Lowest observed adverse effect level (LOAEL). The lowest tested dose or concentration of a substance which resulted in an observed adverse effect in exposed test organisms when all higher doses or concentrations resulted in the same or more severe effects.

No observed adverse effect level (NOAEL). The highest tested dose or concentration of a substance which resulted in no observed adverse effect in exposed test organisms where higher doses or concentrations resulted in an adverse effect.

Quantitative structure activity relationship (OSAR) or structure activity relationship (SAR). A mathematical relationship between a property (activity) of a chemical and a number of descriptors of the chemical. These descriptors are chemical or physical characteristics obtained experimentally or predicted from the structure of the chemical.

Relative source contribution (RSC). The factor (percentage) used in calculating an HNV or HNC to account for all sources of exposure to a contaminant. The RSC reflects the percent of total exposure which can be attributed to surface water through water intake and fish consumption.

Risk associated dose (RAD). A dose of a known or presumed carcinogenic substance in (mg/kg/day) which, over a lifetime of exposure, is estimated to be associated with a plausible upper bound incremental cancer risk equal to one in 100,000.

Slope factor. Also known as q_1*, slope factor is the incremental rate of cancer development calculated through use of a linearized multistage model or other appropriate model. It is expressed in (mg/kg/day) of exposure to the chemical in question.

Threshold effect. An effect of a substance for which there is a theoretical or empirically established dose or concentration below which the effect does not occur.

Uncertainty factor (UF). One of several numeric factors used in operationally deriving criteria from experimental data to account for the quality or quantity of the available data.

C. Level of Protection. The criteria developed shall provide a level of protection likely to be without appreciable risk of carcinogenic and/or noncarcinogenic effects. Criteria are a function of the level of designated risk or no adverse effect estimation, selection of data and exposure assumptions. Ambient criteria for single carcinogens shall not be set at a level representing a lifetime upper-bound incremental risk greater than one in 100,000 of developing cancer using the hazard assessment techniques and exposure assumptions described herein. Criteria affording protection from noncarcinogenic effects shall be established at levels that, taking into account uncertainties, are considered likely to be without an appreciable risk of adverse human health effects (i.e., acute, subchronic and chronic toxicity including reproductive and developmental effects) during a lifetime of exposure, using the risk assessment techniques and exposure assumptions described herein.

D. Two-tiered Classification. Chemical concentration levels in surface water protective of human health shall be derived based on either a Tier I or Tier II classification. The two Tiers are primarily distinguished by the amount of toxicity data available for deriving the concentration levels and the quantity and quality of data on bioaccumulation.

II. Minimum Data Requirements

The best available toxicity data on the adverse health effects of a chemical and the best data on bioaccumulation factors shall be used when developing human health Tier I criteria or Tier II values. The best available toxicity data shall include data from well ***15407** -conducted epidemiologic and/or animal studies which provide, in the case of carcinogens, an adequate weight of evidence of potential human carcinogenicity and, in the case of noncarcinogens, a dose-response relationship involving critical effects biologically relevant to humans. Such information should be obtained from the EPA Integrated Risk Information System (IRIS) database, the scientific literature, and other informational databases, studies and/or reports containing adverse health effects data of adequate quality for use in this procedure. Strong consideration shall be given to the most currently available guidance provided by IRIS in deriving criteria or values, supplemented with any recent data not incorporated into IRIS. When deviations from IRIS are anticipated or considered necessary, it is strongly recommended that such actions be communicated to the EPA Reference Dose (RfD) and/or the Cancer Risk Assessment Verification Endeavor (CRAVE) workgroup immediately. The best available bioaccumulation data shall include data from field studies and well-conducted laboratory studies.

A. Carcinogens. Tier I criteria and Tier II values shall be derived using the methodologies described in section III.A of this appendix when there is adequate evidence of potential human carcinogenic effects for a chemical. It is strongly recommended that the EPA classification system for chemical carcinogens, which is described in the 1986 EPA Guidelines for Carcinogenic Risk Assessment (U.S. EPA, 1986), or future modifications thereto, be used in determining whether adequate evidence of potential carcinogenic effects exists. Carcinogens are classified, depending on the weight of evidence, as either human carcinogens, probable human carcinogens, or possible human carcinogens. The human evidence is considered inadequate and therefore the chemical cannot be classified as a human carcinogen, if one of two conditions exists: (a) there are few pertinent data, or (b) the available studies, while showing evidence of association, do not exclude chance, bias, or confounding and therefore a casual interpretation is not credible. The animal evidence is considered inadequate, and therefore the chemical cannot

be classified as a probable or possible human carcinogen, when, because of major qualitative or quantitative limitations, the evidence cannot be interpreted as showing either the presence or absence of a carcinogenic effect.

Chemicals are described as “human carcinogens” when there is sufficient evidence from epidemiological studies to support a causal association between exposure to the chemicals and cancer. Chemicals described as “probable human carcinogens” include chemicals for which the weight of evidence of human carcinogenicity based on epidemiological studies is limited. Limited human evidence is that which indicates that a causal interpretation is credible, but that alternative explanations, such as chance, bias, or confounding, cannot adequately be excluded. Probable human carcinogens are also agents for which there is sufficient evidence from animal studies and for which there is inadequate evidence or no data from epidemiologic studies. Sufficient animal evidence is data which indicates that there is an increased incidence of malignant tumors or combined malignant and benign tumors: (a) in multiple species or strains; (b) in multiple experiments (e.g., with different routes of administration or using different dose levels); or (c) to an unusual degree in a single experiment with regard to high incidence, unusual site or type of tumor, or early age at onset. Additional evidence may be provided by data on dose-response effects, as well as information from short-term tests (such as mutagenicity/genotoxicity tests which help determine whether the chemical interacts directly with DNA) or on chemical structure, metabolism or mode of action.

“Possible human carcinogens” are chemicals with limited evidence of carcinogenicity in animals in the absence of human data. Limited animal evidence is defined as data which suggests a carcinogenic effect but are limited because: (a) The studies involve a single species, strain, or experiment and do not meet criteria for sufficient evidence (see preceding paragraph); or (b) the experiments are restricted by inadequate dosage levels, inadequate duration of exposure to the agent, inadequate period of follow-up, poor survival, too few animals, or inadequate reporting; or (c) the studies indicate an increase in the incidence of benign tumors only. More specifically, this group can include a wide variety of evidence, e.g., (a) a malignant tumor response in a single well-conducted experiment that does not meet conditions for sufficient evidence, (b) tumor response of marginal statistical significance in studies having inadequate design or reporting, (c) benign but not malignant tumors with an agent showing no response in a variety of short-term tests for mutagenicity, and (d) response of marginal statistical significance in a tissue known to have a high or variable background rate.

1. Tier I: Weight of evidence of potential human carcinogenic effects sufficient to derive a Tier I HCC shall generally include human carcinogens, probable human carcinogens and can include, on a case-by-case basis, possible human carcinogens if studies have been well-conducted albeit based on limited evidence, when compared to studies used in classifying human and probable human carcinogens. The decision to use data on a possible human carcinogen for deriving Tier I criteria shall be a case-by-case determination. In determining whether to derive a Tier I HCC, additional evidence that shall be considered includes but is not limited to available information on mode of action, such as mutagenicity/genotoxicity (determinations of whether the chemical interacts directly with DNA), structure activity, and metabolism.

2. Tier II: Weight of evidence of possible human carcinogenic effects sufficient to derive a Tier II human cancer value shall include those possible human carcinogens for which there are at a minimum, data sufficient for quantitative risk assessment, but for which data are inadequate for Tier I criterion development due to a tumor response of marginal statistical significance or inability to derive a strong dose-response relationship. In determining whether to derive Tier II human cancer values, additional evidence that shall be considered includes but is not limited to available information on mode of action such as mutagenicity/ genotoxicity (determinations of whether the chemical interacts directly with DNA), structure activity and metabolism. As with the use of data on possible human carcinogens in developing Tier I criteria, the decision to use data on possible human carcinogens to derive Tier II values shall be made on a case-by-case basis.

B. Noncarcinogens. All available toxicity data shall be evaluated considering the full range of possible health effects of a chemical, i.e., acute/subacute, chronic/subchronic and reproductive/developmental effects, in order to best describe the dose-response relationship of the chemical, and to calculate human noncancer criteria and values which will protect against the most sensitive endpoint(s) of toxicity. Although it is desirable to have an extensive database which considers a wide range of possible adverse effects, this type of data exists for a very limited number of chemicals. For many others, there is a range in quality

and quantity of data available. To assure minimum reliability of criteria and values, it is necessary to establish a minimum database with which to develop Tier I criteria or Tier II values. The following represent the minimum data sets necessary for this procedure.

1. Tier I: The minimum data set sufficient to derive a Tier I human HNC shall include at least one well-conducted epidemiologic study or animal study. A well-conducted epidemiologic study for a Tier I HNC must quantify exposure level(s) and demonstrate positive association between exposure to a chemical and adverse effect(s) in humans. A well-conducted study in animals must demonstrate a dose response relationship involving one or more critical effect(s) biologically relevant to humans. (For example, study results from an animal whose pharmacokinetics and toxicokinetics match those of a human would be considered most biologically relevant.) Ideally, the duration of a study should span multiple generations of exposed test species or at least a major portion of the lifespan of one generation. This type of data is currently very limited. By the use of uncertainty adjustments, shorter term studies (such as 90-day subchronic studies) with evaluation of more limited effect(s) may be used to extrapolate to longer exposures or to account for a variety of adverse effects. For Tier I criteria developed pursuant to this procedure, such a limited study must be conducted for at least 90 days in rodents or 10 percent of the lifespan of other appropriate test species and demonstrate a no observable adverse effect level (NOAEL). Chronic studies of one year or longer in rodents or 50 percent of the lifespan or greater in other appropriate test species that demonstrate a lowest observable adverse effect level (LOAEL) may be sufficient for use in Tier I criterion derivation if the effects observed at the LOAEL were relatively mild and reversible as compared to ***15408** effects at higher doses. This does not preclude the use of a LOAEL from a study (of chronic duration) with only one or two doses if the effects observed appear minimal when compared to effect levels observed at higher doses in other studies.

2. Tier II: When the minimum data for deriving Tier I criteria are not available to meet the Tier I data requirements, a more limited database may be considered for deriving Tier II values. As with Tier I criteria, all available data shall be considered and ideally should address a range of adverse health effects with exposure over a substantial portion of the lifespan (or multiple generations) of the test species. When such data are lacking it may be necessary to rely on less extensive data in order to establish a Tier II value. With the use of appropriate uncertainty factors to account for a less extensive database, the minimum data sufficient to derive a Tier II value shall include a NOAEL from at least one well-conducted short-term repeated dose study. This study shall be of at least 28 days duration, in animals demonstrating a dose-response, and involving effects biologically relevant to humans. Data from studies of longer duration (greater than 28 days) and LOAELs from such studies (greater than 28 days) may be more appropriate in some cases for derivation of Tier II values. Use of a LOAEL should be based on consideration of the following information: severity of effect, quality of the study and duration of the study.

C. Bioaccumulation factors (BAFs).

1. Tier I for Carcinogens and Noncarcinogens: To be considered a Tier I cancer or noncancer human health criterion, along with satisfying the minimum toxicity data requirements of sections II.A.1 and II.B.1 of this appendix, a chemical must have the following minimum bioaccumulation data. For all organic chemicals either: (a) a field-measured BAF; (b) a BAF derived using the BSAF methodology; or (c) a chemical with a BAF less than 125 regardless of how the BAF was derived. For all inorganic chemicals, including organometals such as mercury, either: (a) a field-measured BAF or (b) a laboratory-measured BCF.

2. Tier II for Carcinogens and Noncarcinogens: A chemical is considered a Tier II cancer or noncancer human health value if it does not meet either the minimum toxicity data requirements of sections II.A.1 and II.B.1 of this appendix or the minimum bioaccumulation data requirements of section II.C.1 of this appendix.

III. Principles for Development of Tier I Criteria or Tier II Values

The fundamental components of the procedure to calculate Tier I criteria or Tier II values are the same. However, certain of the aspects of the procedure designed to account for short-duration studies or other limitations in data are more likely to be relevant in deriving Tier II values than Tier I criteria.

A. Carcinogens.

1. A non-threshold mechanism of carcinogenesis shall be assumed unless biological data adequately demonstrate the existence of a threshold on a chemical-specific basis.

2. All appropriate human epidemiologic data and animal cancer bioassay data shall be considered. Data specific to an environmentally appropriate route of exposure shall be used. Oral exposure should be used preferentially over dermal and inhalation since, in most cases, the exposure routes of greatest concern are fish consumption and drinking water/incidental ingestion. The risk associated dose shall be set at a level corresponding to an incremental cancer risk of one in 100,000. If acceptable human epidemiologic data are available for a chemical, it shall be used to derive the risk associated dose. If acceptable human epidemiologic data are not available, the risk associated dose shall be derived from available animal bioassay data. Data from a species that is considered most biologically relevant to humans (i.e., responds most like humans) is preferred where all other considerations regarding quality of data are equal. In the absence of data to distinguish the most relevant species, data from the most sensitive species tested, i.e., the species showing a carcinogenic effect at the lowest administered dose, shall generally be used.

3. When animal bioassay data are used and a non-threshold mechanism of carcinogenicity is assumed, the data are fitted to a linearized multistage computer model (e.g., Global '86 or equivalent model). Global '86 is the linearized multistage model, derived by Howe, Crump and Van Landingham (1986), which EPA uses to determine cancer potencies. The upper-bound 95 percent confidence limit on risk (or, the lower 95 percent confidence limit on dose) at the one in 100,000 risk level shall be used to calculate a risk associated dose (RAD). Other models, including modifications or variations of the linear multistage model which are more appropriate to the available data may be used where scientifically justified.

4. If the duration of the study is significantly less than the natural lifespan of the test animal, the slope may be adjusted on a case-by-case basis to compensate for latent tumors which were not expressed (e.g., U.S. EPA, 1980) In the absence of alternative approaches which compensate for study durations significantly less than lifetime, the permitting authority may use the process described in the 1980 National Guidelines (see 45 FR 79352).

5. A species scaling factor shall be used to account for differences between test species and humans. It shall be assumed that milligrams per surface area per day is an equivalent dose between species (U.S. EPA, 1986). All doses presented in mg/kg bodyweight will be converted to an equivalent surface area dose by raising the mg/kg dose to the 2/3 power. However, if adequate pharmacokinetic and metabolism studies are available, these data may be factored into the adjustment for species differences on a case-by-case basis.

6. Additional data selection and adjustment decisions must also be made in the process of quantifying risk. Consideration must be given to tumor selection for modeling, e.g., pooling estimates for multiple tumor types and identifying and combining benign and malignant tumors. All doses shall be adjusted to give an average daily dose over the study duration. Adjustments in the rate of tumor response must be made for early mortality in test species. The goodness-of-fit of the model to the data must also be assessed.

7. When a linear, non-threshold dose response relationship is assumed, the RAD shall be calculated using the following equation:

Where:

RAD=risk associated dose in milligrams of toxicant per kilogram body weight per day (mg/kg/day).

0.00001 (110^{5})=incremental risk of developing cancer equal to one in 100,000.

q_1*=slope factor $(mg/kg/day)^{1}$.

8. If human epidemiologic data and/or other biological data (animal) indicate that a chemical causes cancer via a threshold mechanism, the risk associated dose may, on a case-by-case basis, be calculated using a method which assumes a threshold mechanism is operative.

B. Noncarcinogens.

1. Noncarcinogens shall generally be assumed to have a threshold dose or concentration below which no adverse effects should be observed. Therefore, the Tier I criterion or Tier II value is the maximum water concentration of a substance at or below which a lifetime exposure from drinking the water, consuming fish caught in the water, and ingesting water as a result of participating in water-related recreation activities is likely to be without appreciable risk of deleterious effects.

For some noncarcinogens, there may not be a threshold dose below which no adverse effects should be observed. Chemicals acting as genotoxic teratogens and germline mutagens are thought to possibly produce reproductive and/or developmental effects via a genetically linked mechanism which may have no threshold. Other chemicals also may not demonstrate a threshold. Criteria for these types of chemicals will be established on a case-by-case basis using appropriate assumptions reflecting the likelihood that no threshold exists.

2. All appropriate human and animal toxicologic data shall be reviewed and evaluated. To the maximum extent possible, data most specific to the environmentally relevant route of exposure shall be used. Oral exposure data should be used preferentially over dermal and inhalation since, in most cases, the exposure routes of greatest concern are fish consumption and drinking water/incidental ingestion. When acceptable human data are not available (e.g., well-conducted epidemiologic studies), animal data from species most biologically relevant to humans shall be used. In the absence of data to distinguish the most relevant species, data from the most sensitive animal species tested, i.e., the species showing a toxic effect at the lowest administered dose (given a relevant route of exposure), should generally be used.

***15409** 3. Minimum data requirements are specified in section II.B of this appendix. The experimental exposure level representing the highest level tested at which no adverse effects were demonstrated (NOAEL) from studies satisfying the provisions of section II.B of this appendix shall be used for criteria calculations. In the absence of a NOAEL, the LOAEL from studies satisfying the provisions of section II.B of this appendix may be used if it is based on relatively mild and reversible effects.

4. Uncertainty factors shall be used to account for the uncertainties in predicting acceptable dose levels for the general human population based upon experimental animal data or limited human data.

a. An uncertainty factor of 10 shall generally be used when extrapolating from valid experimental results from studies on prolonged exposure to average healthy humans. This 10-fold factor is used to protect sensitive members of the human population.

b. An uncertainty factor of 100 shall generally be used when extrapolating from valid results of long-term studies on experimental animals when results of studies of human exposure are not available or are inadequate. In comparison to a, above, this represents an additional 10-fold uncertainty factor in extrapolating data from the average animal to the average human.

c. An uncertainty factor of up to 1000 shall generally be used when extrapolating from animal studies for which the exposure duration is less than chronic, but greater than subchronic (e.g., 90 days or more in length), or when other significant deficiencies in study quality are present, and when useful long-term human data are not available. In comparison to b, above, this represents an additional UF of up to 10-fold for less than chronic, but greater than subchronic, studies.

d. An UF of up to 3000 shall generally be used when extrapolating from animal studies for which the exposure duration is less than subchronic (e.g., 28 days). In comparison to b above, this represents an additional UF of up to 30-fold for less than

subchronic studies (e.g., 28-day). The level of additional uncertainty applied for less than chronic exposures depends on the duration of the study used relative to the lifetime of the experimental animal.

e. An additional UF of between one and ten may be used when deriving a criterion from a LOAEL. This UF accounts for the lack of an identifiable NOAEL. The level of additional uncertainty applied may depend upon the severity and the incidence of the observed adverse effect.

f. An additional UF of between one and ten may be applied when there are limited effects data or incomplete sub-acute or chronic toxicity data (e.g., reproductive/developmental data). The level of quality and quantity of the experimental data available as well as structure-activity relationships may be used to determine the factor selected.

g. When deriving an UF in developing a Tier I criterion or Tier II value, the total uncertainty, as calculated following the guidance of sections 4.a through f, cited above, shall not exceed 10,000 for Tier I criteria and 30,000 for Tier II values.

5. All study results shall be converted, as necessary, to the standard unit for acceptable daily exposure of milligrams of toxicant per kilogram of body weight per day (mg/kg/day). Doses shall be adjusted for continuous exposure (i.e., seven days/week, 24 hours/day, etc.).

C. Criteria and Value Derivation.

1. Standard Exposure Assumptions. The following represent the standard exposure assumptions used to calculate Tier I criteria and Tier II values for carcinogens and noncarcinogens. Higher levels of exposure may be assumed by States and Tribes pursuant to Clean Water Act (CWA) section 510, or where appropriate in deriving site-specific criteria pursuant to procedure 1 in appendix F to part 132.

BW = body weight of an average human (BW = 70kg).

WC_d = per capita water consumption (both drinking and incidental exposure) for surface waters classified as public water supplies = two liters/day.

—or—

WC_r = per capita incidental daily water ingestion for surface waters not used as human drinking water sources = 0.01 liters/day.

FC = per capita daily consumption of regionally caught freshwater fish = 0.015kg/day (0.0036 kg/day for trophic level 3 and 0.0114 kg/day for trophic level 4).

BAF = bioaccumulation factor for trophic level 3 and trophic level 4, as derived using the BAF methodology in appendix B to part 132.

2. Carcinogens. The Tier I human cancer criteria or Tier II values shall be calculated as follows:

Where:

HCV=Human Cancer Value in milligrams per liter (mg/L).

RAD=Risk associated dose in milligrams toxicant per kilogram body weight per day (mg/kg/day) that is associated with a lifetime incremental cancer risk equal to one in 100,000.

BW=weight of an average human (BW=70 kg).

WC_d=per capita water consumption (both drinking and incidental exposure) for surface waters classified as public water supplies=two liters/day.

or

WC_r=per capita incidental daily water ingestion for surface waters not used as human drinking water sources=0.01 liters/day.

FC_{TL3}=mean consumption of trophic level 3 of regionally caught freshwater fish=0.0036 kg/day.

FC_{TL4}=mean consumption of trophic level 4 of regionally caught freshwater fish=0.0114 kg/day.

BAF^{HH}_{TL3}=bioaccumulation factor for trophic level 3 fish, as derived using the BAF methodology in appendix B to part 132.

BAF^{HH}_{TL4}=bioaccumulation factor for trophic level 4 fish, as derived using the BAF methodology in appendix B to part 132.
3. Noncarcinogens. The Tier I human noncancer criteria or Tier II values shall be calculated as follows:

Where:

HNV=Human noncancer value in milligrams per liter (mg/L).

ADE=Acceptable daily exposure in milligrams toxicant per kilogram body weight per day (mg/kg/day).

RSC=Relative source contribution factor of 0.8. An RSC derived from actual exposure data may be developed using the methodology outlined by the 1980 National Guidelines (see 45 FR 79354).

BW=weight of an average human (BW=70 kg).

WC_d=per capita water consumption (both drinking and incidental exposure) for surface waters classified as public water supplies=two liters/day.

or

WC_r=per capita incidental daily water ingestion for surface waters not used as human drinking water sources=0.01 liters/day.

***15410** FC_{TL3}=mean consumption of trophic level 3 fish by regional sport fishers of regionally caught freshwater fish=0.0036 kg/day.

FC_{TL4}=mean consumption of trophic level 4 fish by regional sport fishers of regionally caught freshwater fish=0.0114 kg/day.

BAF^{HH}_{TL3}=human health bioaccumulation factor for edible portion of trophic level 3 fish, as derived using the BAF methodology in appendix B to part 132.

BAF^{HH}_{TL4}=human health bioaccumulation factor for edible portion of trophic level 4 fish, as derived using the BAF methodology in appendix B to part 132.

Appendix D to Part 132—Great Lakes Water Quality Initiative Methodology for the Development of Wildlife Criteria

Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) this appendix.

I. Introduction

A. A Great Lakes Water Quality Wildlife Criterion (GLWC) is the concentration of a substance which is likely to, if not exceeded, protect avian and mammalian wildlife populations inhabiting the Great Lakes basin from adverse effects resulting from the ingestion of water and aquatic prey taken from surface waters of the Great Lakes System. These criteria are based on existing toxicological studies of the substance of concern and quantitative information about the exposure of wildlife species to the substance (i.e., food and water consumption rates). Since toxicological and exposure data for individual wildlife species are limited, a GLWC is derived using a methodology similar to that used to derive noncancer human health criteria (Barnes and Dourson, 1988; NAS, 1977; NAS, 1980; U.S. EPA, 1980). Separate avian and mammalian values are developed using taxonomic class-specific toxicity data and exposure data for five representative Great Lakes basin wildlife species. The wildlife species selected are representative of avian and mammalian species resident in the Great Lakes basin which are likely to experience the highest exposures to bioaccumulative contaminants through the aquatic food web; they are the bald eagle, herring gull, belted kingfisher, mink, and river otter.

B. This appendix establishes a methodology which is required when developing Tier I wildlife criteria for bioaccumulative chemicals of concern (BCCs). The use of the equation provided in the methodology is encouraged, but not required, for the development of Tier I criteria or Tier II values for pollutants other than those identified in Table 6-A for which Tier I criteria or Tier II values are determined to be necessary for the protection of wildlife in the Great Lakes basin. A discussion of the methodology for deriving Tier II values can be found in the Great Lakes Water Quality Initiative Technical Support Document for Wildlife Criteria (Wildlife TSD).

C. In the event that this methodology is used to develop criteria for pollutants other than BCCs, or in the event that the Tier II methodology described in the Wildlife TSD is used to derive Tier II values, the methodology for deriving bioaccumulation factors under appendix B to part 132 must be used in either derivation. For chemicals which do not biomagnify to the extent of BCCs, it may be appropriate to select different representative species which are better examples of species with the highest exposures for the given chemical. The equation presented in this methodology, however, is still encouraged. In addition, procedure 1 of appendix F of this part describes the procedures for calculating site-specific wildlife criteria.

D. The term “wildlife value” (WV) is used to denote the value for each representative species which results from using the equation presented below, the value obtained from averaging species values within a class, or any value derived from application of the site-specific procedure provided in procedure 1 of appendix F of this part. The WVs calculated for the representative species are used to calculate taxonomic class-specific WVs. The WV is the concentration of a substance which, if not exceeded, should better protect the taxon in question.

E. “Tier I wildlife criterion,” or “Tier I criterion” is used to denote the number derived from data meeting the Tier I minimum database requirements, and which will be protective of the two classes of wildlife. It is synonymous with the term “GLWC,” and the two are used interchangeably.

II. Calculation of Wildlife Values for Tier I Criteria

Table 4 of Part 132 and Table D-1 of this appendix contain criteria calculated by EPA using the methodology provided below.

A. Equation for Avian and Mammalian Wildlife Values. Tier I wildlife values for the pollutants designated BCCs pursuant to part 132 are to be calculated using the equation presented below.

Where:

WV=Wildlife Value in milligrams of substance per liter (mg/L).

TD=Test Dose (TD) in milligrams of substance per kilograms per day (mg/kg-d) for the test species. This shall be either a NOAEL or a LOAEL.

UF_A=Uncertainty Factor (UF) for extrapolating toxicity data across species (unitless). A species-specific UF shall be selected and applied to each representative species, consistent with the equation.

UF_S=UF for extrapolating from subchronic to chronic exposures (unitless).

UF_L=UF for LOAEL to NOAEL extrapolations (unitless).

Wt=Average weight in kilograms (kg) for the representative species.

W=Average daily volume of water consumed in liters per day (L/d) by the representative species.

F_{TLi}=Average daily amount of food consumed from trophic level i in kilograms per day (kg/d) by the representative species.

BAF^{WL}_{TLi}=Bioaccumulation factor (BAF) for wildlife food in trophic level i in liters per kilogram (L/kg), developed using the BAF methodology in appendix B to part 132, Methodology for Development of Bioaccumulation Factors. For consumption of piscivorous birds by other birds (e.g., herring gull by eagles), the BAF is derived by multiplying the trophic level 3 BAF for fish by a biomagnification factor to account for the biomagnification from fish to the consumed birds.

B. Identification of Representative Species for Protection. For bioaccumulative chemicals, piscivorous species are identified as the focus of concern for wildlife criteria development in the Great Lakes. An analysis of known or estimated exposure components for avian and mammalian wildlife species is presented in the Wildlife TSD. This analysis identifies three avian species (eagle, kingfisher and herring gull) and two mammalian species (mink and otter) as representative species for protection. The TD obtained from toxicity data for each taxonomic class is used to calculate WVs for each of the five representative species.

C. Calculation of Avian and Mammalian Wildlife Values and GLWC Derivation. The avian WV is the geometric mean of the WVs calculated for the three representative avian species. The mammalian WV is the geometric mean of the WVs calculated for the two representative mammalian species. The lower of the mammalian and avian WVs must be selected as the GLWC.

III. Parameters of the Effect Component of the Wildlife Criteria Methodology

A. Definitions. The following definitions provide additional specificity and guidance in the evaluation of toxicity data and the application of this methodology.

Acceptable endpoints. For the purpose of wildlife criteria derivation, acceptable subchronic and chronic endpoints are those which affect reproductive or developmental success, organismal viability or growth, or any other endpoint which is, or is directly related to, parameters that influence population dynamics.

***15411** Chronic effect. An adverse effect that is measured by assessing an acceptable endpoint, and results from continual exposure over several generations, or at least over a significant part of the test species' projected life span or life stage.

Lowest-observed-adverse-effect-level (LOAEL). The lowest tested dose or concentration of a substance which resulted in an observed adverse effect in exposed test organisms when all higher doses or concentrations resulted in the same or more severe effects.

No-observed-adverse-effect-level (NOAEL). The highest tested dose or concentration of a substance which resulted in no observed adverse effect in exposed test organisms where higher doses or concentrations resulted in an adverse effect.

Subchronic effect. An adverse effect, measured by assessing an acceptable endpoint, resulting from continual exposure for a period of time less than that deemed necessary for a chronic test.

B. Minimum Toxicity Database for Tier I Criteria Development. A TD value is required for criterion calculation. To derive a Tier I criterion for wildlife, the data set shall provide enough data to generate a subchronic or chronic dose-response curve for any given substance for both mammalian and avian species. In reviewing the toxicity data available which meet the minimum data requirements for each taxonomic class, the following order of preference shall be applied to select the appropriate TD to be used for calculation of individual WVs. Data from peer-reviewed field studies of wildlife species take precedence over other types of studies, where such studies are of adequate quality. An acceptable field study must be of subchronic or chronic duration, provide a defensible, chemical-specific dose-response curve in which cause and effect are clearly established, and assess acceptable endpoints as defined in this document. When acceptable wildlife field studies are not available, or determined to be of inadequate quality, the needed toxicity information may come from peer-reviewed laboratory studies. When laboratory studies are used, preference shall be given to laboratory studies with wildlife species over traditional laboratory animals to reduce uncertainties in making interspecies extrapolations. All available laboratory data and field studies shall be reviewed to corroborate the final GLWC, to assess the reasonableness of the toxicity value used, and to assess the appropriateness of any UFs which are applied. When evaluating the studies from which a test dose is derived in general, the following requirements must be met:

1. The mammalian data must come from at least one well-conducted study of 90 days or greater designed to observe subchronic or chronic effects as defined in this document.

2. The avian data must come from at least one well-conducted study of 70 days or greater designed to observe subchronic or chronic effects as defined in this document.

3. In reviewing the studies from which a TD is derived for use in calculating a WV, studies involving exposure routes other than oral may be considered only when an equivalent oral daily dose can be estimated and technically justified because the criteria calculations are based on an oral route of exposure.

4. In assessing the studies which meet the minimum data requirements, preference should be given to studies which assess effects on developmental or reproductive endpoints because, in general, these are more important endpoints in ensuring that a population's productivity is maintained. The Wildlife TSD provides additional discussion on the selection of an appropriate toxicity study.

C. Selection of TD Data. In selecting data to be used in the derivation of WVs, the evaluation of acceptable endpoints, as defined in Section III.A of this appendix, will be the primary selection criterion. All data not part of the selected subset may be used to assess the reasonableness of the toxicity value and the appropriateness of the Ufs which are applied.

1. If more than one TD value is available within a taxonomic class, based on different endpoints of toxicity, that TD, which is likely to reflect best potential impacts to wildlife populations through resultant changes in mortality or fecundity rates, shall be used for the calculation of WVs.

2. If more than one TD is available within a taxonomic class, based on the same endpoint of toxicity, the TD from the most sensitive species shall be used.

3. If more than one TD based on the same endpoint of toxicity is available for a given species, the TD for that species shall be calculated using the geometric mean of those TDs.

D. Exposure Assumptions in the Determination of the TD. 1. In those cases in which a TD is available in units other than milligrams of substance per kilograms per day (mg/kg/d), the following procedures shall be used to convert the TD to the appropriate units prior to calculating a WV.

2. If the TD is given in milligrams of toxicant per liter of water consumed by the test animals (mg/L), the TD shall be multiplied by the daily average volume of water consumed by the test animals in liters per day (L/d) and divided by the average weight of the test animals in kilograms (kg).

3. If the TD is given in milligrams of toxicant per kilogram of food consumed by the test animals (mg/kg), the TD shall be multiplied by the average amount of food in kilograms consumed daily by the test animals (kg/d) and divided by the average weight of the test animals in kilograms (kg).

E. Drinking and Feeding Rates. 1. When drinking and feeding rates and body weight are needed to express the TD in milligrams of substance per kilograms per day (mg/kg/d), they are obtained from the study from which the TD was derived. If not already determined, body weight, and drinking and feeding rates are to be converted to a wet weight basis.

2. If the study does not provide the needed values, the values shall be determined from appropriate scientific literature. For studies done with domestic laboratory animals, either the Registry of Toxic Effects of Chemical Substances (National Institute for Occupational Safety and Health, the latest edition, Cincinnati, OH), or Recommendations for and Documentation of Biological Values for Use in Risk Assessment (U.S. EPA, 1988) should be consulted. When these references do not contain exposure information for the species used in a given study, either the allometric equations from Calder and Braun (1983) and Nagy (1987), which are presented below, or the exposure estimation methods presented in Chapter 4 of the Wildlife Exposure Factors Handbook (U.S. EPA, 1993), should be applied to approximate the needed feeding or drinking rates. Additional discussion and recommendations are provided in the Wildlife TSD. The choice of the methods described above is at the discretion of the State or Tribe.

3. For mammalian species, the general allometric equations are:

a. $F = 0.0687 (Wt)^{0.82}$

Where:

F = Feeding rate of mammalian species in kilograms per day (kg/d) dry weight.

Wt = Average weight in kilograms (kg) of the test animals.

b. $W = 0.099 (Wt)^{0.90}$

Where:

W = Drinking rate of mammalian species in liters per day (L/d).

Wt = Average weight in kilograms (kg) of the test animals.
4. For avian species, the general allometric equations are:

a. $F = 0.0582 (Wt)^{0.65}$

Where:

F = Feeding rate of avian species in kilograms per day (kg/d) dry weight.

Wt = Average weight in kilograms (kg) of the test animals.
b. $W = 0.059 (Wt)^{0.67}$

Where:

W = Drinking rate of avian species in liters per day (L/d).

Wt = Average weight in kilograms (kg) of the test animals.
F. LOAEL to NOAEL Extrapolations (UF_L). In those cases in which a NOAEL is unavailable as the TD and a LOAEL is available, the LOAEL may be used to estimate the NOAEL. If used, the LOAEL shall be divided by an UF to estimate a NOAEL for use in deriving WVs. The value of the UF shall not be less than one and should not exceed 10, depending on the dose-response curve and any other available data, and is represented by UF_L in the equation expressed in Section II.A of this appendix. Guidance for selecting an appropriate UF_L, based on a review of available wildlife toxicity data, is available in the Wildlife TSD.

G. Subchronic to Chronic Extrapolations (US_S). In instances where only subchronic data are available, the TD may be derived from subchronic data. In such cases, the TD shall be divided by an UF to extrapolate from subchronic to chronic levels. The value of the UF shall not be less than one and should not exceed 10, and is represented by UF_S in the equation expressed in Section II.A of this appendix. This factor is to be used when assessing highly bioaccumulative substances where toxicokinetic considerations suggest that a bioassay of limited length ***15412** underestimates chronic effects. Guidance for selecting an appropriate UF_S, based on a review of available wildlife toxicity data, is available in the Wildlife TSD.

H. Interspecies Extrapolations (UF_A). 1. The selection of the UF_A shall be based on the available toxicological data and on available data concerning the physicochemical, toxicokinetic, and toxicodynamic properties of the substance in question and the amount and quality of available data. This value is an UF that is intended to account for differences in toxicological sensitivity among species. Guidance for selecting an appropriate UF_A, based on a review of available wildlife toxicity data, is available in the Wildlife TSD. Additional discussion of an interspecies UF located in appendix A to the Great Lakes Water Quality Initiative Technical Support Document for Human Health Criteria may be useful in determining the appropriate value for UF_A.

2. For the derivation of Tier I criteria, a UF_A shall not be less than one and should not exceed 100, and shall be applied to each of the five representative species, based on existing data and best professional judgment. The value of UF_A may differ for each of the representative species.

3. For Tier I wildlife criteria, the UF_A shall be used only for extrapolating toxicity data across species within a taxonomic class, except as provided below. The Tier I UF_A is not intended for interclass extrapolations because of the poorly defined comparative toxicokinetic and toxicodynamic parameters between mammals and birds. However, an interclass extrapolation

employing a UF_A may be used for a given chemical if it can be supported by a validated biologically-based dose-response model or by an analysis of interclass toxicological data, considering acceptable endpoints, for a chemical analog that acts under the same mode of toxic action.

IV. Parameters of the Exposure Component of the Wildlife Criteria Methodology

A. Drinking and Feeding Rates of Representative Species. The body weights (Wt), feeding rates (F_{Tli}), drinking rates (W), and trophic level dietary composition (as food ingestion rate and percent in diet) for each of the five representative species are presented in Table D-2 of this appendix. Guidance on incorporating the non-aquatic portion of the bald eagle and mink diets in the criteria calculations is available in the Wildlife TSD.

B. BAFs. The Methodology for Development of Bioaccumulation Factors is presented in appendix B to part 132. Trophic level 3 and 4 BAFs are used to derive Wvs because these are the trophic levels at which the representative species feed.

Appendix E to Part 132—Great Lakes Water Quality Initiative Antidegradation Policy

Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) appendix E to part 132.

The State or Tribe shall adopt an antidegradation standard applicable to all waters of the Great Lakes System and identify the methods for implementing such a standard. Consistent with 40 CFR 131.12, an acceptable antidegradation standard and implementation procedure are required elements of a State's or Tribe's water quality standards program. Consistent with 40 CFR 131.6, a complete water quality standards submission needs to include both an antidegradation standard and antidegradation implementation procedures. At a minimum, States and Tribes shall adopt provisions in their antidegradation standard and implementation methods consistent with sections I, II, III and IV of this appendix, applicable to pollutants identified as bioaccumulative chemicals of concern (BCCs).

I. Antidegradation Standard

This antidegradation standard shall be applicable to any action or activity by any source, point or nonpoint, of pollutants that is anticipated to result in an increased loading of BCCs to surface waters of the Great Lakes System and for which independent regulatory authority exists requiring compliance with water quality standards. Pursuant to this standard:

A. Existing instream water uses, as defined pursuant to 40 CFR 131, and the level of water quality necessary to protect existing uses shall be maintained and protected. Where designated uses of the waterbody are impaired, there shall be no lowering of the water quality with respect to the pollutant or pollutants which are causing the impairment;

B. Where, for any parameter, the quality of the waters exceed levels necessary to support the propagation of fish, shellfish, and wildlife and recreation in and on the waters, that water shall be considered high quality for that parameter consistent

with the definition of high quality water found at section II.A of this appendix and that quality ***15413** shall be maintained and protected unless the State or Tribe finds, after full satisfaction of intergovernmental coordination and public participation provisions of the State's or Tribe's continuing planning process, that allowing lower water quality is necessary to accommodate important economic or social development in the area in which the waters are located. In allowing such degradation, the State or Tribe shall assure water quality adequate to protect existing uses fully. Further, the State or Tribe shall assure that there shall be achieved the highest statutory and regulatory requirements for all new and existing point sources and all cost-effective and reasonable best management practices for nonpoint source control. The State or Tribe shall utilize the Antidegradation Implementation Procedures adopted pursuant to the requirements of this regulation in determining if any lowering of water quality will be allowed;

C. Where high quality waters constitute an outstanding national resource, such as waters of national and State parks and wildlife refuges and waters of exceptional recreational or ecological significance, that water quality shall be maintained and protected; and

D. In those cases where the potential lowering of water quality is associated with a thermal discharge, the decision to allow such degradation shall be consistent with section 316 of the Clean Water Act (CWA).

II. Antidegradation Implementation Procedures

A. Definitions.

Control Document. Any authorization issued by a State, Tribal or Federal agency to any source of pollutants to waters under its jurisdiction that specifies conditions under which the source is allowed to operate.

High quality waters. High quality waters are water bodies in which, on a parameter by parameter basis, the quality of the waters exceeds levels necessary to support propagation of fish, shellfish, and wildlife and recreation in and on the water.

Lake Superior Basin—Outstanding International Resource Waters. Those waters designated as such by a Tribe or State consistent with the September 1991 Bi-National Program to Restore and Protect the Lake Superior Basin. The purpose of such designations shall be to ensure that any new or increased discharges of Lake Superior bioaccumulative substances of immediate concern are subject to best technology in process and treatment requirements.

Lake Superior Basin—Outstanding National Resource Waters. Those waters designated as such by a Tribe or State consistent with the September 1991 Bi-National Program to Restore and Protect the Lake Superior Basin. The purpose of such designations shall be to prohibit new or increased discharges of Lake Superior bioaccumulative substances of immediate concern from point sources in these areas.

Lake Superior bioaccumulative substances of immediate concern. A list of substances identified in the September 1991 Bi-National Program to Restore and Protect the Lake Superior Basin. They include: 2, 3, 7, 8-TCDD; octachlorostyrene; hexachlorobenzene; chlordane; DDT, DDE, and other metabolites; toxaphene; PCBs; and mercury. Other chemicals may be added to the list following States' or Tribes' assessments of environmental effects and impacts and after public review and comment.

Outstanding National Resource Waters. Those waters designated as such by a Tribe or State. The State or Tribal designation shall describe the quality of such waters to serve as the benchmark of the water quality that shall be maintained and protected. Waters that may be considered for designation as Outstanding National Resource Waters include, but are not limited to, water bodies that are recognized as:

Important because of protection through official action, such as Federal or State law, Presidential or secretarial action, international treaty, or interstate compact;

Having exceptional recreational significance;

Having exceptional ecological significance;

Having other special environmental, recreational, or ecological attributes; or waters whose designation as Outstanding National Resource Waters is reasonably necessary for the protection of other waters so designated.

Significant Lowering of Water Quality. A significant lowering of water quality occurs when there is a new or increased loading of any BCC from any regulated existing or new facility, either point source or nonpoint source for which there is a control document or reviewable action, as a result of any activity including, but not limited to:

(1) Construction of a new regulated facility or modification of an existing regulated facility such that a new or modified control document is required;

(2) Modification of an existing regulated facility operating under a current control document such that the production capacity of the facility is increased;

(3) Addition of a new source of untreated or pretreated effluent containing or expected to contain any BCC to an existing wastewater treatment works, whether public or private;

(4) A request for an increased limit in an applicable control document;

(5) Other deliberate activities that, based on the information available, could be reasonably expected to result in an increased loading of any BCC to any waters of the Great Lakes System.

b. Notwithstanding the above, changes in loadings of any BCC within the existing capacity and processes, and that are covered by the existing applicable control document, are not subject to an antidegradation review. These changes include, but are not limited to:

(1) Normal operational variability;

(2) Changes in intake water pollutants;

(3) Increasing the production hours of the facility, (e.g., adding a second shift); or

(4) Increasing the rate of production.

C. Also, excluded from an antidegradation review are new effluent limits based on improved monitoring data or new water quality criteria or values that are not a result of changes in pollutant loading.

B. For all waters, the Director shall ensure that the level of water quality necessary to protect existing uses is maintained. In order to achieve this requirement, and consistent with 40 CFR 131.10, water quality standards use designations must include all existing uses. Controls shall be established as necessary on point and nonpoint sources of pollutants to ensure that the criteria applicable to the designated use are achieved in the water and that any designated use of a downstream water is protected. Where water quality does not support the designated uses of a waterbody or ambient pollutant concentrations exceed water quality criteria applicable to that waterbody, the Director shall not allow a lowering of water quality for the pollutant or pollutants preventing the attainment of such uses or exceeding such criteria.

C. For Outstanding National Resource Waters:

1. The Director shall ensure, through the application of appropriate controls on pollutant sources, that water quality is maintained and protected.

2. Exception. A short-term, temporary (i.e., weeks or months) lowering of water quality may be permitted by the Director.

D. For high quality waters, the Director shall ensure that no action resulting in a lowering of water quality occurs unless an antidegradation demonstration has been completed pursuant to section III of this appendix and the information thus provided is determined by the Director pursuant to section IV of this appendix to adequately support the lowering of water quality.

1. The Director shall establish conditions in the control document applicable to the regulated facility that prohibit the regulated facility from undertaking any deliberate action, such that there would be an increase in the rate of mass loading of any BCC, unless an antidegradation demonstration is provided to the Director and approved pursuant to section IV of this appendix prior to commencement of the action. Imposition of limits due to improved monitoring data or new water quality criteria or values, or changes in loadings of any BCC within the existing capacity and processes, and that are covered by the existing applicable control document, are not subject to an antidegradation review.

2. For BCCs known or believed to be present in a discharge, from a point or nonpoint source, a monitoring requirement shall be included in the control document. The control document shall also include a provision requiring the source to notify the Director or any increased loadings. Upon notification, the Director shall require actions as necessary to reduce or eliminate the increased loading.

3. Fact Sheets prepared pursuant to 40 CFR 124.8 and 124.56 shall reflect any conditions developed under sections II.D.1 or II.D.2 of this appendix and included in a permit.

E. Special Provisions for Lake Superior.The following conditions apply in addition to those specified in section II.B through II.C of this appendix for waters of Lake Superior so designated.

1. A State or Tribe may designate certain specified areas of the Lake Superior Basin as Lake Superior Basin—Outstanding National Resource Waters for the purpose of prohibiting the new or increased discharge of Lake Superior bioaccumulative substances of immediate concern from point sources in these areas.

2. States and Tribes may designate all waters of the Lake Superior Basin as Outstanding International Resource Waters for the purpose of restricting the increased discharge of ***15414** Lake Superior bioaccumulative substances of immediate concern from point sources consistent with the requirements of sections III.C and IV.B of this appendix.

F. Exemptions. Except as the Director may determine on a case-by-case basis that the application of these procedures is required to adequately protect water quality, or as the affected waterbody is an Outstanding National Resource Water as defined in section II.A of this appendix, the procedures in this part do not apply to:

1. Short-term, temporary (i.e., weeks or months) lowering of water quality;

2. Bypasses that are not prohibited at 40 CFR 122.41(m); and

3. Response actions pursuant to the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA), as amended, or similar Federal, State or Tribal authorities, undertaken to alleviate a release into the environment of hazardous substances, pollutants or contaminants which may pose an imminent and substantial danger to public health or welfare.

III. Antidegradation Demonstration

Any entity seeking to lower water quality in a high quality water or create a new or increased discharge of Lake Superior bioaccumulative substances of immediate concern in a Lake Superior Outstanding International Resource Water must first, as required by sections II.D or II.E.2 of this appendix, submit an antidegradation demonstration for consideration by the Director. States and Tribes should tailor the level of detail and documentation in antidegradation reviews, to the specific circumstances encountered. The antidegradation demonstration shall include the following:

A. Pollution Prevention Alternatives Analysis. Identify any cost-effective pollution prevention alternatives and techniques that are available to the entity, that would eliminate or significantly reduce the extent to which the increased loading results in a lowering of water quality.

B. Alternative or Enhanced Treatment Analysis. Identify alternative or enhanced treatment techniques that are available to the entity that would eliminate the lowering of water quality and their costs relative to the cost of treatment necessary to achieve applicable effluent limitations.

C. Lake Superior. If the States or Tribes designate the waters of Lake Superior as Outstanding International Resource Waters pursuant to section II.E.2 of this appendix, then any entity proposing a new or increased discharge of any Lake Superior bioaccumulative substance of immediate concern to the Lake Superior Basin shall identify the best technology in process and treatment to eliminate or reduce the extent of the lowering of water quality. In this case, the requirements in section III.B of this appendix do not apply.

D. Important Social or Economic Development Analysis. Identify the social or economic development and the benefits to the area in which the waters are located that will be foregone if the lowering of water quality is not allowed.

E. Special Provision for Remedial Actions. Entities proposing remedial actions pursuant to the CERCLA, as amended, corrective actions pursuant to the Resource Conservation and Recovery Act, as amended, or similar actions pursuant to other Federal or State environmental statutes may submit information to the Director that demonstrates that the action utilizes the most cost effective pollution prevention and treatment techniques available, and minimizes the necessary lowering of water quality, in lieu of the information required by sections III.B through III.D of this appendix.

