers: Should these components under a "worst case" scenario interact what would the results be of that interaction? If violent how far beyond the property lines would the impact be?

What would that impact be if it involves an explosion?

Also given the type of fuel, gases that are involved the production of this material what will the local fire departments, medical personnel be required to be equipped with to try and gain control of the situation at the plant site?

What type of training will be required?

Can this be managed by a Volunteer Fire Department?

What amount of equipment would be required to respond to this event?

Thank you for your time.
