How would the waste treatment center in Newport have to be altered to accommodate the higher volume of people using the facilities? Would it have to be expanded in any way to help with the new workers moving to Newport to work at the smelter? Also, how are you able to know that none of the tailings from the smelting process will leak into the aquifer? With the transportation of raw materials such as coal, there is often dust that comes off it and gets into the ground water. Do you know of any way to prevent these tailings from leaking into the ground water? Or is there evidence of an already constructed solution to this issue?