IV. Antidegradation Decision

A. Once the Director determines that the information provided by the entity proposing to increase loadings is administratively complete, the Director shall use that information to determine whether or not the lowering of water quality is necessary, and, if it is necessary, whether or not the lowering of water quality will support important social and economic development in the area. If the proposed lowering of water quality is either not necessary, or will not support important social and economic development, the Director shall deny the request to lower water quality. If the lowering of water quality is necessary, and will support important social and economic development, the Director may allow all or part of the proposed lowering to occur as necessary to accommodate the important social and economic development. In no event may the decision reached under this section allow water quality to be lowered below the minimum level required to fully support existing and designated uses. The decision of the Director shall be subject to the public participation requirements of 40 CFR 25.

B. If States designate the waters of Lake Superior as Outstanding International Resource Waters pursuant to section II.E.2 of this appendix, any entity requesting to lower water quality in the Lake Superior Basin as a result of the new or increased discharge of any Lake Superior bioaccumulative substance of immediate concern shall be required to install and utilize the best technology in process and treatment as identified by the Director.

Appendix F to Part 132—Great Lakes Water Quality Initiative Implementation Procedures

Procedure 1: Site-specific Modifications to Criteria and Values

Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) this procedure.

A. Requirements for Site-specific Modifications to Criteria and Values. Criteria and values may be modified on a site-specific basis to reflect local environmental conditions as restricted by the following provisions. Any such modifications must be protective of designated uses and aquatic life, wildlife or human health and be submitted to EPA for approval. In addition, any site-specific modifications that result in less stringent criteria must be based on a sound scientific rationale and shall not be likely to jeopardize the continued existence of endangered or threatened species listed or proposed under section 4 of the Endangered Species Act (ESA) or result in the destruction or adverse modification of such species' critical habitat. More stringent modifications shall be developed to protect endangered or threatened species listed or proposed under section 4 of the ESA, where such modifications are necessary to ensure that water quality is not likely to jeopardize the continued existence of such species or result in the destruction or adverse modification of such species' critical habitat. More stringent modifications may also be developed to protect candidate (C1) species being considered by the U.S. Fish and Wildlife Service (FWS) for listing under section 4 of the ESA, where such modifications are necessary to protect such species.

1. Aquatic Life.

a. Aquatic life criteria or values may be modified on a site-specific basis to provide an additional level of protection, pursuant to authority reserved to the States and Tribes under Clean Water Act (CWA) section 510.

Guidance on developing site-specific criteria in these instances is provided in Chapter 3 of the U.S. EPA Water Quality Standards Handbook, Second Edition—Revised (1994).

b. Less stringent site-specific modifications to chronic or acute aquatic life criteria or values may be developed when:

i. The local water quality characteristics such as Ph, hardness, temperature, color, etc., alter the biological availability or toxicity of a pollutant; or

ii. The sensitivity of the aquatic organisms species that “occur at the site” differs from the species actually tested in developing the criteria. The phrase “occur at the site” includes the species, genera, families, orders, classes, and phyla that: are usually present at the site; are present at the site only seasonally due to migration; are present intermittently because they periodically return to or extend their ranges into the site; were present at the site in the past, are not currently present at the site due to degraded conditions, and are expected to return to the site when conditions improve; are present in nearby bodies of water, are not currently present at the site due to degraded conditions, and are expected to be present at the site when conditions improve. The taxa that “occur at the site” cannot be determined merely by sampling downstream and/or upstream of the site at one point in time. “Occur at the site” does not include taxa that were once present at the site but cannot exist at the site now due to permanent physical alteration of the habitat at the site resulting, for example, from dams, etc.

c. Less stringent modifications also may be developed to acute and chronic aquatic life criteria or values to reflect local physical and hydrological conditions.

Guidance on developing site-specific criteria is provided in Chapter 3 of the U.S. EPA Water Quality Standards Handbook, Second Edition—Revised (1994).

***15415** d. Any modifications to protect threatened or endangered aquatic species required by procedure 1.A of this appendix may be accomplished using either of the two following procedures:

i. If the Species Mean Acute Value (SMAV) for a listed or proposed species, or for a surrogate of such species, is lower than the calculated Final Acute Value (FAV), such lower SMAV may be used instead of the calculated FAV in developing site-specific modified criteria; or,

ii. The site-specific criteria may be calculated using the recalculation procedure for site-specific modifications described in Chapter 3 of the U.S. EPA Water Quality Standards Handbook, Second Edition—Revised (1994).

2. Wildlife.

a. Wildlife water quality criteria may be modified on a site-specific basis to provide an additional level of protection, pursuant to authority reserved to the States and Tribes under CWA section 510.

b. Less stringent site-specific modifications to wildlife water quality criteria may be developed when a site-specific bioaccumulation factor (BAF) is derived which is lower than the system-wide BAF derived under appendix B of this part. The modification must consider both the mobility of prey organisms and wildlife populations in defining the site for which criteria are developed. In addition, there must be a showing that:

i. Any increased uptake of the toxicant by prey species utilizing the site will not cause adverse effects in wildlife populations; and

ii. Wildlife populations utilizing the site or downstream waters will continue to be fully protected.

c. Any modification to protect endangered or threatened wildlife species required by procedure 1.A of this appendix must consider both the mobility of prey organisms and wildlife populations in defining the site for which criteria are developed, and may be accomplished by using the following recommended method.

i. The methodology presented in appendix D to part 132 is used, substituting appropriate species-specific toxicological, epidemiological, or exposure information, including changes to the BAF;

ii. An interspecies uncertainty factor of 1 should be used where epidemiological data are available for the species in question. If necessary, species-specific exposure parameters can be derived as presented in Appendix D of this part;

iii. An intraspecies uncertainty factor (to account for protection of individuals within a wildlife population) should be applied in the denominator of the effect part of the wildlife equation in appendix D of this part in a manner consistent with the other uncertainty factors described in appendix D of this part; and

iv. The resulting wildlife value for the species in question should be compared to the two class-specific wildlife values which were previously calculated, and the lowest of the three shall be selected as the site-specific modification.

Note: Further discussion on the use of this methodology may be found in the Great Lakes Water Quality Initiative Technical Support Document for Wildlife Criteria.

3. BAFs.

a. BAFs may be modified on a site-specific basis to larger values, pursuant to the authority reserved to the States and Tribes under CWA section 510, where reliable data show that local bioaccumulation is greater than the system-wide value.

b. BAFs may be modified on a site-specific basis to lower values, where scientifically defensible, if:

i. The fraction of the total chemical that is freely dissolved in the ambient water is different than that used to derive the system-wide BAFs (i.e., the concentrations of particulate organic carbon and the dissolved organic carbon are different than those used to derive the system-wide BAFs);

ii. Input parameters of the Gobas model, such as the structure of the aquatic food web and the disequilibrium constant, are different at the site than those used to derive the system-wide BAFs;

iii. The percent lipid of aquatic organisms that are consumed and occur at the site is different than that used to derive the system-wide BAFs; or

iv. Site-specific field-measured BAFs or biota-sediment accumulation factor (BSAFs) are determined.

If site-specific BAFs are derived, they shall be derived using the methodology in appendix B of this part.

c. Any more stringent modifications to protect threatened or endangered species required by procedure 1.A of this appendix shall be derived using procedures set forth in the methodology in appendix B of this part.

4. Human Health.

a. Human health criteria or values may be modified on a site-specific basis to provide an additional level of protection, pursuant to authority reserved to the States and Tribes under CWA section 510. Human health criteria or values shall be modified on a site-specific basis to provide additional protection appropriate for highly exposed subpopulations.

b. Less stringent site-specific modifications to human health criteria or values may be developed when:

i. local fish consumption rates are lower than the rate used in deriving human health criteria or values under appendix C of this part; and/or

ii. a site-specific BAF is derived which is lower than that used in deriving human health criteria or values under appendix C of this part.

B. Notification Requirements. When a State proposes a site-specific modification to a criterion or value as allowed in section 4.A above, the State should notify the other Great Lakes States of such a proposal and, for less stringent criteria, supply appropriate justification.

C. References.

U.S. EPA. 1984. Water Quality Standards Handbook—Revised. Chapter 3 and Appendices. U.S. Environmental Protection Agency, Office of Water Resource Center (RC-4100), 401 M Street, SW., Washington, DC 20960.

Procedure 2: Variances from Water Quality Standards for Point Sources

The Great Lakes States or Tribes may adopt water quality standards (WQS) variance procedures and may grant WQS variances for point sources pursuant to such procedures. Variance procedures shall be consistent with (as protective as) the provisions in this procedure.

A. Applicability. A State or Tribe may grant a variance to a WQS which is the basis of a water quality-based effluent limitation included in a National Pollutant Discharge Elimination System (NPDES) permit. A WQS variance applies only to the permittee requesting the variance and only to the pollutant or pollutants specified in the variance. A variance does not affect, or require the State or Tribe to modify, the corresponding water quality standard for the waterbody as a whole.

1. This provision shall not apply to new Great Lakes dischargers or recommencing dischargers.

2. A variance to a water quality standard shall not be granted that would likely jeopardize the continued existence of any endangered or threatened species listed under Section 4 of the Endangered Species Act (ESA) or result in the destruction or adverse modification of such species' critical habitat.

3. A WQS variance shall not be granted if standards will be attained by implementing effluent limits required under sections 301(b) and 306 of the Clean Water Act (CWA) and by the permittee implementing cost-effective and reasonable best management practices for nonpoint source control.

B. Maximum Timeframe for Variances. A WQS variance shall not exceed five years or the term of the NPDES permit, whichever is less. A State or Tribe shall review, and modify as necessary, WQS variances as part of each water quality standards review pursuant to section 303(c) of the CWA.

C. Conditions to Grant a Variance. A variance may be granted if:

1. The permittee demonstrates to the State or Tribe that attaining the WQS is not feasible because:

a. Naturally occurring pollutant concentrations prevent the attainment of the WQS;

b. Natural, ephemeral, intermittent or low flow conditions or water levels prevent the attainment of the WQS, unless these conditions may be compensated for by the discharge of sufficient volume of effluent to enable WQS to be met without violating State or Tribal water conservation requirements;

c. Human-caused conditions or sources of pollution prevent the attainment of the WQS and cannot be remedied, or would cause more environmental damage to correct than to leave in place;

d. Dams, diversions or other types of hydrologic modifications preclude the attainment of the WQS, and it is not feasible to restore the waterbody to its original condition or to operate such modification in a way that would result in the attainment of the WQS;

e. Physical conditions related to the natural features of the waterbody, such as the lack of a proper substrate cover, flow, depth, pools, riffles, and the like, unrelated to chemical water quality, preclude attainment of WQS; or

***15416** f. Controls more stringent than those required by sections 301(b) and 306 of the CWA would result in substantial and widespread economic and social impact.

2. In addition to the requirements of C.1, above, the permittee shall also:

a. Show that the variance requested conforms to the requirements of the State's or Tribe's antidegradation procedures; and

b. Characterize the extent of any increased risk to human health and the environment associated with granting the variance compared with compliance with WQS absent the variance, such that the State or Tribe is able to conclude that any such increased risk is consistent with the protection of the public health, safety and welfare.

D. Submittal of Variance Application. The permittee shall submit an application for a variance to the regulatory authority issuing the permit. The application shall include:

1. All relevant information demonstrating that attaining the WQS is not feasible based on one or more of the conditions in section C.1 of this procedure; and,

2. All relevant information demonstrating compliance with the conditions in section C.2 of this procedure.

E. Public Notice of Preliminary Decision. Upon receipt of a complete application for a variance, and upon making a preliminary decision regarding the variance, the State or Tribe shall public notice the request and preliminary decision for public comment pursuant to the regulatory authority's Administrative Procedures Act and shall notify the other Great Lakes States and Tribes of the preliminary decision. This public notice requirement may be satisfied by including the supporting information for the variance and the preliminary decision in the public notice of a draft NPDES permit.

F. Final Decision on Variance Request. The State or Tribe shall issue a final decision on the variance request within 90 days of the expiration of the public comment period required in section E of this procedure. If all or part of the variance is approved by the State or Tribe, the decision shall include all permit conditions needed to implement those parts of the variance so approved. Such permit conditions shall, at a minimum, require:

1. Compliance with an initial effluent limitation which, at the time the variance is granted, represents the level currently achievable by the permittee, and which is no less stringent than that achieved under the previous permit;

2. That reasonable progress be made toward attaining the water quality standards for the waterbody as a whole through appropriate conditions;

3. When the duration of a variance is shorter than the duration of a permit, compliance with an effluent limitation sufficient to meet the underlying water quality standard, upon the expiration of said variance; and

4. A provision that allows the permitting authority to reopen and modify the permit based on any State or Tribal triennial water quality standards revisions to the variance.

The State shall deny a variance request if the permittee fails to make the demonstrations required under section C of this procedure.

G. Incorporating Variance into Permit. The State or Tribe shall establish and incorporate into the permittee's NPDES permit all conditions needed to implement the variance as determined in section F of this procedure.

H. Renewal of Variance. A variance may be renewed, subject to the requirements of sections A through G of this procedure. As part of any renewal application, the permittee shall again demonstrate that attaining WQS is not feasible based on the requirements of section C of this procedure. The permittee's application shall also contain information concerning its compliance with the conditions incorporated into its permit as part of the original variance pursuant to sections F and G of this procedure. Renewal of a variance may be denied if the permittee did not comply with the conditions of the original variance.

I. EPA Approval. All variances and supporting information shall be submitted by the State or Tribe to the appropriate EPA regional office and shall include:

1. Relevant permittee applications pursuant to section D of this procedure;

2. Public comments and records of any public hearings pursuant to section E of this procedure;

3. The final decision pursuant to section F of this procedure; and,

4. NPDES permits issued pursuant to section G of this procedure.

5. Items required by sections I.1 through I.3. of this procedure shall be submitted by the State within 30 days of the date of the final variance decision. The item required by section I.4 of this procedure shall be submitted in accordance with the State or Tribe Memorandum of Agreement with the Regional Administrator pursuant to 40 CFR 123.24.
40 CFR § 123.4440 CFR § 131.21
6. EPA shall review the State or Tribe submittal for compliance with the CWA pursuant to 40 CFR 123.44, and 40 CFR 131.21.

J. State WQS Revisions. All variances shall be appended to the State or Tribe WQS rules.

Procedure 3: Total Maximum Daily Loads, Wasteload Allocations for Point Sources, Load Allocations for Nonpoint Sources, Wasteload Allocations in the Absence of a TMDL, and Preliminary Wasteload Allocations for Purposes of Determining the Need for Water Quality Based Effluent Limits

The Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) this procedure 3 for the purpose of developing Total Maximum Daily Loads (TMDLs), Wasteload Allocations (WLAs) in the Absence of TMDLs, and Preliminary Wasteload Allocations for Purposes of Determining the Need for Water Quality Based Effluent Limits (WQBELs), except as specifically provided.

A. Where a State or Tribe develops an assessment and remediation plan that the State or Tribe certifies meets the requirements of sections B through F of this procedure and public participation requirements applicable to TMDLs, and that has been approved by EPA as meeting those requirements under 40 CFR 130.6, the assessment and remediation plan may be used in lieu of a TMDL for purposes of appendix F to part 132. Assessment and remediation plans under this procedure may include, but are not limited to, Lakewide Management Plans, Remedial Action Plans, and State Water Quality Management Plans. Also, any part of an assessment and remediation plan that also satisfies one or more requirements under Clean Water Act (CWA) section 303(d) or implementing regulations may be incorporated by reference into a TMDL as appropriate. Assessment and remediation plans under this section should be tailored to the level of detail and magnitude for the watershed and pollutant being assessed.

B. General Conditions of Application. Except as provided in §132.4, the following are conditions applicable to establishing TMDLs for all pollutants and pollutant parameters in the Great Lakes System, with the exception of whole effluent toxicity, unless otherwise provided in procedure 6 of appendix F. Where specified, these conditions also apply to wasteload allocations (WLAs) calculated in the absence of TMDLs and to preliminary WLAs for purposes of determining the needs for WQBELs under procedure 5 of appendix F.

1. TMDLs Required. TMDLs shall, at a minimum, be established in accordance with the listing and priority setting process established in section 303(d) of the CWA and at 40 CFR 130.7. Where water quality standards cannot be attained immediately, TMDLs must reflect reasonable assurances that water quality standards will be attained in a reasonable period of time. Some TMDLs may be based on attaining water quality standards over a period of time, with specific controls on individual sources being implemented in stages. Determining the reasonable period of time in which water quality standards will be met is a case-specific determination considering a number of factors including, but not limited to: receiving water characteristics; persistence, behavior and ubiquity of pollutants of concern; type of remediation activities necessary; available regulatory and non-regulatory controls; and individual State or Tribal requirements for attainment of water quality standards.

2. Attainment of Water Quality Standards. A TMDL must ensure attainment of applicable water quality standards, including all numeric and narrative criteria, Tier I criteria, and Tier II values for each pollutant or pollutants for which a TMDL is established.

3. TMDL Allocations.

a. TMDLs shall include WLAs for point sources and load allocations (LAs) for nonpoint sources, including natural background, such that the sum of these allocations is not greater than the loading capacity of the water for the pollutant(s) addressed by the TMDL, minus the sum of a specified margin of safety (MOS) and any capacity reserved for future growth.

b. Nonpoint source LAs shall be based on:

i. Existing pollutant loadings if changes in loadings are not reasonably anticipated to occur;

ii. Increases in pollutant loadings that are reasonably anticipated to occur;

***15417** iii. Anticipated decreases in pollutant loadings if such decreased loadings are technically feasible and are reasonably anticipated to occur within a reasonable time period as a result of implementation of best management practices or other load reduction measures. In determining whether anticipated decreases in pollutant loadings are technically feasible and can reasonably be expected to occur within a reasonable period of time, technical and institutional factors shall be considered. These decisions are case-specific and should reflect the particular TMDL under consideration.

c. WLAs. The portion of the loading capacity not assigned to nonpoint sources including background, or to an MOS, or reserved for future growth is allocated to point sources. Upon reissuance, NPDES permits for these point sources must include effluent limitations consistent with WLAs in EPA-approved or EPA-established TMDLs.

d. Monitoring. For LAs established on the basis of subsection b.iii above, monitoring data shall be collected and analyzed in order to validate the TMDL's assumptions, to varify anticipated load reductions, to evaluate the effectiveness of controls being used to implement the TMDL, and to revise the WLAs and LAs as necessary to ensure that water quality standards will be achieved within the time-period established in the TMDL.

4. WLA Values. If separate EPA-approved or EPA-established TMDLs are prepared for different segments of the same watershed, and the separate TMDLs each include WLAs for the same pollutant for one or more of the same point sources, then WQBELs for that pollutant for the point source(s) shall be consistent with the most stringent of those WLAs in order to ensure attainment of all applicable water quality standards.

5. Margin of Safety (MOS). Each TMDL shall include a MOS sufficient to account for technical uncertainties in establishing the TMDL and shall describe the manner in which the MOS is determined and incorporated into the TMDL. The MOS may be provided by leaving a portion of the loading capacity unallocated or by using conservative modeling assumptions to establish WLAs and LAs. If a portion of the loading capacity is left unallocated to provide a MOS, the amount left unallocated shall be described. If conservative modeling assumptions are relied on to provide a MOS, the specific assumptions providing the MOS shall be identified.

6. More Stringent Requirements. States and Tribes may exercise authority reserved to them under section 510 of the CWA to develop more stringent TMDLs (including WLAs and LAs) than are required herein, provided that all LAs in such TMDLs reflect actual nonpoint source loads or those loads that can reasonably be expected to occur within a reasonable time-period as a result of implementing nonpoint source controls.

7. Accumulation in Sediments. TMDLs shall reflect, where appropriate and where sufficient data are available, contributions to the water column from sediments inside and outside of any applicable mixing zones. TMDLs shall be sufficiently stringent so as to prevent accumulation of the pollutant of concern in sediments to levels injurious to designated or existing uses, human health, wildlife and aquatic life.

8. Wet Weather Events. Notwithstanding the exception provided for the establishment of controls on wet weather point sources in §132.4(e)(1), TMDLs shall reflect, where appropriate and where sufficient data are available, discharges resulting from wet

weather events. This procedure does not provide specific procedures for considering discharges resulting from wet weather events. However, some of the provisions of procedure 3 may be deemed appropriate for considering wet weather events on a case-by-case basis.

9. Background Concentration of Pollutants. The representative background concentration of pollutants shall be established in accordance with this subsection to develop TMDLs, WLAs calculated in the absence of a TMDL, or preliminary WLAs for purposes of determining the need for WQBELs under procedure 5 of appendix F. Background loadings may be accounted for in a TMDL through an allocation to a single “background” category or through individual allocations to the various background sources.

a. Definition of Background. “Background” represents all loadings that: (1) flow from upstream waters into the specified watershed, waterbody or waterbody segment for which a TMDL, WLA in the absence of a TMDL or preliminary WLA for the purpose of determining the need for a WQBEL is being developed; (2) enter the specified watershed, waterbody or waterbody segment through atmospheric deposition or sediment release or resuspension; or (3) occur within the watershed, waterbody or waterbody segment as a result of chemical reactions.

b. Data considerations. When determining what available data are acceptable for use in calculating background, the State or Tribe should use best professional judgment, including consideration of the sampling location and the reliability of the data through comparison to reported analytical detection levels and quantification levels. When data in more than one of the data sets or categories described in section B.9.c.i through B.9.c.iii below exist, best professional judgment should be used to select the one data set that most accurately reflects or estimates background concentrations. Pollutant degradation and transport information may be considered when utilizing pollutant loading data.

c. Calculation requirements. Except as provided below, the representative background concentration for a pollutant in the specified watershed, waterbody or waterbody segment shall be established on a case-by-case basis as the geometric mean of:

i. Acceptable available water column data; or

ii. Water column concentrations estimated through use of acceptable available caged or resident fish tissue data; or

iii. Water column concentrations estimated through use of acceptable available or projected pollutant loading data.

d. Detection considerations.

i. Commonly accepted statistical techniques shall be used to evaluate data sets consisting of values both above and below the detection level.

ii. When all of the acceptable available data in a data set or category, such as water column, caged or resident fish tissue or pollutant loading data, are below the level of detection for a pollutant, then all the data for that pollutant in that data set shall be assumed to be zero.

10. Effluent Flow. If WLAs are expressed as concentrations of pollutants, the TMDL shall also indicate the point source effluent flows assumed in the analyses. Mass loading limitations established in NPDES permits must be consistent with both the WLA and assumed effluent flows used in establishing the TMDL.

11. Reserved Allocations. TMDLs may include reserved allocations of loading capacity to accommodate future growth and additional sources. Where such reserved allocations are not included in a TMDL, any increased loadings of the pollutant for which the TMDL was developed that are due to a new or expanded discharge shall not be allowed unless the TMDL is revised in accordance with these proceudres to include an allocation for the new or expanded discharge.

C. Mixing Zones for Bioaccumulative Chemicals of Concern (BCCs). The following requirements shall be applied in establishing TMDLs, WLAs in the absence of TMDLs, and preliminary WLAs for purposes of determining the need for WQBELs under procedure 5 of appendix F, for BCCs:

1. Beginning on March 23, 1997, there shall be no mixing available for new discharges of BCCs to the Great Lakes System. WLAs established through TMDLs, WLAs in the absence of TMDLs, and preliminary WLAs for purposes of determining the need for WQBELs for new discharges of BCCs shall be set equal to the most stringent applicable water quality criteria or values for the BCCs in question.

2. For purposes of section C of procedure 3 of appendix F, new discharges are defined as: (1) discharges from new Great Lakes dischargers; or (2) new or expanded discharges from an existing Great Lakes discharger. All other discharges of BCCs are defined as existing discharges.

3. Up until March 23, 2007, mixing zones for BCCs may be allowed for existing discharges to the Great Lakes System pursuant to the procedures specified in sections D and E of this procedure.

4. Except as provided in sections C.5 and C.6 of this procedure, permits issued on or after March 23, 1997 shall not authorize mixing zones for existing discharges of BCCs to the Great Lakes System after March 23, 2007. After March 23, 2007, WLAs established through TMDLs, WLAs established in the absence of TMDLs and preliminary WLAs for purposes of determining the need for WQBELs under procedure 5 of appendix F for existing dischrges of BCCs to the Great Lakes System shall be set equal to the most stringent applicable water quality criteria or values for the BCCs in question.

5. Exception for Water Conservation. States and Tribes may grant mixing zones for any existing discharge of BCCs to the Great Lakes ***15418** System beyond the dates specified in sections C.3 and C.4 of this procedure, where it can be demonstrated, on a case-by-case basis, that failure to grant a mixing zone would preclude water conservation measures that would lead to overall load reductions in BCCs, even though higher concentrations of BCCs occur in the effluent. Such mixing zones must also be consistent with sections D and E of this procedure.

6. Exception for Technical and Economic Considerations. States and Tribes may grant mixing zones beyond the dates specified in sections C.3 and C.4 of this procedure for any existing discharges of a BCC to the Great Lakes System upon the request of a discharger subject to the limited circumstances specified in sections C.6.a through C.6.d below. Such mixing zones shall also be consistent with sections D and E of this procedure.

a. The permitting authority must determine that:

i. The discharger is in compliance with and will continue to implement all applicable technology-based treatment and pretreatment requirements of CWA sections 301, 302, 304, 306, 307, 401, and 402, and is in compliance with its existing NPDES water quality-based effluent limitations, including those based on a mixing zone; and

ii. The discharger has reduced and will continue to reduce the loading of the BCC for which a mixing zone is requested to the maximum extent possible.

b. In making the determination in section C.6.a above, the State or Tribal authority should consider:

i. The availability and feasibility, including cost effectiveness, of additional controls or pollution prevention measures for reducing and ultimately eliminating BCCs for that discharger, including those used by similar dischargers;

ii. Whether the discharger or affected communities will suffer unreasonable economic effects if the mixing zone is eliminated;

iii. The extent to which the discharger will implement an ambient monitoring plan to ensure compliance with water quality criteria at the edge of any authorized mixing zone or to ensure consistency with any applicable TMDL or such other strategy consistent with section A of this procedure; and,

iv. Other information the State or Tribe deems appropriate.

c. Any exceptions to the mixing zone elimination provision for existing discharges of BCCs granted pursuant to this section shall:

i. Not result in any less stringent limitations than those existing March 23, 1997;

ii. Not likely jeopardize the continued existence of any endangered or threatened species listed under section 4 of the ESA or result in the destruction or adverse modification of such species' critical habitat;

iii. Be limited to one permit term unless the permitting authority makes a new determination in accordance with this section for each successive permit application in which a mixing zone for the BCC(s) is sought;

iv. Reflect all information relevant to the size of the mixing zone considered by the State or Tribe under subsection b above;

v. Protect all designated and existing uses of the receiving water;

vi. Meet all applicable aquatic life, wildlife and human health criteria and values at the edge of the mixing zone and, as appropriate, within the mixing zone or be consistent with any appropriate TMDL or such other strategy consistent with section A of this procedure;

vii. Ensure the discharger has developed and conducted a pollutant minimization program for the BCC(s) if required to do so under regulations adopted consistent with procedure 8 of appendix F; and

viii. Ensure that alternative means for reducing BCCs elsewhere in the watershed are evaluated.

d. For each draft NPDES permit that would allow a mixing zone for one or more BCCs after March 23, 2007, the fact sheet or statement of basis for the draft permit, required to be made available through public notice under 40 CFR 124.6(e), shall:

i. Specify the mixing provisions used in calculating the permit limits; and

ii. Identify each BCC for which a mixing zone is proposed.

D. Deriving TMDLs, WLAs, and LAs for Point and Nonpoint Sources: WLAs in the Absence of a TMDL; and Preliminary WLAs for Purposes of Determining the Need for WQBELs for OWGL. This section addresses conditions for deriving TMDLs for Open Waters of the Great Lakes (OWGL), inland lakes and other waters of the Great Lakes System with no appreciable flow relative to their volumes. State and Tribal procedures to derive TMDLs under this section must be consistent with (as protective as) the general conditions in section B of this procedure, CWA section 303(d), existing regulations (40 CFR 130.7), section C of this procedure, and sections D.1. through D.4 below. State and Tribal procedures to derive WLAs calculated in the absence of a TMDL and preliminary WLAs for purposes of determining the need for WQBELs under procedure 5 of appendix F must be consistent with sections B.9, C.1, C3 through C.6, and D. 1 through D.4 of this procedure.

1. Individual point source WLAs and preliminary WLAs for purposes of determining the need for WQBELs under procedure 5 of appendix F shall assume no greater dilution than one part effluent to 10 parts receiving water for implementation of numeric

and narrative chronic criteria and values (including, but not limited to human cancer criteria, human cancer values, human noncancer values, human noncancer criteria, wildlife criteria, and chronic aquatic life criteria and values) unless an alternative mixing zone is demonstrated as appropriate in a mixing zone demonstration conducted pursuant to section F of this procedure. In no case shall a mixing zone be granted that exceeds the area where discharge-induced mixing occurs.

2. Appropriate mixing zone assumptions to be used in calculating load allocations for nonpoint sources shall be determined, consistent with applicable State or Tribal requirements, on a case-by-case basis.

3. WLAs and preliminary WLAs based on acute aquatic life criteria or values shall not exceed the Final Acute Value (FAV), unless a mixing zone demonstration is conducted and approved pursuant to section F of this procedure. If mixing zones from two or more proximate sources interact or overlap, the combined effect must be evaluated to ensure that applicable criteria and values will be met in the area where acute mixing zones overlap.

4. In no case shall a mixing zone be granted that would likely jeopardize the continued existence of any endangered or threatened species listed under section 4 of the ESA or result in the destruction or adverse modification of such species' critical habitat.

E. Deriving TMDLs, WLAs, and LAs for Point and Nonpoint Sources; WLAs in the Absence of a TMDL; and Preliminary WLAs for the Purposes of Determining the Need for WQBELs for Great Lakes Systems Tributaries and Connecting Channels. This section describes conditions for deriving TMDLs for tributaries and connecting channels of the Great Lakes System that exhibit appreciable flows relative to their volumes. State and Tribal procedures to derive TMDLs must be consistent with the general conditions listed in section B of this procedure, section C of this procedure, existing TMDL regulations (40 CFR 130.7) and specific conditions E.1 through E.5. State and Tribal procedures to derive WLAs calculated in the absence of a TMDL, and preliminary WLAs for purposes of determining reasonable potential under procedure 5 of this appendix for discharges to tributaries and connecting channels must be consistent with sections B.9, C.1, C.3 through C.6, and E.1 through E.5 of this procedure.

1. Stream Design. These design flows must be used unless data exist to demonstrate that an alternative stream design flow is appropriate for stream-specific and pollutant-specific conditions. For purposes of calculating a TMDL, WLAs in the absence of a TMDL, or preliminary WLAs for the purposes of determining reasonable potential under procedure 5 of this appendix, using a steady-state model, the stream design flows shall be:

a. The 7-day, 10-year stream design flow (7Q10), or the 4-day, 3-year biologically-based stream design flow for chronic aquatic life criteria or values;

b. The 1-day, 10-year stream design flow (1Q10), for acute aquatic life criteria or values;

c. The harmonic mean flow for human health criteria or values;

d. The 90-day, 10-year flow (90Q10) for wildlife criteria.

e. TMDLs, WLAs in the absence of TMDLs, and preliminary WLAs for the purpose of determining the need for WQBELs calculated using dynamic modelling do not need to incorporate the stream design flows specified in sections E.1.a through E.1.d of this procedure.

2. Loading Capacity. The loading capacity is the greatest amount of loading that a water can receive without violating water quality standards. The loading capacity is initially calculated at the farthest downstream location in the watershed drainage basin. The maximum allowable loading consistent with the attainment of each applicable numeric ***15419** criterion or value for a given pollutant is determined by multiplying the applicable criterion or value by the flow at the farthest downstream location in the tributary basin at the design flow condition described above. This loading is then compared to the loadings at

sites within the basin to assure that applicable numeric criteria or values for a given pollutant are not exceeded at all applicable sites. The lowest load is then selected as the loading capacity.

3. Polluant Degradation. TMDLs, WLAs in the absence of a TMDL and preliminary WLAs for purposes of determining the need for WQBELs under procedure 5 of appendix F shall be based on the assumption that a pollutant does not degrade. However, the regulatory authority may take into account degradation of the pollutant if each of the following conditions are met.

a. Scientifically valid field studies or other relevant information demonstrate that degradation of the pollutant is expected to occur under the full range of environmental conditions expected to be encountered;

b. Scientifically valid field studies or other relevant information address other factors that affect the level of pollutants in the water column including, but not limited to, resuspension of sediments, chemical speciation, and biological and chemical transformation.

4. Acute Aquatic Life Criteria and Values. WLAs and LAs established in a TMDL, WLAs in the absence of a TMDL, and preliminary WLAs for the purpose of determining the need for WQBELs based on acute aquatic life criteria or values shall not exceed the FAV, unless a mixing zone demonstration is completed and approved pursuant to section F of this procedure. If mixing zones from two or more proximate sources interact or overlap, the combined effect must be evaluated to ensure that applicable criteria and values will be met in the area where any applicable acute mixing zones overlap. This acute WLA review shall include, but not be limited to, consideration of:

a. The expected dilution under all effluent flow and concentration conditions at stream design flow;

b. Maintenance of a zone of passage for aquatic organisms; and

c. Protection of critical aquatic habitat.

In no case shall a permitting authority grant a mixing zone that would likely jeopardize the continued existence of any endangered or threatened species listed under section 4 of the ESA or result in the destruction or adverse modification of such species' critical habitat.

5. Chronic Mixing Zones. WLAs and LAs established in a TMDL, WLAs in the absence of a TMDL, and preliminary WLAs for the purposes of determining the need for WQBELs for protection of aquatic life, wildlife and human health from chronic effects shall be calculated using a dilution fraction no greater than 25 percent of the stream design flow unless a mixing zone demonstration pursuant to section F of this procedure is conducted and approved. A demonstration for a larger mixing zone may be provided, if approved and implemented in accordance with section F of this procedure. In no case shall a permitting authority grant a mixing zone that would likely jeopardize the continued existence of any endangered or threatened species listed under section 4 of the ESA or result in the destruction or adverse modification of such species' critical habitat.

F. Mixing Zone Demonstration Requirements.

1. For purposes of establishing a mixing zone other than as specified in sections D and E above, a mixing zone demonstration must:

a. Describe the amount of dilution occurring at the boundaries of the proposed mixing zone and the size, shape, and location of the area of mixing, including the manner in which diffusion and dispersion occur;

b. For sources discharging to the open waters of the Great Lakes (OWGLs), define the location at which discharge-induced mixing ceases;

c. Document the substrate character and geomorphology within the mixing zone;

d. Show that the mixing zone does not interfere with or block passage of fish or aquatic life;

e. Show that the mixing zone will be allowed only to the extent that the level of the pollutant permitted in the waterbody would not likely jeopardize the continued existence of any endangered or threatened species listed under section 4 of the ESA or result in the destruction or adverse modification of such species' critical habitat;

f. Show that the mixing zone does not extend to drinking water intakes;

g. Show that the mixing zone would not otherwise interfere with the designated or existing uses of the receiving water or downstream waters;

h. Document background water quality concentrations;

i. Show that the mixing zone does not promote undesirable aquatic life or result in a dominance of nuisance species; and

j. Provide that by allowing additional mixing/dilution:

i. Substances will not settle to form objectionable deposits;

ii. Floating debris, oil, scum, and other matter in concentrations that form nuisances will not be produced; and

iii. Objectionable color, odor, taste or turbidity will not be produced.

2. In addition, the mixing zone demonstration shall address the following factors:

a. Whether or not adjacent mixing zones overlap;

b. Whether organisms would be attracted to the area of mixing as a result of the effluent character; and

c. Whether the habitat supports endemic or naturally occurring species.

3. The mixing zone demonstration must be submitted to EPA for approval. Following approval of a mixing zone demonstration consistent with sections F.1 and F.2, adjustment to the dilution ratio specified in section D.1 of this procedure shall be limited to the dilution available in the area where discharger-induced mixing occurs.

4. The mixing zone demonstration shall be based on the assumption that a pollutant does not degrade within the proposed mixing zone, unless:

a. Scientifically valid field studies or other relevant information demonstrate that degradation of the pollutant is expected to occur under the full range of environmental conditions expected to be encountered; and

b. Scientifically valid field studies or other relevant information address other factors that affect the level of pollutants in the water column including, but not limited to, resuspension of sediments, chemical speciation, and biological and chemical transformation.

Procedure 4: Additivity

The Great Lakes States and Tribes shall adopt additivity provisions consistent with (as protective as) this procedure.

A. The Great Lakes States and Tribes shall adopt provisions to protect human health from the potential adverse additive effects from both the noncarcinogenic and carcinogenic components of chemical mixtures in effluents. For the chlorinated dibenzo-p-dioxins (CDDs) and chlorinated dibenzofurans (CDFs) listed in Table 1, potential adverse additive effects in effluents shall be accounted for in accordance with section B of this procedure.

B. Toxicity Equivalency Factors (TEFs)/Bioaccumulation Equivalency Factors (BEFs).

1. The TEFs in Table 1 and BEFs in Table 2 shall be used when calculating a 2,3,7,8-TCDD toxicity equivalence concentration in effluent to be used when implementing both human health noncancer and cancer criteria. The chemical concentration of each CDDs and CDFs in effluent shall be converted to a 2,3,7,8-TCDD toxicity equivalence concentration in effluent by (a) multiplying the chemical concentration of each CDDs and CDFs in the effluent by the appropriate TEF in Table 1 below, (b) multiplying each product from step (a) by the BEF for each CDDs and CDFs in Table 2 below, and (c) adding all final products from step (b). The equation for calculating the 2,3,7,8-TCDD toxicity equivalence concentration in effluent is:

where:

$(TEC)_{tcdd}$=2,3,7,8-TCDD toxicity equivalence concentration in effluent

$(C)_x$=concentration of total chemical x in effluent

$(TEF)_x$=TCDD toxicity equivalency factor for x

$(BEF)_x$=TCDD bioaccumulation equivalency factor for x

2. The 2,3,7,8-TCDD toxicity equivalence concentration in effluent shall be used when developing waste load allocations under procedure 3, preliminary waste load allocations for purposes of determining reasonable potential under procedure 5, and for purposes of establishing effluent quality limits under procedure 5.

***15420 Procedure 5: Reasonable Potential To Exceed Water Quality Standards**

Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) this procedure. If a permitting authority determines that a pollutant is or may be discharged into the Great Lakes System at a level which will cause, have the reasonable potential to cause, or contribute to an excursion above any Tier I criterion or Tier II value, the permitting authority shall incorporate a water quality-based effluent limitation (WQBEL) in an NPDES permit for the discharge of that pollutant. When facility-specific effluent monitoring data are available, the permitting authority shall make this determination by developing preliminary effluent limitations (PEL) and comparing those effluent limitations to the projected effluent quality (PEQ) of the discharge in accordance with the following procedures. In all cases, the permitting authority shall use any valid, relevant, representative information that indicates a reasonable potential to exceed any Tier I criterion or Tier II value.

A. Developing Preliminary Effluent Limitations on the Discharge of a Pollutant From a Point Source.

1. The permitting authority shall develop preliminary wasteload allocations (WLAs) for the discharge of the pollutant from the point source to protect human health, wildlife, acute aquatic life, and chronic aquatic life, based upon any existing Tier I criteria. Where there is no Tier I criterion nor sufficient data to calculate a Tier I criterion, the permitting authority shall calculate a Tier II value for such pollutant for the protection of human health, and aquatic life and the preliminary WLAs shall be based upon such values. Where there is insufficient data to calculate a Tier II value, the permitting authority shall apply the procedure set forth in section C of this procedure to determine whether data must be generated to calculate a Tier II value.

2. The following provisions in procedure 3 of appendix F shall be used as the basis for determining preliminary WLAs in accordance with section 1 of this procedure: procedure 3.B.9, Background Concentrations of Pollutants; procedure 3.C, Mixing Zones for Bioaccumulative Chemicals of Concern (BCCs), procedures 3.C.1, and 3.C.3 through 3.C.6; procedure 3.D, Deriving TMDLs for Discharges to Lakes (when the receiving water is an open water of the Great Lakes (OWGL), an inland lake or other water of the Great Lakes System with no appreciable flow relative to its volume); procedure 3.E, Deriving TMDLs, WLAs and Preliminary WLAs, and load allocations (LAs) for Discharges to Great Lakes System Tributaries (when the receiving water is a tributary or connecting channel of the Great Lakes that exhibits appreciable flow relative to its volume); and procedure 3.F, Mixing Zone Demonstration Requirements.

3. The permitting authority shall develop PELs consistent with the preliminary WLAs developed pursuant to sections A.1 and A.2 of this procedure, and in accordance with existing State or Tribal procedures for converting WLAs into WQBELs. At a minimum:

a. The PELs based upon criteria and values for the protection of human health and wildlife shall be expressed as monthly limitations;

b. The PELs based upon criteria and values for the protection of aquatic life from chronic effects shall be expressed as either monthly limitations or weekly limitations; and

c. The PELs based upon the criteria and values for the protection of aquatic life from acute effects shall be expressed as daily limitations.

B. Determining Reasonable Potential Using Effluent Pollutant Concentration Data.

If representative, facility-specific effluent monitoring data samples are available for a pollutant discharged from a point source to the waters of the Great Lakes System, the permitting authority shall apply the following procedures:

1. The permitting authority shall specify the PEQ as the 95 percent confidence level of the 95th percentile based on a log-normal distribution of the effluent concentration; or the maximum observed effluent concentration, whichever is greater. In calculating the PEQ, the permitting authority shall identify the number of effluent samples and the coefficient of variation of the effluent data, obtain the appropriate multiplying factor from Table 1 of procedure 6 of appendix F, and multiply the maximum effluent

concentration by that factor. The coefficient of variation of the effluent data shall be calculated as the ratio of the standard deviation of the effluent data divided by the arithmetic average of the effluent data, except that where there are fewer than ten effluent concentration data points the coefficient of variation shall be specified as 0.6. If the PEQ exceeds any of the PELs developed in accordance with section A.3 of this procedure, the permitting authority shall establish a WQBEL in a NPDES permit for such pollutant.

2. In lieu of following the procedures under section B.1 of this procedure, the permitting authority may apply procedures consistent with the following:

a. The permitting authority shall specify the PEQ as the 95th percentile of the distribution of the projected population of daily values of the facility-specific effluent monitoring data projected using a scientifically defensible statistical method that accounts for and captures the long-term daily variability of the effluent quality, accounts for limitations associated with sparse data sets and, unless otherwise shown by the effluent data set, assumes a lognormal distribution of the facility-specific effluent data. If the PEQ exceeds the PEL based on the criteria and values for the protection of aquatic life from acute effects developed in accordance with section A.3 of this procedure, the permitting authority shall establish a WQBEL in an NPDES permit for such pollutant;

b. The permitting authority shall calculate the PEQ as the 95th percentile of the distribution of the projected population of monthly averages of the facility-specific effluent monitoring data using a scientifically defensible statistical method that accounts for and captures the long-term variability of the monthly average effluent quality, accounts for limitations associated with sparse data sets and, unless otherwise shown by the effluent data set, assumes a lognormal distribution of the facility-specific effluent data. If the PEQ exceeds the PEL based on criteria and values for the protection of aquatic life from chronic effects, human health or wildlife developed in accordance with section A.3 of this procedure, the permitting authority shall establish a WQBEL in an NPDES permit for such pollutant; and

c. The permitting authority shall calculate the PEQ as the 95th percentile of the distribution of the projected population of weekly averages of the facility-specific effluent monitoring data using a scientifically defensible statistical method that accounts for and captures the long-term variability of the weekly average effluent quality, accounts for limitations associated with sparse data sets and, unless otherwise shown by the effluent data set, assumes a lognormal distribution of the facility-specific effluent data. If the PEQ exceeds the PEL based on criteria and values to protect aquatic life from chronic effects developed in accordance with section A.3 of this procedure, the permitting ***15421** authority shall establish a WQBEL in an NPDES permit for such pollutant.

C. Developing Necessary Data to Calculate Tier II Values Where Such Data Does Not Currently Exist.
40 CFR § 122.44
1. Except as provided in sections C.2, C.4, or D of this procedure, for each pollutant listed in Table 6 of part 132 that a permittee reports as known or believed to be present in its effluent, and for which pollutant data sufficient to calculate Tier II values for non-cancer human health, acute aquatic life and chronic aquatic life do not exist, the permitting authority shall take the following actions:

a. The permitting authority shall use all available, relevant information, including Quantitative Structure Activity Relationship information and other relevant toxicity information, to estimate ambient screening values for such pollutant which will protect humans from health effects other than cancer, and aquatic life from acute and chronic effects.

b. Using the procedures specified in sections A.1 and A.2 of this procedure, the permitting authority shall develop preliminary WLAs for the discharge of the pollutant from the point source to protect human health, acute aquatic life, and chronic aquatic life, based upon the estimated ambient screening values.

c. The permitting authority shall develop PELs in accordance with section A.3 of this procedure, which are consistent with the preliminary WLAs developed in accordance with section C.1.b of this procedure.

d. The permitting authority shall compare the PEQ developed according to the procedures set forth in section B of this procedure to the PELs developed in accordance with section C.1.c of this procedure. If the PEQ exceeds any of the PELs, the permitting authority shall generate or require the permittee to generate the data necessary to derive Tier II values for noncancer human health, acute aquatic life and chronic aquatic life.

e. The data generated in accordance with section C.1.d of this procedure shall be used in calculating Tier II values as required under section A.1 of this procedure. The calculated Tier II value shall be used in calculating the preliminary WLA and PEL under section A of this procedure, for purposes of determining whether a WQBEL must be included in the permit. If the permitting authority finds that the PEQ exceeds the calculated PEL, a WQBEL for the pollutant or a permit limit on an indicator parameter consistent with 40 CFR 122.44(d)(1)(vi)(C) must be included in the permit.

2. With the exception of bioaccumulative chemicals of concern (BCCs), a permitting authority is not required to apply the procedures set forth in section C.1 of this procedure or include WQBELs to protect aquatic life for any pollutant listed in Table 6 of part 132 discharged by an existing point source into the Great Lakes System, if:

a. There is insufficient data to calculate a Tier I criterion or Tier II value for aquatic life for such pollutant;

b. The permittee has demonstrated through a biological assessment that there are no acute or chronic effects on aquatic life in the receiving water; and

c. The permittee has demonstrated in accordance with procedure 6 of this appendix that the whole effluent does not exhibit acute or chronic toxicity.

3. Nothing in sections C.1 or C.2 of this procedure shall preclude or deny the right of a permitting authority to:

a. Determine, in the absence of the data necessary to derive a Tier II value, that the discharge of the pollutant will cause, have the reasonable potential to cause, or contribute to an excursion above a narrative criterion for water quality; and

b. Incorporate a WQBEL for the pollutant into an NPDES permit.

4. If the permitting authority develops a WQBEL consistent with section C.3 of this procedure, and the permitting authority demonstrates that the WQBEL developed under section C.3 of this procedure is at least as stringent as a WQBEL that would have been based upon the Tier II value or values for that pollutant, the permitting authority shall not be obligated to generate or require the permittee to generate the data necessary to derive a Tier II value or values for that pollutant.

D. Consideration of Intake Pollutants in Determining Reasonable Potential.
40 CFR § 122.44
1. General.

a. Any procedures adopted by a State or Tribe for considering intake pollutants in water quality-based permitting shall be consistent with this section and section E.

b. The determinations under this section and section E shall be made on a pollutant-by-pollutant, outfall-by-outfall, basis.

c. This section and section E apply only in the absence of a TMDL applicable to the discharge prepared by the State or Tribe and approved by EPA, or prepared by EPA pursuant to 40 CFR 130.7(d), or in the absence of an assessment and remediation

plan submitted and approved in accordance with procedure 3.A. of appendix F. This section and section E do not alter the permitting authority's obligation under 40 CFR 122.44(d)(vii)(B) to develop effluent limitations consistent with the assumptions and requirements of any available WLA for the discharge, which is part of a TMDL prepared by the State or Tribe and approved by EPA pursuant to 40 CFR 130.7, or prepared by EPA pursuant to 40 CFR 130.7(d).

