Based on the publicly available data, TCE and PCE are present in groundwater at levels that exceed screening levels and pose a risk to vapor intrusion. The previous sub-slab sampling was incredibly limited and did not assess VI risk in all buildings in proximity. TCE in groundwater in close proximity to buildings that include women of child-bearing age may require immediate action based on Ecology and EPA guidance. This is especially concerning for the daycare located just to the southwest of the known contamination, but also applicable for the Skyway Mart and church. If additional sub-slab and indoor sampling has not already been completed to assess VI, the GW concentrations warrant immediate investigation.