2. Definition of Same Body of Water.

a. This definition applies to this section and section E of this procedure.

b. An intake pollutant is considered to be from the same body of water as the discharge if the permitting authority finds that the intake pollutant would have reached the vicinity of the outfall point in the receiving water within a reasonable period had it not been removed by the permittee. This finding may be deemed established if:

i. The background concentration of the pollutant in the receiving water (excluding any amount of the pollutant in the facility's discharge) is similar to that in the intake water;

ii. There is a direct hydrological connection between the intake and discharge points; and

iii. Water quality characteristics (e.g., temperature, Ph, hardness) are similar in the intake and receiving waters.

c. The permitting authority may also consider other site-specific factors relevant to the transport and fate of the pollutant to make the finding in a particular case that a pollutant would or would not have reached the vicinity of the outfall point in the receiving water within a reasonable period had it not been removed by the permittee.

d. An intake pollutant from groundwater may be considered to be from the same body of water if the permitting authority determines that the pollutant would have reached the vicinity of the outfall point in the receiving water within a reasonable period had it not been removed by the permittee, except that such a pollutant is not from the same body of water if the groundwater contains the pollutant partially or entirely due to human activity, such as industrial, commercial, or municipal operations, disposed actions, or treatment processes.

e. An intake pollutant is the amount of a pollutant that is present in waters of the United States (including groundwater as provided in section D.2.d of this procedure) at the time it is withdrawn from such waters by the discharger or other facility (e.g., public water supply) supplying the discharger with intake water.

3. Reasonable Potential Determination.

a. The permitting authority may use the procedure described in this section of procedure 5 in lieu of procedures 5.A through C provided the conditions specified below are met.

b. The permitting authority may determine that there is no reasonable potential for the discharge of an identified intake pollutant or pollutant parameter to cause or contribute to an excursion above a narrative or numeric water quality criterion within an applicable water quality standard where a discharger demonstrates to the satisfaction of the permitting authority (based upon information provided in the permit application or other information deemed necessary by the permitting authority) that:

i. The facility withdraws 100 percent of the intake water containing the pollutant from the same body of water into which the discharge is made;

ii. The facility does not contribute any additional mass of the identified intake pollutant to its wastewater;

iii. The facility does not alter the identified intake pollutant chemically or physically in a manner that would cause adverse water quality impacts to occur that would not occur if the pollutants were left in-stream;

iv. The facility does not increase the identified intake pollutant concentration, as defined by the permitting authority, at the edge of the mixing zone, or at the point of discharge if a mixing zone is not allowed, as compared to the pollutant concentration in the intake water, unless the increased concentration does not cause or contribute to an excursion above an applicable water quality standard; and

v. The timing and location of the discharge would not cause adverse water quality impacts to occur that would not occur if the identified intake pollutant were left in-stream.

c. Upon a finding under section D.3.b of this procedure that a pollutant in the ***15422** discharge does not cause, have the reasonable potential to cause, or contribute to an excursion above an applicable water quality standard, the permitting authority is not required to include a WQBEL for the identified intake pollutant in the facility's permit, provided:

i. The NPDES permit fact sheet or statement of basis includes a specific determination that there is no reasonable potential for the discharge of an identified intake pollutant to cause or contribute to an excursion above an applicable narrative or numeric water quality criterion and references appropriate supporting documentation included in the administrative record;

ii. The permit requires all influent, effluent, and ambient monitoring necessary to demonstrate that the conditions in section D.3.b of this procedure are maintained during the permit term; and

iii. The permit contains a reopener clause authorizing modification or revocation and reissuance of the permit if new information indicates changes in the conditions in section D.3.b of this procedure.

d. Absent a finding under section D.3.b of this procedure that a pollutant in the discharge does not cause, have the reasonable potential to cause, or contribute to an excursion above an applicable water quality standard, the permitting authority shall use the procedures under sections 5.A through C of this procedure to determine whether a discharge causes, has the reasonable potential to cause, or contribute to an excursion above an applicable narrative or numeric water quality criterion.

E. Consideration of Intake Pollutants in Establishing WQBELs.

1. General. This section applies only when the concentration of the pollutant of concern upstream of the discharge (as determined using the provisions in procedure 3.B.9 of appendix F) exceeds the most stringent applicable water quality criterion for that pollutant.

2. The requirements of sections D.1-D.2 of this procedure shall also apply to this section.

3. Intake Pollutants from the Same Body of Water.

a. In cases where a facility meets the conditions in sections D.3.b.i and D.3.b.iii through D.3.b.v of this procedure, the permitting authority may establish effluent limitations allowing the facility to discharge a mass and concentration of the pollutant that are no greater than the mass and concentration of the pollutant identified in the facility's intake water (“no net addition limitations”). The permit shall specify how compliance with mass and concentration limitations shall be assessed. No permit may authorize “no net addition limitations” which are effective after March 23, 2007. After that date, WQBELs shall be established in accordance with procedure 5.F.2 of appendix F.

b. Where proper operation and maintenance of a facility's treatment system results in removal of a pollutant, the permitting authority may establish limitations that reflect the lower mass and/or concentration of the pollutant achieved by such treatment, taking into account the feasibility of establishing such limits.

c. For pollutants contained in intake water provided by a water system, the concentration of the intake pollutant shall be determined at the point where the raw water supply is removed from the same body of water, except that it shall be the point where the water enters the water supplier's distribution system where the water treatment system removes any of the identified pollutants from the raw water supply. Mass shall be determined by multiplying the concentration of the pollutant determined in accordance with this paragraph by the volume of the facility's intake flow received from the water system.

4. Intake Pollutants from a Different Body of Water. Where the pollutant in a facility's discharge originates from a water of the United States that is not the same body of water as the receiving water (as determined in accordance with section D.2 of this procedure), WQBELs shall be established based upon the most stringent applicable water quality criterion for that pollutant.

5. Multiple Sources of Intake Pollutants. Where a facility discharges intake pollutants that originate in part from the same body of water, and in part from a different body of water, the permitting authority may apply the procedures of sections E.3 and E.4 of this procedure to derive an effluent limitation reflecting the flow-weighted average of each source of the pollutant, provided that adequate monitoring to determine compliance can be established and is included in the permit.

F. Other Applicable Conditions.

1. In addition to the above procedures, effluent limitations shall be established to comply with all other applicable State, Tribal and Federal laws and regulations, including technology-based requirements and antidegradation policies.

2. Once the permitting authority has determined in accordance with this procedure that a WQBEL must be included in an NPDES permit, the permitting authority shall:

a. Rely upon the WLA established for the point source either as part of any TMDL prepared under procedure 3 of this appendix and approved by EPA pursuant to 40 CFR 130.7, or as part of an assessment and remediation plan developed and approved in accordance with procedure 3.A of this appendix, or, in the absence of such TMDL or plan, calculate WLAs for the protection of acute and chronic aquatic life, wildlife and human health consistent with the provisions referenced in section A.1 of this procedure for developing preliminary wasteload allocations, and

b. Develop effluent limitations consistent with these WLAs in accordance with existing State or Tribal procedures for converting WLAs into WQBELs.

3. When determining whether WQBELs are necessary, information from chemical-specific, whole effluent toxicity and biological assessments shall be considered independently.

4. If the geometric mean of a pollutant in fish tissue samples collected from a waterbody exceeds the tissue basis of a Tier I criterion or Tier II value, after consideration of the variability of the pollutant's bioconcentration and bioaccumulation in fish, each facility that discharges detectable levels of such pollutant to that water has the reasonable potential to cause or contribute to an excursion above a Tier I criteria or a Tier II value and the permitting authority shall establish a WQBEL for such pollutant in the NPDES permit for such facility.

Procedure 6: Whole Effluent Toxicity Requirements

The Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) procedure 6 of appendix F of part 132.

The following definitions apply to this part:

Acute toxic unit (TU_a). $100/LC_{50}$ where the LC_{50} is expressed as a percent effluent in the test medium of an acute whole effluent toxicity (WET) test that is statistically or graphically estimated to be lethal to 50 percent of the test organisms.

Chronic toxic unit (TU_c). 100/NOEC or $100/IC_{25}$, where the NOEC and IC_{25} are expressed as a percent effluent in the test medium.

Inhibition concentration 25 (IC_{25}). the toxicant concentration that would cause a 25 percent reduction in a non-quantal biological measurement for the test population. For example, the IC_{25} is the concentration of toxicant that would cause a 25 percent reduction in mean young per female or in growth for the test population.

No observed effect concentration (NOEC). The highest concentration of toxicant to which organisms are exposed in a full life-cycle or partial life-cycle (short-term) test, that causes no observable adverse effects on the test organisms (i.e., the highest concentration of toxicant in which the values for the observed responses are not statistically significantly different from the controls).

A. Whole Effluent Toxicity Requirements. The Great Lakes States and Tribes shall adopt whole effluent toxicity provisions consistent with the following:

1. A numeric acute WET criterion of 0.3 acute toxic units (TU_a) measured pursuant to test methods in 40 CFR part 136, or a numeric interpretation of a narrative criterion establishing that 0.3 TU_a measured pursuant to test methods in 40 CFR part 136 is necessary to protect aquatic life from acute effects of WET. At the discretion of the permitting authority, the foregoing requirement shall not apply in an acute mixing zone that is sized in accordance with EPA-approved State and Tribal methods.

2. A numeric chronic WET criterion of one chronic toxicity unit (TU_c) measured pursuant to test methods in 40 CFR part 136, or a numeric interpretation of a narrative criterion establishing that one TU_c measured pursuant to test methods in 40 CFR part 136 is necessary to protect aquatic life from the chronic effects of WET. At the discretion of the permitting authority, the foregoing requirements shall not apply within a chronic mixing zone consistent with: (a) procedures 3.D.1 and 3.D.4, for discharges to the open of the Great Lakes (OWGL), inland ***15423** lakes and other waters of the Great Lakes System with no appreciable flow relative to their volume, or (b) procedure 3.E.5 for discharges to tributaries and connecting channels of the Great Lakes System.

B. WET Test Methods. All WET tests performed to implement or ascertain compliance with this procedure shall be performed in accordance with methods established in 40 CFR part 136.

C. Permit Conditions.

40 CFR § 122.44

1. Where a permitting authority determines pursuant to section D of this procedure that the WET of an effluent is or may be discharged at a level that will cause, have the reasonable potential to cause, or contribute to an excursion above any numeric WET criterion or narrative criterion within a State's or Tribe's water quality standards, the permitting authority:

a. Shall (except as provided in section C.1.e of this procedure) establish a water quality-based effluent limitation (WQBEL) or WQBELs for WET consistent with section C.1.b of this procedure;

b. Shall calculate WQBELs pursuant to section C.1.a. of this procedure to ensure attainment of the State's or Tribe's chronic WET criteria under receiving water flow conditions described in procedures 3.E.1.a (or where applicable, with procedure 3.E.1.e) for Great Lakes System tributaries and connecting channels, and with mixing zones no larger than allowed pursuant to section A.2. of this procedure. Shall calculate WQBELs to ensure attainment of the State's or Tribe's acute WET criteria under receiving water flow conditions described in procedure 3.E.1.b (or where applicable, with procedure 3.E.1.e) for Great Lakes System

tributaries and connecting channels, with an allowance for mixing zones no greater than specified pursuant to section A.1 of this procedure.

c. May specify in the NPDES permit the conditions under which a permittee would be required to perform a toxicity reduction evaluation.

d. May allow with respect to any WQBEL established pursuant to section C.1.a of this procedure an appropriate schedule of compliance consistent with procedure 9 of appendix F; and

e. May decide on a case-by-case basis that a WQBEL for WET is not necessary if the State's or Tribe's water quality standards do not contain a numeric criterion for WET, and the permitting authority demonstrates in accordance with 40 CFR 122.44(d)(1)(v) that chemical-specific effluent limits are sufficient to ensure compliance with applicable criteria.

2. Where a permitting authority lacks sufficient information to determine pursuant to section D of this procedure whether the WET of an effluent is or may be discharged at levels that will cause, have the reasonable potential to cause, or contribute to an excursion above any numeric WET criterion or narrative criterion within a State's or Tribe's water quality standards, then the permitting authority should consider including in the NPDES permit appropriate conditions to require generation of additional data and to control toxicity if found, such as:

a. WET testing requirements to generate the data needed to adequately characterize the toxicity of the effluent to aquatic life;

b. Language requiring a permit reopener clause to establish WET limits if any toxicity testing data required pursuant to section C.2.a of this procedure indicate that the WET of an effluent is or may be discharged at levels that will cause, have the reasonable potential to cause, or contribute to an excursion above any numeric WET criterion or narrative criterion within a State's or Tribe's water quality standards.
40 CFR § 122.44
3. Where sufficient data are available for a permitting authority to determine pursuant to section D of this procedure that the WET of an effluent neither is nor may be discharged at a level that will cause, have the reasonable potential to cause, or contribute to an excursion above any numeric WET criterion or narrative criterion within a State's or Tribe's water quality standards, the permitting authority may include conditions and limitations described in section C.2 of this procedure at its discretion.

D. Reasonable Potential Determinations. The permitting authority shall take into account the factors described in 40 CFR 122.44(d)(1)(ii) and, where representative facility-specific WET effluent data are available, apply the following requirements in determining whether the WET of an effluent is or may be discharged at a level that will cause, have the reasonable potential to cause, or contribute to an excursion above any numeric WET criterion or narrative criterion within a State's or Tribe's water quality standards.

1. The permitting authority shall characterize the toxicity of the discharge by:

a. Either averaging or using the maximum of acute toxicity values collected within the same day for each species to represent one daily value. The maximum of all daily values for the most sensitive species tested is used for reasonable potential determinations;

b. Either averaging or using the maximum of chronic toxicity values collected within the same calendar month for each species to represent one monthly value. The maximum of such values, for the most sensitive species tested, is used for reasonable potential determinations:

c. Estimating the toxicity values for the missing endpoint using a default acute-chronic ratio (ACR) of 10, when data exist for either acute WET or chronic WET, but not for both endpoints.

2. The WET of an effluent is or may be discharged at a level that will cause, have the reasonable potential to cause, or contribute to an excursion above any numeric acute WET criterion or numeric interpretation of a narrative criterion within a State's or Tribe's water quality standards, when effluent-specific information demonstrates that:

(TU_a effluent) (B) (effluent flow/(Qad+effluent flow))>AC

Where TU_a effluent is the maximum measured acute toxicity of 100 percent effluent determined pursuant to section D.1.a. of this procedure, B is the multiplying factor taken from Table F6-1 of this procedure to convert the highest measured effluent toxicity value to the estimated 95th percentile toxicity value for the discharge, effluent flow is the same effluent flow used to calculate the preliminary wasteload allocations (WLAs) for individual pollutants to meet the acute criteria and values for those pollutants, AC is the numeric acute WET criterion or numeric interpretation of a narrative criterion established pursuant to section A.1 of this procedure and expressed in TU_a, and Qad is the amount of the receiving water available for dilution calculated using: (i) the specified design flow(s) for tributaries and connecting channels in section C.1.b of this procedure, or where appropriate procedure 3.E.1.e of appendix F, and using EPA-approved State and Tribal procedures for establishing acute mixing zones in tributaries and connecting channels, or (ii) the EPA-approved State and Tribal procedures for establishing acute mixing zones in OWGLs. Where there are less than 10 individual WET tests, the multiplying factor taken from Table F6-1 of this procedure shall be based on a coefficient of variation (CV) or 0.6. Where there are 10 or more individual WET tests, the multiplying factor taken from Table F6-1 shall be based on a CV calculated as the standard deviation of the acute toxicity values found in the WET tests divided by the arithmetic mean of those toxicity values.

3. The WET of an effluent is or may be discharged at a level that will cause, have the reasonable potential to cause, or contribute to an excursion above any numeric chronic WET criterion or numeric interpretation of a narrative criterion within a State's or Tribe's water quality standards, when effluent-specific information demonstrates that:

(TU_c effluent) (B) (effluent flow/Qad+effluent flow))>CC

Where TU_c effluent is the maximum measured chronic toxicity value of 100 percent effluent determined in accordance with section D.1.b. of this procedure, B is the multiplying factor taken from Table F6-1 of this procedure, effluent flow is the same effluent flow used to calculate the preliminary WLAs for individual pollutants to meet the chronic criteria and values for those pollutants, CC is the numeric chronic WET criterion or numeric interpretation of a narrative criterion established pursuant to section A.2 of this procedure and expressed in TU_c, and Qad is the amount of the receiving water available for dilution calculated using: (i) the design flow(s) for tributaries and connecting channels specified in procedure 3.E.1.a of appendix F, and where appropriate procedure 3.E.1.e of appendix F, and in accordance with the provisions of procedure 3.E.5 for chronic mixing zones, or (ii) procedures 3.D.1 and 3.D.4 for discharges to the OWGLs. Where there are less than 10 individual WET tests, the multiplying factor taken from Table F6-1 of this procedure shall be based on a CV of 0.6. Where there are 10 more individual WET tests, the multiplying factor taken from Table F6-1 of this procedure shall be based on a CV calculated as the standard deviation of the WET tests divided by the arithmetic mean of the WET tests.

Table F6-1.— Reasonable Potential Multiplying Factors: 95% Confidence Level and 95% Probability Basis

***15424 Procedure 7: Loading Limits**

The Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) this procedure.

Whenever a water quality-based effluent limitation (WQBEL) is developed, the WQBEL shall be expressed as both a concentration value and a corresponding mass loading rate.

A. Both mass and concentration limits shall be based on the same permit averaging periods such as daily, weekly, or monthly averages, or in other appropriate permit averaging periods.

B. The mass loading rates shall be calculated using effluent flow rates that are consistent with those used in establishing the WQBELs expressed in concentration.

Procedure 8: Water Quality-based Effluent Limitations Below the Quantification Level

The Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) this procedure.

When a water quality-based effluent limitation (WQBEL) for a pollutant is calculated to be less than the quantification level:

A. Permit Limits. The permitting authority shall designate as the limit in the NPDES permit the WQBEL exactly as calculated.

B. Analytical Method and Quantification Level.

1. The permitting authority shall specify in the permit the most sensitive, applicable, analytical method, specified in or approved under 40 CFR part 136, or other appropriate method if one is not available under 40 CFR part 136, to be used to monitor for the presence and amount in an effluent of the pollutant for which the WQBEL is established; and shall specify in accordance with section B.2 of this procedure, the quantification level that can be achieved by use of the specified analytical method.

2. The quantification level shall be the minimum level (ML) specified in or approved under 40 CFR part 136 for the method for that pollutant. If no such ML exists, or if the method is not specified or approved under 40 CFR part 136, the quantification level shall be the lowest quantifiable level practicable. The permitting authority may specify a higher quantification level if the permittee demonstrates that a higher quantification level is appropriate because of effluent-specific matrix interference.

3. The permit shall state that, for the purpose of compliance assessment, the analytical method specified in the permit shall be used to monitor the amount of pollutant in an effluent down to the quantification level, provided that the analyst has complied with the specified quality assurance/quality control procedures in the relevant method.

4. The permitting authority shall use applicable State and Tribal procedures to average and account for monitoring data. The permitting authority may specify in the permit the value to be used to interpret sample values below the quantification level.

C. Special Conditions. The permit shall contain a reopener clause authorizing modification or revocation and reissuance of the permit if new information generated as a result of special conditions included in the permit indicates that presence of the pollutant in the discharge at levels above the WQBEL. Special conditions that may be included in the permit include, but are not limited to, fish tissue sampling, whole effluent toxicity (WET) tests, limits and/or monitoring requirements on internal waste streams, and monitoring for surrogate parameters. Data generated as a result of special conditions can be used to reopen the permit to establish more stringent effluent limits or conditions, if necessary.

D. Pollutant Minimization Program. The permitting authority shall include a condition in the permit requiring the permittee to develop and conduct a pollutant minimization program for each pollutant with a WQBEL below the quantification level. The goal of the pollutant minimization program shall be to reduce all potential sources of the pollutant to maintain the effluent at or below the WQBEL. In addition, States and Tribes may consider cost-effectiveness when establishing the requirements of a PMP. The pollutant minimization program shall include, but is not limited to, the following:

1. An annual review and semi-annual monitoring of potential sources of the pollutant, which may include fish tissue monitoring and other bio-uptake sampling;

2. Quarterly monitoring for the pollutant in the influent to the wastewater treatment system;

3. Submittal of a control strategy designed to proceed toward the goal of maintaining all sources of the pollutant to the wastewater collection system below the WQBEL;

4. When the sources of the pollutant are discovered, appropriate cost-effective control ***15425** measures shall be implemented, consistent with the control strategy; and

5. An annual status report that shall be sent to the permitting authority including:

a. All minimization program monitoring results for the previous year;

b. A list of potential sources of the pollutant; and

c. A summary of all action taken to reduce or eliminate the identified sources of the pollutant.
40 CFR § 122.44
6. Any information generated as a result of procedure 8.D can be used to support a request for subsequent permit modifications, including revisions to (e.g., more or less frequent monitoring), or removal of the requirements of procedure 8.D, consistent with 40 CFR 122.44, 122.62 and 122.63.

Procedure 9: Compliance Schedules
The Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) procedure 9 of appendix F of part 132.

A. Limitations for New Great Lakes Dischargers. When a permit issued on or after March 23, 1997 to a new Great Lakes discharger (defined in Part 132.2) contains a water quality-based effluent limitation (WQBEL), the permittee shall comply with such a limitation upon the commencement of the discharge.

B. Limitations for Existing Great Lakes Dischargers.

1. Any existing permit that is reissued or modified on or after March 23, 1997 to contain a new or more restrictive WQBEL may allow a reasonable period of time, up to five years from the date of permit issuance or modification, for the permittee to comply with that limit, provided that the Tier I criterion or whole effluent toxicity (WET) criterion was adopted (or, in the case of a narrative criterion, Tier II value, or Tier I criterion derived pursuant to the methodology in appendix A of part 132, was newly derived) after July 1, 1977.

2. When the compliance schedule established under paragraph 1 goes beyond the term of the permit, an interim permit limit effective upon the expiration date shall be included in the permit and addressed in the permit's fact sheet or statement of basis. The administrative record for the permit shall reflect the final limit and its compliance date.

3. If a permit establishes a schedule of compliance under paragraph 1 which exceeds one year from the date of permit issuance or modification, the schedule shall set forth interim requirements and dates for their achievement. The time between such interim dates may not exceed one year. If the time necessary for completion of any interim requirement is more than one year and is not readily divisible into stages for completion, the permit shall require, at a minimum, specified dates for annual submission of progress reports on the status of any interim requirements.

C. Delayed Effectiveness of Tier II Limitations for Existing Great Lakes Discharges.

1. Whenever a limit (calculated in accordance with Procedure 3) based upon a Tier II value is included in a reissued or modified permit for an existing Great Lakes discharger, the permit may provide a reasonable period of time, up to two years, in which to provide additional studies necessary to develop a Tier I criterion or to modify the Tier II value. In such cases, the permit shall require compliance with the Tier II limitation within a reasonable period of time, no later than five years after permit issuance or modification, and contain a reopener clause.

2. The reopener clause shall authorize permit modifications if specified studies have been completed by the permittee or provided by a third-party during the time allowed to conduct the specified studies, and the permittee or a third-party demonstrates, through such studies, that a revised limit is appropriate. Such a revised limit shall be incorporated through a permit modification and a reasonable time period, up to five years, shall be allowed for compliance. If incorporated prior to the compliance date of the original Tier II limitation, any such revised limit shall not be considered less-stringent for purposes of the anti-backsliding provisions of section 402(o) of the Clean Water Act.

3. If the specified studies have been completed and do not demonstrate that a revised limit is appropriate, the permitting authority may provide a reasonable additional period of time, not to exceed five years with which to achieve compliance with the original effluent limitation.

4. Where a permit is modified to include new or more stringent limitations, on a date within five years of the permit expiration date, such compliance schedules may extend beyond the term of a permit consistent with section B.2 of this procedure.

5. If future studies (other than those conducted under paragraphs 1, 2, or 3 above) result in a Tier II value being changed to a less stringent Tier II value or Tier I criterion, after the effective date of a Tier II-based limit, the existing Tier II-based limit may be revised to be less stringent if:

(a) It complies with sections 402(o) (2) and (3) of the CWA; or,

(b) In non-attainment waters, where the existing Tier II limit was based on procedure 3, the cumulative effect of revised effluent limitation based on procedure 3 of this appendix will assure compliance with water quality standards; or,

(c) In attained waters, the revised effluent limitation complies with the State or Tribes' antidegradation policy and procedures.

ENVIRONMENTAL PROTECTION AGENCY

[FRL 1623-3]

Water Quality Criteria Documents; Availability

AGENCY: Environmental Protection Agency.

ACTION: Notice of Water Quality Criteria Documents.

SUMMARY: EPA announces the availability and provides summaries of water quality criteria documents for 64 toxic pollutants or pollutant categories. These criteria are published pursuant to section 304(a)(1) of the Clean Water Act.

AVAILABILITY OF DOCUMENTS: Summaries of both aquatic-based and health-based criteria from the documents are published below. Copies of the complete documents for individual pollutants may be obtained from the National Technical Information Service (NTIS), 5285 Port Royal Road, Springfield, VA 22161, (703-487-4650). A list of the NTIS publication order numbers for all 64 criteria documents is published below. These documents are also available for public inspection and copying during normal business hours at: Public Information Reference Unit, U.S. Environmental Protection Agency, Room 2404 (rear), 401 M St., S.W., Washington, D.C. 20460. As provided in 40 CFR Part 2, a reasonable fee may be charged for copying services. Copies of these documents are also available for review in the EPA Regional Office libraries.

Copies of the documents are not available from the EPA office listed below. Requests sent to that office will be forwarded to NTIS or returned to the sender.

FOR FURTHER INFORMATION CONTACT: Dr. Frank Gostomski, Criteria and Standards Division (WH-585), United States Environmental Protection Agency, 401 M Street, S.W., Washington, D.C. 20460, (202) 245-3042.

SUPPLEMENTARY INFORMATION:

Background

Pursuant to section 304(a)(1) of the Clean Water Act, 33 U.S.C. 1314(a)(1), EPA is required to periodically review and publish criteria for water quality accurately reflecting the latest scientific knowledge:

(A) on the kind and extent of all identifiable effects on health and welfare including, but not limited to, plankton, fish, shellfish, wildlife, plant life, shorelines, beaches, esthetics, and recreation which may be expected from the presence of pollutants in any body of water, including groundwater, (B) on the concentration and dispersal of pollutants, or their byproducts, through biological, physical, and chemical processes, and (C) on the effects of pollutants on biological community diversity, productivity, and stability, including information on the factors affecting rates of eutrophication and rates of organic and inorganic sedimentation for varying types of receiving waters.

EPA is today announcing the availability of criteria documents for 64 of the 65 pollutants designated as toxic under section 307(a)(1) of the Act. The document on TCDD (Dioxin) will be published within the next month after review of recent studies. Criteria for the section 307(a)(1) toxic pollutants being published today will replace the criteria for those same pollutants found in the EPA publication, *Quality Criteria for Water*, (the "Red Book.") Criteria for all other pollutants and water constituents found in the "Red Book" remain valid. The criteria published today have been derived using revised methodologies for determining pollutant concentrations that will, when not exceeded, reasonably protect human health and aquatic life. Draft criteria documents were made available for public comment (44 FR 15926, March 15, 1979, 44 FR 43660, July 25, 1979, 44 FR 56628, October 1, 1979). These final criteria have been derived after consideration of all comments received.

These criteria documents are also issued in satisfaction of the Settlement Agreement in *Natural Resources Defense Council, et al.* v. *Train*, 8 E.R.C. 2120 (1976), modified, 12 E.R.C. 1833 (D.D.C. 1979). Pursuant to paragraph 11 of that agreement, EPA is required to publish criteria documents for the 65 pollutants which Congress, in the 1977 amendments to the Act, designated as toxic under section 307(a)(1). These documents contain recommended maximum permissible pollutant concentrations consistent with the protection of aquatic organisms, human health, and some recreational activities. Although paragraph 11 imposes certain obligations on the Agency, it does not create additional authority.

The Development of Water Quality Criteria

Section 304(a)(1) criteria contain two essential types of information: (1) discussions of available scientific data on the effects of pollutants on public health and welfare, aquatic life and recreation, and (2) quantitative concentrations or qualitative assessments of the pollutants in water which will generally ensure water

section 304(a)(1) criteria codified in the "Red Book." Presumptive applicability meant that a State had to adopt a criterion for a particular water quality parameter at least as stringent as the recommendation in the Red Book unless the State was able to justify a less stringent criterion based on: natural background conditions, more recent scientific evidence, or local, site-specific information. EPA is rescinding the policy of presumptive applicability because it has proven to be too inflexible in actual practice.

Although the section 304(a)(1) criteria represent a reasonable estimate of pollutant concentrations consistent with the maintenance of designated water uses, States may appropriately modify these values to reflect local conditions. In certain circumstances, the criteria may not accurately reflect the toxicity of a pollutant because of the effect of local water quality characteristics or varying sensitivities of local populations. For example, in some cases, ecosystem adaptation may enable a viable, balanced aquatic population to exist in waters with high natural background levels of certain pollutants. Similarly, certain compounds may be more or less toxic in some waters because of differences in alkalinity, temperature, hardness, and other factors.

Methods for adjusting the section 304(a)(1) criteria to reflect these local differences are discussed below.

Relationship of Section 304(a)(1) Criteria to Designated Water Uses:

The criteria published today can be used to support the designated uses which are generally found in State standards. The following section discusses the relationship between the criteria and individual use classifications. Where a water body is designated for more than one use, criteria necessary to protect the most sensitive use should be applied.

1. *Recreation:* Recreational uses of water include such activities as swimming, wading, boating and fishing. Although insufficient data exist on the effects of toxic pollutants resulting from exposure through such primary contact as swimming, section 304(a)(1) criteria based on human health effects may be used to support this designated use where fishing is included in the State definition of "recreation." In this situation only the portion of the criterion based on fish consumption should be used.

2. *Protection and Propagation of Fish and Other Aquatic Life:* The section 304(a)(1) criteria based on toxicity to aquatic life may be used directly to support this designated use.

3. *Agricultural and Industrial Uses:* The section 304(a)(1) criteria were not specifically developed to reflect the impact of pollutants on agricultural and industrial uses. However, the criteria developed for human health and aquatic life are sufficiently stringent to protect these other uses. States may establish criteria specifically designed to protect these uses.

4. *Public Water Supply:* The drinking water exposure component of the human health effects criteria can apply directly to this use classification or may be appropriately modified depending upon whether the specific water supply system falls within the auspices of the Safe Drinking Water Act's (SDWA) regulatory control, and the type and level of treatment imposed upon the supply before delivery to the consumer. The SDWA controls the presence of toxic pollutants in finished ("end-of-tap") drinking water. A brief description of relevant sections of this Act is necessary to explain how the SDWA will work in conjunction with section 304(a)(1) criteria in protecting human health from the effects of toxics due to consumption of water.

Pursuant to section 1412 of the SDWA, EPA has promulgated "National Interim Primary Drinking Water Standards" for certain organic and inorganic substances. These standards establish "maximum contaminant levels" ("MCLs") which specify the maximum permissible level of a contaminant in water which may be delivered to a user of a public water system now defined as serving a minimum of 25 people. MCLs are established based on consideration of a range of factors including not only the health effects of the contaminants but also technological and economic feasibility of the contaminants' removal from the supply. EPA is required to establish revised primary drinking water regulations based on the effects of a contaminant on human health, and include treatment capability, monitoring availability, and costs. Under Section 1401(1)(D)(i) of the SDWA, EPA is also allowed to establish the minimum quality criteria for water which may be taken into a public water supply system.

Section 304(a)(1) criteria provide estimates of pollutant concentrations protective of human health, but do not consider treatment technology, costs and other feasibility factors. The section 304(a)(1) criteria also include fish bioaccumulation and consumption factors in addition to direct human drinking water intake. These numbers were not developed to serve as "end of tap" drinking water standards, and they have no regulatory significance under the SDWA. Drinking water standards are established based on considerations, including technological and economic feasibility, not relevant to section 304(a)(1) criteria. Section 304(a)(1) criteria may be analogous to the recommended maximum contaminant levels (RMCLs) under section 1412(b)(1)(B) of the SDWA in which, based upon a report from the National Academy of Sciences, the Administrator should set target levels for contaminants in drinking water at which "no known or anticipated adverse effects occur and which allows an adequate margin of safety". RMCLs do not take treatment, cost, and other feasibility factors into consideration. Section 304(a)(1) criteria are, in concept, related to the health-based goals specified in the RMCLs. Specific mandates of the SDWA such as the consideration of multi-media exposure, as well as different methods for setting maximum contaminant levels under the two Acts, may result in differences between the two numbers.

MCLs of the SDWA, where they exist, control toxic chemicals in finished drinking water. However, because of variations in treatment and the fact that only a relatively small number of MCLs have been developed, ambient water criteria may be used by the States as a supplement to SDWA regulations. States will have the option of applying MCLs, section 304(a)(1) human health effects criteria, modified section 304(a)(1) criteria or controls more stringent than these three to protect against the effects of toxic pollutants by ingestion from drinking water.

For untreated drinking water supplies, States may control toxics in the ambient water through either use of MCLs (if they exist for the pollutants of concern), section 304(a)(1) human health effects criteria, or a more strigent contaminant level than the former two options.

For treated drinking water supplies serving less than 25 people, States may choose toxics control through application of MCLs (if they exist for the pollutants of concern and are attainable by the type of treatment) in the finished drinking water. States also have the options to control toxics in the ambient water by choosing section 304(a)(1) criteria, adjusted section 304(a)(1) criteria resulting from the reduction of the direct drinking water exposure component in the criteria calculation to the extent that the treatment procedure reduces the level of pollutants, or a more stringent contaminant level than the former three options.

For treated drinking water supplies serving 25 people or greater, States *must* control toxics down to levels at least as stringent as MCLs (where they exist for

probably some untested species, will have sensitivities below the maximum value or the 24-hour average under some conditions and would be adversely affected if the highest allowable pollutant concentrations and the worst conditions existed for a long time. In actual practice, such a situation is not likely to occur and thus the aquatic community as a whole will normally be protected if the criteria are not exceeded. In any aquatic community there is a wide range of individual species sensitivities to the effects of toxic pollutants. A criterion adequate to protect the most susceptible life stage of the most sensitive species would in many cases be more stringent than necessary to protect the overall aquatic community.

The aquatic life criteria specify both maximum and 24-hour average values. The combination of the two values is designed to provide adequate protection of aquatic life and its uses from acute and chronic toxicity and bioconcentration without being as restrictive as a one-number criterion would have to be to provide the same amount of protection. A time period of 24 hours was chosen in order to ensure that concentrations not reach harmful levels for unacceptably long periods. Averaging for longer periods, such as a week or a month for example, could permit high concentrations to persist long enough to produce significant adverse effects. A 24-hour period was chosen instead of a slightly longer or shorter period in recognition of daily fluctuations in waste discharges and of the influence of daily cycles of sunlight and darkness and temperature on both pollutants and aquatic organisms.

The maximum value, which is derived from acute toxicity data, prevents significant risk of adverse impact to organisms exposed to concentrations above the 24-hour average. Merely specifying the average value over a specified time period is insufficient because concentrations of chemicals higher than the average value can kill or cause irreparable damage in short periods. Furthermore, for some chemicals the effect of intermittent high exposures is cumulative. It is therefore necessary to place an upper limit on pollutant concentrations to which aquatic organisms might be exposed. The two-number criterion is intended to describe the highest average ambient water concentration which will produce a water quality generally suited to the maintenance of aquatic life while restricting the extent and duration of the excursions over that average to levels which will not cause harm. The only way to assure the same degree of protection with a one-number criterion would be to use the 24-hour average as a concentration that is not to be exceeded at any time in any place.

Since some substances may be more toxic in freshwater than in saltwater, or vice versa, provision is made for deriving separate water quality criteria for freshwater and for saltwater for each substance. However, for some substances sufficient data may not be available to derive one or both of these criteria using the Guidelines.

Specific aquatic life criteria have not been developed for all of the 65 toxic pollutants. In those cases where there were insufficient data to allow the derivation of a criterion, narrative descriptions of apparent threshold levels for acute and/or chronic effects based on the available data are presented. These descriptions are intended to convey a sense of the degree of toxicity of the pollutant in the absence of a criterion recommendation.

Summary of the Aquatic Life Guidelines

The Guidelines for Deriving Water Quality Criteria for the Protection of Aquatic Life and its Uses were developed to describe an objective, internally consistent, and appropriate way of ensuring that water quality criteria for aquatic life would provide, on the average, a reasonable amount of protection without an unreasonable amount of overprotection or underprotection. The resulting criteria are not intended to provide 100 percent protection of all species and all uses of aquatic life all of the time, but they are intended to protect most species in a balanced, healthy aquatic community. The Guidelines are published as Appendix B of this Notice. Responses to public comments on these Guidelines are attached as Appendix D.

Minimum data requirements are identified in four areas: acute toxicity to animals (eight data points), chronic toxicity to animals (three data points), toxicity to plants, and residues. Guidance is also given for discarding poor quality data.

Data on acute toxicity are needed for a variety of fish and invertebrate species and are used to derive a Final Acute Value. By taking into account the number and relative sensitivities of the tested species, the Final Acute Value is designed to protect most, but not necessarily all, of the tested and untested species.

Data on chronic toxicity to animals can be used to derive a Final Chronic Value by two different means. If chronic values are available for a specified number and array of species, a final chronic value can be calculated directly. If not, an acute-chronic ratio is derived and then used with the Final Acute Value to obtain the Final Chronic Value.

The Final Plant Value is obtained by selecting the lowest plant toxicity value based on measured concentrations.

The Final Residue Value is intended to protect wildlife which consume aquatic organisms and the marketability of aquatic organisms. Protection of the marketability of aquatic organisms is, in actuality, protection of a use of that water body ("commercial fishery"). Two kinds of data are necessary to calculate the Final Residue Value: a bioconcentration factor (BCF) and a maximum permissible tissue concentration, which can be an FDA action level or can be the result of a chronic wildlife feeding study. For lipid soluble pollutants, the BCF is normalized for percent lipids and then the Final Residue Value is calculated by dividing the maximum permissible tissue concentration by the normalized BCF and by an appropriate percent lipid value. BCFs are normalized for percent lipids since the BCF measured for any individual aquatic species is generally proportional to the percent lipids in that species.

If sufficient data are available to demonstrate that one or more of the final values should be related to a water quality characteristic, such as salinity, hardness, or suspended solids, the final value(s) are expressed as a function of that characteristic.

After the four final values (Final Acute Value, Final Chronic Value, Final Plant Value, and Final Residue Value) have been obtained, the criterion is established with the Final Acute Value becoming the maximum value and the lowest of the other three values becoming the 24-hour average value. All of the data used to calculate the four final values and any additional pertinent information are then reviewed to determine if the criterion is reasonable. If sound scientific evidence indicates that the criterion should be raised or lowered, appropriate changes are made as necessary.

The present Guidelines have been revised from the earlier published versions (43 FR 21506, May 18, 1978; 43 FR 29028, July 5, 1978; 44 FR 15926, March 15, 1979). Details have been added in many places and the concept of a minimum data base has been incorporated. In addition, three adjustment factors and the species sensitivity factor have been deleted. These modifications were the result of the Agency's analysis of public comments and comments received from the Science Advisory Board on earlier

human epidemiology studies using the following basic exposure assumptions: a 70-kilogram male person (*Report of the Task Group on Reference Man*, International Commission for Radiation Protection, November 23, 1957) as the exposed individual; the average daily consumption of freshwater and estuarine fish and shellfish products equal to 6.5 grams/day; and the average ingestion of two liters/day of water (*Drinking Water and Health*, National Academy of Sciences, National Research Council, 1977). Criteria based on these assumptions are estimated to be protective of an adult male who experiences average exposure conditions.

Two basic methods were used to formulate health criteria, depending on whether the prominent adverse effect was cancer or other toxic manifestations. The following sections detail these methods.

Carcinogens

Extrapolation of cancer responses from high to low doses and subsequent risk estimation from animal data is performed using a linearized multi-stage model. This procedure is flexible enough to fit all monotonically-increasing dose response data, since it incorporates several adjustable parameters. The multi-stage model is a linear non-threshold model as was the "one-hit" model originally used in the proposed criteria documents. The linearized multi-stage model and its characteristics are described fully in Appendix C. The linear non-threshold concept has been endorsed by the four agencies in the Interagency Regulatory Liaison Group and is less likely to underestimate risk at the low doses typical of environmental exposure than other models that could be used. Because of the uncertainties associated with dose response, animal-to-human extrapolation and other unknown factors, because of the use of average exposure assumptions, and because of the serious public health consequences that could result if risk were underestimated, EPA believes that it is prudent to use conservative methods to estimate risk in the water quality criteria program. The linearized multistage model is more systematic and invokes fewer arbitrary assumptions than the "one-hit" procedure previously used.

It should be noted that extrapolation models provide estimates of risk since a variety of assumptions are built into any model. Models using widely different assumptions may produce estimates ranging over several orders of magnitude. Since there is at present no way to demonstrate the scientific validity of any model, the use of risk extrapolation models is a subject of debate in the scientific community. However, risk extrapolation is generally recognized as the only tool available at this time for estimating the magnitude of health hazards associated with non-threshold toxicants and has been endorsed by numerous Federal agencies and scientific organizations, including EPA's Carcinogen Assessment Group, the National Academy of Sciences, and the Interagency Regulatory Liaison Group as a useful means of assessing the risks of exposure to various carcinogenic pollutants.

Non-Carcinogens

Health criteria based on toxic effects of pollutants other than carcinogenicity are estimates of concentrations which are not expected to produce adverse effects in humans. They are based upon Acceptable Daily Intake (ADI) levels and are generally derived using no-observed-adverse-effect-level (NOAEL) data from animal studies although human data are used wherever available. The ADI is calculated using safety factors to account for uncertainties inherent in extrapolation from animal to man. In accordance with the National Research Council recommendations (*Drinking Water and Health*, National Academy of Sciences, National Research Council, 1977), safety factors of 10, 100, or 1,000 are used depending on the quality and quantity of data. In some instances extrapolations are made from inhalation studies or limits to approximate a human response from ingestion using the Stokinger-Woodward model (Journal of American Water Works Association, 1958). Calculations of criteria from ADIs are made using the standard exposure assumptions (2 liters of water, 6.5 grams of edible aquatic products, and an average body weight of 70 kg).

Dated: October 24, 1980.

Douglas M. Costle,

Administrator.

Appendix A—Summary of Water Quality Criteria

Acenaphthene

Freshwater Aquatic Life

The available data for acenaphthene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 1,700 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of acenaphthene to sensitive freshwater aquatic animals but toxicity to freshwater algae occur at concentrations as low as 520 μg/l.

Saltwater Aquatic Life

The available data for acenaphthene indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 970 and 710 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested. Toxicity to algae occurs at concentrations as low as 500 μg/l.

Human Health

Sufficient data is not available for acenaphthene to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 20 μg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

Acrolein

Freshwater Aquatic Life

The available data for acrolein indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 68 and 21 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data for acrolein indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 55 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of acrolein to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of acrolein ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 320 μg/l.

For the protection of human health from the toxic properties of acrolein ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 780 μg/l.

Acrylonitrile

Freshwater Aquatic Life

The available data for acrylonitrile indicate that acute toxicity to freshwater aquatic life occurs at concentrations as

estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 22 ng/l, 2.2 ng/l, and .22 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 175 ng/l, 17.5 ng/l, and 1.75 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Asbestos

Freshwater Aquatic Life

No freshwater organisms have been tested with any asbestiform mineral and no statement can be made concerning acute or chronic toxicity.

Saltwater Aquatic Life

No saltwater organisms have been tested with any asbestiform mineral and no statement can be made concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of asbestos through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 300,000 fibers/1,30,000 fibers/1, and 3,000 fibers/1, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Benzene

Freshwater Aquatic Life

The available data for benzene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 5,300 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of benzene to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for benzene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 5,100 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of benzene to sensitive saltwater aquatic life, but adverse effects occur at concentrations as low as 700 μg/l with a fish species exposed for 168 days.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of benzene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 6.6 μg/l, .66 μg/l, and .066 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 400 μg/l, 40.0 μg/l, and 4.0 μg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Benzidine

Freshwater Aquatic Life

The available data for benzidine indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 2,500 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of benzidine to sensitive freshwater aquatic life.

Saltwater Aquatic Life

No saltwater organisms have been tested with benzidine and no statement can be made concerning acute and chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of benzidine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 1.2 ng/1, .12 ng/1, and .01 ng/1, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 5.3 ng/1, .53 ng/1, and .05 ng/1, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Beryllium

Freshwater Aquatic Life

The available data for beryllium indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 130 and 5.3 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested. Hardness has a substantial effect on acute toxicity.

Salt water Aquatic Life

The limited saltwater data base available for beryllium does not permit any statement concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of beryllium through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 37 ng/l, 3.7 ng/l, and .37 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 641 ng/l, 64.1 ng/l, and 6.41 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Cadmium

Freshwater Aquatic Life

For total recoverable cadmium the criterion (in μg/l) to protect freshwater aquatic life as derived using the Guidelines is the numerical value given

this time due to the insufficiency in the available data for trichlorobenzene.

For comparison purposes, two approaches were used to derive criterion levels for monochlorobenzene. Based on available toxicity data, for the protection of public health, the derived level is 488 μg/l. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 20 μg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

Chlorinated Ethanes

Freshwater Aquatic Life

The available freshwater data for chlorinated ethanes indicate that toxicity increases greatly with increasing chlorination, and that acute toxicity occurs at concentrations as low as 118,000 μg/l for 1,2-dichloroethane, 18,000 μg/l for two trichloroethanes, 9,320 μg/l for two tetrachloroethanes, 7,240 μg/l for pentachloroethane, and 980 μg/l for hexachloroethane. Chronic toxicity occurs at concentrations as low as 20,000 μg/l for 1,2-dichloroethane, 3400 μg/l for 1,1,2-trichloroethane, 2,400 μg/l for 1,1,2,2,-tetrachloroethane, 1,100 μg/l for pentachloroethane, and 540 μg/l for hexachloroethane. Acute and chronic toxicity would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available saltwater data for chlorinated ethanes indicate that toxicity increases greatly with increasing chlorination and that acute toxicity to fish and invertebrate species occurs at concentrations as low as 113,000 μg/l for 1,2-dichloroethane, 31,200 μg/l for 1,1,1-trichloroethane, 9,020 μg/l for 1,1,2,2-tetrachloroethane, 390 μg/l for pentachloroethane, and 940 μg/l for hexachloroethane. Chronic toxicity occurs at concentrations as low as 201 μg/l for pentachloroethane. Acute and chronic toxicity would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of 1,2-dichloroethane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 9.4 μg/l, .94 μg/l, and .094 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 2,430 μg/l, 243 μg/l, and 24.3 μg/l respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the protection of human health from the toxic properties of 1,1,1-trichloroethane ingested through water and contaminated aquatic organism, the ambient water criterion is determined to be 18.4 mg/l.

For the protection of human health from the toxic properties of 1,1,1,-trichloroethane ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 1.03 g/l.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of 1,1,2-trichloroethane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 6.0 μg/l, .6 μg/l, and .06 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 418 μg/l, 41.8 μg/l, and 4.18 μg/l respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of 1,1,2,2-tetrachloroethane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 1.7 μg/l, .17 μg/l, and .017 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 107 μg/l, 10.7 μg/l, and 1.07 μg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of hexachloroethane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 19 μg/l, 1.9 μg/l, and .19 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 87.4 μg/l, 8.74 μg/l, and .87 μg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for monochloroethane.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for 1,1,-dichloroethane.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for 1,1,1,2-tetrachloroethane.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for pentachloroethane.

Chlorinated Naphthalenes

Freshwater Aquatic Life

The available data for chlorinated naphthalenes indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 1,600 μg/l and would occur at lower concentrations among species that are

recognized that organoleptic data as a basis for establishing a water quality criterion have limitations and have no demonstrated relationship to potential adverse human health effects.

Sufficient data is not available for 3-methyl-4-chlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 3000 μg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criterion have limitations and have no demonstrated relationship to potential adverse human health effects.

Sufficient data is not available for 3-methyl-6-chlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 20 μg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criterion have limitations and have no demonstrated relationship to potential adverse human health effects.

Chloroalkyl Ethers

Freshwater Aquatic Life

The available data for chloroalkyl ethers indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 238,000 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of chloroalkyl ethers to sensitive freshwater aquatic life.

Saltwater Aquatic Life

No saltwater organisms have been tested with any chloroalkyl ether and no statement can be made concerning acute and chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of bis-(chloromethyl)-ether through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are .038 ng/l, .0038 ng/l, and .00038 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 18.4 ng/l, 1.84 ng/l, and .184 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of bis (2-chloroethyl) ether through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are .3 μg/l, .03 μg/l, and .003 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 13.6 μg/l, 1.36 μg/l, and .136 μg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the protection of human health from the toxic properties of bis (2-chloroisopropyl) ether ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 34.7 μg/l.

For the protection of human health from the toxic properties of bis (2-chloroisopropyl) ether ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 4.36 mg/l.

Chloroform

Freshwater Aquatic Life

The available data for choloroform indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 28,900 μg/l, and would occur at lower concentrations among species that are more sensitive than the three tested species. Twenty-seven-day LC50 values indicate that chronic toxicity occurs at concentrations as low as 1,240 μg/l, and could occur at lower concentrations among species or other life stages that are more sensitive than the earliest life cycle stage of the rainbow trout.

Saltwater Aquatic Life

The data base for saltwater species is limited to one test and no statement can be made concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of chloroform through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 1.90 μg/l, .19 μg/l, and .019 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 157 μg/l, 15.7 μg/l, and 1.57 μg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

2-Chlorophenol

Freshwater Aquatic Life

The availabe data for 2-chlorophenol indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 4,380 μg/l and would occur at lower concentrations among species that are more sensitive that those tested. No definitive data are available concerning the chronic toxicity of 2-chlorophenol to sensitive freshwater aquatic life but flavor impairment occurs in one species of fish at concentrations as low as 2,000 μg/l.

Saltwater Aquatic Life

No saltwater organisms have been tested with 2-chlorophenol and no statement can be made concerning acute and chronic toxicity.

Human Health

Sufficient data is not available for 2-chlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 0.1 μg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no

chronic toxicity of TDE to sensitive saltwater aquatic life.

DDE

The available data for DDE indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 14 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of DDE to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of DDT through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are .24 ng/l, .024 ng/l, and .0024 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are .24 ng/l, .024 ng/l, and .0024 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment of an "acceptable" risk level.

Dichlorobenzenes

Freshwater Aquatic Life

The available data for dichlorobenzenes indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 1,120 and 763 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data for dichlorobenzenes indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 1,970 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of dichlorobenzenes to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of dichlorobenzenes (all isomers) ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 400 μg/l.

For the protection of human health from the toxic properties of dichlorobenzenes (all isomers) ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 2.6 mg/l.

Dichlorobenzidines

Freshwater Aquatic Life

The data base available for dichlorobenzidines and freshwater organisms is limited to one test on bioconcentration of 3,3'-dichlorobenzidine and no statement can be made concerning acute or chronic toxicity.

Saltwater Aquatic Life

No saltwater organisms have been tested with any dichlorobenzidine and no statement can be made concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of dichlorobenzidine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero base on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are .103 μg/l, .0103 μg/l, and .00103 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are .204 μg/l, .0204 μg/l, and .00204 μg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Dichloroethylenes

Freshwater Aquatic Life

The available data for dichloroethylenes indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 11,600 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of dichlorethylenes to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for dichlorethylenes indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 224,000 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity dichloroethylenes to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of 1,1-dichloroethylene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are .33 μg/l, .033 μg/l, and .0033 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 18.5 μg/l, 1.85 μg/l, and .185 μg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficency in the available data for 1,2-dichloroethylene.

2,4-Dichlorophenol

Freshwater Aquatic Life

The available data for 2,4-dichlorophenol indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 2,020 and 365 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive that those tested. Mortality to early life stages of one species of fish occurs at concentrations as low as 70 μg/l.

Saltwater Aquatic Life

Only one test has been conducted with saltwater organisms on 2,4-dichlorophenol and no statement can be made concerning acute or chronic toxicity.

Human Health

For comparison purposes, two approaches were used to derive criterion levels for 2,4-dichlorophenol.

epresent an Agency judgment on an "acceptable" risk level.

Endosulfan

Freshwater Aquatic Life

For endosulfan the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.056 μg/l as a 24-hour average and the concentration should not exceed 0.22 μg/l at any time.

Saltwater Aquatic Life

For endosulfan the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.0087 μg/l as a 24-hour average and the concentration should not exceed 0.034 μg/l at any time.

Human Health

For the protection of human health from the toxic properties of endosulfan ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 74 μg/l.

For the protection of human health from the toxic properties of endosulfan ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 159 μg/l.

Endrin

Freshwater Aquatic Life

For endrin the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.0023 μg/l as a 24-hour average and the concentration should not exceed 0.18 μg/l at any time.

Saltwater Aquatic Life

For endrin the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.0023 μg/l as a 24-hour average and the concentration should not exceed 0.037 μg/l at any time.

Human Health

The ambient water quality criterion for endrin is recommended to be identical to the existing drinking water standard which is 1 μg/l. Analysis of the toxic effects data resulted in a calculated level which is protective of human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 grams of aquatic organisms was not derived.

Ethylbenzene

Freshwater Aquatic Life

The available data for ethylbenzene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 32,000 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of ethylbenzene to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for ethylbenzene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 430 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of ethylbenzene to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of ethylbenzene ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 1.4 mg/l.

For the protection of human health from the toxic properties of ethylbenzene ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 3.28 mg/l.

Fluoranthene

Freshwater Aquatic Life

The available data for fluoranthene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 3980 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of fluoranthene to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for fluoranthene indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 40 and 16 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For the protection of human health from the toxic properties of fluoranthene ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 42 μg/l.

For the protection of human health from the toxic properties of fluoranthene ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 54 μg/l.

Haloethers

Freshwater Aquatic Life

The available data for haloethers indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 360 and 122 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

No saltwater organisms have been tested with any haloether and no statement can be made concerning acute or chronic toxicity.

Human Health

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for haloethers.

Halomethanes

Freshwater Aquatic Life

The available data for halomethanes indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 11,000 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of halomethanes to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for halomethanes indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 12,000 and 6,400 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested. A decrease in algal cell numbers occurs at concentrations as low as 11,500 μg/l.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of chloromethane, bromomethane, dichloromethane, bromodichloromethane, tribromomethane, dichlorodifluoromethane, trichlorofluoromethane, or combinations of these chemicals through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are

represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of tech-HCH through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 123 ng/l, 12.3 ng/l, and 1.23 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 414 ng/l, 41.4 ng/l, and 4.14 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of gamma-HCH through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 186 ng/l, 18.6 ng/l, and 1.86 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 625 ng/l, 62.5 ng/l, 6.25 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for delta-HCH.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for epsilon-HCH.

Hexachlorocyclopentadiene

Freshwater Aquatic Life

The available data for hexachlorocyclopentadiene indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 7.0 and 5.2 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data to hexachlorocyclopentadiene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 7.0 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of hexachlorocyclopentadiene to sensitive saltwater aquatic life.

Human Health

For comparison purposes, two approaches were used to derive criterion levels for hexachlorocyclopentadiene. Based on available toxicity data, for the protection of public health, the derived level is 206 μg/l. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 1.0 μg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criterion have limitations and have no demonstrated relationship to potential adverse human health effects.

Isophorone

Freshwater Aquatic Life

The available data for isophorone indicate that acute toxicity to freshwater aquatic life ocurs at concentrations as low as 117,000 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of isophorone to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for isophorone indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 12,900 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of isophorone to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of isophorone ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 5.2 mg/l.

For the protection of human health from the toxic properties of isophorone ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 520 mg/l.

Lead

Freshwater Aquatic Life

For total recoverable lead the criterion (in μg/l) to protect freshwater aquatic life as derived using the Guidelines is the numerical value given by e(2.35[ln(hardness)]-9.48) as a 24-hour average and the concentration (in μg/l) should not exceed the numerical value given by e(1.22[ln(hardness)]-0.47) at any time. For example, at hardnesses of 50, 100, and 200 mg/l as $CaCO_3$ the criteria are 0.75, 3.8, and 20 μg/l, respectively, as 24-hour averages, and the concentrations should not exceed 74, 170, and 400 μg/l, respectively, at any time.

Saltwater Aquatic Life

The available data for total recoverable lead indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 668 and 25 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

The ambient water quality criterion for lead is recommended to be identical to the existing drinking water standard which is 50 μg/l. Analysis of the toxic effects data resulted in a calculated level which is protective to human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 grams of aquatic organisms was not derived.

Mercury

Freshwater Aquatic Life

For total recoverable mercury the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.00057 μg/l as a 24-hour average and the concentration should not exceed 0.0017 μg/l at any time.

Saltwater Aquatic Life

For total recoverable mercury the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.025 μg/l as a 24-hour average and the concentration should not exceed 3.7 μg/l at any time.

Human Health

For the protection of human health from the toxic properties of mercury

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of n-nitrosodimethylamine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 14 ng/l, 1.4 ng/l, and .14 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 160,000 ng/l, 16,000 ng/l, and 1,600 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of n-nitrosodiethylamine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 8 ng/l, 0.8 ng/l, and 0.08 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 12,400 ng/l, 1,240 ng/l, and 124 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure in n-nitrosodi-n-butylamine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 64 ng/l 6.4 ng/l and .064 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 5,868 ng/l, 587 ng/l, and 58.7 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure in n-nitrosodiphenylamine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 49,000 ng/l 4,900 ng/l and 490 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 161,000 ng/l, 16,100 ng/l, and 1,610 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure in n-nitrosopyrrolidine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 160 ng/l 16.0 ng/l and 1.60 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 919,000 ng/l, 91,900 ng/l, and 9,190 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Pentachlorophenol

Freshwater Aquatic Life

The available data for pentachlorophenol indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 55 and 3.2 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data for pentachlorophenol indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 53 and 34 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For comparison purposes, two approaches were used to derive criterion levels for pentachlorophenol. Based on available toxicity data, for the protection of public health, the derived level is 1.01 mg/l. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 30 μg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criterion have limitations and have no demonstrated relationship to potential adverse human health effects.

Phenol

Freshwater Aquatic Life

The available data for phenol indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 10,200 and 2,560 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data for phenol indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 5,800 ug/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of phenol to sensitive saltwater aquatic life.

Human Health

For comparison purposes, two approaches were used to derive criterion levels for phenol. Based on available toxicity data, for the protection of public health, the derived level is 3.5 mg/l. Using available organoleptic data, for controlling

than those tested. No data are available concerning the chronic toxicity of inorganic selenate to sensitive freshwater aquatic life.

Saltwater Aquatic Life

For total recoverable inorganic selenite the criterion to protect saltwater aquatic life as derived using the Guidelines is 54 μg/l as a 24-hour average and the concentration should not exceed 410 μg/l at any time.

No data are available concerning the toxicity of inorganic selenate to saltwater aquatic life.

Human Health

The ambient water quality criterion for selenium is recommended to be identical to the existing drinking water standard which is 10 μg/l. Analysis of the toxic effects data resulted in a calculated level which is protective of human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 grams of aquatic organisms was not derived.

Silver

Freshwater Aquatic Life

For freshwater aquatic life the concentration (in μg/l) of total recoverable silver should not exceed the numerical value given by "e[1.72(ln (hardness)-6.52)]" at any time. For example, at hardnesses of 50, 100, 200 mg/l as $CaCO_3$ the concentration of total recoverable silver should not exceed 1.2, 4.1, and 13 μg/l, respectively, at any time. The available data indicate that chronic toxicity to freshwater aquatic life may occur at concentrations as low as 0.12 μg/l.

Saltwater Aquatic Life

For saltwater aquatic life the concentration of total recoverable silver should not exceed 2.3 μg/l at any time. No data are available concerning the chronic toxicity of silver to sensitive saltwater aquatic life.

Human Health

The ambient water quality criterion for silver is recommended to be identical to the existing drinking water standard which is 50 μg/l. Analysis of the toxic effects data resulted in a calculated level which is protective of human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 grams of aquatic organisms was not derived.

Tetrachloroethylene

Freshwater Aquatic Life

The available data for tetrachloroethylene indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 5,280 and 840 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data for tetrachloroethylene indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations low as 10,200 and 450 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of tetrachloroethylene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 8 μg/l, .8 μg/l, and .08 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 88.5 μg/l, 8.85 μg/l, and .88 μg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Thallium

Freshwater Aquatic Life

The available data for thallium indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 1,400 and 40 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested. Toxicity to one species of fish occurs at concentrations as low as 20 μg/l after 2,600 hours of exposure.

Saltwater Aquatic Life

The available data for thallium indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 2,130 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of thallium to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of thallium ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 13 μg/l.

For the protection of human health from the toxic properties of thallium ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 48 μg/l.

Toluene

Freshwater Aquatic Life

The available data for toluene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 17,500 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of toluene to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for toluene indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 6,300 and 5,000 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For the protection of human health from the toxic properties of toluene ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 14.3 mg/l.

For the protection of human health from the toxic properties of toluene ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 424 mg/l.

Toxaphene

Freshwater Aquatic Life

For toxaphene the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.013 μg/l as a 24-hour average and the concentration should not exceed 1.6 μg/l at any time.

Saltwater Aquatic Life

For saltwater aquatic life the concentration of toxaphene should not exceed 0.070 μg/l at any time. No data

necessarily all of the species all of the time. Aquatic communities can tolerate some stress and occasional adverse effects on a few species, and so total protection of all of the species all of the time is not necessary. Rather, the Guidelines attempt to provide a reasonable and adequate amount of protection with only a small possibility of considerable overprotection or underprotection. Within these constraints, it seems appropriate to err on the side of overprotection.

The numerical aquatic life criteria derived using the Guidelines are expressed as two numbers, rather than the traditional one number, so that the criteria can more accurately reflect toxicological and practical realities. The combination of both a maximum value and a 24-hour average value is designed to provide adequate protection of aquatic life and its uses from acute and chronic toxicity to animals, toxicity to plants and bioconcentration by aquatic organisms without being as restrictive as a one-number criterion would have to be to provide the same amout of protection. The only way to assure the same degree of protection with a one-number criterion would be to use the 24-hour average as a concentration that is not to be exceeded at any time in any place.

The two-number criterion is intended to identify an average pollutant concentration which will produce a water qualtiy generally suited to the maintenance of aquatic life and its uses while restricting the extent and duration of excursions over the average so that the total exposure will not cause unacceptable adverse effects. Merely specifying an average value over a time period is insufficient, unless the period of time is rather short, because of concentration higher than the average value can kill or cause substantial damage in short periods. Furthermore, for some substances the effect of intermittent high exposures is cumulative. It is therefore necessary to place an upper limit on pollutant concentrations to which aquatic organisms might be exposed, especially when the maximum value is not much higher than the average value. For some substances the maximum may be so much higher than the 24-hour average that in any real-world situation the maximum will never be reached if the 24-hour average is achieved. In such cases the 24-hour average will be limiting and the maximum will have no practical significance, except to indicate that elevated concentrations are acceptable as long as the 24-hour average is achieved.

These Guidelines have been developed on the assumption that the results of laboratory tests are generally useful for predicting what will happen in field situations. The resulting criteria are meant to apply to most bodies of water in the United States, except for the Great Salt Lake. All aquatic organisms and their common uses are meant to be considered, but not necessarily protected, if relevant data are available, with at least one specific exception. This exception is the accumulation of residues of organic compounds in the siscowet subspecies of lake trout which occurs in Lake Superior and contains up to 67% fat in the fillets (Thurston, C.E., 1962, Physical Characteristics and Chemical Composition of Two Subspecies of Lake Trout, J. Fish. Res. Bd. Canada 19:39–44). Neither siscowet nor organisms in the Great Salt Lake are intentionally protected by these Guidelines because both may be too atypical.

With appropriate modifications these Guidelines can be used to derive criteria for any specified geographical area, body of water (such as the Great Salt Lake), or group of similar bodies of water. Thus with appropriate modifications the Guidelines can be used to derive national, state, or local criteria if adequate information is available concerning the effects of the substance of concern on appropriate species and their uses. However, the basic concepts described in the Guidelines should be modified only when sound scientific evidence indicates that a criterion produced using the Guidelines would probably significantly overprotect or underprotect the presence or uses of aquatic life.

Criteria produced by these Guidelines are not enforceable numbers. They may be used in developing enforceable numbers, such as water quality standards and effluent standards. However, the development of standards may take into account additional factors such as social, legal, economic, and hydrological considerations, the environmental and analytical chemistry of the substance, the extrapolation from laboratory data to field situations, and the relationship between the species for which data are available and the species which are to be protected.

Because fresh water and salt water (including both estuarine and marine waters) have basically different chemical compositions and because freshwater and saltwater species rarely inhabit the same water simultaneously, separate criteria should be derived for these two kinds of waters. However, for some substances sufficient data may not be available to allow derivation of one or both of these criteria using the Guidelines.

These Guidelines are meant to be used after a decision is made that a criterion is needed for a substance. The Guidelines do not address the rationale for making that decision. If the potential for adverse effects on aquatic life and its uses are part of the basis for deciding whether or not a criterion is needed for a substance, these Guidelines may be helpful in the collection and interpretation of relevant data.

I. Define the Substance for Which the Criterion Is To Be Derived

A. Each separate chemical which would not ionize significantly in most natural bodies of water should usually be considered a separate substance, except possibly for structurally similar organic compounds that only differ in the number and location of atoms of a specific halogen, and only exist in large quantities as commercial mixtures of the various compounds, and apparently have similar chemical, biological, and toxicological properties.

B. For chemicals, which would ionize significantly in most natural bodies of water, such as inorganic salts, organic acids and phenols, all forms that would be in chemical equilibrium should usually be considered one substance. For metals, each different valence and each different covalently bonded organometallic compound should usually be considered a separate substance.

C. The definition of the substance may also need to take into account the analytical chemistry and fate of the substance.

II. Collect and Review Available Data

A. Collect all available data on the substance concerning (1) toxicity to, and bioaccumulation by, aquatic animals and plants, (2) FDA action levels, and (3) chronic feeding studies with wildlife.

B. Discard all data that are not available in hard copy (publication, manuscript, letter, memorandum, etc.) with enough supporting information to indicate that acceptable test procedures were used and that the results are reliable. Do not assume that all published data are acceptable.

C. Discard questionable data. For example, discard data from tests for which no control treatment existed, in which too many organisms in the control treatment died or showed signs of stress or disease, or in which distilled or deionized water was used as the dilution water for aquatic organisms. Discard data on formulated mixtures and emulsifiable concentrates of the

xposure to toxicant or for whom the cute adverse effect of the exposure cannot be adequately measured. Such freshwater and saltwater animals include air-breathing molluscs, unionid clams, operculate snails, and bivalve molluscs, except for some species that cannot "close up" and thus prevent exposure to toxicant, such as the bay scallop (*Argopecten irradians*).

F. For the use of LC50 or EC50 values for durations shorter and longer than those listed above, see Section X.

G. If the acute toxicity of the substance to aquatic animals has been shown to be related to a water quality characteristic such as hardness for freshwater organisms or salinity for saltwater organisms, a Final Acute Equation should be derived based on that water quality characteristic. Go to Section V.

H. If the acute toxicity of the substance has not been adequately shown to be related to a water quality characteristic, for each species for which at least one acute value is available, calculate the geometric mean of the results of all flow-through tests in which the toxicant concentrations were measured. For a species for which no such result is available, calculate the geometric mean of all available acute values, i.e., results of flow-through tests in which the toxicant concentrations were not measured and results of static and renewal tests based on initial total toxicant concentrations.

Note.—The geometric mean of N numbers is obtained by taking the N^{th} root of the product of N numbers. Alternatively, the geometric mean can be calculated by adding the logarithms of the N numbers, dividing the sum by N, and taking the antilog of the quotient. The geometric mean of two numbers can also be calculated as the square root of the product of the two numbers. The geometric mean of one number is that number. Either natural (base e) or common (base 10) logarithms can be used to calculate geometric means as long as they are used consistently within each set of data, i.e., the antilog used must match the logarithm used.

I. Count the number=N of species for which a species mean acute value is available.

J. Order the species mean acute values from low to high. Take the common logarithms of the N values (log mean values).

K. The intervals (cell widths) for the lower cumulative proportion calculations are 0.11 common log units apart, starting from the lowest log value. The value of 0.11 is an estimate of average precision and was calculated from replicate species acute values.

L. Starting with the lowest log mean value, separate the N values into intervals (or cells) calculated in Step IV. K.

M. Calculate cumulative proportions for each non-empty interval by summing the number of values in the present and all lower intervals and dividing by N. These calculations only need to be done for the first three non-empty intervals (or cells).

N. Calculate the arithmetic mean of the log mean values for each of the three intervals.

O. Using the two interval mean acute values and cumulative proportions closest to 0.05, linearly extrapolate or interpolate to the 0.05 log concentration. The Final Acute Value is the antilog of the 0.05 concentration.

In other words, where

Prop(1) and conc(1) are the cumulative proportion and mean log value for the lowest non-empty interval.

Prop(2) and conc(2) are the cumulative proportion and mean log value for the second lowest non-empty interval.

A=Slope of the cumulative proportions

B=The 0.05 log value

Then:

$A=[0.05-Prop(1)]/[Prop(2)-Prop(1)]$

$B=conc(1)+A\,[conc(2)-conc(1)]$

Final Acute Value $=10^B$

P. If for an important species, such as a recreationally or commercially important species, the geometric mean of the acute values from flow-through tests in which the toxicant concentrations were measured is lower than the Final Acute Value, then that geometric mean should be used as the Final Acute Value.

Q. Go to Section VI.

V. Final Acute Equation

A. When enough data are available to show that acute toxicity to two or more species is similarly affected by a water quality characteristic, this effect can be taken into account as described below. Pooled regression analysis should produce similar results, although data available for individual species would be weighted differently.

B. For each species for which comparable acute toxicity values are available at two or more different values of a water quality characteristic which apparently affects toxicity, perform a least squares regression of the natural logarithms of the acute toxicity values on the natural logarithms of the values of the water quality characteristic. [Natural logarithms [logarithms to the base e, denoted as ln] are used herein merely because they are easier to use on some hand calculators and computers than common logarithms [logarithms to the base 10]. Consistent use of either will produce the same result.] No transformation or a different transformation may be used if it fits the data better, but appropriate changes will be necessary throughout this section.

C. Determine whether or not each acute slope is meaningful, taking into account the range and number of values of the water quality characteristic tested. For example, a slope based on four data points may be of limited value if it is based only on data for a narrow range of values of the water quality characteristic. On the other hand, a slope based on only two data points may be meaningful if it is consistent with other information and if the two points cover a broad enough range of the water quality characteristic. If meaningful slopes are not available for at least two species or if the available slopes are not similar, return to Section IV. H., using the results of tests conducted under conditions and in water similar to those commonly used for toxicity tests with the species.

D. Calculate the mean acute slope (V) as the arithmetic average of all the meaningful acute slopes for individual species.

E. For each species calculate the geometric mean (W) of the acute toxicity values and the geometric mean (X) of the related values of the water quality characteristic.

F. For each species calculate the logarithmic intercept (Y) using the equation: $Y=\ln W-V(\ln X)$.

G. For each species calculate the species mean acute intercept as the antilog of Y.

H. Obtain the Final Acute Intercept by using the procedure described in Section IV. I–O, except insert "Intercept" for "Value".

I. If for an important species, such as a recreationally or commercially important species, the intercept calculated only from results of flow-through tests in which the toxicant concentrations were measured is lower than the Final Acute Intercept, then that intercept should be used as the Final Acute Intercept.

J. The Final Acute Equation is written as $e^{(V[\ln(\text{water quality characteristic})]+\ln Z)}$, where V=mean acute slope and Z=Final Acute Intercept.

VI. Final Chronic Value

A. The Final Chronic Value can be calculated in the same manner as the Final Acute Value or by dividing the Final Acute Value by the Final Acute-Chronic Ratio, depending on the data available. In some cases it will not be possible to calculate a Final Chronic Value.

B. Use only the results of flow-through (except renewal is acceptable for

meaningful chronic slope is not available for at least one species, return to Section VI. H.

C. Calculate the mean chronic slope (L) as the arithmetic average of all the meaningful chronic slopes for individual species.

D. For each species calculate the geometric mean (M) of the toxicity values and the geometric mean (P) of the related values of the water quality characteristic.

E. For each species calculate the logarithmic intercept (Q) using the equation: $Q = \ln M - L(\ln P)$.

F. For each species calculate a species mean chronic intercept as the antilog of Q.

G. Obtain the Final Chronic Intercept by using the procedure described in Section IV. I–O, except insert "Intercept" for "Value".

H. If the species mean chronic intercept of an important species, such as a commercially or recreationally important species, is lower than the Final Chronic Intercept, then that species mean chronic intercept should be used as the Final Chronic Intercept.

I. The Final Chronic Equation is written as $e^{(L[\ln(\text{Water quality characteristic})]+\ln R)}$, where L = mean chronic slope and R = Final Chronic Intercept.

VIII. Final Plant Value

A. Appropriate measures of the toxicity of the substance to aquatic plants are used to compare the relative sensitivities of aquatic plants and animals.

B. A value is a concentration which decreased growth (as measured by dry weight, chlorophyll, etc.) in a 96-hr or longer test with an alga or in a chronic test with an aquatic vascular plant.

C. Obtain the Final Plant Value by selecting the lowest plant value from a test in which the toxicant concentrations were measured.

IX. Final Residue Value

A. The Final Residue Value is derived in order to (1) prevent commercially or recreationally important aquatic organisms from exceeding relevant FDA action levels and (2) protect wildlife, including fishes and birds, that eat aquatic organisms from demonstrated adverse effects. A residue value is calculated by dividing a maximum permissible tissue concentration by an appropriate bioconcentration factor (BCF), where the BCF is the quotient of the concentration of a substance in all or part of an aquatic organism divided by the concentration in water to which the organism has been exposed. A maximum permissible tissue concentration is either (1) an action level from the FDA Administrative Guidelines Manual for fish oil or for the edible portion of fish or shellfish, or (2) a maximum acceptable dietary intake based on observations on survival, growth or reproduction in a chronic wildlife feeding study. If no maximum permissible tissue concentration is available, go to Section X because no Final Residue Value can be derived.

B. 1. A BCF determined in a laboratory test should be used only if it was calculated based on measured concentrations of the substance in the test solution and was based on an exposure that continued until either steady-state or 28-days was reached. Steady-state is reached when the BCF does not change significantly over a period of time, such as two days or 16 percent of the length of the exposure, whichever is longer. If a steady-state BCF is not available for a species, the available BCF for the longest exposure over 28 days should be used for that species.

2. A BCF from a field exposure should be used only when it is known that the concentration of the substance was reasonably constant for a long enough period of time over the range of territory inhabited by the organisms.

3. If BCF values from field exposures are consistently lower or higher than those from laboratory exposures, then only those values from field exposures should be used if possible.

4. A BCF should be calculated based on the concentration of the substance and its metabolites, which are structurally similar and are not much more soluble in water than the parent compound, in appropriate tissue and should be corrected for the concentration in the organisms at the beginning of the test.

5. A BCF value obtained from a laboratory or field exposure that caused an observable adverse effect on the test organism may be used only if it is similar to that obtained with unaffected organisms at lower concentrations in the same test.

6. Whenever a BCF is determined for a lipid-soluble substance, the percent lipids should also be determined in the tissue for which the BCF was calculated.

C. A BCF calculated using dry tissue weights must be converted to a wet tissue weight basis by multiplying the dry weight BCF value by 0.1 for plankton and by 0.2 for individual species of fishes and invertebrates.

Note.—The values of 0.2 and 0.1 were derived from data published in:

McDiffett, W. F., 1970. Ecology 51:975–988.
Brocksen, R. W., et al. 1968. J. Wildlife Management 32:52–75.

Love, R. M., 1957. In The Physiology of Fishes, Vol. I, M. E. Brown, ed. Academic Press, New York. p. 411.
Ruttner, F., 1963. Fundamentals of Limnology. 3rd ed. Trans. by D. G. Frey and F. E. J. Fry. Univ. of Toronto Press, Toronto.

Some additional values can be found in:

Sculthorpe, C. D., 1967. The Biology of Aquatic Vascular Plants. Arnold Publishing Ltd., London.

D. If enough pertinent data exist, several residue values can be calculated by dividing maximum permissible tissue concentrations by appropriate BCF values.

1. For each available maximum acceptable dietary intake derived from a chronic feeding study with wildlife, including birds and aquatic organisms, the appropriate BCF is based on the whole body of aquatic species which constitute or represent a major portion of the diet of the tested wildlife species.

2. For an FDA action level, the appropriate BCF is the highest geometric mean species BCF for the edible portion (muscle for decapods, muscle with or without skin for fishes, adductor muscle for scallops and total living tissue for other bivalve molluscs) of a consumed species. The highest species BCF is used because FDA action levels are applied on a species-by-species basis.

E. For lipid-soluble substances, it may be possible to calculate additional residue values. Because steady-state BCF values for a lipid-soluble chemical seem to be proportional to percent lipids from one tissue to another and from one species to another, extrapolations can be made from tested tissues or species to untested tissues or species on the basis of percent lipids.

1. For each BCF for which the percent lipids is known for the same tissue for which the BCF was measured, the BCF should be normalized to a one percent lipid basis by dividing the BCF by the percent lipids. This adjustment to a one percent lipid basis makes all the measured BCF values comparable regardless of the species or tissue for which the BCF was measured.

2. Calculate the geometric mean normalized BCF. Data for both saltwater and freshwater species can be used to determine the mean normalized BCF, because the normalized BCF seems to be about the same for both kinds of organisms.

3. Residue values can then be calculated by dividing the maximum permissible tissue concentrations by the mean normalized BCF and by a percent lipids value appropriate to the maximum permissible tissue concentration, *i.e.*,

riteria for carcinogens are presented as a range of pollutant concentrations associated with corresponding incremental risks.

For compounds which do not manifest any apparent carcinogenic effect, the threshold assumption is used in deriving a criterion. This assumption is based on the premise that a physiological reserve capacity exists within the organism which is thought to be depleted before clinical disease ensues. Alternatively, it may be assumed that the rate of damage will be insignificant over the life span of the organism. Thus, ambient water quality criteria are derived for non-carcinogenic chemicals, and presumably result in no observable-adverse-effect levels (NOAELs) in the exposed human population.

In some instances, criteria are based on organoleptic characteristics, i.e., thresholds for taste or odor. Such criteria are established when insufficient information is available on toxicologic effects or when the estimate of the level of the pollutant in ambient water based on organoleptic effects is lower than the level calculated from toxicologic data. It should be recognized that criteria based solely on organoleptic effects do not necessarily represent approximations of acceptable risk levels for human health.

Several ambient water quality criteria documents deal with classes of compounds which include chemicals exhibiting varying degrees of structural similarity. Because prediction of biological effects based solely on structural parameters is difficult, the derivation of compound-specific criteria is preferable to a class criterion. A compound-specific criterion is defined as a level derived from data on each individual subject compound that does not represent a significant risk to the public. For some chemical classes, however, a compound-specific criterion cannot be derived for each member of a class. In such instances, it is sometimes justifiable to derive a class criterion in which available data on one member of a class may be used to estimate criteria for other chemicals of the class because a sufficient data base is not available for those compounds.

For some chemicals and chemical classes, the data base was judged to be insufficient for the derivation of a criterion. In those cases, deficiencies in the available information are detailed.

III. Approach

The human health effects chapters attempt to summarize all information on the individual chemicals or classes of chemicals which might be useful in the risk assessment process to develop water quality criteria. Although primary emphasis is placed on identifying epidemiologic and toxicologic data, these assessments typically contain discussions on four topics: existing levels of human exposure, pharmacokinetics, toxic effects, and criterion formulation.

For all documents, an attempt is made to include the known relevant information. Review articles and reports are often used in the process of data evaluation and synthesis. Scientific judgment is exercised in the review and evaluation of the data in each document and in the identification of the adverse effects against which protective criteria are sought. In addition, each of these documents is reviewed by a peer committee of scientists familiar with the specific compound(s). These work groups evaluate the quality of the available data, the completeness of the data summary, and the validity of the derived criterion.

In the analysis and organization of the data, an attempt is made to be consistent with respect to the format and the application of acceptable scientific principles. Evaluation procedures used in the hazard assessment process follow the principles outlined by the National Academy of Sciences in *Drinking Water and Health* (1977) and the guidelines of the Carcinogen Assessment Group of the U.S. EPA.

A. Exposure

The exposure section of the health effects chapters reviews known information on current levels of human exposure to the individual pollutant from all sources. Much of the data was obtained from monitoring studies of air, water, food, soil, and human or animal tissue residues. The major purpose of this section is to provide background information on the contribution of water exposure relative to all other sources. Consequently, the exposure section includes subsections reviewing different routes of exposure including water and food ingestion, inhalation, and dermal contact.

Information on exposure can be valuable in developing and assessing a water quality criterion. In these documents exposure from consumption of contaminated water and contaminated fish and shellfish products is used in criterion formulation. Data for all modes of exposure are useful in relating total intake to the expected contribution from contaminated water, fish, and shellfish. In addition, information for all routes of exposure, not limited to drinking water and fish and shellfish ingestion, can be used to justify or assess the feasibility of the formulation of criteria for ambient water.

The use of fish consumption as an exposure factor requires the quantitation of pollutant residues in the edible portions of the ingested species. Accordingly, bioconcentration factors (BCFs) are used to relate pollutant residues in aquatic organisms to the pollutant concentration in the ambient waters in which they reside.

To estimate the average per capita intake of a pollutant due to consumption of contaminated fish and shellfish the results of a diet survey were analyzed to calculate the average consumption of freshwater and estuarine fish and shellfish (U.S. EPA, 1980). A species is considered to be a consumed freshwater or estuarine fish and shellfish species if at some stage in its life cycle, it is harvested from fresh or estuarine water for human consumption in significant quantities (Stephan, 1980).

Three different procedures are used to estimate the weighted average BCF depending upon the lipid solubility of the chemical and the availability of bioconcentration data.

For lipid-soluble compounds, the average BCF is calculated from the weighted average percent lipids in the edible portions of consumed freshwater and estuarine fish and shellfish which was calculated from data on consumption of each species and its corresponding percent lipids to be 3.0 percent (Stephan, 1980). Because the steady-state BCFs for lipid-soluble compounds are proportional to percent lipids, bioconcentration factors for fish and shellfish can be adjusted to the average percent lipids for aquatic organisms consumed by Americans. For many lipid-soluble pollutants, there exists at least one BCF for which the percent lipid value was measured for the tissues for which the BCF is determined.

With 3.0 percent as the weighted average percent lipids for freshwater and estuarine fish and shellfish in the average diet, a BCF, and a corresponding percent lipid value, the weighted average bioconcentration factor can be calculated.

Example:

Weighted average percent lipids for average diet = 3.0 percent

Measured BCF of 17 for trichloroethylene with bluegills at 4.8 percent lipids

Weighted average BCF for average diet equals

$$17 \times \frac{3.0\%}{4.8\%} = 10.6$$

significance, is not available for most of the compounds under study. Consequently, most NOAELs derived from chronic studies are based either on gross toxic effects or on effects directly related to functional impairment or defined pathological lesions.

For compounds on which adequate chronic toxicity studies are not available, studies on acute and subacute toxicity assume greater significance. Acute toxicity studies usually involve single exposures at lethal or near lethal doses. Subacute studies often involve exposures exceeding 10 percent of the life span of the test organism, e.g., 90 days for the rat with an average life span of 30 months. Such studies are useful in establishing the nature of the compound's toxic effects and other parameters of compound toxicity, such as target organ effects, metabolic behavior, physiological/biochemical effects, and patterns of retention and tissue distribution. The utility of acute and subacute studies in deriving environmentally meaningful NOELs is uncertain, although McNamara (1976) has developed application factors for such derivations.

In some cases where adequate data are not available from studies utilizing oral routes of administration, no-effect levels for oral exposures may be estimated from dermal or inhalation studies. Such estimates involve approximations of the total dose administered based on assumptions about breathing rates and/or magnitude of absorption.

D. Criterion Rationale

This section reviews existing standards for the chemical(s), summarizes data on current levels of human exposure, attempts to identify special groups at risk, and defines the basis for the recommended criterion.

Information on existing standards is included primarily for comparison with the proposed water quality criteria. Some of the present standards, such as those recommended by the Occupational Safety and Health Administration (OSHA) or the American Conference of Governmental Industrial Hygienists (ACGIH), are based on toxicologic data but are intended as acceptable levels for occupational rather than environmental exposure. Other levels, such as those recommended by the National Academy of Sciences in *Drinking Water and Health* (1977) or in the U.S. EPA Interim Primary Drinking Water Standards, are more closely related to proposed water quality criteria. Emphasis is placed on detailing the basis for the existing standards wherever possible.

Summaries of current levels of human exposure, presented in this section, specifically address the suitability of the data to derive water quality criteria. The identification of special groups at risk, either because of geographical or occupational differences in exposure or biological differences in susceptibility to the compound(s), focuses on the impact that these groups should have on the development of water quality criteria.

The basis for the recommended criteria section summarizes and qualifies all of the data used in developing the criteria.

IV. Guidelines for Criteria Derivation

The derivation of water quality criteria from laboratory animal toxicity data is essentially a two-step procedure. First, a total daily intake for humans must be estimated which establishes either a defined level of risk for non-threshold effects or a no-effect level for threshold effects. Secondly, assumptions must be made about the contribution of contaminated water and the consumption of fish/shellfish to the total daily intake of the chemical. These estimates are then used to establish the tolerable daily intake and consequently the water quality criterion.

A. Non-Threshold Effects

After the decision has been made that a compound has the potential for causing cancers in humans and that data exist which permit the derivation of a criterion, the water concentration which is estimated to cause a lifetime carcinogenic risk of 10^{-5} is determined. The lifetime carcinogenicity risk is the probability that a person would get cancer sometime in his or her life assuming continuous exposure to the compound. The water concentration is calculated by using the low-dose extrapolation procedure proposed by Crump (1980). This procedure is an improvement on the multistage low dose extrapolation procedure by Crump, et al. (1977).

The data used for quantitative estimates are of two types: (1) lifetime animal studies, and (2) human studies where excess cancer risk has been associated with exposure to the agent. In animal studies it is assumed, unless evidence exists to the contrary, that if a carcinogenic response occurs at the dose levels used in the study, then proportionately lower responses will also occur at all lower doses, with an incidence determined by the extrapolation model discussed below.

1. Choice of Model.

There is no really solid scientific basis for any mathematical extrapolation model which relates carcinogen exposure to cancer risks at the extremely low levels of concentration that must be dealt with in evaluating the environmental hazards. For practical reasons, such low levels of risk cannot be measured directly either using animal experiments or epidemiologic studies. We must, therefore, depend on our current understanding of the mechanisms of carcinogenesis for guidance as to which risk model to use. At the present time, the dominant view of the carcinogenic process involves the concept that most agents which cause cancer also cause irreversible damage to DNA. This position is reflected by the fact that a very large proportion of agents which cause cancer are also mutagenic. There is reason to expect that the quantal type of biological response that is characteristic of mutagenesis is associated with a linear non-threshold dose-response relationship. Indeed, there is substantial evidence from mutagenesis studies with both ionizing radiation and with a wide variety of chemicals that this type of dose-response model is the appropriate one to use. This is particularly true at the lower end of the dose-response curve; at higher doses, there can be an upward curvature, probably reflecting the effects of multistage processes on the mutagenic response. The linear non-threshold dose-response relationship is also consistent with the relatively few epidemiological studies of cancer responses to specific agents that contain enough information to make the evaluation possible (e.g., radiation-induced leukemia, breast and thyroid cancer, skin cancer induced by arsenic in drinking water, and liver cancer induced by aflatoxin in the diet). There is also some evidence from animal experiments that is consistent with the linear non-threshold hypothesis (e.g., liver tumors induced in mice by 2-acetylaminofluorene in the large scale ED_{01} study at the National Center of Toxicological Research, and the initiation stage of the two-stage carcinogenesis model in the rat liver and the mouse skin).

Because it has the best, albeit limited, scientific basis of any of the current mathematical extrapolation models, the linear non-threshold model has been adopted as the primary basis for risk extrapolation to low levels of the dose-response relationship. The risk assessments made with this model should be regarded as conservative, representing the most plausible upper limit for the risk; i.e., the true risk is not likely to be higher than the estimate, but it could be smaller.

where ppm is parts per million of the carcinogenic agent in the diet, F is the weight of the food consumed per day in kgms, and r is the absorption fraction.

In the absence of any data to the contrary, r is assumed to be one. For a uniform diet the weight of the food consumed is proportional to the calories required, which, in turn, is proportional to the surface area or the ⅔rds power of the weight, so that: $m \alpha ppm \times W^{2/3} \times r$ or

$$\frac{m}{rW^{2/3}} \alpha ppm$$

As a result, ppm in the diet is often assumed to be an equivalent exposure between species. However, we feel that this is not justified since the calories/kg of food is significantly different in the diet of man vs. laboratory animals, primarily due to moisture content differences. Instead, we use an empirically derived food factor, f=F/W, which is the fraction of a species body weight that is consumed per day as food. We use the rates given below.

Species	W	f
Man	70	0.028
Rat	0.35	0.05
Mice	0.03	0.13

Thus, when the exposure is given as a certain dietary concentration in ppm, the exposure in $mg/W^{2/3}$ is

$$\frac{m}{r \times W^{2/3}} = \frac{ppm \times F}{W^{2/3}} =$$

$$\frac{ppm \times fxW}{W^{2/3}} = ppm \times f \times W^{1/3}$$

When exposure is given in terms of mg/kg/day=m/Wr=s the conversion is simply:

$$\frac{m}{rW^{2/3}} = s \times W^{1/3}$$

When exposure is via inhalation, the calculation of dose can be considered for two cases where (1) the carcinogenic agent is either a completely water-soluble gas or an aerosol and is absorbed proportionally to the amount of air breathed in, and (2) where the carcinogen is a poorly water-soluble gas which reaches an equilibrium between the air breathed and the body compartments. After equilibrium is reached, the rate of absorption of these agents is expected to be proportional to metabolic rate, which in turn is proportional to the rate of oxygen consumption, which in turn is a function of surface area.

Case 1

Agents that are in the form of particulate matter or virtually completely absorbed gases such as SO_x can reasonably be expected to be absorbed proportional to the breathing rate. In this case the exposure in mg/day may be expressed as: $m=I \times v \times r$ where I is inhalation rate per day in m^3, v is mg/m^3 of the agent in air, and r is the absorption fraction.

The inhalation rates, I, for various species can be calculated from the observation (FASEB, 1974) that 25 gm mice breathe 34.5 liters/day and 113 gm rats breathe 105 liters/day. For mice and rats of other weights, W, (expressed in kg), the surface area proportionality can be used to determine breathing rates (in m^3/day) as follows:

For mice, $I=0.0345\ (W/0.025)^{2/3} m^3$/day

For rats, $I=0.105\ (W/0.113)^{2/3} m^3$/day

For humans, the values of 20 m^3/day [a] is adopted as a standard breathing rate (ICRP, 1977).

The equivalent exposure in $mg/W^{2/3}$ for these agents can be derived from the air intake data in a way analogous to the food intake data. The empirical factors for the air intake per kg per day, i=I/W based upon the previously stated relationships, are as tabulated below:

Species	W	i=I/W
Man	70	0.29
Rat	0.35	0.64
Mice	0.03	1.3

Therefore, for particulates or completely absorbed gases, the equivalent exposure in $mg/W^{2/3}$ is:

$$\frac{m}{W^{2/3}} = \frac{Ivr}{W^{2/3}} = \frac{iWvr}{W^{2/3}} = iW^{1/3}\,vr$$

In the absence of empirical data or a sound theoretical argument to the contrary, the fraction absorbed, r, is assumed to be the same for all species.

Case 2

The dose in mg/day of partially soluble vapors is proportional to the O_2 consumption which in turn is proportional to $W^{2/3}$ and to the solubility of gas in body fluids, which can be expressed as an absorption coefficient r for the gas. Therefore, when expressing the O_2 consumption as $O_2=k\,W^{2/3}$, where k is a constant independent of species, it follows that $m=k\,W^{2/3} \times v \times r$ or

$$d = \frac{m}{W^{2/3}} = kvr$$

As with Case 1, in the absence of experimental information or a sound theoretical argument to the contrary, the absorption fraction, r, is assumed to be the same for all species. Therefore, for these substances a certain concentration in ppm or μ/m^3 in experimental animals is equivalent to the same concentration in humans. This is supported by the observation that the minimum alveolar concentration, necessary to produce a given "stage" of anesthesia, is similar in man and animals (Dripps, et al. 1977). When the animals were exposed via the oral route and human exposure is via inhalation or vice-versa, the assumption is made, unless there is pharmacokinetic evidence to the contrary, that absorption is equal by either exposure route.

e. If the duration of experiment (L_e) is less than the natural life span of the test animal (L), the slope q_1^*, or more generally the exponent g(d), is increased by multiplying a factor $(L/L_e)^3$. We assume that if the average dose, d, is continued, the age specific rate of cancer will continue to increase as a constant function of the background rate. The age specific rates for humans increase at least by the 2nd power of the age and often by a considerably higher power, as demonstrated by Doll (1971). Thus, we would expect the cumulative tumor rate to increase by at least the 3rd power of age. Using this fact, we assume that the slope q_1^*, or more generally, the exponent g(d), would also increase by at least the 3rd power of age. As a result, if the slope q_1^* [or g(d)] is calculated at age L_e, we would expect that if the experiment had been continued for the full life span, L, at the given average exposure, the slope q_1^* [or g(d)] would have been increased by at least $(L/L_e)^3$.

This adjustment is conceptually consistent to the proportional hazard model proposed by Cox (1972) and the time-to-tumor model considered by Crump, et al. (1977) where the probability of cancer at age t and dose d is given by $P(d,t)=1-\exp[-f(t) \times g(d)]$

4. Calculation of Carcinogenic Potency Based on Human Data. If human epidemiology studies and sufficiently valid exposure information are available for the compound, they are always used in some way. If they show a carcinogenic effect, the data are analyzed to give an estimate of the linear dependence of cancer rates on lifetime average dose, which is equivalent to the factor q_1^*. If they show

[a] From "Recommendation of the International Commission on Radiological Protection," page 9, the average breathing rate is 10^7 cm^3 per 8-hour work day and 2×10^7 cm^3 in 24 hours.

"ndication of carcinogenicity" is interpreted as the absence of carcinogenicity data from animal experimental studies or human epidemiology. Available short-term carcinogenicity screening tests are reported in the criteria documents, but they are not used either for derivation of numerical criteria nor to rule out the uncertainty factor approach.

Because of the high degree of judgment involved in the selection of a safety factor, the criterion derivation section of each document should provide a detailed discussion and justification for both the selection of the safety factor and the data to which it is applied. This discussion should reflect a critical review of the available data base. Factors to be considered include number of animals, species, and parameters tested; quality of controls; dose levels; route; and dosing schedules. An effort should be made to differentiate between results which constitute a toxicologically sufficient data base and data which may be spurious in nature.

2. Use of Acceptable Daily Intake (ADI). For carcinogens, the assumption of low dose linearity precludes the necessity for defining total exposure in the estimation of increased incremental risk. For non-carcinogens, ADIs and criteria derived therefrom are calculated from total exposure data that include contributions from the diet and air. The equation used to derive the criterion (C) is: $C=ADI-(DT+IN)/[2\ l+(0.0065\ kg \times R)]$ where 2 l is assumed daily water consumption, 0.0065 kg is assumed daily fish consumption, R is bioconcentration factor in units of l/kg, DT is estimated non-fish dietary intake, and IN is estimated daily intake by inhalation.

If estimates of IN and DT cannot be provided from experimental data, an assumption must be made concerning total exposure. It is recognized that either the inability to estimate DT and IN due to lack of data or the wide variability in DT and IN in different states may add an additional element of uncertainty to the criterion formulation process. In terms of scientific validity, the accurate estimate of the Acceptable Daily Intake is the major factor in satisfactory derivation of water quality criteria.

3. Use of Threshold Limit Values or Animal Inhalation Studies. Threshold Limit Values (TLVs) are established by the American Conference of Governmental and Industrial Hygienists (ACGIH) and represent 8-hour time-weighted average concentrations in air that are intended to protect workers from various adverse health effects over a normal working lifetime. Similar values are set by NIOSH (criteria) and OSHA (standards) for 10- and 8-hour exposures, respectively. To the extent that these values are based on sound toxicologic assessments and have been protective in the work environment, they provide useful information for deriving or evaluating water quality criteria. However, each TLV must be carefully examined to determine if the basis of the TLV contains data which can be used directly to derive a water quality criterion using the uncertainty factor approach. In addition, the history of each TLV must be examined to assess the extent to which it has assured worker safety. In each case, the types of effects against which TLVs are designed to protect are examined in terms of their relevance to exposure from water. It must be demonstrated that the chemical is not a localized irritant and that there is no significant effect at the site of entry irrespective of the routes of exposure (i.e., oral or inhalation).

If the TLV or similar value is recommended as the basis of the criterion, consideration of the above points is explicitly stated in the criterion derivation section of the document. Particular emphasis is placed on the quality of the TLV relative to the available toxicity data that normally is given priority over TLVs or similar established values. If the TLV can be justified as the basis for the cirterion, then the problems associated with the estimation of acceptable oral doses from inhalation data must be addressed.

Estimating equivalencies of dose-response relationships from one route of exposure to another introduces an additional element of uncertainty in the derivation of criteria. Consequently, whenever possible, ambient water quality criteria should be based on data involving oral exposures. if oral data are insufficient, data from other routes of exposure may be useful in the criterion derivation process.

Inhalation data, including TLVs or similar values, are the most common alternatives to oral data. Estimates of equivalent doses can be based upon: (1) available pharmacokinetic data for oral and inhalation routes, (2) measurements of absorption efficiency from ingested or inhaled chemicals, or (3) comparative excretion data when the associated metabolic pathways are equivalent to those following oral ingestion or inhalation. Given that sufficient pharmacokinetic data are available, the use of accepted pharmacokinetic models provides the most satisfactory approach for dose conversions. However, if available pharmacokinetic data are marginal or of questionable quality, pharmacokinetic modeling is inappropriate.

The Stokinger and Woodward (1958) approach, or similar models based on assumptions of breathing rate and absorption efficiency, represents possible alternatives when data are not sufficient to justify pharmacokinetic modeling. Such alternative approaches, however, provide less satisfactory approximations because they are not based on pharmacokinetic data. Consequently, in using the Stokinger and Woodward or related models, the uncertainties inherent in each of the assumptions and the basis of each assumption must be clearly stated in the derivation of the criterion.

The use of data pertaining to other routes of exposure to derive water quality criteria may also be considered. As with inhalation data, an attempt is made to use accepted toxicologic and pharmacokinetic principles to estimate equivalent oral doses. If simplifying assumptions are used, their bases and limitations must be clearly specified.

Because of the uncertainties involved in extrapolating from one route of exposure to another and the consequent limitations that this may place on the derived criterion, the decision to disallow such extrapolation and recommend no criterion is highly judgmental and must be made on a case-by-case basis. A decision for or against criteria derivation must balance the quantity and quality of the available data against a perceived risk to the human population.

If the Stokinger and Woodward (1958) approach is used to calculate an ADI from a TLV, the general equation is:

$ADI=TLV\times BR\times DE\times d\times A_A/(A_O\times SF)$

where:

ADI = Acceptable daily intake in mg
TLV = Concentration in air in mg/m³
DE = Duration of exposure in hours per day
d = 5 days/7 days
A_A = Efficiency of absorption from air
A_O = Efficiency of absorption from oral exposure
SF = Safety factor following guidelines given above
BR = Amount of air breathed per day; assume 10 m³

For deriving an ADI from animal toxicity data, the equation is:

$ADI=C_A\times D_E\times d\times A_A\times BR\times 70\ kg/(BW_A\times A_O\times SF)$

where:

ADI = Acceptable daily intake in mg
C_A = Concentration in air in mg/m³
D_E = Duration of exposure in hours per day
d = Number of days exposed/number of days observed
A_A = Efficiency of absorption from air
BR = Volume of air breathed per day in m³
70 kg = Assumed human body weight
BW_A = Body weight of experimental animals in kg

limitations of the proposed criterion as well as the type of data needed to generate a compound-specific criterion.

A class criterion should be abandoned when there is sufficient data availabe to derive a compound-specific criterion which protects against the biological effect of primary concern; e.g., the availability of a good subchronic study would not necessarily result in the abandonment of a class criterion based on potential carcinogenicity.

The inability to derive a valid class criterion does not, and should not, preclude regulation of a compound or group of compounds based on concern for potential human health effects. The failure to recommend a criterion is simply a statement that the degree of concern cannot be quantified based on the available data and risk assessment methodology.

E. Essential Elements

Some chemicals, particularly certain metals, are essential to biological organisms at low levels but may be toxic and/ or carcinogenic at high levels. Because of potential toxic effects, it is legitimate to establish criteria for such essential elements. However, criteria must consider essentiality and cannot be established at levels which would result in deficiency of the element in the human population.

Elements are accepted as essential if listed by NAS Food and Nutrition Board or a comparably qualified panel. Elements not yet determined to be essential but for which supportive data on essentiality exists need to be further reviewed by such a panel.

To modify the toxicity and carcinogenicity based criteria, essentiality must be quantified either as a "recommended daily allowance" (RDA) or "minimum daily requirement" (MDR). These levels are then compared to estimated daily doses associated with the adverse effect of primary concern. The difference between the RDA or MDR and the daily doses causing a specified risk level for carcinogens or ADIs for non-carcinogens defines the spread of daily doses from which the criterion may be derived. Because errors are inherent in defining both essential and maximum tolerable levels, the criterion is derived from dose levels near the center of such a dose range. The decision to use either the MDR or RDA is guided by the spread of the doses and the quality of the essentiality and toxicity estimates.

The modification of criteria by consideration of essentiality must take into account all routes of exposure. If water is a significant source of the MDR or RDA, the criterion must allow for attainment of essential intake. Conversely, even when essentiality may be attained from nonwater sources, standard criteria derivation methods may be adjusted if the derived criterion represents a small fraction of the ADI or MDR. On a case-by-case basis, the modification in the use of the guidelines may include the use of different safety factors for non-carcinogens or other modifications which can be explicitly justified.

F. Use of Existing Standards

For some chemicals for which criteria are to be established, drinking water standards already exist. These standards represent not only a critical assessment of literature, but also a body of human experience since their promulgation. Therefore, it is valid to accept the existing standard unless there is compelling evidence to the contrary. This decision should be made after considering the existing standards vs. new scientific evidence which has accumulated since the standards have been established. There are several instances where the peer review process recommended usage of the present drinking water standards.

EPA attempted to clearly and concisely deal with all issues which might significantly affect the resulting criteria without going into extreme detail on every potential problem. Because numerous judgments must be made, a reasonable amount of experience in aquatic toxicology will be necessary for a person to utilize the Guidelines effectively.

7. Comment—The Guidelines are too complex.

Response—Deriving a water quality criterion is a complex exercise because several different kinds of data and a wide variety of organisms need to be considered. In addition, because data have been generated using various procedures, numerous individual decisions need to be made and the Guidelines attempt to provide guidance concerning decisions that seem to need to be made frequently. The Guidelines are more complex than initially envisioned to help insure that criteria for different pollutants are derived in a reasonably comparable manner. Although the process of deriving a water quality criterion for aquatic life is complex, the Guidelines help organize the process into logical components and steps.

8. Comment—The Guidelines should be more flexible.

Response—The Guidelines are meant to provide guidance and at the same time allow reasonable flexibility. They have been used with quite a variety of pollutants for which the requirements of the minimum data base are satisfied, and they seem to be reasonably appropriate in all cases because the experiences with these substances were a major part of the basis for the Guidelines. If sound scientific evidence indicates that a particular aspect of the Guidelines is not appropriate for a specific substance, then some other more appropriate procedure should be used. However, the Guidelines should not be changed based on individual whim or personal preference.

9. Comment—The Guidelines should take into account synergism and antagonism by a wide variety of factors and the effect of the pollutant on important ecological relationships.

Response—Very little practically useful information is available on these factors in connection with the effects of pollutants on aquatic organisms. Synergism and antagonism are possible between numerous combination of two or more pollutants, and some data indicate that such interactions are not only species specific, but also vary with the ratios and absolute concentrations of the pollutants and the life stage of the species. Pollutants may affect the structure and function of aquatic ecosystems separate from their effects on individual species, but practical applications of such ideas seem very tenuous at this time. Little information is available concerning such effects, and the significance of the available data is questionable. An obviously important ecological relationship is the dependence of higher organisms on lower organisns for food. Even here, the existence of numerous lower species and their adaptability reduces the importance of any individual food species.

10. Comment—The Guidelines should take into account all identifiable effects—beneficial as well as harmful.

Response—Few tests have been conducted to identify beneficial effects of individual pollutants on aquatic organisms. However, beneficial effects are sometimes observed in chronic toxicity tests at concentrations below those that cause adverse effects. Usually in such cases the organisms in low concentrations of the pollutant are longer or heavier or reproduce more that do the controls. Even if such effects are statistically significant, they are not judged as adverse or harmful. On the other hand, a beneficial effect on one species may ultimately be to the detriment of a community if a balance between species is disturbed. Also, a concentration that benefits one species may harm a more sensitive species.

11. Comment—The Guidelines should take into account analytical methodology.

Response—The Guidelines do take into account analytical methodology in the definition of the substance, when necessary, but not in deriving the numerical value of the criterion. Concentrations which cannot be routinely measured accurately can often be measured accurately by nonroutine methods and, more importantly, do sometimes adversely affect aquatic organisms. When aquatic organisms are more sensitive than routine analytical methods, the proper solution is to develop better analytical methods, not to underprotect aquatic life. One use of criteria should be to identify needs in analytical chemistry.

12. Comment—The Guidelines should take into account (a) production and usage patterns, (b) chemical, physical and biological factors pertaining to degradation and fate of pollutants, including properties such as solubility in water, decay rate, persistence, and transformation pathways, and (c) whether or not a criterion is needed for the substance.

Response—Items included in (a) and (b) may be important in deciding whether a criterion is needed for a substance, but the Guidelines are intended to be used after the decision has been made that a criterion is needed. EPA is presently developing principles that can be used to decide whether or not a criterion is needed for a substance and items such as those listed above are probably some of the factors that should be considered when deciding whether or not a criterion is needed. If the toxicity of the chemical is used to evaluate the need for a criterion, the Guidelines may be useful in the collection and interpretation of the available toxicity data.

13. Comment—The Guidelines should take into account costs to states and industries, technological feasibility, and such characteristics of bodies of water as assimilative capacity, dispersal, dissipative factors, dilution, hydrology, mixing zones, and sediment.

Response—Factors such as these should be considered in developing standards, but not in deriving criteria. EPA is presently developing an implementation policy which will describe which of the above factors and which characteristics of the pollutant should be used, and how they should be used, in developing standards.

14. Comment—The Guidelines are not appropriate for establishing a concentration which may be present in an effluent.

Response—The Guidelines are for deriving water quality criteria, not effluent standards nor mixing zone standards nor water quality standards. Water quality criteria will probably be one factor taken into account in the development of water quality standards and toxicity-based effluent standards, but not technology-based effluent standards. EPA is presently developing policies concerning proper use of water quality criteria in various regulatory activities.

15. Comment—The derivation of criteria should be fundamentally a scientific exercise and should not employ subjective judgments.

Response—No exercise which involves the use and interpretation of data can avoid subjective judgment. Indeed, even the generation of scientific data requires subjective judgment, such as how many test organisms to use, what temperature to use, etc. One may decide to accept the recommendations of experts, but this is usually still a subjective decision. In statistics the subjective decisions are made on the basis of probability statements but the final decisions are still subjective judgments. Although the development of the Guidelines and the derivation of criteria cannot avoid subjective

variables that need to be taken into account. The major advantage of field studies is that conditions are natural (i.e., conditions are not controlled), but this is also the major problem with field studies. With uncontrolled conditions, numerous variables must be taken into account, because any individual variable or combination of variables may affect the results or indeed may be the cause of the results. Therefore, field studies on natural populations usually must last over several seasons and possibly over more than one year to be reasonably sure that proposed cause-and-effect relationships are real.

Another problem with field studies that are based on statistically significant differences is the power of the test. Because natural biological, spacial, and temporal variability is often rather great, a large number of samples is usually required to detect even a moderate change. A field study which purports to show that no change occurred is of no value if the power of the test calculated from the experimental design and observed variability was not high enough.

Because field studies are high cost-high risk ventures, well-designed laboratory tests are usually much more cost-effective for obtaining data on (1) the toxicity of substances to a variety of species and (2) the effect of various water quality characteristics on toxicity. Laboratory tests have been shown to generally be useful predictors of what happens in a field situation, and so it makes little sense to conduct high risk, high cost field studies rather than laboratory tests. Even definitive field studies rarely provide enough information to allow extrapolation of results to other situations, so field studies are more useful in reviewing criteria than in deriving criteria.

22. Comment—Field verification of laboratory tests and of the Guidelines are needed.

Response—Field verification of laboratory tests and of the Guidelines are certainly desirable and provide information that cannot be obtained in a laboratory. Field verification studies do not need to be as risky or as costly as studies on the effects of a pollutant on natural populations because verification studies can be designed (1) as a side-by-side comparison of the results of laboratory tests and field tests or (2) based on existing results of laboratory tests.

23. Comment—EPA should allow criteria to be derived using on-site acute toxicity tests and an application factor.

Response—This approach is usually suggested for developing effluent standards but may be just as applicable to deriving water quality criteria under certain conditions. This approach cannot be used with pollutants whose most sensitive adverse effect is due to residues. Also, it can only be used when the application factor has already been acceptably determined. Finally, acute tests must be determined with either an appropriate range of species or with an appropriate sensitive species. The implementation policy presently being developed by EPA will probably allow the use of appropriate on-site toxicity tests in the development of site-specific criteria and standards.

24. Comment—It is not clear what level of protection is intended.

Response—EPA feels that it is not possible to specify a minimum level of protection that is necessary to "protect aquatic life" or even to protect a particular species for such reasons as:

a. There are so many untested species.

b. Little practically useful information is available concerning synergism, antagonism, ecological relationships, and avoidance.

c. The effect of factors such as temperature on toxicity seems to be species-specific for at least some substances.

d. Information is not available concerning what amount of any effect would be ecologically significant and whether the amount is species-specific.

One possible conclusion is that to protect aquatic life, all species must be adequately protected. A possible extension of this would be that all criteria should be zero because any amount of any pollutant may affect some aquatic organism. Indeed, the assimilative capacity of body of water largely depends on the ability of aquatic life to "process" pollutants and to some extent, any organism which "processes" a pollutant is in some way affected by it.

The apparent level of protection is different for each kind of effect (acute toxicity to animals, chronic toxicity to animals, toxicity to plants, and bioaccumulation) because of the quality and quantity of the available information. An attempt was made to take into account such things as the importance of the effect, the quality of the available data, and the probable ecological relevance of the test methods. Thus it was felt that with regards to toxicity to animals it was probably not necessary to protect all of the species all of the time, but it certainly seems appropriate to protect most of the species most of the time and to protect important species.

On the other hand, the data base on toxicity to aquatic plants is usually very small and a variety of tests and endpoints have been used, especially with algae. Also, little information is available concerning the ecological relevance of the results of any toxicity test with algae in a concentrated test medium, especially because so many species of algae exist in each body of water.

The results of bioconcentration tests with organic chemicals, but not with inorganic chemicals, can apparently be extrapolated reasonably well based on percent lipids from one aquatic animal species to another, at least within commercially and recreationally important species. In addition, the limits on acceptable concentrations in tissue are reasonably well defined in some cases.

These kinds of considerations merely illustrate the complexity of the problem and the necessity for making decisions about each kind of effect individually. In addition, it is important to distinguish between the apparent level of protection provided by the Guidelines and the actual level of protection which will result in a field situation from the use of the implementation policy.

No attempt was made to develop Guidelines which would achieve a predetermined numerical level of protection. For each effect much desirable information is not available, and so it would be misleading to imply a level of sophistication that is not currently possible. EPA believes that the present state-of-the-art in aquatic toxicology does allow some useful conclusions about the ability of a substance to adversely affect aquatic organisms and their uses whenever the requirements of the minimum data base are satisfied, with the full realization that the resulting criterion may be somewhat overprotective or underprotective.

In almost all cases more data would be desirable and so an attempt to reach the "golden mean" will sometimes result incriteria being to high and sometimes too low. One alternative is to derive no criteria until all desirable data are available; this is unacceptable because it will almost always result in no criteria and no protection. The other alternative is to apply safety or uncertainty factors that are inversely proportional to the adequacy of the data base. In the long run this approach would encourage the generation of useful data where it was most needed, but in the short run would require many significant subjective decisions beyond the current state-of-the-art.

25. Comment—The Guidelines should not base criteria on "worst case" assumptions.

is likely to be closer to a lognormal distribution than a normal distribution. Thus the geometric mean, rather than the arithemetic mean, of the upper and lower chronic limits is used.

32. Comment—There should not be any criteria which apply to all bodies of water. Criteria should be specific for individual states, regions, other geographic areas, or bodies of water.

Response—The Guidelines are designed to provide guidance in the collection and interpretation of data concerning the effects of pollutants on aquatic life and its uses. The uses of the resulting criteria will be described by EPA in various regulations. If desired, the Guidelines can be appropriately modified and used to derive a criterion specific to one or more bodies of water or geographic areas if an appropriate data base is available. The critical literature reviews on which the criteria are based will be available for use in the derivation of local, state, or regional criteria. The latitude allowed for deriving local, state, or regional criteria and standards will be determined by the implementation policy presently being developed by EPA.

33. Comment—The Guidelines should result in criteria that are specific for individual species or groups of species (e.g., warmwater and coldwater).

Response—If the necessary data were available, criteria could be derived for any particular species or group of species. It was impractical for EPA to derive criteria for many such groups, but a relatively simple division is freshwater and saltwater organisms because these two groups rarely coexist. Most other possible general divisions of species are faced with the problem that species coexist in various combinations unless the groups are very narrow. In addition, toxicity data are rarely available for very many individual species and so data for representative species must be used, unless appropriate new data are generated. Also, the available data sometimes show wide differences within families so extrapolations from one species to another are often tenuous. Because of these problems, deriving criteria for individual species or groups of species was deemed impractical.

34. Comment—A criterion should be one number, not two.

Response—The two-number criterion is an acknowledgement that aquatic organisms can tolerate short exposures to concentrations that are higher than those they can tolerate continuously. In a two-number criterion, the higher number can assure that short-term fluctuations above the average are not too high, whereas the lower number can assure that the long-term average is not too high. A one-number criterion could be derived by using the existing 24-hour average as an instantaneous maximum. This would certainly provide additional protection, but would provide unnecessary overprotection in most cases. Because a one-number criterion would be more of an approximation than a two-number criterion, one-number criteria would be too high or too low more often and to a greater degree than two-number criteria.

35. Comment—The criteria should not specify sampling schemes.

Response—Criteria should state numerical concentration limits in terms of exposure durations because, everything else being constant, the amount of adverse effect depends on both the concentration of the pollutant and the duration of exposure. Criteria in the Green Book, Blue Book, and Red Book were usually stated as single numbers with no duration expressly stated. The implication was that the criteria were never to be exceeded at any time. Each criterion was apparently and instantaneous maximum. In practice, however, standards derived from these criteria were usually enforced on the basis of 24-hour composite samples. To avoid any ambiguity, the Guidelines specify that a criterion should be explicitly stated in terms of two time frames: an instantaneous maximum and a 24-hour average. However, this is not a specification for a sampling scheme. Standards developed from such a criterion should probably specify a sampling scheme for compliance monitoring, but it would not necessarily be in terms of point measurements and 24-hour averages.

Any sampling scheme used to determine whether or not an ambient concentration exceeds a water quality criterion or a comparable water quality standard should take into account such things as the ratio of the instantaneous maximum and the 24-hour average and the retention time of the body of water because these will primarily determine which portion of the criterion is most limiting in any specific situation. The sampling scheme should probably also take into account the cost of the analyses and results of any past analyses.

36. Comment—The criteria should be stated in terms of time frames longer that an instantaneous maximum and a 24-hour average.

Response—These two time frames were chosen because they would allow the derivation of a criterion which would be less restrictive than, but just as protective as, the previous one-number criterion. These two specific time frames were chosen because they match two kinds of samples that are commonly collected: grab samples and 24-hour composite samples. These specific time frames could probably be changed somewhat without much practical effect, but EPA saw no particular advantage to anyone to introducing novel time periods. For example, for all practical purposes in most situations a 10-minutes average is probably about the same as an instantaneous maximum.

Large increases in the time frames, however, would not provide the same amount of protection. If the instantaneous maximum were changed to a 24- or 96-hour average, and the 24-hour average were changed to a 7- or 30-day average with no change in the numerical limits, the amount of protection afforded aquatic life would fall to an unacceptable level. The longer the time span for the average, the higher the instantaneous concentration could be for short periods of time within that span. Although most chronic tests last for 28-days or longer, some chronic effects may be caused by short exposures of sensitive life stages. If the acute-chronic ratio is small, fluctuations in the instantaneous concentration may even cause acute toxicity, especially for cumulative pollutants, because for some substances the 24-, 48-, and 96-hour acute values do not differ too much.

37. Comment—A two-number criterion will be difficult to enforce.

Response—Criteria are not enforceable. Standards are enforceable. When standards to protect aquatic life are developed, they may or may not be in the same format as the criteria for aquatic life. Few standards are adequately enforced because of the high cost of continuous monitoring. The real value of many criteria and standards is in the design of waste treatment facilities; a two-number criterion should be a better basis for design than a one-number criterion.

38. Comment—The criteria should be expressed to one significant figure, not two.

Response—EPA acknowledges that there is much variability in some of the data and that the range of sensitivites is often great. When the requirements of the minimum data base are satisfied and the data agree reasonably well, two significant figures are not unreasonable. Rounding off to one significant figure could arbitrarily raise or lower the criterion by up to forty percent with no apparent consistent benefits to dischargers, regulators, or aquatic life.

39. Comment—The Guidelines should only use data for species that ought to be protected.

damage than elevated concentrations of a pollutant that produces a wide range of species sensitivities.

49. Comment—The distinction between ionizable and unionizable compounds is not very good because some chemicals ionize and reach chemical equilibrium very slowly and others very rapidly.

Response—Most chemicals can readily be classified into one of three groups:

A. Chemicals that ionize, including hydrolyze, at least 90% and reach 90% of equilibrium in less than 8 hours in most surface waters.

B. Chemicals that ionize, including hydrolyze, less than 10% in 30 days in most surface waters.

C. Chemicals that do not fit into either one of the above categories.

For the purpose of the Guidelines, chemicals in the A group should be considered ionizable, chemicals in the B group should be considered non-ionizable, and chemicals in the C group should be classified on a case-by-case basis. Although the distinction between ionizable and unionizable may not be perfect, it is very useful for most chemicals.

50. Comment—Each individual organic compound should be considered separately.

Response—The vast majority of organic chemicals will be considered separately according to the Guidelines except for structurally similar organic compounds that meet all three specifications given in the Guidelines, such as polychlorinated biphenyls and toxaphene.

51. Comment—In-stream water quality criteria are meaningless for substances that are highly insoluble.

Response—The concentration of some substances in sediment may be important separate from the concentration of the substance in the ambient water and for these compounds a sediment quality criterion may be necessary. Generally such compounds can also cause adverse effects if the concentration in the ambient water is too high even if the concentration in the sediment is low. Thus for such compounds both kinds of criteria may be necessary rather than just one or the other.

52. Comment—If a substance is not dissolved, it is not biologically or toxicologically available.

Response—Although this may usually be true, it certainly does not apply to elemental mercury which can be oxidized and methylated to form a very toxic compound. Some organic acids and phenols and hydroxide and carbonate salts of metals have solubilities which differ substantially from one body of water to another.

53. Comment—Criteria for metals should not be for total metal.

Response—Criteria for metals will generally not be based on total metal. Most will be based on total recoverable metal because forms of metals that are not measured in the total recoverable procedure probably are not, and will not become, toxic. A major problem is that some people use a procedure for total recoverable, but report the results as total, metal. In many situations the two results are about the same, but in some cases the results are quite different.

54. Comment—The Guidelines should give more guidance for distinguishing between acceptable and unacceptable data.

Response—The Guidelines contain as much detail on this subject as EPA believes is currently feasible. Items such as the maximum acceptable control mortality and minimum number of test organisms are based on what many aquatic toxicologists generally feel are acceptable, as expressed in published methods. No data should be used in the derivation of a criteria until their quality and acceptability had been reviewed by a competent person. Competent people will occasionally disagree, but that is a fundamental property of subjective decisions.

55. Comment—Only published data should be used.

Response—Peer review is one of many concepts that is better in theory than in practice. Some poor quality data are published and some high quality data are rejected. In addition, publication is not a particularly rapid process. Whether or not data are used should depend on the applicability and quality of the data, not on whether they have been published. Data that are not published should be made readily available if they are used to derive water quality criteria.

56. Comment—All static test are unacceptable

Response—In general, high quality flow-through acute tests are preferable to high quality static acute tests, but static tests are by no means unacceptable. Few data are available to show whether static tests consistently produce acute values lower or higher or different than flow-through tests. Whereas degradation, violatilization, and buildup of metabolic products are more likely to be a problem in static tests, operator and mechanical errors are more likely in flow-through tests. Static acute tests are certainly not unacceptable for most pollutants, but static chronic tests generally are unacceptable because of changes in the toxicant concentrations and the quality of the dilution water during the test.

57. Comment—Data obtained using test organisms that were previously exposed to the pollutant should be used.

Response—Comparisons of results obtained with unexposed and previously exposed organisms should indicate whether or not acclimation has occurred. Generally, data obtained with acclimated organisms should not be used in deriving criteria because acclimated organisms are the exception rather than the norm. Rarely, if ever, can acclimation be depended on to protect organisms in a field situation because concentrations often fluctuate and motile organisms do not stay in one location very long. Data obtained with acclimated organisms may be acceptable for use in deriving some site-specific criteria.

58. Comment—Foreign species should be used to expand the data base.

Response—Foreign species may be representative of indigenous species, but some of them are quite unusual. Data obtained with foreign species may give good indications of indigenous speceis that should be used in tests on some pollutants and may identify some potential problems that should be investigated.

59. Comment—If data for brine shrimp are not used, the criteria should not apply to saline waters.

Response—Data obtained using brine shrimp are not used because these organisms are atypical. Although they may not be usually sensitive or insensitive to various pollutants, the species found in North America and used for testing only survive in the Great Salt Lake and in salt ponds near San Francisco Bay. These two habitats are unlike any others in the United States. If criteria were to be derived specifically for the Great Salt Lake or for salt ponds, then data for brine shrimp should be used.

60. Comment—Structure-activity relationships should not be used unless proven.

Response—No provision is made in the Guidelines for the use of structure-activity relationships. Such relationships may soon be well enough understood that they can be used in deriving water quality criteria.

61. Comment—A criterion should not be derived for a pollutant until data are available for a broad range of commercially, recreationally, and ecologically important species. Each species should be acutely and chronically tested under a variety of conditions in a number of different waters.

useful, but such a test cannot be used with just two points and does not take into account such things as the comparability of the data, the quality of the test, and the range of the independent variable. A relationship based on six points may not be as significant as it seems if five of the points are tightly grouped.

71. Comment—The Guidelines should not combine 96-hr LC50 values and 48-hr EC50 values.

Response—Both LC50 values and EC50 values are used to measure acute toxicity of a substance to aquatic organisms. In general, an EC50 can be based on a wide variety of effects, but the Guidelines specify that the only effects to be used for deriving criteria are incomplete shell development, immobilization, and loss of equilibrium. All of these are certainly drastic effects. In a field situation these effects probably often lead to death. Just as the endpoint may be specific for the species, so may be the length of the test. The generally accepted length of an acute test with daphnids is 48 hours, whereas for most species of fish, it is 96 hours. Thus the Guidelines use both 48-hr EC50 values and 96-hr LC50 values because they are the widely accepted durations and endpoints used to measure acute toxicity to specific species.

72. Comment—Shell deposition tests are chronic tests and should not be equated with lethality tests.

Response—"Acute" implies "short" not "death". Many acute toxicity tests do use death for the effect, but many also use non-lethal effects. The shell deposition test is one of many non-lethal acute tests and is generally accepted as a short test compared to the average life span of oysters.

73. Comment—Adjustment factors should not be used to adjust for the length of the test, the technique, and unmeasured concentrations.

Response—All three kinds of adjustment factors have been deleted from the Guidelines. The factor for the length of the test was found to be unnecessary because most tests had been conducted for the standard times usually specified for the individual species. Thus the Guidelines now specify that only data from tests conducted for the time specified for the species should be used to calculate the Final Acute Value.

EPA has found that on the average flow-through acute tests give results slightly lower than do static tests, but the relationship does not seem to be too consistent and may vary from species to species for some pollutants. In addition, on the average results based on measured concerntrations do not seem to be much different from those based on unmeasured concentrations.

However, the results of flow-through tests based on measured concentrations are generally accepted as being better measures of acute toxicity than the results of flow-through tests based on unmeasured concentrations or the results of any static or renewal tests.Therefore, whenever the results of flow-through acute tests in which the concentrations were measured are available, the results of all other kinds of acute tests with that species and pollutant are not used in the calculation of the species mean acute value.

74. Comment—Species sensitivity factors should be pollutant-specific; and average factor should not be calculated for a variety of substances.

Response—EPA agrees. The requirement for acute values for at least eight different species was developed in part to allow for a reasonably good calculation of a mean acute value and a species sensitivity factor for each individual pollutant. A better way of using the acute values for the individual species has been developed, but no extrapolations are made from one pollutant to another.

75. Comment—The distribution of species mean acute values for a pollutant will be truncated if the species cannot be killed or affected by concentrations above solubility.

Response—Some species are so resistant to some pollutants that they cannot be killed or affected in acute tests even by concentrations which are much above solubility. Such "greater than" values cannot be used in the calculation of means and variances for pollutants. When the "greater than" values are for insensitive species and are at or above solubility, the values can be used in the calculation of the Final Acute Value by adjusting the cumulative proportions for all the speices with quantitative values. The shape of the curve at the high end cannot be determined, but the Final Acute Value is more dependent on the species mean acute values and the cumulative probabilities at the low end.

76. Comment—Early life-stage tests with fish should be used interchangeably with life-cycle and partial life-cycle tests with fish.

Response—EPA agrees that early life-stage tests with fish generally give about the same results as comparable life-cycle and partial life-cycle tests. However, because the shorter test is merely a predictor of the longer tests, whenever both kinds of results are available, the results of life-cycle and partial life-cycle tests should be used instead of the results of early life-stage tests.

77. Comment—Appropriate measures of chronic toxicity and appropriate lengths of exposure should be defined.

Response—The descriptions of appropriate chronic tests have been clarified.

78. Comment—The factor of 0.44 should not be used.

Response—It is not now used.

79. Comment—The Final Chronic Value should not be lower than the lowest measured species chronic value, even if chronic data are not available for sensitive species.

Response—Aquatic ecosystems cannot be protected from chronic toxicity by protecting only the insensitive species from chronic toxicity. In the past both arbitrary and experimentally determined application factors have been used to relate acute and chronic toxicity. For a variety of reasons the Guidelines do not use an application factor, but instead use the acute-chronic ratio, which is similar to the inverse of an application factor. Thus the acute-chronic ratio should normally be greater than one. The acute-chronic ratio is to be used with invertebrates as well as fish and is to be an experimentally determined value for each individual pollutant. The acute-chronic ratio should also avoid the confusion as to whether a large application factor is one that is close to unity or one that has a denominator that is much larger than the numerator. The acute-chronic ratio is calculated by dividing the appropriate measure of acute toxicity for the species (as specified in the Guidelines) by the appropriate measure of chronic toxicity for the same species (as specified in the Guidelines).

Some people have confused application factors and safety factors and use of the term "acute-chronic ratio" should help avoid this problem. Acute-chronic ratios are a way of estimating the chronic sensitivity of a species for which no chronic toxicity data are available. Safety factors would provide an extra margin of safety beyond the sensitivity of the species. Safety or uncertainty factors are intended to reduce the possibility of underprotection, whereas acute-chronic ratios are intended to estimate the actual chronic sensitivity of the species to the pollutant. This estimate is just as likely to be too high as it is to be too low. A mean acute-chronic ratio will in fact be too high for half the species and too low for the other half.

When three or more acute-chronic ratios have been determined for a pollutant with both fish and

Updated National Recommended Water Quality Criteria for the Protection of Human Health

Tuesday, May 13, 2014

AGENCY: Environmental Protection Agency (EPA).

***27303** ACTION: Notice of Availability.

SUMMARY: EPA is announcing the availability of draft updated national recommended water quality criteria for the protection of human health for the purpose of obtaining public comments. EPA has updated its national recommended water quality criteria for human health for ninety-four chemical pollutants to reflect the latest scientific information and current EPA policies. This draft update is based on EPA's current methodology for deriving human health criteria as described in “Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health (2000)” and does not establish new policy. EPA's recommended water quality criteria provide technical information for States and authorized Tribes to establish water quality standards under the Clean Water Act to protect human health.

DATES: The public comment period begins on May 13, 2014 and ends on July 14, 2014. Technical comments should be submitted to the public EPA docket by July 14, 2014.

ADDRESSES: Submit your comments, identified by Docket ID No. EPA-HQ-OW-2014-0135, by one of the following methods:

• www.regulations.gov: Follow the on-line instructions for submitting comments.

• Mail: Water Docket, Environmental Protection Agency, 28221T, 1200 Pennsylvania Ave., NW., Washington, DC 20460. Attention Docket ID No. EPA-HQ-OW-2014-0135.

• Hand Delivery: Water Docket, EPA Docket Center, EPA WJC West Building Room 3334, 1301 Constitution Ave. NW., Washington, DC, 20004, Attention Docket EPA-HQ-OW-2014-0135. Deliveries to the docket are accepted only during their normal hours of operation: 8:30 a.m. to 4:30 p.m., Monday through Friday, excluding legal holidays. For access to docket materials, call (202) 566-2426, to schedule an appointment.

• Email: ow-docket@epa.gov; Attention Docket No. EPA-HQ-OW-2014-0135. To ensure that EPA can properly respond to comments, commenters should cite the section(s) or chemical(s) in draft updates to which each comment refers. Commenters should use a separate paragraph for each issue discussed, and must submit any references cited in their comments. If you submit an electronic comment, EPA recommends that you include your name and other contact information in the body of your comment. Electronic files should avoid any form of encryption and should be free of any defects or viruses.

Instructions: Direct your comments to Docket ID No. EPA-HQ-OW-2014-0135. EPA's policy is that all comments received will be included in the public docket without change and may be made available online at www.regulations.gov, including any personal information provided, unless the comment includes information claimed to be Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Do not submit information that you consider to be CBI or otherwise protected through www.regulations.gov. The www.regulations.gov Web site is an “anonymous access” system, which means EPA will not know your identity or contact information unless you provide it in the body of your comment. If you send an email comment directly to EPA without going through www.regulations.gov your email address will be automatically

captured and included as part of the comment that is placed in the public docket and made available on the Internet. If you submit an electronic comment, EPA recommends that you include your name and other contact information in the body of your comment and with any disk or CD-ROM you submit. If EPA cannot read your comment due to technical difficulties and cannot contact you for clarification, EPA may not be able to consider your comment. Electronic files should avoid the use of special characters, any form of encryption, and be free of any defects or viruses.

Docket: All documents in the docket are listed in the www.regulations.gov index. Although listed in the index, some information is not publicly available, e.g., CBI or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, will be publicly available only in hard copy. Publicly available docket materials are available either electronically in www.regulations.gov or in hard copy at the Water Docket, EPA/DC, EPA West, Room 3334, 1301 Constitution Ave. NW., Washington, DC. The Public Reading Room is open from 8:30 a.m. to 4:30 p.m., Monday through Friday, excluding legal holidays. The telephone number for the Public Reading Room is (202) 566-1744, and the telephone number for the Water Docket is (202) 566-2426.

FOR FURTHER INFORMATION CONTACT: Heidi Bethel at U.S. EPA, Office of Water, Health and Ecological Criteria Division (Mail Code 4304T), 1200 Pennsylvania Avenue NW., Washington, DC 20460; telephone: (202) 566-2054; or email: bethel.heidi@epa.gov.

SUPPLEMENTARY INFORMATION:

I. What should I consider as I prepare my comments for EPA?

In preparation for submitting comments for EPA on this action, please review the draft chemical-specific support documents EPA is publishing (1) in the public docket for this action under Docket ID No. EPA-HQ-OW-2014-0135, or (2) on EPA's Web site http://water.epa.gov/scitech/swguidance/standards/criteria/current/hhdraft.cfm. Provide EPA with comments regarding scientific views related to the draft updated national recommended water quality criteria for protecting human health. Include any recommended references for data or other scientific information to be considered by EPA.

II. What are recommended water quality criteria?

EPA's recommended water quality criteria are scientifically derived numeric values that protect aquatic life or human health from the deleterious effects of pollutants in ambient water.

***27304** Section 304(a)(1) of the Clean Water Act (CWA) requires EPA to develop and publish and, from time to time, revise, criteria for protection of water quality and human health that accurately reflect the latest scientific knowledge. Water quality criteria developed under section 304(a) are based solely on data and scientific judgments on the relationship between pollutant concentrations and environmental and human health effects. Section 304(a) criteria do not reflect consideration of economic impacts or the technological feasibility of meeting pollutant concentrations in ambient water.

EPA's recommended Section 304(a) criteria provide technical information to States and authorized Tribes in adopting water quality standards that ultimately provide a basis for assessing water body health and controlling discharges or releases of pollutants. Under the CWA and its implementing regulations, States and authorized Tribes are to adopt water quality criteria to protect designated uses (e.g., public water supply, aquatic life, recreational use, or industrial use). EPA's recommended water quality criteria do not substitute for the CWA or regulations, nor are they regulations themselves. Thus, EPA's recommended criteria do not impose legally binding requirements. States and authorized Tribes have the discretion to adopt, where appropriate, other scientifically defensible water quality criteria that differ from these recommendations.

III. What are the updated criteria?

Today, EPA is publishing draft updated national recommended water quality criteria for the protection of human health for ninety-four chemical pollutants. These revisions are based on EPA's current methodology for deriving human health criteria

(See: Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health (2000), EPA-822-B-00-004, October 2000). The methodology describes EPA's current approach for deriving national recommended water quality criteria for the protection of human health.

The revision of these criteria represents a systematic update of EPA's national recommended 304(a) criteria. EPA has previously described its process for publishing revised criteria [see National Recommended Water Quality Criteria—Correction (64 FR 19781; or EPA 822-Z-99-001) or the Federal Register Notice for EPA's 2000 Methodology (65 FR 66444)]. EPA is announcing the availability of the updated human health criteria in today's Notice in order to solicit scientific views. EPA has updated the draft human health criteria using information sources and models that have previously undergone external peer review. A fact sheet and a summary of updated input parameters (e.g., cancer slope factor, reference dose, and bioaccumulation factors) used to derive the updated criteria was prepared to assist reviewers. EPA has also developed chemical-specific support documents for each of the ninety-four chemical pollutants. The support documents detail the latest scientific information supporting the updated draft human health criteria, particularly the updated toxicity and exposure input values. All of these documents are available in the docket (EPA-HQ-OW-2014-0135) and on EPA's Web site http://water.epa.gov/scitech/swguidance/standards/criteria/current/hhdraft.cfm.

IV. What is the relationship between the draft national recommended water quality criteria and your state or tribal water quality standards?

As part of the water quality standards triennial review process defined in section 303(c)(1) of the CWA, the States and authorized Tribes are responsible for maintaining and revising water quality standards. Water quality standards consist of designated uses, water quality criteria to protect those uses, a policy for antidegradation, and may include general policies for application and implementation. Section 303(c)(1) requires States and authorized Tribes to review and modify, if appropriate, their water quality standards at least once every three years.

States and authorized Tribes must adopt water quality criteria that protect designated uses. Protective criteria are based on a sound scientific rationale and contain sufficient parameters or constituents to protect the designated uses. Criteria may be expressed in either narrative or numeric form. States and authorized Tribes have four options when adopting water quality criteria for which EPA has published section 304(a) criteria. They can:

(1) Establish numerical values based on recommended section 304(a) criteria;

(2) Adopt section 304(a) criteria modified to reflect site specific conditions;

(3) Adopt criteria derived using other scientifically defensible methods; or

(4) Establish narrative criteria where numeric criteria cannot be determined (40 CFR 131.11).

EPA believes that it is important for States and authorized Tribes to consider any new or updated 304(a) criteria as part of their triennial review to ensure that state or tribal water quality standards reflect current science and protect applicable designated uses. These updated criteria recommendations may change based on scientific views shared in response to this notice, but once final they would supersede EPA's previous recommendations.

Consistent with 40 CFR 131.21, new or revised water quality criteria adopted into law or regulation by States and authorized Tribes on or after May 30, 2000 are in effect for CWA purposes only after EPA approval.

Dated: April 29, 2014.

Nancy K. Stoner,

Acting Assistant Administrator, Office of Water.

Human Health Ambient Water Quality Criteria: Draft 2014 Update

Summary

EPA is announcing in the Federal Register the availability of draft updated ambient water quality criteria for the protection of human health for the purpose of obtaining public comments. EPA has updated its national recommended water quality criteria for human health for 94 chemical pollutants to reflect the latest scientific information and EPA policies. EPA will accept written scientific views from the public on the draft updated human health criteria for 60 days. Once finalized, EPA water quality criteria provide recommendations to states and tribes authorized to establish water quality standards under the Clean Water Act.

Background

Ambient water quality criteria developed by EPA under the Clean Water Act represent specific levels of chemicals or conditions in a water body that are not expected to cause adverse effects to human health. EPA is required to develop and publish water quality criteria that reflect the latest scientific knowledge. These criteria are not rules, nor do they automatically become part of a state's water quality standards. States may adopt the criteria that EPA publishes, modify EPA's criteria to reflect site-specific conditions, or adopt different criteria based on other scientifically-defensible methods. EPA must, however, approve any new water quality standards adopted by a state before they can be used for Clean Water Act purposes.

In this 2014 update, EPA has revised 94 of the existing human health criteria to reflect the latest scientific information, including updated exposure factors (body weight, drinking water intake, fish consumption rate), bioaccumulation factors, and toxicity factors (reference dose, cancer slope factor). The criteria have also been updated to follow the current EPA methodology for deriving human health criteria (2000). Specific updates are described in detail below.

Due to outstanding technical issues, including new toxicity factors and bioaccumulation factors, EPA is *not* updating criteria for the following chemical pollutants at this time: antimony, arsenic, asbestos, barium, beryllium, cadmium, chromium (III or VI), copper, manganese, methylmercury, nickel, nitrates, nitrosamines, N-nitrosodibutylamine, N-nitrosodiethylamine, N-nitrosopyrrolidine, N-nitrosodimethylamine, N-nitrosodi-n-propylamine, N-nitrosodiphenylamine, polychlorinated biphenyls (PCBs), selenium, thallium, zinc, or 2,3,7,8-TCDD (dioxin).

Updated Exposure Assumptions

Body Weight

EPA has updated the default body weight assumption for human health criteria to 80 kilograms based on National Health and Nutrition Examination Survey (NHANES) data from 1999 to 2006. This represents the mean body weight for adults ages 21 and older. EPA's previously recommended body weight assumption was 70 kilograms, which was based on the mean body weight of adults from the NHANES III database (1988-1994).

Drinking Water

EPA has updated the default drinking water intake rate assumption to 3 liters per day based on NHANES data from 2003 to 2006 for all sources of water at the 90th percentile for adults ages 21 and older. This value is based on consumer-only estimates of direct and indirect water ingestion. EPA previously recommended a default drinking water intake rate of 2 liters per day, which represented the 86th percentile for adults surveyed in the US Department of Agriculture's 1994-1996 Continuing Survey of Food Intake by Individuals (CSFII) analysis and the 88th percentile of adults in the National Cancer Institute study of the 1977-1978 Nationwide Food Consumption Survey.

Fish Consumption

EPA has updated the default fish consumption rate to 22 grams per day. This rate represents the 90th percentile consumption rate of freshwater and estuarine fish for the U.S. adult population 21 years of age and older, based on NHANES data from 2003 to 2010 (USEPA 2014). EPA's previously recommend rate of 17.5 grams per day was based on the 90th percentile consumption rate of freshwater and estuarine fish for the U.S. adult population and was derived from 1994-1996 CSFII data.

As described in EPA's human health criteria methodology (USEPA 2000), the level of fish intake in highly exposed populations varies by geographical location. Therefore, EPA suggests a four preference hierarchy for states and authorized tribes that encourages use of the best local, state, or regional data available to derive fish consumption rates. EPA recommends that states and authorized tribes consider developing criteria to protect highly exposed population groups and use local or regional data over the default values as more representative of their target population group(s). The four preference hierarchy is: (1) use of local data; (2) use of data reflecting similar geography/ population groups; (3) use of data from national surveys; and (4) use of EPA's default intake rates.

Bioaccumulation Factors

EPA's national recommended water quality criteria for the protection of human health have been updated using bioaccumulation factors rather than bioconcentration factors, as recommended in EPA's human health criteria methodology (USEPA 2000). Unlike bioconcentration factors, bioaccumulation factors account for more exposure pathways than direct water contact. As a result, the updated criteria will better represent exposures to pollutants that affect human health. In order to account for the variation in bioaccumulation that is due to trophic position of the organism, EPA's human health criteria methodology (USEPA 2000) recommends that bioaccumulation factors be determined and applied to three trophic levels of fish. EPA used a peer-reviewed model called Estimation Program Interface Suite (EPI Suite) to develop bioaccumulation factors for each trophic level of fish.

Updated Health Risk Factors

EPA has updated the health risk factors using the most current toxicity information. EPA's Integrated Risk Information System (IRIS) is the primary recommended source for reference dose and cancer slope factor information. For some pollutants, more recent assessments may be found using other resources provided by EPA's Office of Water, EPA's Office of Pesticide Programs, and international or state agencies.

Relative Source Contribution

EPA has updated the human health criteria to reflect the recommended default relative source contribution (RSC) of 20 percent, as recommended in EPA's human health criteria methodology (USEPA 2000). The RSC component of the human health criteria calculation for non-carcinogens designates a percentage of the reference dose that accounts for exposures from water and fish (freshwater and estuarine), when there are other possible exposure routes. Other such routes include, but are not limited to, exposure to a particular pollutant from marine fish consumption, non-fish food consumption, dermal exposure, and respiratory exposure. For pollutants exhibiting threshold effects, the use of an RSC ensures that an individual's total exposure from all sources of a pollutant does not exceed that threshold level.

In accordance with EPA's human health criteria methodology (USEPA 2000), an alternative RSC may be used to derive human health criteria when there are sufficient data available to support a scientifically defensible alternative value.

Final Water Quality Guidance for the Great Lakes System

Thursday, March 23, 1995

***15366** AGENCY: U.S. Environmental Protection Agency.

ACTION: Final rule.

SUMMARY: EPA is publishing Final Water Quality Guidance for the Great Lakes System. Great Lakes States and Tribes will use the water quality criteria, methodologies, policies, and procedures in the Guidance to establish consistent, enforceable, long-term protection for fish and shellfish in the Great Lakes and their tributaries, as well as for the people and wildlife who consume them.

The Guidance was initially developed by the Great Lakes States, EPA, and other Federal agencies in open dialogue with citizens, local governments, and industries in the Great Lakes ecosystem. It will affect all types of pollutants, but will target especially the types of long-lasting pollutants that accumulate in the food web of large lakes.

The Guidance consists of water quality criteria for 29 pollutants to protect aquatic life, wildlife, and human health, and detailed methodologies to develop criteria for additional pollutants; implementation procedures to develop more consistent, enforceable water quality-based effluent limits in discharge permits, as well as total maximum daily loads of pollutants that can be allowed to reach the Lakes and their tributaries from all sources; and antidegradation policies and procedures.

Under the Clean Water Act, the States of Illinois, Indiana, Michigan, Minnesota, New York, Ohio, Pennsylvania, and Wisconsin must adopt provisions into their water quality standards and NPDES permit programs within two years (by March 23, 1997) that are consistent with the Guidance, or EPA will promulgate the provisions for them. The Guidance for the Great Lakes System will help establish consistent, enforceable, long-term protection from all types of pollutants, but will place short-term emphasis on the types of long-lasting pollutants that accumulate in the food web and pose a threat to the Great Lakes System. The Guidance includes minimum water quality criteria, antidegradation policies, and implementation procedures that provide a coordinated ecosystem approach for addressing existing and possible pollutant problems and improves consistency in water quality standards and permitting procedures in the Great Lakes System. In addition, the Guidance provisions help establish consistent goals or minimum requirements for Remedial Action Plans (RAPs) and Lakewide Management Plans (LaMPs) that are critical to the success of international multi-media efforts to protect and restore the Great Lakes ecosystem.

EFFECTIVE DATE: April 24, 1995.

ADDRESSES: The public docket for this rulemaking, including applicable Federal Register documents, public comments in response to these documents, the Final Water Quality Guidance for the Great Lakes System, Response to Comments Document, other major supporting documents, and the index to the docket are available for inspection and copying at U.S. EPA Region 5, 77 West Jackson Blvd., Chicago, IL 60604 by appointment only. Appointments may be made by calling Wendy Schumacher (telephone 312-886-0142).

Information concerning the Great Lakes Initiative (GLI) Clearinghouse is available from Ken Fenner, Water Quality Branch Chief, (WQS-16J), U.S. EPA Region 5, 77 W. Jackson Blvd., Chicago, IL 60604 (312-353-2079).

Copies of the Information Collection Request for the Guidance are available by writing or calling Sandy Farmer, Information Policy Branch, EPA, 401 M St., S.W. (Mail Code 2136), Washington, DC 20460 (202-260-2740).

Selected documents supporting the Guidance are also available for viewing by the public at locations listed in section XI of the preamble.

Selected documents supporting the Guidance are available by mail upon request for a fee. Selected documents are also available in electronic format at no incremental cost to users of the Internet. See section XI of the preamble for additional information.

FOR FURTHER INFORMATION CONTACT: Kenneth A. Fenner, Water Quality Branch Chief (WQS-16J), U.S. EPA Region 5, 77 W. Jackson Blvd., Chicago, IL 60604 (312-353-2079).

SUPPLEMENTARY INFORMATION

Preamble Outline

I. Introduction

Section 118(c)(2) of the Clean Water Act (CWA) (Pub. L. 92-500 as amended by the Great Lakes Critical Programs Act of 1990 (CPA), Pub. L. 101-596, November 16, 1990) required EPA to publish proposed and final water quality guidance on minimum water quality standards, antidegradation policies, and implementation procedures for the Great Lakes System. In response to these requirements, EPA published the Proposed Water Quality Guidance for the Great Lakes System (proposed Guidance) in the Federal Register on April 16, 1993 (58 FR 20802). EPA also published four subsequent documents in the Federal Register identifying corrections and requesting comments on additional related materials (April 16, 1993, 58 FR 21046; August 9, 1993, 58 FR 42266; September 13, 1993, 58 FR 47845; and August 30, 1994, 59 FR 44678). EPA received over 26,500 pages of comments, data, and information from over 6,000 commenters in response to ***15367** these documents and from meetings with members of the public.

After reviewing and analyzing the information in the proposal and these comments, EPA has developed the Final Water Quality Guidance for the Great Lakes System (final Guidance), published in this document and codified in 40 CFR part 132, which includes six appendixes of detailed methodologies, policies, and procedures. This preamble describes the background and purpose of the final Guidance, and briefly summarizes the major provisions. Detailed discussion of EPA's reasons for issuing the final Guidance, analysis of comments and issues, description of specific changes made to the proposed Guidance, and further description of the final Guidance, are provided in “Final Water Quality Guidance for the Great Lakes System: Supplementary Information Document” (SID), (EPA, 1995, 820-B-95-001) and in additional technical and supporting documents which are available in the docket for this rulemaking. Copies of the SID and other supporting documents are also available from EPA in electronic format, or in printed form for a fee upon request; see section XI of this preamble.

II. Background

The Great Lakes are one of the outstanding natural resources of the world. They have played a vital role in the history and development of the United States and Canada, and have physical, chemical, and biological characteristics that make them a unique ecosystem. The Great Lakes themselves—Lakes Superior, Huron, Michigan, Erie and Ontario and their connecting channels—plus all of the streams, rivers, lakes and other bodies of water that are within the drainage basin of the Lakes collectively comprise the Great Lakes System.

The System spans over 750 miles across eight States—New York, Pennsylvania, Ohio, Michigan, Indiana, Illinois, Wisconsin and Minnesota—and the Province of Ontario. The Lakes contain approximately 18 percent of the world's and 95 percent of the United States' fresh surface water supply. The Great Lakes are a source of drinking water and energy, and are used for recreational, transportation, agricultural and industrial purposes by the more than 46 million Americans and Canadians who inhabit the Great Lakes region, including 29 Native American tribes. Over 1,000 industries and millions of jobs are dependent upon water from the Great Lakes. The Great Lakes System also supports hundreds of species of aquatic life, wildlife and plants along more than 4,500 miles of coastline which boast six National Parks and Lakeshores, six National Forests, seven National Wildlife Refuges, and hundreds of State parks, forests and sanctuaries.

Because of their unique features, the Great Lakes are viewed as important to the residents of the region, and to the Nation as a whole. The natural resources of the region have contributed to the development of its economy. The Lakes' natural beauty and aquatic resources form the basis for heavy recreational activity. The Great Lakes Basin Ecosystem—the interacting components of air, land, water and living organisms, including humans, that live within the Great Lakes drainage basin—is a remarkably diverse and unique ecosystem important in the global ecology.

In the past few decades, the presence of environmental contaminants in the Great Lakes has been of significant concern. In spite of the fact that the Great Lakes contain 5,500 cubic miles of water that cover a total surface area of 94,000 square miles, they have proved to be sensitive to the effects of pollutants that accumulate in them. The internal responses and processes that operate in the Great Lakes because of their depth and long hydraulic residence times cause pollutants to recycle between biota, sediments and the water column.

The first major basin-wide environmental problem in the Great Lakes emerged in the late 1960s, when increased nutrients had dramatically stimulated the growth of green plants and algae, reduced dissolved oxygen levels, and accelerated the process of eutrophication. As oxygen levels continued to drop, certain species of insects and fish were displaced from affected areas of the Great Lakes Basin Ecosystem. Environmental managers determined that a lakewide approach was necessary to adequately control accelerated eutrophication. From the late 1960s through the late 1970s, United States and Canadian regulatory agencies agreed on measures to limit the loadings of phosphorus, including effluent limits on all major municipal sewage treatment facilities, limitations on the phosphorus content in household detergents, and reductions in nonpoint source runoff loadings. As a result of all of these efforts, open lake phosphorus concentrations have declined, and phosphorus loadings from municipal sewage treatment facilities have been reduced by an estimated 80 to 90 percent. These reductions have resulted in dramatic improvements in nearshore water quality and measurable improvements in open lake conditions.

More recently, scientists and public leaders have reached a general consensus that the presence of environmentally persistent, bioaccumulative contaminants is a serious environmental threat to the Great Lakes Basin Ecosystem. Beginning in 1963, adverse environmental impacts in the form of poor reproductive success and high levels of the pesticide DDT were observed in herring gulls in Lake Michigan. Through ongoing research, scientists have detected 362 contaminants in the Great Lakes System. Of these, approximately one third have toxicological data showing that they can have acute or chronic toxic effects on aquatic life, wildlife and/or human health. Chemicals that have been found to bioaccumulate at levels of concern in the Great Lakes include, but are not limited to, polychlorinated biphenyls (PCBs), mercury, DDT, dioxin, chlordane, and mirex. The main route of exposure to these chemicals for humans is through the consumption of Great Lakes fish.

Potential adverse human health effects by these pollutants resulting from the consumption of fish include both the increased risk of cancer and the potential for systemic or noncancer risks such as kidney damage. EPA has calculated health risks to populations in the Great Lakes basin from consumption of contaminated fish based on exposure to eight bioaccumulative pollutants: chlordane, DDT, dieldrin, hexachlorobenzene, mercury, PCBs, 2,3,7,8-TCDD, and toxaphene. These chemicals were chosen based on their potential to cause adverse human health effects (i.e., cancer or disease) and the availability of information on fish tissue contaminant concentrations from the Great Lakes.

Based on these data, EPA estimates that the lifetime cancer risks for Native Americans in the Great Lakes System due to ingestion of contaminated fish at current concentrations range from $1.8\ 10^{-3}$ (Lake Superior) (1.8 in one thousand) to $3.7\ 10^{-2}$ (Lake Michigan) (3.7 in 100). Estimated risks to low income minority sport anglers range from $2.5\ 10^{-3}$ (2.5 in one thousand) (Lake Superior) to $1.2\ 10^{-2}$ (1.2 in 100) (Lake Michigan). Estimated risks for other sport anglers range from $9.7\ 10^{-4}$ (9.7 in ten thousand) (Lake Superior) to $4.5\ 10^{-3}$ (4.5 in one thousand) (Lake Michigan). (See section I.B.2.a of the SID.) In comparison, EPA has long maintained that $1\ 10^{-4}$ (one in ten thousand) to $1\ 10^{-6}$ (one in 1 million) is an appropriate range of risk to protect human health.

***15368** EPA also estimates a high potential risk of systemic (noncancer) injury to populations in the Great Lakes basin due to ingestion of fish contaminated with these pollutants at current concentrations. The systemic adverse health effects associated with the assessed contaminants are described in section I.B of the SID.

Although the Great Lakes States and EPA have moved forward to deal with these problems, control of persistent, bioaccumulative pollutants proved to be more complex and difficult than dealing with nutrients. As a result, inconsistencies began to be apparent in the ways various States developed and implemented controls for the pollutants. By the mid-1980s, such inconsistencies became of increasing concern to EPA and State environmental managers.

EPA began the Great Lakes Water Quality Initiative (“Initiative”) in cooperation with the Great Lakes States to establish a consistent level of environmental protection for the Great Lakes ecosystem, particularly in the area of State water quality standards and the National Pollutant Discharge Elimination System (NPDES) programs. In the spring of 1989, the Council of Great Lakes Governors unanimously agreed to participate in the Initiative with EPA, because the Initiative supported the principles and goals of the Great Lakes Toxic Substances Control Agreement (Governors' Agreement). Signed in 1986 by the Governors of all eight Great Lakes States, the Governors' Agreement affirmed the Governors' intention to manage and protect the resources of the Great Lakes basin through the joint pursuit of unified and cooperative principles, policies and programs enacted and adhered to by each Great Lakes State.

The Initiative provided a forum for a regional dialogue to establish minimum requirements that would reduce disparities between State water quality controls in the Great Lakes basin. The scope of the Initiative included development of proposed Great Lakes water quality guidance—Great Lakes-specific water quality criteria and methodologies to protect aquatic life, wildlife and human health, procedures to implement water quality criteria, and an antidegradation policy.

Three committees were formed to oversee the Initiative. A Steering Committee (composed of directors of water programs from the Great Lakes States' environmental agencies and EPA's National and Regional Offices) discussed policy, scientific, and technical issues, directed the work of the Technical Work Group and ratified final proposals. The Technical Work Group (consisting of technical staff from the Great Lakes States' environmental agencies, EPA, the U.S. Fish and Wildlife Service, and the National Park Service) prepared proposals on elements of the Guidance for consideration by the Steering Committee. The Public Participation Group (consisting of representatives from environmental groups, municipalities, industry and academia) observed the deliberations of the other two committees, advised them of the public's concerns, and kept its various constituencies apprised of ongoing activities and issues. These three groups were collectively known as the Initiative Committees. From the start, one goal of the Initiative Committees was to develop the Guidance elements in an open public forum, drawing upon the extensive expertise and interest of individuals and groups within the Great Lakes community.

The Initiative efforts were well underway when Congress amended section 118 of the CWA in 1990 through the CPA. The general purpose of these amendments was to improve the effectiveness of EPA's existing programs in the Great Lakes by identifying key treaty provisions agreed to by the United States and Canada in the Great Lakes Water Quality Agreement (GLWQA), imposing statutory deadlines for the implementation of these key activities, and increasing Federal resources for program operations in the Great Lakes System.

Section 118(c)(2) requires EPA to publish proposed and final water quality guidance for the Great Lakes System. This Guidance must conform with the objectives and provisions of the GLWQA (a binational agreement establishing common water quality objectives for the Great Lakes) and be no less restrictive than provisions of the CWA and National water quality criteria and guidance. The Guidance must specify minimum requirements for the waters in the Great Lakes System in three areas: (1) water quality standards (including numerical limits on pollutants in ambient Great Lakes waters to protect human health, aquatic life and wildlife); (2) antidegradation policies; and (3) implementation procedures.

The Great Lakes States must adopt water quality standards, antidegradation policies and implementation procedures for waters within the Great Lakes System which are consistent with the final Guidance within two years of EPA's publication. In the absence of such action, EPA is required to promulgate any necessary requirements within that two-year period. In addition, when an Indian Tribe is authorized to administer the NPDES or water quality standards program in the Great Lakes basin, it will also need to adopt provisions consistent with the final Guidance into their water programs.

On December 6, 1991, the Initiative Steering Committee unanimously recommended that EPA publish the draft Guidance ratified by that group in the Federal Register for public review and comment. The agreement that the draft Great Lakes Guidance was ready for public notice did not represent an endorsement by every State of all of the specific proposals. Rather, all parties agreed on the importance of proceeding to publish the draft Great Lakes Guidance in order to further solicit public comment. State Steering Committee members indicated their intent to develop and submit specific comments on the proposed Guidance during the public comment period. EPA worked to convert the agreements reached in principle by the Steering Committee into a formal package suitable for publication in the Federal Register as proposed Guidance. EPA generally used the draft proposal ratified by the Steering Committee as the basis for preparing the Federal Register proposal package. Modifications were necessary, however, to reflect statutory and regulatory requirements and EPA policy considerations, to propose procedures for State and Tribal adoption of the final Guidance, to provide suitable discussion of various alternative options, and to accommodate necessary format changes. Where modifications were made, the preamble to the proposal described both the modification and the original Steering Committee-approved guidelines, and invited public comment on both. All elements approved by the Steering Committee were either incorporated in the proposed rule or discussed in the preamble to the proposal.

III. Purpose of the Guidance

The final Guidance represents a milestone in the 30 years of effort described above on the part of the Great Lakes stakeholders to define and apply innovative, comprehensive environmental programs in protecting and restoring the Great Lakes. In particular, this publication of the final Guidance culminates six years of intensive, cooperative effort that included participation by the eight Great Lakes States, the environmental community, academia, industry, municipalities and EPA Regional and National offices.

***15369** The final Guidance will help establish consistent, enforceable, long-term protection with respect to all types of pollutants, but will place short-term emphasis on the types of long-lasting pollutants that accumulate in the food web and pose a threat to the Great Lakes System. The final Guidance will establish goals and minimum requirements that will further the next phase of Great Lakes programs, including the Great Lakes Toxic Reduction Effort's integrated, multi-media ecosystem approach.

EPA and State development of the Guidance—from drafting through proposal and now final publication—was guided by several general principles that are discussed below.

A. Use the Best Available Science to Protect Human Health, Aquatic Life, and Wildlife

EPA and the Initiative Committees have been committed throughout the Initiative to using the best available science to develop programs to protect the Great Lakes System. In the 1986 Governors' Agreement, the Governors of the Great Lakes States recognized that the problem of persistent toxic substances was the foremost environmental issue confronting the Great Lakes. They also recognized that the regulation of toxic contaminants was scientifically complex because the pollutants are numerous, their pathways into the Lakes are varied, and their effects on the environment, aquatic life and human health are not completely understood. Based on the importance of the Great Lakes Basin Ecosystem and the documented adverse effects from toxic contamination, however, the Governors directed their environmental administrators to jointly develop an agreement and procedure for coordinating the control of toxic releases and achieving greater uniformity of regulations governing such releases within the Great Lakes basin.

As discussed further above, the Initiative was subsequently created to begin work on these goals. EPA and the Great Lakes States, with input from interested parties in the basin, began collecting and analyzing data, comparing regulatory requirements and technical guidance in their various jurisdictions, and drafting specific methodologies and procedures to control the discharge of toxic contaminants. The provisions of the final Guidance were based in large part on these prior efforts of the Initiative Committees, and incorporate the best available science to protect human health, wildlife and aquatic life in the Great Lakes System. For example, the final Guidance includes new criteria and a methodology developed by the Initiative Committees to specifically protect wildlife; incorporates recent data on the bioavailability of metals into the aquatic life criteria and methodologies; incorporates Great Lakes-specific data on fish consumption rates and fish lipid contents into the human health criteria; and provides a methodology to determine the bioaccumulation properties of individual pollutants. Additionally, EPA understands that the science of risk assessment is rapidly improving. Therefore, in order to ensure that the scientific basis for the criteria methodologies is always current and peer reviewed, EPA will review the methodologies and revise them as appropriate every three years.

B. Recognize the Unique Nature of the Great Lakes Basin Ecosystem

The final Guidance also reflects the unique nature of the Great Lakes Basin Ecosystem by establishing special provisions for chemicals of concern. EPA and the Great Lakes States believe it is reasonable and appropriate to establish special provisions for the chemicals of most concern because of the physical, chemical and biological characteristics of the Great Lakes System, and the documented environmental harm to the ecosystem from the past and continuing presence of these types of pollutants. The Initiative Committees devoted considerable effort to identifying the chemicals of most concern to the Great Lakes System —persistent, bioaccumulative pollutants termed “bioaccumulative chemicals of concern (BCCs)”—and developing the most appropriate criteria, methodologies, policies, and procedures to address them. The special provisions for BCCs, initially developed by the Initiative Committees and incorporated into the final Guidance, include antidegradation procedures, to ensure that future problems are minimized; general phase-out and elimination of mixing zones for BCCs, except in limited circumstances, to reduce their overall loadings to the Lakes; more extensive data generation requirements to ensure that they are not under-regulated for lack of data; and development of water quality criteria that will protect wildlife that feed on aquatic prey.

The final Guidance is designed not only to begin to address existing problems, but also to prevent emerging and potential problems posed by additional chemicals in the future which may damage the overall health of the Great Lakes. The experience with such pollutants as DDT and PCBs indicates that it takes many decades to overcome the damage to the ecosystem caused by even short-term discharges, and that prevention would have been dramatically less costly than clean-up. Issuance of the final Guidance alone will not solve the existing long-term problems in the Great Lakes System from these contaminants. Full implementation of provisions consistent with the final Guidance will, however, provide a coordinated ecosystem approach for addressing possible pollutant problems before they produce adverse and long-lasting basin-wide impacts, rather than waiting to see what the future impacts of the pollutants might be before acting to control them. The comprehensive approach used in the development of the final Guidance provides regulatory authorities with both remedial and preventive ways of gauging the actions and potential effects of chemical stressors upon the Great Lakes Basin Ecosystem. The methodologies, policies and procedures contained in the final Guidance provide mechanisms for appropriately addressing both pollutants that have been or may in the future be documented as chemicals of concern.

C. Promote Consistency in Standards and Implementation Procedures While Allowing Appropriate Flexibility to States and Tribes

Promoting consistency in standards and implementation procedures while providing for appropriate State flexibility was the third principle in State and EPA development of the final Guidance. The underlying rationale for the Governors' Agreement, the Initiative, and the requirements set forth in the CPA was a recognition of the need to promote consistency through adoption of minimum water quality standards, antidegradation policies, and implementation procedures by Great Lakes States and Tribes to protect human health, aquatic life and wildlife. Although provisions in the CWA provide for the adoption of and periodic revisions to State water quality criteria, such provisions do not necessarily ensure that water quality criteria of adjoining States are consistent within a shared water body. For example, ambient water quality criteria in place in six of the eight Great Lakes States to protect aquatic life from acute effects range from 1.79 MUg/L to 15.0 MUg/L for cadmium, and from 0.21 MUg/L to 1.33 MUg/L for dieldrin. Other examples of variations in acute aquatic life criteria include nickel, which ranges from 290.30 MUg/L to 852.669 MUg/L; lindane, ***15370** with a range of no criteria in place to 1.32 MUg/L; and mercury, ranging from 0.5 MUg/L to 2.4 MUg/L. Similar ranges and disparities exist for chronic aquatic life criteria, and for water quality criteria to protect human health.

Disparities also exist among State procedures to translate water quality criteria into individual discharge permits. Wide variations exist, for example, in procedures for the granting of mixing zones, interpretation of background levels of pollutants, consideration of pollutants present in intake waters, controls for pollutants present in concentrations below the level of detection, and determination of appropriate levels for pollutants discharged in mixtures with other pollutants. Additionally, when addressing the accumulation of chemicals by fish that will be consumed by humans and wildlife, some States consider accumulation through multiple steps in the food chain (bioaccumulation) while others consider only the single step of concentration from the water column (bioconcentration). Further disparities exist in different translator methodologies in deriving numeric values for implementing narrative water quality criteria; different assumptions when calculating total maximum daily loads (TMDLs) and wasteload allocations (WLAs), including different assumptions about background concentrations, mixing zones, receiving water flows, or environmental fate; and different practices in deciding what pollutants need to be regulated in a discharge, what effect detection limits have on compliance determinations, and how to develop whole effluent toxicity limitations.

These inconsistencies in State standards and implementation procedures have resulted in the disparate regulation of point source discharges. In the Governors' Agreement, the Governors recognized that the water resources of the basin transcend political boundaries and committed to taking steps to manage the Great Lakes as an integrated ecosystem. The Great Lakes States, as participants in the Initiative Committees, recommended provisions, based on their extensive experience in administering State water programs and knowledge of the significant differences in these programs within the basin, that were ultimately included in the proposed Guidance. The final Guidance incorporates the work begun by the Initiative Committees to identify these disparities and improve consistency in water quality standards and permit procedures in the Great Lakes System.

Although improved consistency in State water programs is a primary goal of the final Guidance, it is also necessary to provide appropriate flexibility to States and Tribes in the development and implementation of water programs. In overseeing States' implementation of the CWA, EPA has found that reasonable flexibility is not only necessary to accommodate site-specific situations and unforeseen circumstances, but is also appropriate to enable innovation and progress as new approaches and information become available. Many commenters, including the Great Lakes States, urged EPA to evaluate the appropriate level of flexibility provided to States and Tribes in the proposed Guidance provisions. EPA reviewed all sections of the proposed Guidance and all comments received to determine the appropriate level of flexibility needed to address these concerns while still providing a minimum level of consistency between the State and Tribal programs. Based on this review, the final Guidance provides flexibility for State and Tribal adoption and implementation of provisions consistent with the final Guidance in many areas, including the following:

—Antidegradation: Great Lakes States and Tribes may develop their own approaches for implementing the prohibition against deliberate actions of dischargers that increase the mass loading of BCCs without an approved antidegradation demonstration. Furthermore, States and Tribes have flexibility in adopting antidegradation provisions regarding non-BCCs.

—TMDLs: Great Lakes States and Tribes may use assessment and remediation plans for the purposes of appendix F to part 132 if the State or Tribe certifies that the assessment and remediation plan meets certain TMDL-related provisions in the final Guidance and public participation requirements applicable to TMDLs, and if EPA approves such plan. Thus, States have the flexibility in many cases to use LAMPs, RAPs and State Water Quality Management Plans in lieu of TMDLs.

—Intake Credits: Great Lakes States and Tribes may consider the presence of intake water pollutants in establishing water quality-based effluent limits (WQBELs) in accordance with procedure 5 of appendix F.

—Site-Specific Modifications: Great Lakes States and Tribes may adopt either more or less stringent modifications to human health, wildlife, and aquatic life criteria and bioaccumulation factors (BAFs) based on site-specific circumstances specified in procedure 1 of appendix F. All criteria, however, must be sufficient not to cause jeopardy to threatened or endangered species listed or proposed to be listed under the Federal Endangered Species Act.

—Variances: Great Lakes States and Tribes may grant variances from water quality standards based on the factors identified in procedure 2 of appendix F.

—Compliance Schedules: Great Lakes States and Tribes may allow existing Great Lakes dischargers additional time to comply with permit limits in order to collect data to derive new or revised Tier I criteria and Tier II values in accordance with procedure 9 of appendix F.

—Mixing Zones: Great Lakes States and Tribes may authorize mixing zones for existing discharges of BCCs after the 10-year phase-out period in accordance with procedure 3.B of appendix F, if the permitting authority determines, among other things, that the discharger has reduced its discharge of the BCC for which a mixing zone is sought to the maximum extent possible. Water conservation efforts that result in overall reductions of BCCs are also allowed even if they result in higher effluent concentrations.

—Scientific Defensibility Exclusion: Great Lakes States and Tribes may apply alternate procedures consistent with Federal, State, and Tribal requirements upon demonstration that a provision in the final Guidance would not be scientifically defensible if applied to a particular pollutant in one or more sites. This provision is in §132.4(h) of the final Guidance.

—Reduced Detail: In many instances, EPA has revised the proposed Guidance to reduce the amount of detail in the provisions without sacrificing the objectives of the provisions. Examples of such revisions include simplification of procedures for developing TMDLs in procedure 3 of appendix F, and simplification of procedures for determining reasonable potential to exceed water quality standards in procedure 5.B of appendix F.

—Other Provisions: Flexibility is also present in provisions for the exercise of best professional judgment by the Great Lakes States and Tribes when implementing many individual provisions in the final Guidance including: determining the appropriate uncertainty factors in the human health and wildlife criteria methodologies; selection of data sets for establishing water quality criteria; identifying reasonable and prudent ***15371** measures in antidegradation provisions; and specifying appropriate margins of safety when developing TMDLs. In all cases, of course, State and Tribal provisions would need to be scientifically defensible and consistent with all applicable regulatory requirements.

D. Establish Equitable Strategies to Control Pollution Sources

Many commenters argued that the proposed Guidance unfairly focused on point source discharges. They asserted that nonpoint sources or diffuse sources of pollution, such as air emissions, are responsible for most of the loadings of some pollutants of concern in the Great Lakes, that increased regulation of point sources will be inequitable and expensive, and that the final Guidance will not result in any environmental improvement given the large, continuing contribution of toxic pollutants by nonpoint sources.

EPA recognizes that regulation of point source discharges alone cannot address all existing or future environmental problems from toxic pollutants in the Great Lakes. In addition to discharges from point sources, toxic pollutants are also contributed to the Great Lakes from industrial and municipal emissions to the air, resuspension of pollutants from contaminated sediments, urban and agricultural runoff, hazardous waste and Superfund sites, and spills. Restoration and maintenance of a healthy ecosystem will require significant efforts in all of these areas. EPA, Canada and the Great Lakes States and Tribes are currently implementing or developing many voluntary and regulatory programs to address these and other nonpoint sources of environmental contaminants in the Great Lakes.

Additionally, EPA intends to use the scientific data developed in the final Guidance and new or revised water quality criteria subsequently adopted by Great Lakes States and Tribes in evaluating and determining appropriate levels of control in other environmental programs. For example, EPA's future biennial reports under section 112(m) of the Clean Air Act will consider the extent to which air discharges cause or contribute to exceedances of water quality criteria in assessing whether additional air emission standards or control measures are necessary to prevent serious adverse effects. Similarly, once provisions consistent with the final Guidance are adopted by the Great Lakes States or Tribes, they will serve as applicable or relevant and appropriate requirements (ARARs) for on-site responses under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA). EPA will also consider the data and criteria developed for the final Guidance, including the information on BCCs, in developing or evaluating LaMPs and RAPs under section 118 of the CWA and Article VI, Annex 2 of the GLWQA; determination of corrective action requirements under sections 3004(u), 3008(h), or 7003 of the Solid Waste Disposal Act; new or existing chemical reviews under the Toxic Substances Control Act (TSCA); pesticide reviews under the Federal Insecticide, Fungicide and Rodenticide Act (FIFRA); and reporting requirements for toxic releases under the Emergency Planning and Community Right-to-Know Act (EPCRA).

The final Guidance also includes provisions to address the contribution of pollutants by nonpoint sources. First, the water quality criteria to protect human health, wildlife and aquatic life, and the antidegradation provisions apply to the waters in the Great Lakes System regardless of whether discharges to the water are from point or nonpoint sources. Accordingly, any regulatory programs for nonpoint sources that require compliance with water quality standards would also be subject to the criteria and antidegradation provisions of the final Guidance once they are adopted into State or Tribal standards.

Second, several elements of the final Guidance would, after State, Tribal or Federal promulgation, require or allow permitting authorities to consider the presence of pollutants in ambient waters—including pollutants from nonpoint source dischargers—in establishing WQBELs for point sources. For example, permit authorities may consider the presence of other point or nonpoint source discharges when evaluating whether to grant a variance from water quality criteria. Additionally, the provisions for TMDLs address nonpoint sources by specifying that the loading capacity of a receiving water that does not meet water quality standards for a particular pollutant be allocated, where appropriate, among nonpoint as well as point sources of the pollutant, including, at a minimum, a margin of safety to account for technical uncertainties in establishing the TMDL.

The development of TMDLs is the preferred mechanism for addressing equitable division of the loading capacities of these nonattained waters. Because TMDLs have not been completed for most nonattained waters, however, the final Guidance promotes the development of TMDLs through a phased approach, where appropriate, and provides for short-term regulatory relief to point source dischargers in the absence of TMDLs through intake credits, variances, and other water quality permitting procedures.

EPA received numerous comments on the problem posed in controlling mercury in particular. Many commenters stated that since the primary source of mercury is now atmospheric deposition, point sources contribute only a minor portion of the total loading of mercury to the Great Lakes System and further restriction of point source discharges would have no apparent effect in improving water quality. Although EPA believes that there is sufficient flexibility in the Guidance to handle the unique problems posed by mercury (e.g., water quality variances, phased TMDLs, intake credits), EPA is committed to developing a mercury permitting strategy to provide a holistic, comprehensive approach for dealing with this pollutant. EPA will publish this strategy no later than two years following publication of this Guidance.

There are also many ongoing voluntary and regulatory activities that address nonpoint sources of toxic pollutants to the Great Lakes System, including activities taken under the Clean Air Act Amendments of 1990 (CAAA), the CWA, and State regulatory and voluntary programs. Some of these activities are summarized in the preamble to the proposed Guidance (58 FR 20826-32) and section I.D of the SID.

In addition to the many ongoing activities, EPA and the Great Lakes States, Tribes, and other federal agencies are pursuing a multi-media program to prevent and to further reduce toxic loadings from all sources of pollution to the Great Lakes System, with an emphasis on nonpoint sources. This second phase of the Great Lakes Water Quality Initiative, called the Great Lakes Toxic Reduction Effort (GLTRE), will build on the open, participative public dialogue established during the development of the final Guidance. Through the GLTRE, the Federal, State, and Tribal agencies intend to coordinate and enhance the effectiveness of ongoing actions and existing tools to prevent and reduce nonpoint source and wet-weather point source contributions of toxic pollutants in the Great Lakes System. A special emphasis will be placed on BCCs identified in the final Guidance.

A partial list of ongoing actions that are being or could be focused on BCCs includes: implementation of the CAAA to reduce atmospheric deposition of toxics; Resource Conservation and Recovery Act and CERCLA remedial actions to reduce loadings of toxics from ***15372** hazardous waste sites; increased focus (through the GLTRE) on toxic pollutants emanating from combined sewer overflows and stormwater outfalls; application in the Great Lakes basin of the National Contaminated Sediment Management Strategy; implementation of spill prevention planning practices to minimize this potential source of loadings to the Great Lakes; improved reporting of toxic pollutants under the Toxic Release Inventory; public education on the dangers of mercury and other BCCs; pesticide registration and re-registration processes; development of a "mass balance" model for fate and transport of pollutants in the Great Lakes; and, development of a "virtual elimination strategy." These programs will prevent and further reduce mass loadings of pollutants and facilitate equitable division of the costs of any necessary control measures between point and nonpoint sources.

In addition to the GLTRE, which is basin-wide in scope, a primary vehicle for coordinating Federal and State programs at the local level for meeting water quality standards and restoring beneficial uses for the open waters of the Great Lakes are LaMPS. LaMPs will define media specific program actions to further reduce loadings of toxic substances, assess whether these programs will ensure restoration and attainment of water quality standards and designated beneficial uses, and recommend any media-specific program enhancements as necessary. Additionally, LaMPs will be periodically updated and revised to assess progress in implementing media-specific programs, assess the reductions in toxic loadings to the Great Lakes System through these programs, incorporate advances in the understanding of the System based on new data and information, and recommend specific adjustments to media programs as appropriate.

E. Promote Pollution Prevention Practices

The final Guidance also promotes pollution prevention practices consistent with EPA's National Pollution Prevention Strategy and the Pollution Prevention Action Plan for the Great Lakes. The Pollution Prevention Act of 1990 declares as National policy that reducing the sources of pollution is the preferred approach to environmental protection. When source reductions are not possible, however, recycling, treating and properly disposing of pollutants in an environmentally safe manner complete the hierarchy of management options designed to prevent pollution from entering the environment.

Consistent with the goals of the Pollution Prevention Act, EPA developed the Great Lakes Pollution Prevention Action Plan (April, 1991). The Great Lakes Pollution Prevention Action Plan highlights how EPA, in partnership with the States, will incorporate pollution prevention into actions designed to reduce the use and release of toxic substances in the Great Lakes basin.

The final Guidance builds upon these two components of the Great Lakes program by promoting the development of pollution prevention analysis and activities in the level of detection, mixing zone, and antidegradation sections of the final Guidance. Also, the decision to provide special provisions for BCCs implements EPA's commitment to pollution prevention by reducing the discharge of these pollutants in the future. This preventive step not only makes good environmental management sense, but is appropriate based on the documented adverse effects that the past and present discharge of these pollutants has produced in the Great Lakes basin.

F. Provide Accurate Assessment of Costs and Benefits

In developing the final Guidance, EPA identified and carefully evaluated the anticipated costs and benefits from implementation of the major provisions. EPA received many comments on the draft cost and benefit studies conducted as part of the proposed Regulatory Impact Analysis (RIA) required by Executive Order 12291, and its successor, Executive Order 12866. Based upon consideration of those comments and further analysis, EPA has revised the RIA. The results of this analysis are summarized in section V of this preamble.

IV. Summary of the Final Guidance

The final Guidance will establish minimum water quality standards, antidegradation policies, and implementation procedures for the waters of the Great Lakes System in the States of Illinois, Indiana, Michigan, Minnesota, New York, Pennsylvania, Ohio and Wisconsin, including waters within the jurisdiction of Indian Tribes. Specifically, the final Guidance specifies numeric criteria for selected pollutants to protect aquatic life, wildlife and human health within the Great Lakes System and provides methodologies to derive numeric criteria for additional pollutants discharged to these waters. The final Guidance also contains minimum procedures to translate the proposed ambient water quality criteria into enforceable controls on discharges of pollutants, and a final antidegradation policy.

The provisions of the final Guidance are not enforceable requirements until adopted by States or Tribes, or promulgated by EPA for a particular State or Tribe. The Great Lakes States and Tribes must adopt water quality standards, antidegradation policies, and implementation procedures for waters within the Great Lakes System consistent with the (as protective as) final Guidance or be subject to EPA promulgation. Great Lakes Tribes include any Tribe within the Great Lakes basin for which EPA has approved water quality standards under section 303 or has authorized to administer a NPDES program under section 402 of the CWA. No Indian Tribe has been authorized to administer these water programs in the Great Lakes basin as of this time. If a Great Lakes State fails to adopt provisions consistent with the final Guidance within two years of this publication in the Federal Register (that is, by March 23, 1997), EPA will publish a final rule at the end of that time period identifying the provisions of the final Guidance that will apply to waters and discharges within that jurisdiction. Additionally, when an Indian Tribe is authorized to administer the NPDES or water quality standards program in the Great Lakes basin, it will also need to adopt provisions consistent with the final Guidance into their water programs.

The following sections provide a brief summary of the provisions of the final Guidance. A more complete discussion of the final Guidance, including EPA's analysis of major comments, issues, and a description of specific changes made to the proposed Guidance, are contained in the SID.

The parenthetical note at the beginning of each section provides references to the primary provisions in the final Guidance being discussed in the section, and to discussions in the SID. The final Guidance is codified as 40 CFR 132, including appendixes A through F. Note that appendix F consists of procedures 1 through 9. For ease of reference, sections in appendix F may be referred to by appending the section designation to the procedure number. For example, section A.1 of procedure 1 may be referred to as procedure 1.A.1 of appendix F.

15373** ***A. Water Quality Criteria and Methodologies

1. Protection of Aquatic Life
(§§132.3(a), 132.3(b), 132.4(a)(2); Tables 1 and 2 to part 132; appendix A to part 132; section III, SID)

The final Guidance contains numeric criteria to protect aquatic life for 15 pollutants, and a two-tiered methodology to derive criteria (Tier I) or values (Tier II) for additional pollutants discharged to the Great Lakes System. Aquatic life criteria are derived to establish ambient concentrations for pollutants, which, if not exceeded in the Great Lakes System, will protect fish, invertebrates, and other aquatic life from adverse effects due to that pollutant. The final Guidance includes both acute and chronic criteria to protect aquatic life from acute and chronic exposures to pollutants.

Tier I aquatic life criteria for each chemical are based on laboratory toxicity data for a variety of aquatic species (e.g., fish and invertebrates) which are representative of species in the freshwater aquatic environment as a whole. The Guidance also includes a Tier II methodology to be used in the absence of the full set of data needed to meet Tier I data requirements. For pollutants for which Tier I criteria have not been adopted into State or Tribal water quality standards, States must use methodologies consistent with either the Tier I or Tier II methodologies, depending on the data available, in conjunction with whole effluent toxicity requirements in the final Guidance (see section IV.B.5 of this preamble), to implement their existing narrative water quality criteria that prohibit toxic pollutants in toxic amounts in all waters. The Great Lakes States and Tribes are not required to use the Tier II methodology to adopt numeric criteria into their water quality standards.

Use of the two-tiered final Guidance methodologies in these situations will enable regulatory authorities to translate narrative criteria to derive TMDLs and individual NPDES permit limits on a more uniform basis. EPA and the States determined that there is a need to regulate pollutants more consistently in the Great Lakes System when faced with limited numbers of criteria. Many of the Great Lakes States are already employing procedures similar to the approach in the final Guidance to implement narrative criteria. EPA determined the Tier II approach improves upon existing mechanisms by utilizing all available data.

The two-tiered methodology allows the application of the final Guidance to all pollutants, except those listed in Table 5 of part 132 (see section IV.E of this preamble). The Tier I aquatic life methodology includes data requirements very similar to those used in current guidelines for developing National water quality criteria guidance under section 304(a) of the CWA. For example, both require that acceptable toxicity data for aquatic species in at least eight different families representing differing habitats and taxonomic groups must exist before a Tier I numeric criterion can be derived. The Tier II aquatic life methodology is used to derive Tier II values which can be calculated with fewer toxicity data than Tier I. Tier II values can, in certain instances, be based on toxicity data from a single taxonomic family, provided the data are acceptable. The Tier II methodology generally produces more stringent values than the Tier I methodology, to reflect greater uncertainty in the absence of additional toxicity data. As more data become available, the derived Tier II values tend to become less conservative. That is, they more closely approximate Tier I numeric criteria. EPA and the States believe it is desirable to continue to supplement toxicity data to ultimately derive Tier I numeric criteria.

One difference from the existing National water quality criteria guidelines is that the final Guidance methodology for aquatic life deletes the provision in the National guidelines to use a Final Residue Value (FRV) in deriving a criterion. The FRV is intended to prevent concentrations of pollutants in commercially or recreationally important aquatic species from affecting the marketability of those species or affecting wildlife that consume them by preventing the exceedance of applicable Food

and Drug Administration action levels and concentrations that affect wildlife. The final Guidance provides specific, separate methodologies to protect wildlife and human health (discussed below) which EPA believes will provide more accurate and appropriate levels of protection than the FRVs.

For pollutants without Tier I criteria but with enough data to derive Tier II values for aquatic life, the proposal would have required permittees to meet permit limits based on both Tier II values and whole effluent toxicity (WET) testing. In response to comments, the final Guidance clarifies that States and Tribes may adopt provisions allowing use of indicator parameter limits consistent with 40 CFR 122.44(d)(1)(vi)(C). When deriving limits to meet narrative criteria, States and Tribes have the option of using an indicator parameter limit, including use of a WET limit under appropriate conditions, in lieu of a Tier II-based limit. If use of an indicator parameter is allowed, the State or Tribe must ensure that the indicator parameter will attain the "applicable water quality standard" (as described in 40 CFR 122.44(d)(1)(vi)(C). The "applicable water quality standard" in this instance would be the State's or Tribe's narrative water quality standard that protects aquatic life.

Finally, the aquatic criteria for metals in the proposed Guidance were expressed as total recoverable concentrations. The final Guidance expresses the criteria for metals in dissolved form because the dissolved metal more closely approximates the bioavailable fraction of metal in the water column than does the total recoverable metal. The dissolved criteria are obtained by multiplying the chronic and/or acute criterion by appropriate conversion factors in Table 1 or 2. This is consistent with many comments on the issue and with the policy on metals detailed in "Office of Water Policy and Technical Guidance on Interpretation and Implementation of Aquatic Life Metals Criteria" (October 1, 1993). A document describing the methodology to convert total recoverable metals criteria to dissolved metals criteria was published in the Federal Register on August 30, 1994 (59 FR 44678). If a State or Tribe fails to adopt approvable aquatic life criteria for metals, EPA will promulgate criteria expressed as dissolved concentrations.

EPA Region 5, in cooperation with EPA Regions 2 and 3 and Headquarters offices, and the Great Lakes States and Tribes, will establish a Great Lakes Initiative (GLI) Clearinghouse to assist States and Tribes in developing numeric Tier I water quality criteria for aquatic life, human health and wildlife and Tier II water quality values for aquatic life and human health. As additional toxicological data and exposure data become available or additional Tier I numeric criteria and Tier II values are calculated by EPA, States, or Tribes, Region 5 will ensure that this information is disseminated to the Great Lakes States and Tribes. EPA believes operation of the GLI Clearinghouse will help ensure consistency during implementation of the final Guidance.

2. Protection of Human Health
(§§132.3(c), 132.4(a)(4); Table 3 to part 132; appendix C to part 132; section V of the SID)

The final Guidance contains numeric human health criteria for 18 pollutants, and includes Tier I and Tier II methodologies to derive cancer and ***15374** non-cancer human health criteria for additional pollutants. The proposed Guidance contained numeric criteria for 20 pollutants, but two pollutants were deleted because they do not meet the more restrictive minimum data requirements for BAFs used in the final Guidance.

Tier I human health criteria are derived to establish ambient concentrations of chemicals which, if not exceeded in the Great Lakes System, will protect individuals from adverse health impacts from that chemical due to consumption of aquatic organisms and water, including incidental water consumption related to recreational activities in the Great Lakes System. For each chemical, chronic criteria are derived to reflect long-term consumption of food and water from the Great Lakes System. Tier II values are intended to provide a conservative, interim level of protection in the establishment of a permit limit, and are distinguished from the Tier I approach by the amount and quality of data used for derivation.

The final Guidance differs from current National water quality criteria guidelines when calculating the assumed human exposure through consumption of aquatic organisms. The final Guidance uses BAFs predicted from biota-sediment accumulation factors (BSAFs) in addition to field-measured BAFs, and uses a food chain multiplier (FCM) to account for biomagnification when using measured or predicted bioconcentration factors (BCFs). BAFs are discussed further in section IV.A.4. of this preamble.

Human health water quality criteria for carcinogens are typically expressed in concentrations associated with a plausible upper bound of increased risk of developing cancer. In practice, the level of cancer risk generally accepted by EPA and the States typically ranges between 10^{4} (one in one thousand) and 10^{6} (one in one million). In contrast, as discussed in section II above, the cancer risk from ingestion of contaminated fish at current concentrations in the Great Lakes System are as high as 1.2 10^{2} (1.2 in 100). The proposed and final Guidance establishes 10^{5} (one in one hundred thousand) as the risk level used for deriving criteria and values for individual carcinogens. This is within the range historically used in EPA actions, and approved for State actions, designed to protect human health. The majority of the Great Lakes States use 10^{5} as a baseline risk level in establishing their water quality standards.

The methodology is designed to protect humans who drink water or consume fish from the Great Lakes System. The portion of the methodology addressing fish consumption includes a factor describing how much fish humans consume per day. The final Guidance includes a Great Lakes-specific fish consumption rate of 15 grams per day, based upon several fish consumption surveys from the Great Lakes, including a recent study by West et al. that was discussed in a Federal Register document on August 30, 1994 (59 FR 44678). This rate differs from the 6.5 grams per day rate which is used in the National water quality criteria guidelines as a National average consumption value. The 15 grams per day represents the mean consumption rate of regional fish caught and consumed by the Great Lakes sport fishing population.

Commenters argued that a 15 gram per day assumption in the methodology would not adequately protect populations that consume greater than this amount (e.g., low-income minority anglers and Native Americans), and that such an approach therefore would be inconsistent with Executive Order 12898 regarding environmental justice (February 16, 1994, 59 FR 7629). EPA believes that the human health criteria methodology, including the fish consumption rate, will provide adequate health protection for the public, including more highly exposed sub-populations. In carrying out regulatory actions under a variety of statutory authorities, including the CWA, EPA has generally viewed an upper bound incremental cancer risk in the range of 10^{4} to 10^{6} as adequately protective of public health. As discussed above, the human health criteria methodology is based on a risk level of 10^{5}. Therefore, if fish are contaminated at the level permitted by criteria derived under the final Guidance, individuals eating up to 10 times (i.e., 150 grams per day) the assumed fish consumption rate would still be protected at the 10^{4} risk level. Available data indicate that, even among low-income minorities who as a group consume more fish than the population on average, the overwhelming majority (approximately 95 percent) consume less than 150 grams per day. The final Guidance requires, moreover, that States and Tribes modify the human health criteria on a site-specific basis to provide additional protection appropriate for highly exposed sub-populations. Thus, where a State or Tribe finds that a population of high-end consumers would not be adequately protected by criteria derived using the 15 gram per day assumption (e.g., where the risk was greater than 10^{4}), the State or Tribe would be required to modify the criteria to provide appropriate additional protection. The final Guidance also requires States and Tribes to adopt provisions to protect human health from the potential adverse effects of mixtures of pollutants in effluents, specifically including mixtures of carcinogens. Understood in the larger context of the human health methodology and the final Guidance as a whole, therefore, EPA believes that the 15 gram per day fish consumption rate provides adequate health protection for the public, including highly exposed populations, and that the final Guidance is therefore consistent with Executive Order 12898.

In developing bioaccumulation factors, the proposed Guidance used a 5.0 percent lipid value for fish consumed by humans, based on Great Lakes-specific data. The current National methodology uses a 3.0 percent lipid value. The final Guidance uses a 3.10 percent lipid value for trophic level 4 fish and 1.82 for trophic level 3 fish. These percent lipid values are based on an analysis of the West et al. study cited above and data from State fish contaminant monitoring programs.

The final Guidance contains specific technical guidelines concerning the range of uncertainty factors that may be applied by the State and Tribal agencies on the basis of their best professional judgment. The final Guidance places a cap of 30,000 on the combined product of uncertainty factors that may be applied in the derivation of non-cancer Tier II values and a combined

uncertainty factor of 10,000 for Tier I criteria. The likely maximum combined uncertainty factor for Tier I criteria in most cases is 3,000. The SID discusses further the use of the uncertainty factors in the derivation of human health criteria and values.

The proposed Guidance used an 80 percent relative source contribution (RSC) from surface water pathways for BCCs, and a 100 percent RSC for all other pollutants, in deriving noncancer criteria. The RSC concept is applied in the National drinking water regulations and is intended to account, at least in part, for exposures from other sources for those bioaccumulative pollutants for which surface water pathways are likely to be major contributors to human exposure. The final Guidance uses the more protective 80 percent RSC for all pollutants in deriving noncancer criteria. This change was made because of concern that for non-BCCs as well as ***15375** BCCs, there may be other sources of exposures for noncarcinogens.

3. Protection of Wildlife

(§§132.3(d), 132.4(a)(5); Table 4 to part 132; appendix D to part 132; section VI of the SID)

The final Guidance contains numeric criteria to protect wildlife for four pollutants and a methodology to derive Tier I criteria for additional BCCs. Wildlife criteria are derived to establish ambient concentrations of chemicals which, if not exceeded, will protect mammals and birds from adverse impacts from that chemical due to consumption of food and/or water from the Great Lakes System.

These are EPA's first water quality criteria specifically for the protection of wildlife. The methodology is based largely on the noncancer human health paradigm. It focuses, however, on endpoints related to reproduction and population survival rather than the survival of individual members of a species. The methodology incorporates pollutant-specific effect data for a variety of mammals and birds and species-specific exposure parameters for two mammals and three birds representative of mammals and birds resident in the Great Lakes basin which are likely to experience significant exposure to bioaccumulative contaminants through the aquatic food web.

In the proposal, EPA included a two-tiered approach similar to that for aquatic life and human health. In response to comments, the final Guidance requires States and Tribes to adopt provisions consistent with only the Tier I wildlife methodology, and only to apply this methodology for BCCs (see section IV.A.4 below). The TSD provides discretionary guidelines for the use of Tier I and Tier II methodologies for other pollutants. The wildlife methodology was limited to the BCCs because these are the chemicals of greatest concern to the higher trophic level wildlife species feeding from the aquatic food web in the Great Lakes basin. This decision is consistent with comments made by the EPA Science Advisory Board (SAB) who agreed that the initial focus for wildlife criteria development should be on persistent, bioaccumulative organic contaminants (USEPA, 1994, EPA-SAB-EPEC-ADV-94-001).

Numerous commenters were concerned that the mercury criterion for wildlife was not scientifically appropriate. After review of all comments and a reevaluation of all the data, the mercury criterion for wildlife has been increased from 180 pg/L to 1300 pg/L. EPA believes the 1300 pg/L is protective of wildlife in the Great Lakes System.

In developing bioaccumulation factors, the proposed Guidance used a 7.9 percent lipid value for fish consumed by wildlife. The final Guidance uses a 10.31 percent lipid value for trophic level 4 fish and 6.46 for trophic level 3 fish. These percent lipid values are based on the actual prey species consumed by the representative wildlife species specified in the methodology, and are used to estimate the BAFs for the trophic levels which those species consume. The percent lipid is based on the preferential consumption patterns of wildlife and cross-referenced with fish weight and size and appropriate percent lipid. This approach is a more accurate reflection of the lipid content of the fish consumed by wildlife species than the approach used in the proposal.

4. Bioaccumulation Methodology

(§132.4(a)(3); appendix B to part 132; section IV of the SID)

The proposed Guidance incorporated BAFs in the derivation of criteria and values to protect human health and wildlife. Bioaccumulation refers to the uptake and retention of a substance by an aquatic organism from its surrounding medium and from food. For certain chemicals, uptake through the aquatic food chain is the most important route of exposure for wildlife and humans. The wildlife criteria and the human health criteria and values incorporate appropriate BAFs in order to more accurately account for the total exposure to a chemical. Current EPA guidelines for the derivation of human health water quality criteria use BCFs, which measure only uptake from water, when field-measured BAFs are not available. EPA believes, however, that the BAF is a better predictor of the concentration of a chemical within fish tissues in the Great Lakes System because it includes consideration of the uptake of contaminants from all routes of exposure.

The proposed Guidance included a hierarchy of three methods for deriving BAFs for non-polar organic chemicals: field-measured BAFs; predicted BAFs derived by multiplying a laboratory-measured BCF by a food-chain multiplier; and BAFs predicted by multiplying a BCF calculated from the log K_{ow} by a food-chain multiplier. For inorganic chemicals, the proposal would have required either a field-measured BAF or laboratory-measured BCF. On August 30, 1994, EPA published a document in the Federal Register (59 FR 44678) requesting comments on revising the hierarchy of methods for deriving BAFs for organic chemicals, and issues pertaining to the model used to assist in predicting BAFs when a field-measured BAF is not available. Based on the comments received, the final Guidance modifies the proposed hierarchy by adding a predicted BAF based on a BSAF as the second method in the hierarchy. BSAFs may be used for predicting BAFs from concentrations of chemicals in surface sediments. In addition, the final Guidance uses a model to assist in predicting BAFs that includes both benthic and pelagic food chains thereby incorporating exposures of organisms to chemicals from both the sediment and the water column. The model used in the proposal only included the pelagic food chain, and therefore, did not account for exposure to aquatic organisms from sediment.

The proposed Guidance used the total concentration of a chemical in the ambient water when deriving BAFs for organic chemicals. In the preamble to the proposed Guidance and in the Federal Register document cited above, EPA requested comments on deriving BAFs in terms of the freely dissolved concentration of the chemical in the ambient water. Based on comments received from the proposal and the document, the final Guidance uses the freely dissolved concentration of a chemical instead of the total concentration in the derivation of BAFs for organic chemicals. Use of the freely dissolved concentration will improve the accuracy of extrapolations between water bodies.

Finally, as discussed in section II of this preamble, bioaccumulation of persistent pollutants is a serious environmental threat to the Great Lakes Basin Ecosystem. Because of these concerns, the proposed Guidance would have required that pollutants with human health BAFs greater than 1000 receive increased attention and more stringent controls within the Great Lakes System. These pollutants are termed BCCs. EPA identified 28 BCCs in the proposed Guidance. The additional controls for BCCs are specified in certain of the implementation procedures and the antidegradation procedures, and are discussed further in the SID. The final Guidance continues to include increased attention on and more stringent controls for BCCs within the Great Lakes System. The final Guidance identifies 22 BCCs that are targeted for special controls instead of the 28 in the proposed Guidance. Six BCCs were deleted from the proposed list because of concern that the methods used to estimate the BAFs may not ***15376** account for the metabolism or degradation of the pollutants in the environment. States and Tribes may identify more BCCs as additional BAF data become available. The final Guidance designates as BCCs only those chemicals with human health BAFs greater than 1000 that were derived from either a field-measured BAF or a predicted BAF based on a field-measured BSAF (for non-metals) or from a field-measured BAF or a laboratory-measured BCF (for metals). Field-measured BAFs and BSAFs, unlike BAFs based only on laboratory analyses or calculations, account for the effects of metabolism.

B. Implementation Procedures

(§§132.4(a)(7), 132.4(e); appendix F to part 132; section VIII of the SID)
This section of the preamble discusses nine specific procedures contained in the final Guidance for implementing water quality standards and developing NPDES permits to attain the standards.

1. Site-Specific Modifications

(Procedure 1 of appendix F to part 132; section VIII.A of the SID)
The proposed Guidance would have allowed States and Tribes to adopt site-specific modifications to water quality criteria and values under certain circumstances. States and Tribes could modify aquatic life criteria to be either more stringent or less stringent when local water quality characteristics altered the biological availability or toxicity of a pollutant, or where local species' sensitivities differed from tested species. Less stringent modifications to chronic aquatic life criteria could also be made to reflect local physical and hydrological conditions. States and Tribes could also modify BAFs and human health and wildlife criteria to be more stringent, but not less stringent than the final Guidance.

The final Guidance retains most of the above provisions, but in addition allows less stringent modifications to acute aquatic life criteria and values to reflect local physical and hydrological conditions, less stringent modifications to BAFs in developing human health and wildlife criteria, and the use of fish consumption rates lower than 15 grams per day if justified. The final Guidance also specifies that site-specific modifications must be made to prevent water quality that would cause jeopardy to endangered or threatened species that are listed or proposed under the ESA, and prohibits any less-stringent site-specific modifications that would cause such jeopardy. Other issues related to the ESA are discussed in section IX of this preamble.

2. Variances from Water Quality Standards for Point Sources

(Procedure 2 of appendix F to part 132; section VIII.B of the SID)
The final Guidance allows Great Lakes States and Tribes to adopt variances from water quality standards, applicable to individual existing Great Lakes dischargers for up to five years, where specified conditions exist. For example, a variance may be granted when compliance with a criterion would result in substantial and widespread social and economic impacts or where certain stream conditions prevent the attainment of the criterion. No significant changes were made in this section from the proposed Guidance.

3. TMDLs and Mixing Zones

(Procedure 3 of appendix F to part 132; section VIII.C of the SID)
Section 303(d) of the CWA and implementing regulations at 40 CFR 130.7 require the establishment of TMDLs for waters not attaining water quality standards after implementation of existing or planned pollution controls. The TMDL quantifies the maximum allowable loading of a pollutant to a water body and allocates the loading capacity to contributing point and nonpoint sources (including natural background) such that water quality standards for that pollutant will be attained. A TMDL must incorporate a margin of safety (MOS) that accounts for uncertainty about the relationship between pollutant loads and water quality. TMDLs may involve single point sources or multiple sources (e.g., point sources and nonpoint sources) and may be established for geographic areas that range in size from large watersheds to relatively small water body segments.

The proposal attempted to develop a single, consistent approach for developing TMDLs to be used by all States and Tribes in the Great Lakes System. Current practice in the eight Great Lakes States includes distinct technical procedures and program approaches that differ in scale, emphasis, scope and level of detail. Two options for TMDL development were proposed. One, Option A, focused on first evaluating the basin as a whole and then conducting individual site-by-site adjustments as necessary to ensure attainment of water quality standards at each location in the basin. The other, Option B, focused on evaluating limits needed for individual point sources with supplemental emphasis on basin-wide considerations as necessary. Both approaches are consistent with the CWA, but result in different methodologies for TMDL development.

Both options proposed that within 10 years of the effective date of the final Guidance (i.e., two five-year NPDES permit terms), mixing zones would be prohibited for BCCs for existing point source discharges to the Great Lakes System. Further, both proposed that mixing zones be denied for new point source discharges of BCCs as of the effective date of the final Guidance.

Both options also specified procedures for determining background levels of pollutants present in ambient waters. In addition, the proposal would have tightened the relationship between TMDL development and NPDES permit issuance by providing that TMDLs be established for each pollutant causing an impairment in a water body prior to the issuance or reissuance of any NPDES permits for that pollutant.

The final Guidance merges both Options A and B into one single set of minimum regulatory requirements for TMDL development. In general, the final TMDL procedures are less detailed than the proposal, and offer more flexibility for States and Tribes in establishing TMDLs. The final TMDL procedures contain elements from both Options A and B that were deemed critical for a minimum level of consistency among the Great Lakes States and Tribes. These critical elements include: mixing zone specifications, design flows, and procedures for determining background concentrations.

The final Guidance also includes a prohibition on mixing zones for BCCs after 12 years in most circumstances. Maintaining these restrictions on the availability of mixing zones is consistent with both the Steering Committee's policy views and the bi-national GLWQA goal of virtual elimination of persistent, bioaccumulative toxics. Because of the unique nature of the Great Lakes ecosystem, documented ecological impacts, and the need for consistency, EPA believes that the general prohibition on mixing zones for BCCs is reasonable and appropriate. However, a new exception is allowed if a facility with an existing BCC discharge can demonstrate that it is reducing that discharge to the maximum extent feasible (considering technical and economic factors) but cannot meet WQBELs for that discharge without a mixing zone. EPA, in conjunction with stakeholders within the Great Lakes Basin, will develop guidance for use by ***15377** States and Tribes in exercising the exception provision with special focus on the technical and economic feasibility criteria. This guidance will also consider the notice, public hearing, monitoring and pollution prevention demonstration elements of the exception criteria.

The final Guidance also retains many of the proposed provisions for calculating background concentrations used in TMDLs and WLAs established in the absence of TMDLs. The procedure addressing data points below the level of detection, however, has been modified so that it no longer specifies the use of default values (i.e., half of the level of detection).

The final TMDL procedures do not require that TMDLs be established for point sources prior to the issuance/reissuance of NPDES permits. The final Guidance defers to the existing National program for determining when a TMDL is required. Lastly, the final Guidance allows assessment and remediation plans that are approved by EPA under 40 CFR 130.6 to be used in lieu of a TMDL for purposes of appendix F as long as they meet the general conditions of a TMDL as outlined by procedure 3 of appendix F, and the public participation requirements applicable to TMDLs.

4. Additivity

(Procedure 4 of appendix F to part 132; section VIII.D of the SID)
EPA has traditionally developed numeric water quality criteria on a single pollutant basis. While some potential environmental hazards involve significant exposure to only a single compound, most instances of contamination in surface waters involve mixtures of two or more pollutants. The individual pollutants in such mixtures can act or interact in various ways which may affect the magnitude and nature of risks or effects on human health, aquatic life and wildlife. WET tests are available to generally address interactive effects of mixtures on aquatic organisms. EPA's 1986 “Guidelines for the Health Risk Assessment of Chemical Mixtures” set forth principles and procedures for human health risk assessment of chemical mixtures. There are currently no technical guidelines on how to assess effects on wildlife from chemical mixtures.

The preamble for the proposed Guidance discussed several possible approaches to address additive effects from multiple pollutants. Proposed regulatory language was provided for two specific options, each with separate provisions related to aquatic life, wildlife and human health. One approach was developed by the Initiative Committees, modified to delete the application of toxicity equivalency factors (TEFs) for PCBs to wildlife. The other approach was developed by EPA. Neither approach addressed the possible toxicologic interactions between pollutants in a mixture (e.g., synergism or antagonism) because of the limited data available on these interactive effects. In the absence of contrary data, both approaches recommended that the risk

to human health from individual carcinogens in a mixture be considered additive, and that a 10^{-5} risk level be adopted as a cap for the cancer risk associated with mixtures. Both approaches also proposed using TEFs to assess the risk to humans and wildlife from certain chemical classes. The TEF approach converts the concentration of individual components in a mixture of chemicals to an "equivalent" concentration expressed in terms of a reference chemical. Both approaches used the 17 TEFs for dioxins and furans identified in the 1989 EPA document, "Estimating Risks Associated with Exposures to Mixtures of Chlorinated Dibenzo-p-Dioxins and -Dibenzofurans," and the 1989 update.

The final Guidance includes a general requirement for States and Tribes to adopt an additivity provision consistent with procedure 4 of appendix F to protect human health from the potential additive adverse effects from both the noncarcinogenic and carcinogenic components of chemical mixtures in effluents. The final Guidance also requires the use of the 17 TEFs included in the proposed Guidance to protect human health from the potential additive adverse effects in effluents.

5. Determining the Need for WQBELs (Reasonable Potential)

(Procedure 5 of appendix F to part 132; section VIII.E of the SID)
EPA's existing regulations require NPDES permits to include WQBELs to control all pollutants or pollutant parameters which the permitting authority determines are or may be discharged at a level which will cause, have the reasonable potential to cause or contribute to an excursion of any applicable water quality standard. If the permitting authority determines that a discharge has the reasonable potential to cause or contribute to an excursion of an applicable numeric water quality criterion, it must include a WQBEL for the individual pollutant in the permit. In the absence of an adopted numeric water quality criterion for an individual pollutant, the permitting authority must derive appropriate WQBELs from the State or Tribal narrative water quality criterion by either calculating a numeric criterion for the pollutant; applying EPA's water quality criteria developed under section 304(a) of the CWA, supplemented with other information where necessary; or establishing effluent limitations on an indicator pollutant. See 40 CFR 122.44(d)(1).

The final Guidance implements these National requirements by specifying procedures for determining whether a discharge has the reasonable potential to cause or contribute to an exceedance of Tier I criteria or Tier II values based on facility-specific effluent data. The final Guidance also specifies procedures for determining whether permitting authorities must generate or require permittees to generate data sufficient to calculate Tier II values when specified pollutants of concern in the Great Lakes System are known or suspected of being discharged, but neither Tier I criteria nor Tier II values have been derived due to a lack of toxicological data. EPA believes that the data necessary to calculate Tier II values for aquatic life, wildlife and human health currently exists for most of the specified pollutants of concern.

The final Guidance maintains all the basic requirements from the proposed procedure. Some minor changes are that the procedure no longer includes a special provision for effluent dominated streams, and the procedure allows a broader range of statistical approaches to be used when evaluating effluent data, which provides added simplicity and flexibility to States and Tribes.

Another change from the proposal is the relationship in the final Guidance between the reasonable potential and TMDL procedures. Numerous commenters pointed out that the proposed Guidance indicated that TMDLs would be required for any water receiving effluent from a discharger found to exhibit reasonable potential. Given the fact that there are many waterbodies in the Great Lakes basin for which TMDLs have not been developed, and the obvious need for permitting to proceed in the interim until TMDLs are completed, the final Guidance provides that the permitting authority can establish waste load allocations and WQBELs in the absence of a TMDL or an assessment and remediation plan developed and approved in accordance with procedure 3.A of appendix F. A more detailed discussion of the assessment and remediation plan and its relationship to a TMDL can be found in section VIII.C.2 of the SID. Procedures for establishing such WLAs are therefore addressed in the final Guidance.

***15378 6. Intake Pollutants**

(Procedures 5.D and 5.E of appendix F to part 132; section VIII.E of the SID)
The proposed Guidance allowed a permitting authority to determine that the return of an identified intake water pollutant to the same body of water under specified circumstances does not cause, have the reasonable potential to cause, or contribute to an excursion above water quality standards, and therefore, that a WQBEL would not be required for that pollutant. Under the proposal, this "pass through" of intake water pollutants would be allowed if the facility returns the intake water containing the pollutant of concern to the same waterbody; does not contribute additional mass of pollutant; does not increase the concentration of the intake water pollutant; and does not discharge at a time or location, or alter the pollutant in a manner which would cause adverse impacts to occur that would not occur if the pollutant were left in-stream.

EPA received numerous comments on the proposal. Some commenters argued that the proposed provision was too narrow because relief would not be available if the facility added any amount of the pollutant to the discharge, even where the facility was not contributing any additional mass or concentration to the waterbody than was contained in the intake water. After consideration of public comments, EPA decided to expand the intake pollutant provisions to include not only a reasonable potential procedure like the one contained in the proposal, but also a provision that allows the permitting authority to take into account the presence of pollutants in intake water in deriving WQBELs. Specifically, the final Guidance authorizes the permitting authority to establish limits based on a principle of "no net addition" (i.e., the limit would allow the mass and concentration of the pollutant in the discharge up to the mass and concentration of the pollutant in the intake water). This provision would be available where the facility's discharge is to the same body of water as the intake water, and could be applied for up to 12 years after publication of the final Guidance. After that time, if a TMDL or comparable plan that meets the requirements of procedure 3 of appendix F has not been completed, the facility's WQBEL must be established in accordance with the "baseline" provisions in procedure 5.F.2 of appendix F. This time limit provides a period of relief for dischargers that are not causing increased impacts on the waterbody by virtue of their discharge that would not have occurred had the pollutant remained in-stream, while maintaining the incentive for development of a comprehensive assessment and remediation plan for achieving attainment of water quality standards, which EPA believes is a critical element of the final Guidance for addressing pollutants for which a large contributor to non-attainment is nonpoint source pollution.

The final Guidance allows States and Tribes to address intake pollutants in a manner consistent with assessment and remediation plans that have been developed through mechanisms other than TMDLs in order to provide flexibility where such plans comprehensively address the point and non-point sources of non-attainment in a waterbody and the means for attaining compliance with standards.

EPA believes that 12 years provides sufficient time for States to develop and complete the water quality assessments that would serve as the basis for establishing effluent limits (including "no net addition" limits, where appropriate) under procedure 3.A of appendix F. However, EPA also recognizes that unforeseen events could delay State completion of these assessments, and therefore will, at 7 years following promulgation, in consultation with the States, evaluate the progress of the assessments. If this evaluation shows that completion of the assessments may not be accomplished by the 12 year date, EPA will revisit these provisions, and consider proposing extensions if appropriate.

Under the final Guidance, the permitting authority can permit the discharge of intake pollutants to a different body of water that is in non-attainment provided limitations require the discharge to meet a WQBEL for the pollutant equal to the pollutant's water quality criterion. Because inter-waterbody transfers of pollutants introduce pollutants to the receiving water that would not be present in that waterbody in the absence of the facility's discharge, EPA does not believe that relief for such pollutants comparable to the "no net addition" approach would be appropriate. However, to address the concern raised by commenters about facilities with multiple sources of intake water, the permitting authority may use a flow-weighted combination of these approaches when the facility has co-mingled sources of intake water from the same and different bodies of water.

EPA maintains that the preferred approach to deal with non-attainment waters, particularly when multiple sources contribute a pollutant for which the receiving water exceeds the applicable criterion, is development of a TMDL or comparable assessment and remediation plan. The above “no net addition” permitting approach provides additional flexibility in situations where a TMDL or comparable plan has not yet been developed. Other existing relief mechanisms include variances to water quality standards, removal of non-existing uses, and site-specific criteria.

7. WET

(Procedure 6 of appendix F to part 132; section VIII.F of the SID)
Existing EPA regulations define WET as “the aggregate toxic effect of an effluent measured directly by a toxicity test.” These regulations require WET limits to be included in permits in most circumstances in which the WET of a discharge has the reasonable potential to cause or contribute to an in-stream excursion above either a State's numeric criteria for toxicity or narrative criteria for water quality (40 CFR 122.2, 122.44(d)(1)). The regulations allow States and Tribes the flexibility to control for WET with either numeric or narrative criteria. Current technical guidelines recommend that no discharge should exceed 0.3 acute toxic units (TUa = 100/LC50) at the edge of an acute mixing zone and 1.0 chronic toxic units (TUc = 100/NOEC, the No Observed Effect Concentration) at the edge of a chronic mixing zone.

The proposed Guidance would have continued to allow States and Tribes the flexibility to choose to control WET with either numeric or narrative criteria, but specified that no discharge could exceed 1.0 TU_a at the point of discharge (i.e., no acute mixing zones) and 1.0 TU_c at the edge of a chronic mixing zone (with some exceptions). In addition, the proposal contained minimum requirements for appropriate test methods to measure WET and for permit conditions, and procedures for determining whether or not limits for WET are necessary.

The final Guidance differs principally from the proposal in requiring States and Tribes to adopt 0.3 TU_a and 1.0 TU_c either as numeric criteria or as an equivalent numeric interpretation of narrative criteria. The final Guidance also allows the use of acute mixing zones for the application of the acute criterion. This approach will promote consistency among States and Tribes in controlling WET, while still permitting considerable flexibility regarding implementation measures, consistent with current National policies and guidelines.

***15379 8. Loading Limits**

(Procedure 9 of appendix F to part 132; section VIII.G of the SID)
The final Guidance provides that WQBELs be expressed in terms of both concentration and mass loading rate, except for those pollutants that cannot appropriately be expressed in terms of mass. These provisions clarify the application of existing Federal regulations at 40 CFR 122.45(f), and are consistent with current EPA guidance which requires the inclusion of any limits determined necessary based on best professional judgment to meet water quality standards, including, where appropriate, mass loading rate limits. They are also consistent with the antidegradation policy for the Great Lakes System in appendix E of the final Guidance.

9. Levels of Quantification

(Procedure 8 of appendix F to part 132; section VIII.H of the SID)
Many of the pollutants of concern in the Great Lakes System cause unacceptable toxic effects at very low concentrations. This results in instances where WQBELs are below levels of reliable quantification. When this occurs, the permitting authority may not be able to determine whether the pollutant concentration is above or below the WQBEL. The final Guidance requires adoption of pollutant minimization programs (PMPs) for such permits to increase the likelihood that the concentration of the pollutant is as close to the effluent limit as possible. The PMP is an ongoing, iterative process that requires, among other things,

internal wastestream monitoring and submission of status reports. The use of PMPs for facilities with pollutants below the level of quantification is consistent with existing EPA guidance.

Unlike the proposal, however, the final Guidance eliminates additional minimum requirements for BCCs. For example, the final Guidance recommends but does not require bio-uptake studies that had been proposed to assess impacts to the receiving water and evaluate the effectiveness of the PMP.

10. Compliance Schedules

(Procedure 9 of appendix F to part 132; section VIII.I of the SID)
The final Guidance includes a procedure that allows Great Lakes States and Tribes to include schedules of compliance in permits for existing Great Lakes dischargers for effluent limitations based on new water quality criteria and certain other requirements. Generally, compliance schedules may provide for up to five years to comply with the effluent limitation in question and may, in specified cases, allow the compliance schedule to go beyond the term of the permit. Existing Great Lakes dischargers are those whose construction commenced before March 23, 1997. Thus the term, existing Great Lakes discharges, covers expanding dischargers who were ineligible for compliance schedules under the proposal. The final Guidance also provides the opportunity for States and Tribes to allow dischargers additional time to comply with effluent limitations based on Tier II values while conducting studies to justify modifications of those limitations.

C. Antidegradation Provisions

(§132.4(a)(6); appendix E to part 132; section VII of the SID)
EPA's existing regulations, at 40 CFR 131.6, establish an antidegradation policy as one of the minimum requirements of an acceptable water quality standards submittal. Section 131.12 describes the required elements of an antidegradation policy. These are: protection of water quality necessary to maintain existing uses, protection of high quality waters (those where water quality exceeds levels necessary to support propagation of fish, shellfish, and wildlife and recreation in and on the waters) and protection of water quality in those water bodies identified as outstanding National resources.

The proposed Guidance provided detailed procedures for implementing antidegradation that were not part of the existing regulations. The detailed implementation procedures were intended to result in greater consistency in how antidegradation was applied throughout the Great Lakes System. The proposed Guidance specified, among other things, how high quality waters should be identified, what activities should and should not require review under antidegradation, and the information necessary to support a request to lower water quality and the procedures to be followed by a Tribe or State in making a decision whether or not to allow a lowering of water quality.

The final Guidance maintains the overall structure of the proposed Guidance while allowing Tribes and States greater flexibility in how antidegradation is implemented. As in the proposal, the final Guidance is composed of an antidegradation standard, antidegradation implementation procedures, antidegradation demonstration and antidegradation decision. However, many of the detailed requirements found in the proposed Guidance appear in the SID accompanying the final Guidance as nonbinding guidelines, including provisions specific to non-BCCs.

Key elements of the proposed Guidance that are retained in the final Guidance for BCCs include: identification of high quality waters on a pollutant-by-pollutant basis; requirements for States and Tribes to adopt an antidegradation standard consistent with the final Guidance for BCCs; minimum requirements for conducting an antidegradation review of any activity expected to result in a significant lowering of water quality due to BCCs, minimum requirements for notifying permitting authorities of increases in discharges of BCCs; and, minimum requirements for an antidegradation demonstration consisting of a pollution prevention analysis, an alternative treatment analysis and a showing that the significant lowering of water quality will allow for important social and economic development. Significant changes from the proposed Guidance include: encouraging, but not

requiring, States and Tribes to adopt provisions consistent with the antidegradation standard and implementation procedures for non-BCCs; replacement of numeric existing effluent quality-based (EEQ) limits as a means of implementing antidegradation for BCCs with a narrative description of the types of activities that will trigger an antidegradation review; and greater flexibility in the implementation, demonstration and decision components. A detailed discussion of the basis for each of the changes is provided in Section VII the SID.

D. Regulatory Requirements

(Part 132; Tables 5 and 6 to part 132; section II of the SID)
The Great Lakes States must adopt water quality standards, anti-degradation policies, and implementation procedures for waters within the Great Lakes System which are consistent with the final Guidance within two years of this publication. If a Great Lakes State fails to adopt such standards, policies, and procedures, section 118(c)(2)(C) of the CWA requires EPA to promulgate them not later than the end of that two-year period. Additionally, when an Indian Tribe is authorized to administer the NPDES or water quality standards program in the Great Lakes basin, it will also need to adopt provisions consistent with the final Guidance into its water program.

Part 132 establishes requirements and procedures to implement section 118(c)(2)(C). Sections 132.3 and 132.4 ***15380** require Great Lakes States and Tribes to adopt criteria, methodologies, policies, and procedures consistent with the criteria, methodologies, policies, and procedures contained in part 132—that is, the definitions in §132.2, the numeric criteria in Tables 1 through 4, the criteria development methodologies in appendixes A through D, the antidegradation policy in appendix E, and the implementation procedures in appendix F. Section 132.5 specifies the procedures for States and Tribes to make their submissions to EPA, and for EPA to approve or disapprove the submissions. The section specifies that in reviewing submissions, EPA will consider provisions of State and Tribal submissions to be "consistent with" the final Guidance if each provision is as protective as the corresponding provision of the final Guidance. If a State or Tribe fails to make a submission, or if provisions of the submission are not consistent with the final Guidance, §132.5 provides that EPA will publish a final rule in the Federal Register identifying the final Guidance provisions that will apply to discharges within the particular State or Federal Indian Reservation.

Section 132.4 specifies that water quality criteria adopted by States and Tribes consistent with the final Guidance will apply to all waters of the Great Lakes System, regardless of designated uses of the waters in most cases, with some variations in human health criteria depending on whether the waters are designated for drinking water use. Section 132.4 also contains certain exceptions in applying the final Guidance methodologies and procedures. First, States and Tribes do not have to adopt and apply the final Guidance methodologies and procedures for the 14 pollutants listed in Table 5 of part 132. EPA believes that some or all of the methodologies and procedures are not scientifically appropriate for these pollutants. Second, if a State or Tribe demonstrates that the final Guidance methodologies or procedures are not scientifically defensible for a particular pollutant, the State or Tribe may use alternate methodologies or procedures so long as they meet all applicable Federal, State, and Tribal laws. Third, §132.4 specifies that for wet-weather point sources, States and Tribes generally do not have to adopt and apply the final Guidance implementation procedures. The exception is the TMDL general condition for wet weather events. Fourth, pursuant to section 510 of the CWA, part 132 specifies that nothing in the final Guidance prohibits States or Tribes from adopting provisions more stringent than the final Guidance.

As discussed further in section IX of this preamble, §132.4 also provides that State and Tribal submissions will need to include any provisions that EPA determines, based on EPA's authorities under the CWA and the results of consultation with the U.S. Fish and Wildlife Service (FWS) under section 7 of the ESA, are necessary to ensure that water quality is not likely to cause jeopardy to any endangered or threatened species listed under the ESA.

Part 132 extends the requirements of section 118(c)(2)(C) to Indian Tribes within the Great Lakes basin for which EPA has approved water quality standards under section 303 of the CWA or which EPA has authorized to administer an NPDES program under section 402 of the CWA. EPA believes that inclusion of Great Lakes Tribes in this way is necessary and appropriate to be

consistent with section 518 of the CWA. The reasons for EPA's proposal are discussed further in the preamble to the proposed Guidance (58 FR 20834), and section II.D.3 of the SID. As a practical matter, no Great Lakes Tribes currently have approved water quality standards or authorized NPDES programs, so the submission requirements of part 132 do not apply to any Great Lakes Tribes. Tribes that are approved or authorized in the future, however, will need to adopt provisions consistent with the final Guidance in their water programs.

V. Costs, Cost-Effectiveness and Benefits

(Section IX of the SID)
Under Executive Order 12866 (58 FR 51735, October 4, 1993), EPA must determine whether the regulatory action is "significant" and therefore subject to Office of Management and Budget (OMB) review and the requirements of the Executive Order. The Order defines "significant regulatory action" as one that is likely to result in a rule that may:

(1) Have an annual effect on the economy of $100 million or more or adversely affect in a material way the economy, a sector of the economy, competition, jobs, the environment, public health or safety, or State, local, or Tribal governments or communities;

(2) Create a serious inconsistency or otherwise interfere with an action taken or planned by another agency;

(3) Materially alter the budgetary impact of entitlements, grants, user fees, or loan programs or the rights and obligations of recipients thereof; or

(4) Raise novel legal or policy issues arising out of legal mandates, the President's priorities, or the principles set forth in the Executive Order.

Pursuant to the terms of Executive Order 12866, it has been determined that this rule is a "significant regulatory action" because it raises novel policy issues arising out of the development of a comprehensive ecosystem-based approach for a large geographic area involving several States, Tribal governments, local governments, and a large number of regulated dischargers. This approach, including the Great Lakes Water Quality Initiative which developed the core concepts of the final Guidance, is a unique and precedential approach to the implementation of environmental programs. As such, this action was submitted to OMB for review pursuant to Executive Order 12866. Changes made in response to OMB suggestions or recommendations will be documented in the public record.

The following is a summary of major elements of the "Regulatory Impact Analysis of the Final Great Lakes Water Quality Guidance" (RIA) (EPA 820-B-95-011) that has been prepared in compliance with Executive Order 12866. Further discussion is included in section IX of the SID, and in the full RIA, which is available in the docket for this rulemaking.

The provisions of the final Guidance are not enforceable requirements until adopted by States or Tribes, or promulgated by EPA for a particular State or Tribe. Therefore, this publication of the final Guidance does not have an immediate effect on dischargers. Until actions are taken to promulgate and implement these provisions (or equally protective provisions consistent with the final Guidance), there will be no economic effect on any dischargers. For the purposes of the RIA, EPA's analysis of costs and benefits assumes that either State or EPA promulgations occur consistent with the final Guidance within the next two years.

Under the CWA, costs cannot be a basis for adopting water quality criteria that will not be protective of designated uses. If a range of scientifically defensible criteria that are protective can be identified, however, costs may be considered in selecting a particular criterion within that range. Costs may also be relevant under the antidegradation standard as applied to high quality waters.

EPA has assessed compliance costs for facilities that could be affected by provisions adopted by States or Tribes consistent with the final Guidance. EPA has also assessed basin-wide risk reduction benefits to sport anglers and Native American subsistence

anglers in the basin, and benefits for three case study sites in the Great Lakes System. ***15381** The methodology used in each assessment and the results of these assessments are discussed below.

EPA solicited public comment and supporting data on the RIA methodology used to estimate both costs and benefits for implementation of the proposed Guidance. EPA evaluated these comments and supporting data as well as comments provided by OMB and revised the RIA methodology prior to performing these assessments for the final Guidance.

A. Costs

Based on the information provided by each State and a review of the permit files, EPA identified about 3,800 direct dischargers that could be affected by State or Tribal adoption or subsequent EPA promulgation, if necessary, of requirements consistent with the final Guidance. Of these, about 590 are major dischargers and the remaining 3,210 are minor dischargers. Of the 590 majors, about 275 are industrial facilities and 315 are publicly owned treatment works (POTWs). Out of these dischargers, EPA used a stratified random sampling procedure to select 59 facilities (50 major and nine minor) that it considered representative of all types and sizes of facilities in the basin.

EPA divided the major facilities into nine industrial categories and a category for POTWs. The nine industrial categories are: mining, food and food products, pulp and paper, inorganic chemical manufacturing, organic chemical manufacturing/petroleum refining, metals manufacturing, electroplating/metal fabrication, steam electric power plants, and miscellaneous facilities.

For each major and minor facility in the sample, EPA estimated incremental costs to comply with subsequently promulgated provisions consistent with the final Guidance, using a baseline of compliance with the requirements of section 303(c)(2)(B) of the CWA. Using a decision matrix, costs were developed for two different scenarios—a “low-end” cost scenario and a “high-end” cost scenario—to account for the range of regulatory flexibility available to States and Tribes when adopting and implementing provisions consistent with the final Guidance. In addition, the decision matrix specified assumptions used for selection of control options in the cost analysis such as optimization of existing treatment processes and operations, in-plant pollutant minimization and prevention, and “end of pipe” effluent treatment.

The annualized costs for direct and indirect dischargers to implement the final Guidance are estimated to be between $60 million (low end) and $380 million (high end) (first quarter 1994 dollars). EPA believes the costs for implementing the final Guidance, which balance pollution prevention, “end-of-pipe” treatment and regulatory flexibility, will approach the low end of the cost range. Costs are unlikely to reach the high end of the cost range because State and Tribal authorities are likely to choose implementation options that provide some degree of relief to point source dischargers, especially because in many cases the nonpoint source contributions will be significant. Furthermore, cost estimates for both scenarios, but especially for the high-end scenario, may be overstated because in cases where the final Guidance provides States and Tribes flexibility in selecting less costly approaches when implementing provisions consistent with the final Guidance, the most costly approach was used to estimate the costs. This approach was used to reduce uncertainty in the cost analysis for the final Guidance.

Under the low-end cost scenario, major industrial facilities and POTWs would account for about 65 percent of the costs, indirect dischargers about 33 percent, and minor dischargers about two percent. Among the major dischargers three categories would account for most of the costs—POTWs (39 percent), pulp and paper (14 percent), and miscellaneous (eight percent). The average per plant costs for different industry categories range from zero to $168,000. The two highest average cost categories are pulp and paper ($151,000) and miscellaneous ($168,000). Although major POTWs make up a large portion of the total cost, the average cost per plant under the low-end scenario is not among the highest at $75,000 per facility. About half of the low-end costs are associated with pollution prevention activities, and about half are for capital and operating costs for wastewater treatment.

For the high-end cost scenario, direct dischargers account for 98 percent of the total estimated cost, and indirect dischargers account for two percent. This shift in proportion of costs between direct and indirect dischargers and between the low and the high estimates are due to the assumption that more direct dischargers will need to use end-of-pipe treatment under the high-end

scenario. In addition, it was assumed that a smaller proportion of indirect dischargers (10 percent) would be impacted under the high-end scenario, since municipalities are adding end-of-pipe treatment which should reduce the need for source controls (i.e., reduce the need for increased pretreatment program efforts) by indirect discharges. Less than 10 percent of the high-end costs are associated with pollution prevention activities, and over 90 percent are for capital and operating costs for wastewater treatment.

Under the high-end scenario for the direct dischargers, municipal major dischargers are expected to incur just under 70 percent of total costs, and industrial major dischargers account for 29 percent of total costs. Minor direct dischargers are estimated to incur less than one percent of the total costs. The two major industrial categories with the largest total annualized cost are the pulp and paper (23 percent of total) and miscellaneous (three percent) categories. The food and food products and metal finishing categories are estimated to incur less than 1 percent of the total annualized cost.

Under the high-end scenario, the average annual cost per major municipal facility is just over $822,000 per facility. Average annualized costs for industrial majors vary widely across categories, with the highest average cost estimated for pulp and paper ($1,583,000 per plant) and miscellaneous ($433,700 per plant) categories. Regardless of the scenario, the average costs for minor facilities are negligible at an estimated $500 per facility.

The costs described above account for the costs of eliminating mixing zones for BCCs except in narrow circumstances, costs related to implementation of Tier II values, and specific calculated costs related to intake credits. The cost assessment also projects the potential cost savings across the different scenarios that facilities may realize if States or Tribes use existing regulatory relief mechanisms to modify or eliminate the need for a WQBEL for an identified pollutant (e.g., variances, TMDLs, site-specific modifications to criteria, and changes in designated uses).

In addition to the cost estimates described above, EPA estimated the cost to comply with requirements consistent with the antidegradation provisions of the final Guidance. This potential future cost is expressed as a “lost opportunity” cost for facilities impacted by the antidegradation requirements. This cost could result in the addition of about $22 million each year.

B. Cost-Effectiveness

EPA estimated the cost-effectiveness of the final Guidance in terms of the cost of reducing the loadings of toxic pollutants from point sources. The cost-effectiveness (cost per pound removed) is derived by dividing the annualized costs of implementing the final ***15382** Guidance by the toxicity-weighted pounds (pound-equivalents) of pollutants removed. Pound-equivalents are calculated by multiplying pounds of each pollutant removed by the toxic weight (based on the toxicity of copper) for that pollutant.

It is estimated that implementation of provisions consistent with the final Guidance would be responsible for the reduction of about six to eight million toxic pounds per year, or 16 to 22 percent of the toxic-weighted baseline for the low- and high-end scenarios, respectively. The cost-effectiveness of the scenarios, over the baseline, is quite good, ranging from $10 to $50 per pound-equivalent.

Approximately 80 percent of the pollutant load reduction from implementation of the final Guidance, regardless of the scenario, is attributable to reducing BCCs as a result of PMPs and end-of-pipe treatment. The largest pollutant load reductions occur for chlordane, dieldrin, heptachlor, lead, and pentachlorobenzene.

In a separate analysis, EPA also investigated the cost-effectiveness of regulating point and nonpoint sources of mercury and PCBs, two contaminants associated with fish advisories in the Great Lakes basin. Although data and resource constraints limited the findings from these analyses, the preliminary results indicate that point sources may factor cost-effectively into pollutant reduction scenarios. For both contaminants, the cost-effectiveness of point and nonpoint source controls are likely to be highly site-specific.

C. Benefits

The benefits analysis is intended to provide insight into both the types and potential magnitude of the economic benefits expected to arise as a result of implementation of provisions adopted by States and Tribes consistent with the final Guidance. To the extent feasible, empirical estimates of the potential magnitude of the benefits are developed and then compared to the estimated costs of implementing provisions adopted by States and Tribes consistent with the final Guidance.

The benefits analysis is based on a case study approach, using benefits transfer applied to three case studies. The case study approach was used because it is more amenable to meaningful benefit-cost analyses than are studies of larger aggregate areas. Although the results obtained for a case study site may not apply uniformly to the entire Great Lakes basin, the case study approach does provide a pragmatic and realistic perspective of how implementation of the final Guidance can generate benefits, the types of benefits anticipated, and how these benefits compare to costs.

The case studies include: (1) the lower Fox River drainage, including Green Bay, located on Lake Michigan in northeastern Wisconsin; (2) the Saginaw River and Saginaw Bay, located on Lake Huron in northeastern Michigan; and (3) the Black River, located on Lake Erie in north-central Ohio. The case studies were selected from a list of candidate sites (i.e., designated Areas of Concern (AOCs) in the Great Lakes basin) on the basis of data availability and the relevance of the water quality problems to the final Guidance (i.e., areas in which problems were more likely to be associated with on-going point source discharges rather than historic loadings from Superfund sites and other sources). Geographic diversity was also considered in selecting the sites so that the analyses might better promote a broad perspective of the final Guidance's benefits and costs.

For each of the three case studies, EPA estimated future toxics-oriented water quality benefits, and then attributed a percentage of these benefits to implementation of the final Guidance. The attribution of benefits was based only on the estimated reduction in loadings from point sources at the case study sites and information on the relative contribution of point sources to total loadings in the basin. EPA did not attempt to calculate the longer-term benefits to human health, wildlife, and aquatic life once the final Guidance provisions are fully implemented by nonpoint sources as well as point sources and the minimum protection levels are attained in the ambient water.

In the Fox River and Green Bay case study, total annual undiscounted benefits attributable to the final Guidance range from $0.3 million to $8.5 million (first quarter 1994 dollars). Human health benefits account for between 29 percent and 72 percent of the estimated benefits, recreational fishing accounts for between eight percent and 45 percent, and nonuse/ecologic benefits account for between nine percent and 23 percent. Municipal and industrial dischargers in this case study are estimated to incur annualized costs of about $3.6 million.

In the Saginaw River/Bay case study, total annual undiscounted benefits range from $0.2 million to $7.7 million. Recreational fishing benefits account for between 36 percent and 60 percent of the estimated benefits, non-use benefits account for between 18 percent and 30 percent, and human health benefits account for between eight percent and 36 percent. Total annualized costs to municipal and industrial dischargers are estimated to be about $2.6 million.

In the Black River case study, total annual undiscounted benefits range from $0.4 million to $1.5 million. Recreational fishing benefits account for between 48 percent and 63 percent of the estimated benefits, and nonuse benefits account for between 32 percent and 44 percent. Total annualized costs to municipal and industrial dischargers are estimated to be $2.1 million.

An inherent limitation of the case study approach is the inability to extrapolate from a limited set of river-based sites to the Great Lakes basin as a whole. Accordingly, extrapolation of the case study results to the Great Lakes basin is not recommended. However, as noted above, the three case studies were selected on the basis of data availability, the relative importance of point source discharges to the watersheds' problems, and an attempt to portray spatial diversity throughout the Great Lakes basin. Thus, there is no reason to conclude that the selected sites are not reflective of the basin, even though benefits (and costs) tend to be highly site-specific. In addition, the benefits extend from the case study rivers into the larger, open-water environment of the Great Lakes.

The representativeness of the case study sites was assessed by comparing the percentage of total benefits estimated to accrue in the case study areas to the percentage of basin-wide costs incurred by the case study sites. Benefits-related measures (such as population, recreational angling days, and nonconsumptive recreation days) were used in place of total benefits for this analysis because there is no estimate of benefits for the entire Great Lakes basin. The three case studies combine to account for nearly 14 percent of the total cost of the final Guidance, nearly 17 percent of the loadings reductions, and from four percent to 10 percent of the benefits proxies (i.e., basin-wide population, recreational angling, nonconsumptive recreation, and commercial fishery harvest). Thus, the three case studies may represent a reasonably proportionate share of costs and benefits.

In addition to the case study analyses, a basin-wide risk assessment was conducted for Great Lakes anglers. EPA collected data and information on the consumption of Great Lakes basin fish to estimate baseline risk levels and reductions in risks due to implementation of the final Guidance for two populations at risk: Great Lakes sport anglers (including minority and ***15383** low-income anglers) and Native Americans engaged in subsistence fishing in the basin. For sport anglers, EPA estimated that the projected reduction in loadings from point sources based on controls consistent with the final Guidance would result in a reduction of annual excess lifetime cancer cases (potential cancer cases assuming a 70-year lifetime exposure period) of 2.2 to 4.1 for low-income minorities in lakeshore counties; 0.4 to 0.8 for other minorities in lakeshore counties; and 21.9 to 41.9 for all other sport anglers. For Native American subsistence anglers, EPA estimated that reductions from point source loadings attributable to the final Guidance would result in a reduction of excess lifetime cancer cases of between 0.1 and 0.3 using a low fish ingestion scenario and 0.5 to 1.1 using a high fish ingestion scenario. Note that these estimates do not include the long-term benefits (including reduced cancer cases) that will result once the final Guidance provisions are fully implemented and the minimum protection levels are attained in the ambient water.

In total, using the most conservative consumption scenario for Native Americans, these reductions represent between 0.35 and 0.67 excess cancer cases per year, and potential basin-wide benefits of the final Guidance for this one benefits category of between $0.7 million and $6.7 million per year, based on the estimated value of a statistical life of between $2.0 million and $10.0 million. Comparison to case study results, which were based on a more comprehensive sample of facilities within case study areas than was possible for the entire basin, indicates these values likely underestimate the potential risk reduction benefits of the final Guidance at the basin level. For example, if the average percentage load reduction for PCBs for the three case studies is used to reflect reductions in PCBs for the basin, the reduction in excess cancer cases increases to between three and six cases per year, and potential benefits increase to between $6.6 and $60 million per year.

The reduction in pollutant loadings for PCBs was likely understated in the basin-wide analysis because the analysis did not count pollutant load reduction benefits when the current State-based permit limit and the final Guidance-based permit limit were both below the pollutant analytical method detection limit (MDL). Only three sample facilities in the population of 59 sample facilities used to project basin-wide costs and human health benefits had State-based permit limits for PCBs. Since the current State-based permit limit and the final Guidance-based permit limit were below the MDL in all three facilities, “zero” reduction in PCB loadings for the basin was estimated. This, of course, is an artifact of the methodology and the size of the sample population selected for the analysis, and would not occur, as demonstrated in the case study analysis, if a larger sample population had been used.

VI. Regulatory Flexibility Act

Under the Regulatory Flexibility Act (RFA), EPA generally is required to conduct a final regulatory flexibility analysis (FRFA) describing the impact of the regulatory action on small entities as part of the final rulemaking. However, under section 605(b) of the RFA, if EPA certifies that the rule will not have a significant economic impact on a substantial number of small entities, EPA is not required to prepare a FRFA.

Implementation of the final Guidance is dependent upon future promulgation of provisions consistent with it by State or Tribal agencies or, if necessary, EPA. Until actions are taken to promulgate and implement these provisions, or equally protective provisions consistent with the final Guidance, there will be no economic effect of this rule on any entities, large or small. For

that reason, and pursuant to Section 605(b) of the RFA, EPA is certifying that this rule itself will not have a significant economic impact on a substantial number of small entities.

Although EPA is certifying that this rule will not have a significant economic impact on a substantial number of small entities, and therefore is not required to prepare a FRFA, it is nevertheless including for public information in the RIA a discussion of the possible economic effects to small entities that could result from State or Tribal adoption of provisions consistent with the final Guidance or subsequent EPA promulgation, if necessary. As discussed above, small facilities are projected to incur costs of only approximately $500 per facility to comply with subsequently promulgated requirements that are consistent with the final Guidance. Accordingly, EPA believes there will be no significant economic impact on a substantial number of small entities as a result of State or Tribal implementation of the final Guidance.

VII. Enhancing the Intergovernmental Partnership Under Executive Order 12875

In compliance with Executive Order 12875 (58 FR 58093, October 28, 1993), EPA has involved State, Tribal, and local governments in the development of the final Guidance.

As described in section II above, the core elements of the final Guidance were developed by the Great Lakes States, EPA, and other Federal agencies in open dialogue with citizens, local governments, and industries in the Great Lakes ecosystem over a five-year period through the Initiative. The Initiative process marks the first time that EPA has developed a major rulemaking effort in the water program through a regional public forum. The Initiative process is described further in the preamble to the proposed Guidance (58 FR 20820-23) and section II of this preamble.

In addition to the participation by State and local governments in the initial development of the proposed Guidance and in the public comment process, several activities have been carried out since the publication of the proposed Guidance. These include:

(1) On April 26, 1994, EPA held a public meeting to solicit additional information from interested parties on the proposed Guidance. As part of EPA's outreach efforts to State, Tribal and local governments, a special invitation was sent inviting elected officials and other State, Tribal and local representatives to participate in the public meeting. EPA specifically welcomed Tribal and local officials and opened the floor to them to hear and discuss their specific concerns and views on the final Guidance.

(2) A series of meetings and teleconferences were held with Great Lakes States in early 1994 to discuss their comments on several issues, including development of water quality criteria, State adoption requirements, WET, BAFs, additivity, compliance schedules, anti-backsliding, nonpoint sources, and international concerns.

(3) In October, 1994, EPA met with each individual State in the Great Lakes basin to discuss the nature, form, and scope of the proposed Guidance, and State concerns with implementation of the provisions under consideration. The following issues were discussed at each of the meetings: intake credits, antidegradation and EEQ, wildlife criteria, excluded pollutants (e.g., ammonia and chlorine), elimination of mixing zones, site-specific modifications, fish consumption, appropriate degrees of flexibility for implementation (e.g., guidance vs. regulation), and implementation procedures.

(4) In 1994 and 1995, EPA met with representatives of the National Wildlife Federation to discuss EPA's activities in developing the final Guidance in ***15384** accordance with the terms of a consent decree governing the schedule for development of the final Guidance.

(5) In 1994, EPA also met with elected officials and other representatives from several local communities in the Great Lakes basin to discuss issues regarding the economic impact of the proposed Guidance on local communities and POTWs. Issues discussed include cost impacts associated with implementing water quality criteria, methodologies, and implementation procedures; dealing with pollution from nonpoint sources; public outreach to control pollutants such as mercury instead of costly end-of-pipe treatment; and applicability of provisions in the final Guidance to the National water quality program.

(6) EPA held an additional 18 consultations with the regulated community throughout 1994. Such meetings allowed representatives of dischargers to share additional data, which has been placed in the docket for this rulemaking, and concerns about a range of issues, including cost concerns, that the dischargers expect to arise in implementation of the final Guidance.

(7) In 1994, EPA met with State representatives to conduct initial planning for implementation of the GLI Clearinghouse. All Great Lakes States agreed to participate in this effort, which will involve the sharing of toxicological and other data to assist in the development of additional water quality criteria and values.

The results of the above efforts have assisted in the development of the final Guidance through broad communication with a full range of interested parties, sharing of additional information, and incorporation of features to improve the implementation of the final Guidance.

EPA has estimated the total annual State government burden to implement the final Guidance as approximately 5,886 hours, resulting in a State government cost of $175,992 annually. Such burden and costs were estimated based upon the burden and costs associated with developing water quality criteria, review of antidegradation policy demonstrations, review of approvable control strategies and BCC monitoring data, and review of variance requests. The total annual local government burden is estimated to be 42,296 hours with an associated cost of $2,008,624. All of the burden and costs to local governments are associated with being a regulated entity as an operator of a POTW.

VIII. Paperwork Reduction Act

The information collection requirements in this final Guidance have been approved by OMB under the Paperwork Reduction Act, 44 U.S.C. 3501 et seq., and have been assigned OMB control number 2040-0180. EPA has prepared an Information Collection Request (ICR) document (ICR No. 1639.02). A copy of ICR 1639.02 may be obtained by writing to Ms. Sandy Farmer, Information Policy Branch, EPA 2136, Washington, D.C. 20460, or by calling (202) 260-2740.

The annual public reporting and record keeping burden for this regulation is estimated to be 128,787 hours for the affected 3,795 permittees, or an average of 34 hours. This includes the total annual burden to local governments as POTW operators, estimated to be 45,296 hours. The total annual burden to State governments is estimated to be 5,886 hours. These estimates include time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information.

Send comments regarding the burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden to Chief, Information Policy Branch, Mail Code 2136, U.S. Environmental Protection Agency, 401 M St., S.W., Washington, DC 20460; and to the Office of Information and Regulatory Affairs, Office of Management and Budget, Washington, DC 20503.

In this rulemaking EPA is also amending the table of currently approved ICR control numbers issued by OMB for various regulations into 40 CFR 9.1. This amendment updates the table to accurately display those information requirements promulgated under the CWA. The affected regulations are codified at 40 CFR parts 122, 123, 131, and 132. EPA will continue to present OMB control numbers in a consolidated table format. The table will be codified in 40 CFR part 9 of EPA's regulations and in each 40 CFR volume containing EPA regulations. The table lists the section numbers with reporting and recordkeeping requirements, and the current OMB control numbers. This display of the OMB control numbers and their subsequent codification in the CFR satisfies the requirements of the Paperwork Reduction Act (44 U.S.C. 3501 et seq.) and OMB's implementing regulations at 5 CFR part 1320.

The ICR for this rulemaking was previously subject to public notice and comment prior to OMB approval. As a result, EPA finds that there is “good cause” under section 553(b)(B) of the Administrative Procedure Act (5 U.S.C. 553(b)(B)) to amend this table without prior notice and comment. Due to the technical nature of the table, further notice and comment would be unnecessary.

IX. Endangered Species Act

Pursuant to section 7(a)(2) of the ESA, EPA consulted with the FWS concerning EPA's publication of the final Guidance. EPA and the FWS have now completed both informal and formal consultation conducted over a two-year period.

As a result of the consultation, as well as an analysis of comments, EPA modified several provisions of the final Guidance. The procedure for site-specific modifications provides that Great Lakes States and Tribes must make site-specific modifications to criteria and values where necessary to ensure the resulting water quality does not cause jeopardy to listed or proposed species. Similarly, the antidegradation policy and implementation procedures restrict certain actions States and Tribes may take to allow lowering of water quality in high quality waters, or to adopt variances or mixing zones. Additionally, the regulatory requirements were modified to require Great Lakes States and Tribes to include in their part 132 submissions any provisions that EPA determines, based on EPA's authorities under the CWA and the results of consultation under section 7 of the ESA, are necessary to ensure that water quality is not likely to cause jeopardy to listed species. EPA and the FWS also agreed on how further consultations will be conducted as the final Guidance is implemented. The two agencies also agreed that EPA will undertake a review of water quality standards and implementation of those standards for ammonia and chlorine in the Great Lakes basin as part of EPA's responsibilities under section 303(c) of the CWA.

During the consultation, two issues were identified that required formal consultation, as defined in 40 CFR part 402. These issues were: the absence of toxicological data concerning effects of contaminants on three species of freshwater mussels in the Great Lakes basin, and the adequacy of the wildlife criteria methodology to protect three endangered or threatened wildlife species in the basin. On February 21, 1995, the FWS provided EPA with a written Biological Opinion (Opinion) on these issues. The Opinion is available in the docket for this rulemaking. On both issues, the FWS concluded that the water quality resulting from implementation of the final Guidance will not cause jeopardy to the listed species. To minimize the amount or extent of any incidental take that might ***15385** occur, the FWS consulted closely with EPA to develop a coordinated approach. The final Opinion specified reasonable and prudent measures that the FWS considers necessary or appropriate to minimize such impact. EPA has agreed to implement the measures, and the FWS and EPA will continue to work cooperatively during the implementation.

X. Judicial Review of Provisions Not Amended

In some situations, EPA has renumbered or included other editorial changes to regulations that have been promulgated in past rulemakings. Additionally, to provide for ease in reading changes to existing regulations, EPA has in some cases repeated entire sections, including portions not changed. The promulgation of this final rule, however, does not provide another opportunity to seek judicial review on the substance of the existing regulations.

XI. Supporting Documents

All documents that are referenced in this preamble are available for inspection and photocopying in the docket for this rulemaking at the address listed at the beginning of this preamble. A reasonable fee will be charged for photocopies.

Selected documents supporting the final Guidance are also available for viewing by the public at locations listed below:

PART 122—EPA ADMINISTERED PERMIT PROGRAMS: THE NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM

3. The authority citation for part 122 continues to read as follows:

Authority: The Clean Water Act, 33 U.S.C. 1251 et seq.

40 CFR § 122.44

4. Section 122.44 is amended by adding a new paragraph (r) to read as follows:

40 CFR § 122.44

§122.44 Establishing limitations, standards, and other permit conditions (applicable to State NPDES programs, see §123.25).

* * * * *

(r) Great Lakes. When a permit is issued to a facility that discharges into the Great Lakes System (as defined in 40 CFR 132.2), conditions promulgated by the State, Tribe, or EPA pursuant to 40 CFR part 132.

PART 123—STATE PROGRAM REQUIREMENTS

5. The authority citation for part 123 continues to read as follows:

Authority: Clean Water Act, 33 U.S.C. 1251 et seq.

40 CFR § 123.25

6. Section 123.25 is amended by removing “and” at the end of paragraph (a)(36), removing the period at the end of paragraph (a)(37) and adding “; and” in its place, and adding a new paragraph (a)(38) to read as follows:

40 CFR § 123.25

§123.25 Requirements for permitting.

(a) * * *

(38) For a Great Lakes State or Tribe (as defined in 40 CFR 132.2), 40 CFR part 132 (NPDES permitting implementation procedures only).

* * * * *40 CFR § 123.44

7. Section 123.44 is amended by adding a new paragraph (c)(9) to read as follows:

40 CFR § 123.44

§123.44 EPA review of and objections to State permits.

* * * * *

(c) * * *

(9) For a permit issued by a Great Lakes State or Tribe (as defined in 40 CFR 132.2), the permit does not satisfy the conditions promulgated by the State, Tribe, or EPA pursuant to 40 CFR part 132.

* * * * *40 CFR § 123.62

8. Section 123.62 is amended by adding a new paragraph (f) to read as follows:

40 CFR § 123.62

§123.62 Procedures for revision of State programs.

* * * * *

(f) Revision of a State program by a Great Lakes State or Tribe (as defined in 40 CFR 132.2) to conform to section 118 of the CWA and 40 CFR part 132 shall be accomplished pursuant to 40 CFR part 132.

40 CFR § 123.63

9. Section 123.63 is amended by adding a new paragraph (a)(6) and adding and reserving paragraph (b) to read as follows:

40 CFR § 123.63

§123.63 Criteria for withdrawal of State programs.

(a) * * *

(6) Where a Great Lakes State or Tribe (as defined in 40 CFR 132.2) fails to adequately incorporate the NPDES permitting implementation procedures promulgated by the State, Tribe, or EPA pursuant to 40 CFR part 132 into individual permits.

(b) [Reserved]

PART 131—WATER QUALITY STANDARDS

10. The authority citation for part 131 continues to read as follows:

Authority: 33 U.S.C. 1251 et seq.

40 CFR § 131.1

11. Section 131.1 is revised to read as follows:

40 CFR § 131.1

§131.1 Scope.

40 CFR § 132.2

This part describes the requirements and procedures for developing, reviewing, revising, and approving water quality standards by the States as authorized by section 303(c) of the Clean Water Act. Additional specific procedures for developing, reviewing, revising, and approving water quality standards for Great Lakes States or Great Lakes Tribes (as defined in 40 CFR 132.2) to conform to section 118 of the ***15387** Clean Water Act and 40 CFR part 132, are provided in 40 CFR part 132.

40 CFR § 131.5

12. Section 131.5 is amended by revising paragraph (a)(5), by redesignating paragraph (b) as paragraph (c), and by adding a new paragraph (b) to read as follows:

40 CFR § 131.5

§131.5 EPA Authority.

(a) * * *

(5) Whether the State submission meets the requirements included in §131.6 of this part and, for Great Lakes States or Great Lakes Tribes (as defined in 40 CFR 132.2) to conform to section 118 of the Act, the requirements of 40 CFR part 132.

(b) If EPA determines that the State's or Tribe's water quality standards are consistent with the factors listed in paragraphs (a)(1) through (a)(5) of this section, EPA approves the standards. EPA must disapprove the State's or Tribe's water quality standards and promulgate Federal standards under section 303(c)(4), and for Great Lakes States or Great Lakes Tribes under section 118(c)(2)(C) of the Act, if State or Tribal adopted standards are not consistent with the factors listed in paragraphs (a)(1) through (a)(5) of this section. EPA may also promulgate a new or revised standard when necessary to meet the requirements of the Act.

* * * * *40 CFR § 131.21

13. Section 131.21 is amended by revising paragraph (b) to read as follows:

40 CFR § 131.21

§131.21 EPA review and approval of water quality standards.

* * * * *

(b) The Regional Administrator's approval or disapproval of a State water quality standard shall be based on the requirements of the Act as described in §§131.5 and 131.6, and, with respect to Great Lakes States or Tribes (as defined in 40 CFR 132.2), 40 CFR part 132.

* * * * *

14. Part 132 is added as follows:

PART 132—WATER QUALITY GUIDANCE FOR THE GREAT LAKES SYSTEM

Sec.

Tables to Part 132

Authority: 33 U.S.C. 1251 et seq.

40 CFR § 132.1

§132.1 Scope, purpose, and availability of documents.

(a) This part constitutes the Water Quality Guidance for the Great Lakes System (Guidance) required by section 118(c)(2) of the Clean Water Act (33 U.S.C. 1251 et seq.) as amended by the Great Lakes Critical Programs Act of 1990 (Pub. L. 101-596, 104 Stat. 3000 et seq.). The Guidance in this part identifies minimum water quality standards, antidegradation policies, and implementation procedures for the Great Lakes System to protect human health, aquatic life, and wildlife.

(b) The U.S. Environmental Protection Agency, Great Lakes States, and Great Lakes Tribes will use the Guidance in this part to evaluate the water quality programs of the States and Tribes to assure that they are protective of water quality. State and Tribal programs do not need to be identical to the Guidance in this part, but must contain provisions that are consistent with (as protective as) the Guidance in this part. The scientific, policy and legal basis for EPA's development of each section of the final Guidance in this part is set forth in the preamble, Supplementary Information Document, Technical Support Documents,

and other supporting documents in the public docket. EPA will follow the guidance set out in these documents in reviewing the State and Tribal water quality programs in the Great Lakes for consistency with this part.

(c) The Great Lakes States and Tribes must adopt provisions consistent with the Guidance in this part applicable to waters in the Great Lakes System or be subject to EPA promulgation of its terms pursuant to this part.

(d) EPA understands that the science of risk assessment is rapidly improving. Therefore, to ensure that the scientific basis for the methodologies in appendices A through D are always current and peer reviewed, EPA will review the methodologies and revise them, as appropriate, every 3 years.

(e) Certain documents referenced in the appendixes to this part with a designation of NTIS and/or ERIC are available for a fee upon request to the National Technical Information Center (NTIS), U.S. Department of Commerce, 5285 Port Royal Road, Springfield, VA 22161. Alternatively, copies may be obtained for a fee upon request to the Educational Resources Information Center/Clearinghouse for Science, Mathematics, and Environmental Education (ERIC/CSMEE), 1200 Chambers Road, Room 310, Columbus, Ohio 43212. When ordering, please include the NTIS or ERIC/CSMEE accession number.
40 CFR § 132.2

§132.2 Definitions.
The following definitions apply in this part. Terms not defined in this section have the meaning given by the Clean Water Act and EPA implementing regulations.

Acute-chronic ratio (ACR) is a standard measure of the acute toxicity of a material divided by an appropriate measure of the chronic toxicity of the same material under comparable conditions.

Acute toxicity is concurrent and delayed adverse effect(s) that results from an acute exposure and occurs within any short observation period which begins when the exposure begins, may extend beyond the exposure period, and usually does not constitute a substantial portion of the life span of the organism.

Adverse effect is any deleterious effect to organisms due to exposure to a substance. This includes effects which are or may become debilitating, harmful or toxic to the normal functions of the organism, but does not include non-harmful effects such as tissue discoloration alone or the induction of enzymes involved in the metabolism of the substance.

Bioaccumulation is the net accumulation of a substance by an organism as a result of uptake from all environmental sources.

Bioaccumulation factor (BAF) is the ratio (in L/kg) of a substance's concentration in tissue of an aquatic organism to its concentration in the ambient water, in situations where both the organism and its food are exposed and the ratio does not change substantially over time.

Bioaccumulative chemical of concern (BCC) is any chemical that has the potential to cause adverse effects which, upon entering the surface waters, by itself or as its toxic transformation ***15388** product, accumulates in aquatic organisms by a human health bioaccumulation factor greater than 1000, after considering metabolism and other physicochemical properties that might enhance or inhibit bioaccumulation, in accordance with the methodology in appendix B of this part. Chemicals with half-lives of less than eight weeks in the water column, sediment, and biota are not BCCs. The minimum BAF information needed to define an organic chemical as a BCC is either a field-measured BAF or a BAF derived using the BSAF methodology. The minimum BAF information needed to define an inorganic chemical, including an organometal, as a BCC is either a field-measured BAF or a laboratory-measured BCF. BCCs include, but are not limited to, the pollutants identified as BCCs in section A of Table 6 of this part.

Bioconcentration is the net accumulation of a substance by an aquatic organism as a result of uptake directly from the ambient water through gill membranes or other external body surfaces.

Bioconcentration factor (BCF) is the ratio (in L/kg) of a substance's concentration in tissue of an aquatic organism to its concentration in the ambient water, in situations where the organism is exposed through the water only and the ratio does not change substantially over time.

Biota-sediment accumulation factor (BSAF) is the ratio (in kg of organic carbon/kg of lipid) of a substance's lipid-normalized concentration in tissue of an aquatic organism to its organic carbon-normalized concentration in surface sediment, in situations where the ratio does not change substantially over time, both the organism and its food are exposed, and the surface sediment is representative of average surface sediment in the vicinity of the organism.

Carcinogen is a substance which causes an increased incidence of benign or malignant neoplasms, or substantially decreases the time to develop neoplasms, in animals or humans. The classification of carcinogens is discussed in section II.A of appendix C to part 132.

Chronic toxicity is concurrent and delayed adverse effect(s) that occurs only as a result of a chronic exposure.

Connecting channels of the Great Lakes are the Saint Mary's River, Saint Clair River, Detroit River, Niagara River, and Saint Lawrence River to the Canadian Border.

Criterion continuous concentration (CCC) is an estimate of the highest concentration of a material in the water column to which an aquatic community can be exposed indefinitely without resulting in an unacceptable effect.

Criterion maximum concentration (CMC) is an estimate of the highest concentration of a material in the water column to which an aquatic community can be exposed briefly without resulting in an unacceptable effect.

EC50 is a statistically or graphically estimated concentration that is expected to cause one or more specified effects in 50 percent of a group of organisms under specified conditions.

Endangered or threatened species are those species that are listed as endangered or threatened under section 4 of the Endangered Species Act.

Existing Great Lakes discharger is any building, structure, facility, or installation from which there is or may be a “discharge of pollutants” (as defined in 40 CFR 122.2) to the Great Lakes System, that is not a new Great Lakes discharger.

Federal Indian reservation, Indian reservation, or reservation means all land within the limits of any Indian reservation under the jurisdiction of the United States Government, notwithstanding the issuance of any patent, and including rights-of-way running through the reservation.

Final acute value (FAV) is (a) a calculated estimate of the concentration of a test material such that 95 percent of the genera (with which acceptable acute toxicity tests have been conducted on the material) have higher GMAVs, or (b) the SMAV of an important and/or critical species, if the SMAV is lower than the calculated estimate.

Final chronic value (FCV) is (a) a calculated estimate of the concentration of a test material such that 95 percent of the genera (with which acceptable chronic toxicity tests have been conducted on the material) have higher GMCVs, (b) the quotient of an FAV divided by an appropriate acute-chronic ratio, or (c) the SMCV of an important and/or critical species, if the SMCV is lower than the calculated estimate or the quotient, whichever is applicable.

Final plant value (FPV) is the lowest plant value that was obtained with an important aquatic plant species in an acceptable toxicity test for which the concentrations of the test material were measured and the adverse effect was biologically important.

Genus mean acute value (GMAV) is the geometric mean of the SMAVs for the genus.

Genus mean chronic value (GMCV) is the geometric mean of the SMCVs for the genus.

Great Lakes means Lake Ontario, Lake Erie, Lake Huron (including Lake St. Clair), Lake Michigan, and Lake Superior; and the connecting channels (Saint Mary's River, Saint Clair River, Detroit River, Niagara River, and Saint Lawrence River to the Canadian Border).

Great Lakes States and Great Lakes Tribes, or Great Lakes States and Tribes means the States of Illinois, Indiana, Michigan, Minnesota, New York, Ohio, Pennsylvania, and Wisconsin, and any Indian Tribe as defined in this part which is located in whole or in part within the drainage basin of the Great Lakes, and for which EPA has approved water quality standards under section 303 of the Clean Water Act or which EPA has authorized to administer an NPDES program under section 402 of the Clean Water Act.

Great Lakes System means all the streams, rivers, lakes and other bodies of water within the drainage basin of the Great Lakes within the United States.

Human cancer criterion (HCC) is a Human Cancer Value (HCV) for a pollutant that meets the minimum data requirements for Tier I specified in appendix C of this part.

Human cancer value (HCV) is the maximum ambient water concentration of a substance at which a lifetime of exposure from either: drinking the water, consuming fish from the water, and water-related recreation activities; or consuming fish from the water, and water-related recreation activities, will represent a plausible upper-bound risk of contracting cancer of one in 100,000 using the exposure assumptions specified in the Methodologies for the Development of Human Health Criteria and Values in appendix C of this part.

Human noncancer criterion (HNC) is a Human Noncancer Value (HNV) for a pollutant that meets the minimum data requirements for Tier I specified in appendix C of this part.

Human noncancer value (HNV) is the maximum ambient water concentration of a substance at which adverse noncancer effects are not likely to occur in the human population from lifetime exposure via either: drinking the water, consuming fish from the water, and water-related recreation activities; or consuming fish from the water, and water-related recreation activities using the Methodologies for the Development of Human Health Criteria and Values in appendix C of this part.

Indian Tribe or Tribe means any Indian Tribe, band, group, or community recognized by the Secretary of the Interior and exercising governmental authority over a Federal Indian reservation.

LC50 is a statistically or graphically estimated concentration that is expected ***15389** to be lethal to 50 percent of a group of organisms under specified conditions.

Load allocation (LA) is the portion of a receiving water's loading capacity that is attributed either to one of its existing or future nonpoint sources or to natural background sources, as more fully defined at 40 CFR 130.2(g). Nonpoint sources include: in-place contaminants, direct wet and dry deposition, groundwater inflow, and overland runoff.

Loading capacity is the greatest amount of loading that a water can receive without violating water quality standards.

Lowest observed adverse effect level (LOAEL) is the lowest tested dose or concentration of a substance which resulted in an observed adverse effect in exposed test organisms when all higher doses or concentrations resulted in the same or more severe effects.

Method detection level is the minimum concentration of an analyte (substance) that can be measured and reported with a 99 percent confidence that the analyte concentration is greater than zero as determined by the procedure set forth in appendix B of 40 CFR part 136.

Minimum Level (ML) is the concentration at which the entire analytical system must give a recognizable signal and acceptable calibration point. The ML is the concentration in a sample that is equivalent to the concentration of the lowest calibration standard analyzed by a specific analytical procedure, assuming that all the method-specified sample weights, volumes and processing steps have been followed.

New Great Lakes discharger is any building, structure, facility, or installation from which there is or may be a “discharge of pollutants” (as defined in 40 CFR 122.2) to the Great Lakes System, the construction of which commenced after March 23, 1997.

No observed adverse effect level (NOAEL) is the highest tested dose or concentration of a substance which resulted in no observed adverse effect in exposed test organisms where higher doses or concentrations resulted in an adverse effect.

No observed effect concentration (NOEC) is the highest concentration of toxicant to which organisms are exposed in a full life-cycle or partial life-cycle (short-term) test, that causes no observable adverse effects on the test organisms (i.e., the highest concentration of toxicant in which the values for the observed responses are not statistically significantly different from the controls).

Open waters of the Great Lakes (OWGLs) means all of the waters within Lake Erie, Lake Huron (including Lake St. Clair), Lake Michigan, Lake Ontario, and Lake Superior lakeward from a line drawn across the mouth of tributaries to the Lakes, including all waters enclosed by constructed breakwaters, but not including the connecting channels.

Quantification level is a measurement of the concentration of a contaminant obtained by using a specified laboratory procedure calibrated at a specified concentration above the method detection level. It is considered the lowest concentration at which a particular contaminant can be quantitatively measured using a specified laboratory procedure for monitoring of the contaminant.

Quantitative structure activity relationship (QSAR) or structure activity relationship (SAR) is a mathematical relationship between a property (activity) of a chemical and a number of descriptors of the chemical. These descriptors are chemical or physical characteristics obtained experimentally or predicted from the structure of the chemical.

Risk associated dose (RAD) is a dose of a known or presumed carcinogenic substance in (mg/kg)/day which, over a lifetime of exposure, is estimated to be associated with a plausible upper bound incremental cancer risk equal to one in 100,000.

Species mean acute value (SMAV) is the geometric mean of the results of all acceptable flow-through acute toxicity tests (for which the concentrations of the test material were measured) with the most sensitive tested life stage of the species. For a species for which no such result is available for the most sensitive tested life stage, the SMAV is the geometric mean of the results of all acceptable acute toxicity tests with the most sensitive tested life stage.

Species mean chronic value (SMCV) is the geometric mean of the results of all acceptable life-cycle and partial life-cycle toxicity tests with the species; for a species of fish for which no such result is available, the SMCV is the geometric mean of all acceptable early life-stage tests.

Stream design flow is the stream flow that represents critical conditions, upstream from the source, for protection of aquatic life, human health, or wildlife.

Threshold effect is an effect of a substance for which there is a theoretical or empirically established dose or concentration below which the effect does not occur.

Tier I criteria are numeric values derived by use of the Tier I methodologies in appendixes A, C and D of this part, the methodology in appendix B of this part, and the procedures in appendix F of this part, that either have been adopted as numeric criteria into a water quality standard or are used to implement narrative water quality criteria.

Tier II values are numeric values derived by use of the Tier II methodologies in appendixes A and C of this part, the methodology in appendix B of this part, and the procedures in appendix F of this part, that are used to implement narrative water quality criteria.

Total maximum daily load (TMDL) is the sum of the individual wasteload allocations for point sources and load allocations for nonpoint sources and natural background, as more fully defined at 40 CFR 130.2(i). A TMDL sets and allocates the maximum amount of a pollutant that may be introduced into a water body and still assure attainment and maintenance of water quality standards.

Tributaries of the Great Lakes System means all waters of the Great Lakes System that are not open waters of the Great Lakes, or connecting channels.

Uncertainty factor (UF) is one of several numeric factors used in operationally deriving criteria from experimental data to account for the quality or quantity of the available data.

Uptake is acquisition of a substance from the environment by an organism as a result of any active or passive process.

Wasteload allocation (WLA) is the portion of a receiving water's loading capacity that is allocated to one of its existing or future point sources of pollution, as more fully defined at 40 CFR 130.2(h). In the absence of a TMDL approved by EPA pursuant to 40 CFR 130.7 or an assessment and remediation plan developed and approved in accordance with procedure 3.A of appendix F of this part, a WLA is the allocation for an individual point source, that ensures that the level of water quality to be achieved by the point source is derived from and complies with all applicable water quality standards.

Wet weather point source means any discernible, confined and discrete conveyance from which pollutants are, or may be, discharged as the result of a wet weather event. Discharges from wet weather point sources shall include only: discharges of storm water from a municipal separate storm sewer as defined at 40 CFR 122.26(b)(8); storm water discharge associated with industrial activity as defined at 40 CFR 122.26(b)(14); discharges of storm water and sanitary wastewaters (domestic, ***15390** commercial, and industrial) from a combined sewer overflow; or any other stormwater discharge for which a permit is required under section 402(p) of the Clean Water Act. A storm water discharge associated with industrial activity which is mixed with process wastewater shall not be considered a wet weather point source.

40 CFR § 132.3

§132.3 Adoption of criteria.

The Great Lakes States and Tribes shall adopt numeric water quality criteria for the purposes of section 303(c) of the Clean Water Act applicable to waters of the Great Lakes System in accordance with §132.4(d) that are consistent with:

(a) The acute water quality criteria for protection of aquatic life in Table 1 of this part, or a site-specific modification thereof in accordance with procedure 1 of appendix F of this part;

(b) The chronic water quality criteria for protection of aquatic life in Table 2 of this part, or a site-specific modification thereof in accordance with procedure 1 of appendix F of this part;

(c) The water quality criteria for protection of human health in Table 3 of this part, or a site-specific modification thereof in accordance with procedure 1 of appendix F of this part; and

(d) The water quality criteria for protection of wildlife in Table 4 of this part, or a site-specific modification thereof in accordance with procedure 1 of appendix F of this part.

40 CFR § 132.4

§132.4 State adoption and application of methodologies, policies and procedures.

(a) The Great Lakes States and Tribes shall adopt requirements applicable to waters of the Great Lakes System for the purposes of sections 118, 301, 303, and 402 of the Clean Water Act that are consistent with:

(1) The definitions in §132.2;

(2) The Methodologies for Development of Aquatic Life Criteria and Values in appendix A of this part;

(3) The Methodology for Development of Bioaccumulation Factors in appendix B of this part;

(4) The Methodologies for Development of Human Health Criteria and Values in appendix C of this part;

(5) The Methodology for Development of Wildlife Criteria in appendix D of this part;

(6) The Antidegradation Policy in appendix E of this part; and

(7) The Implementation Procedures in appendix F of this part.

(b) Except as provided in paragraphs (g), (h), and (i) of this section, the Great Lakes States and Tribes shall use methodologies consistent with the methodologies designated as Tier I methodologies in appendixes A, C, and D of this part, the methodology in appendix B of this part, and the procedures in appendix F of this part when adopting or revising numeric water quality criteria for the purposes of section 303(c) of the Clean Water Act for the Great Lakes System.

(c) Except as provided in paragraphs (g), (h), and (i) of this section, the Great Lakes States and Tribes shall use methodologies and procedures consistent with the methodologies designated as Tier I methodologies in appendixes A, C, and D of this part, the Tier II methodologies in appendixes A and C of this part, the methodology in appendix B of this part, and the procedures in appendix F of this part to develop numeric criteria and values when implementing narrative water quality criteria adopted for purposes of section 303(c) of the Clean Water Act.

(d) The water quality criteria and values adopted or developed pursuant to paragraphs (a) through (c) of this section shall apply as follows:

(1) The acute water quality criteria and values for the protection of aquatic life, or site-specific modifications thereof, shall apply to all waters of the Great Lakes System.

(2) The chronic water quality criteria and values for the protection of aquatic life, or site-specific modifications thereof, shall apply to all waters of the Great Lakes System.

(3) The water quality criteria and values for protection of human health, or site-specific modifications thereof, shall apply as follows:

(i) Criteria and values derived as HCV-Drinking and HNV-Drinking shall apply to the Open Waters of the Great Lakes, all connecting channels of the Great Lakes, and all other waters of the Great Lakes System that have been designated as public water supplies by any State or Tribe in accordance with 40 CFR 131.10.

(ii) Criteria and values derived as HCV-Nondrinking and HNV-Nondrinking shall apply to all waters of the Great Lakes System other than those in paragraph (d)(3)(i) of this section.

(4) Criteria for protection of wildlife, or site-specific modifications thereof, shall apply to all waters of the Great Lakes System.

(e) The Great Lakes States and Tribes shall apply implementation procedures consistent with the procedures in appendix F of this part for all applicable purposes under the Clean Water Act, including developing total maximum daily loads for the purposes of section 303(d) and water quality-based effluent limits for the purposes of section 402, in establishing controls on the discharge of any pollutant to the Great Lakes System by any point source with the following exceptions:

(1) The Great Lakes States and Tribes are not required to apply these implementation procedures in establishing controls on the discharge of any pollutant by a wet weather point source. Any adopted implementation procedures shall conform with all applicable Federal, State and Tribal requirements.

(2) The Great Lakes States and Tribes may, but are not required to, apply procedures consistent with procedures 1, 2, 3, 4, 5, 7, 8, and 9 of appendix F of this part in establishing controls on the discharge of any pollutant set forth in Table 5 of this part. Any procedures applied in lieu of these implementation procedures shall conform with all applicable Federal, State, and Tribal requirements.

(f) The Great Lakes States and Tribes shall apply an antidegradation policy consistent with the policy in appendix E for all applicable purposes under the Clean Water Act, including 40 CFR 131.12.

(g) For pollutants listed in Table 5 of this part, the Great Lakes States and Tribes shall:

(1) Apply any methodologies and procedures acceptable under 40 CFR part 131 when developing water quality criteria or implementing narrative criteria; and

(2) Apply the implementation procedures in appendix F of this part or alternative procedures consistent with all applicable Federal, State, and Tribal laws.

(h) For any pollutant other than those in Table 5 of this part for which the State or Tribe demonstrates that a methodology or procedure in this part is not scientifically defensible, the Great Lakes States and Tribes shall:

(1) Apply an alternative methodology or procedure acceptable under 40 CFR part 131 when developing water quality criteria; or

(2) Apply an alternative implementation procedure that is consistent with all applicable Federal, State, and Tribal laws.

(i) Nothing in this part shall prohibit the Great Lakes States and Tribes from adopting numeric water quality criteria, narrative criteria, or water quality values that are more stringent than criteria or values specified in §132.3 or that would be derived from application of the methodologies set forth in appendixes A, B, C, and D of this part, or to adopt antidegradation standards and implementation procedures more ***15391** stringent than those set forth in appendixes E and F of this part.
40 CFR § 132.5

§132.5 Procedures for adoption and EPA review.

(a) Except as provided in paragraph (c) of this section, the Great Lakes States and Tribes shall adopt and submit for EPA review and approval the criteria, methodologies, policies, and procedures developed pursuant to this part no later than September 23, 1996.

(b) The following elements must be included in each submission to EPA for review:

(1) The criteria, methodologies, policies, and procedures developed pursuant to this part;

(2) Certification by the Attorney General or other appropriate legal authority pursuant to 40 CFR 123.62 and 40 CFR 131.6(e) as appropriate;

(3) All other information required for submission of National Pollutant Discharge Elimination System (NPDES) program modifications under 40 CFR 123.62; and

(4) General information which will aid EPA in determining whether the criteria, methodologies, policies and procedures are consistent with the requirements of the Clean Water Act and this part, as well as information on general policies which may affect their application and implementation.

(c) The Regional Administrator may extend the deadline for the submission required in paragraph (a) of this section if the Regional Administrator believes that the submission will be consistent with the requirements of this part and can be reviewed and approved pursuant to this section no later than March 23, 1997.

(d) If a Great Lakes State or Tribe makes no submission pursuant to this part to EPA for review, the requirements of this part shall apply to discharges to waters of the Great Lakes System located within the State or Federal Indian reservation upon EPA's publication of a final rule indicating the effective date of the part 132 requirements in the identified jurisdictions.

(e) If a Great Lakes State or Tribe submits criteria, methodologies, policies, and procedures pursuant to this part to EPA for review that contain substantial modifications of the State or Tribal NPDES program, EPA shall issue public notice and provide a minimum of 30 days for public comment on such modifications. The public notice shall conform with the requirements of 40 CFR 123.62.

(f) After review of State or Tribal submissions under this section, and following the public comment period in subparagraph (e) of this section, if any, EPA shall either:

(1) Publish notice of approval of the submission in the Federal Register within 90 days of such submission; or

(2) Notify the State or Tribe within 90 days of such submission that EPA has determined that all or part of the submission is inconsistent with the requirements of the Clean Water Act or this part and identify any necessary changes to obtain EPA approval. If the State or Tribe fails to adopt such changes within 90 days after the notification, EPA shall publish a notice in the Federal Register identifying the approved and disapproved elements of the submission and a final rule in the Federal Register identifying the provisions of part 132 that shall apply to discharges within the State or Federal Indian reservation.

(g) EPA's approval or disapproval of a State or Tribal submission shall be based on the requirements of this part and of the Clean Water Act. EPA's determination whether the criteria, methodologies, policies, and procedures in a State or Tribal submission are consistent with the requirements of this part will be based on whether:

(1) For pollutants listed in Tables 1, 2, 3, and 4 of this part. The Great Lakes State or Tribe has adopted numeric water quality criteria as protective as each of the numeric criteria in Tables 1, 2, 3, and 4 of this part, taking into account any site-specific criteria modifications in accordance with procedure 1 of appendix F of this part;

(2) For pollutants other than those listed in Tables 1, 2, 3, 4, and 5 of this part. The Great Lakes State or Tribe demonstrates that either:

(i) It has adopted numeric criteria in its water quality standards that were derived, or are as protective as or more protective than could be derived, using the methodologies in appendixes A, B, C, and D of this part, and the site-specific criteria modification procedures in accordance with procedure 1 of appendix F of this part; or

(ii) It has adopted a procedure by which water quality-based effluent limits and total maximum daily loads are developed using the more protective of:

(A) Numeric criteria adopted by the State into State water quality standards and approved by EPA prior to March 23, 1997; or

(B) Water quality criteria and values derived pursuant to §132.4(c); and

(3) For methodologies, policies, and procedures. The Great Lakes State or Tribe has adopted methodologies, policies, and procedures as protective as the corresponding methodology, policy, or procedure in §132.4. The Great Lakes State or Tribe may adopt provisions that are more protective than those contained in this part. Adoption of a more protective element in one provision may be used to offset a less protective element in the same provision as long as the adopted provision is as protective as the corresponding provision in this part; adoption of a more protective element in one provision, however, is not justification for adoption of a less protective element in another provision of this part.

(h) A submission by a Great Lakes State or Tribe will need to include any provisions that EPA determines, based on EPA's authorities under the Clean Water Act and the results of consultation under section 7 of the Endangered Species Act, are necessary to ensure that water quality is not likely to jeopardize the continued existence of any endangered or threatened species listed under section 4 of the Endangered Species Act or result in the destruction or adverse modification of such species' critical habitat.

(i) EPA's approval of the elements of a State's or Tribe's submission will constitute approval under section 118 of the Clean Water Act, approval of the submitted water quality standards pursuant to section 303 of the Clean Water Act, and approval of the submitted modifications to the State's or Tribe's NPDES program pursuant to section 402 of the Clean Water Act.
40 CFR § 132.6

§132.6 Application of part 132 requirements in Great Lakes States and Tribes. [Reserved]

Appendix A to part 132—Great Lakes Water Quality Initiative Methodologies for Developments of Aquatic Life Criteria and Values

Methodology for Deriving Aquatic Life Criteria: Tier I

Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) this appendix.

15394** ***I. Definitions

A. Material of Concern. When defining the material of concern the following should be considered:

1. Each separate chemical that does not ionize substantially in most natural bodies of water should usually be considered a separate material, except possibly for structurally similar organic compounds that only exist in large quantities as commercial mixtures of the various compounds and apparently have similar biological, chemical, physical, and toxicological properties.

2. For chemicals that ionize substantially in most natural bodies of water (e.g., some phenols and organic acids, some salts of phenols and organic acids, and most inorganic salts and coordination complexes of metals and metalloid), all forms that would be in chemical equilibrium should usually be considered one material. Each different oxidation state of a metal and each different non-ionizable covalently bonded organometallic compound should usually be considered a separate material.

3. The definition of the material of concern should include an operational analytical component. Identification of a material simply as “sodium,” for example, implies “total sodium,” but leaves room for doubt. If “total” is meant, it must be explicitly stated. Even “total” has different operational definitions, some of which do not necessarily measure “all that is there” in all samples. Thus, it is also necessary to reference or describe the analytical method that is intended. The selection of the operational analytical component should take into account the analytical and environmental chemistry of the material and various practical considerations, such as labor and equipment requirements, and whether the method would require measurement in the field or would allow measurement after samples are transported to a laboratory.

a. The primary requirements of the operational analytical component are that it be appropriate for use on samples of receiving water, that it be compatible with the available toxicity and bioaccumulation data without making extrapolations that are too hypothetical, and that it rarely result in underprotection or overprotection of aquatic organisms and their uses. Toxicity is the property of a material, or combination of materials, to adversely affect organisms.

b. Because an ideal analytical measurement will rarely be available, an appropriate compromise measurement will usually have to be used. This compromise measurement must fit with the general approach that if an ambient concentration is lower than the criterion, unacceptable effects will probably not occur, i.e., the compromise measure must not err on the side of underprotection when measurements are made on a surface water. What is an appropriate measurement in one situation might not be appropriate for another. For example, because the chemical and physical properties of an effluent are usually quite different from those of the receiving water, an analytical method that is appropriate for analyzing an effluent might not be appropriate for expressing a criterion, and vice versa. A criterion should be based on an appropriate analytical measurement, but the criterion is not rendered useless if an ideal measurement either is not available or is not feasible.

Note: The analytical chemistry of the material might have to be taken into account when defining the material or when judging the acceptability of some toxicity tests, but a criterion must not be based on the sensitivity of an analytical method. When aquatic organisms are more sensitive than routine analytical methods, the proper solution is to develop better analytical methods.

4. It is now the policy of EPA that the use of dissolved metal to set and measure compliance with water quality standards is the recommended approach, because dissolved metal more closely approximates the bioavailable fraction of metal in the water column that does total recoverable metal. One reason is that a primary mechanism for water column toxicity is adsorption at the gill surface which requires metals to be in the dissolved form. Reasons for the consideration of total recoverable metals criteria include risk management considerations not covered by evaluation of water column toxicity. A risk manager may consider sediments and food chain effects and may decide to take a conservative approach for metals, considering that metals are very persistent chemicals. This approach could include the use of total recoverable metal in water quality standards. A range of different risk management decisions can be justified. EPA recommends that State water quality standards be based on dissolved metal. EPA will also approve a State risk management decision to adopt standards based on total recoverable metal, if those standards are otherwise approvable under this program.

B. Acute Toxicity. Concurrent and delayed adverse effect(s) that results from an acute exposure and occurs within any short observation period which begins when the exposure begins, may extend beyond the exposure period, and usually does not constitute a substantial portion of the life span of the organism. (Concurrent toxicity is an adverse effect to an organism that results from, and occurs during, its exposure to one or more test materials.) Exposure constitutes contact with a chemical or physical agent. Acute exposure, however, is exposure of an organism for any short period which usually does not constitute a substantial portion of its life span.

C. Chronic Toxicity. Concurrent and delayed adverse effect(s) that occurs only as a result of a chronic exposure. Chronic exposure is exposure of an organism for any long period or for a substantial portion of its life span.

II. Collection of Data

A. Collect all data available on the material concerning toxicity to aquatic animals and plants.

B. All data that are used should be available in typed, dated, and signed hard copy (e.g., publication, manuscript, letter, memorandum, etc.) with enough supporting information to indicate that acceptable test procedures were used and that the results are reliable. In some cases, it might be appropriate to obtain written information from the investigator, if possible. Information that is not available for distribution shall not be used.

C. Questionable data, whether published or unpublished, must not be used. For example, data must be rejected if they are from tests that did not contain a control treatment, tests in which too many organisms in the control treatment died or showed signs of stress or disease, and tests in which distilled or deionized water was used as the dilution water without the addition of appropriate salts.

D. Data on technical grade materials may be used if appropriate, but data on formulated mixtures and emulsifiable concentrates of the material must not be used.

E. For some highly volatile, hydrolyzable, or degradable materials, it might be appropriate to use only results of flow-through tests in which the concentrations of test material in test solutions were measured using acceptable analytical methods. A flow-through test is a test with aquatic organisms in which test solutions flow into constant-volume test chambers either intermittently (e.g., every few minutes) or continuously, with the excess flowing out.

F. Data must be rejected if obtained using:

1. Brine shrimp, because they usually only occur naturally in water with salinity greater than 35 g/kg.

2. Species that do not have reproducing wild populations in North America.

3. Organisms that were previously exposed to substantial concentrations of the test material or other contaminants.

4. Saltwater species except for use in deriving acute-chronic ratios. An ACR is a standard measure of the acute toxicity of a material divided by an appropriate measure of the chronic toxicity of the same material under comparable conditions.

G. Questionable data, data on formulated mixtures and emulsifiable concentrates, and data obtained with species non-resident to North America or previously exposed organisms may be used to provide auxiliary information but must not be used in the derivation of criteria.

III. Required Data

A. Certain data should be available to help ensure that each of the major kinds of possible adverse effects receives adequate consideration. An adverse effect is a change in an organism that is harmful to the organism. Exposure means contact with a chemical or physical agent. Results of acute and chronic toxicity tests with representative species of aquatic animals are necessary so that data available for tested species can be considered a useful indication of the sensitivities of appropriate untested species. Fewer data concerning toxicity to aquatic plants are usually available because procedures for conducting tests with plants and interpreting the results of such tests are not as well developed.

B. To derive a Great Lakes Tier I criterion for aquatic organisms and their uses, the following must be available:

1. Results of acceptable acute (or chronic) tests (see section IV or VI of this appendix) with at least one species of freshwater animal in at least eight different families such that all of the following are included:

***15395** a. The family Salmonidae in the class Osteichthyes;

b. One other family (preferably a commercially or recreationally important, warmwater species) in the class Osteichthyes (e.g., bluegill, channel catfish);

c. A third family in the phylum Chordata (e.g., fish, amphibian);

d. A planktonic crustacean (e.g., a cladoceran, copepod);

e. A benthic crustacean (e.g., ostracod, isopod, amphipod, crayfish);

f. An insect (e.g., mayfly, dragonfly, damselfly, stonefly, caddisfly, mosquito, midge);

g. A family in a phylum other than Arthropoda or Chordata (e.g., Rotifera, Annelida, Mollusca);

h. A family in any order of insect or any phylum not already represented.

2. Acute-chronic ratios (see section VI of this appendix) with at least one species of aquatic animal in at least three different families provided that of the three species:

a. At least one is a fish;

b. At least one is an invertebrate; and

c. At least one species is an acutely sensitive freshwater species (the other two may be saltwater species).

3. Results of at least one acceptable test with a freshwater algae or vascular plant is desirable but not required for criterion derivation (see section VIII of this appendix). If plants are among the aquatic organisms most sensitive to the material, results of a test with a plant in another phylum (division) should also be available.

C. If all required data are available, a numerical criterion can usually be derived except in special cases. For example, derivation of a chronic criterion might not be possible if the available ACRs vary by more than a factor of ten with no apparent pattern. Also, if a criterion is to be related to a water quality characteristic (see sections V and VII of this appendix), more data will be required.

D. Confidence in a criterion usually increases as the amount of available pertinent information increases. Thus, additional data are usually desirable.

IV. Final Acute Value

A. Appropriate measures of the acute (short-term) toxicity of the material to a variety of species of aquatic animals are used to calculate the Final Acute Value (FAV). The calculated Final Acute Value is a calculated estimate of the concentration of a test material such that 95 percent of the genera (with which acceptable acute toxicity tests have been conducted on the material) have higher Genus Mean Acute Values (GMAVs). An acute test is a comparative study in which organisms, that are subjected to different treatments, are observed for a short period usually not constituting a substantial portion of their life span. However, in some cases, the Species Mean Acute Value (SMAV) of a commercially or recreationally important species of the Great Lakes System is lower than the calculated FAV, then the SMAV replaces the calculated FAV in order to provide protection for that important species.

B. Acute toxicity tests shall be conducted using acceptable procedures. For good examples of acceptable procedures see American Society for Testing and Materials (ASTM) Standard E 729, Guide for Conducting Acute Toxicity Tests with Fishes, Macroinvertebrates, and Amphibians.

C. Except for results with saltwater annelids and mysids, results of acute tests during which the test organisms were fed should not be used, unless data indicate that the food did not affect the toxicity of the test material. (Note: If the minimum acute-chronic ratio data requirements (as described in section III.B.2 of this appendix) are not met with freshwater data alone, saltwater data may be used.)

D. Results of acute tests conducted in unusual dilution water, e.g., dilution water in which total organic carbon or particulate matter exceeded five mg/L, should not be used, unless a relationship is developed between acute toxicity and organic carbon or particulate matter, or unless data show that organic carbon or particulate matter, etc., do not affect toxicity.

E. Acute values must be based upon endpoints which reflect the total severe adverse impact of the test material on the organisms used in the test. Therefore, only the following kinds of data on acute toxicity to aquatic animals shall be used:

1. Tests with daphnids and other cladocerans must be started with organisms less than 24 hours old and tests with midges must be started with second or third instar larvae. It is preferred that the results should be the 48-hour EC50 based on the total percentage of organisms killed and immobilized. If such an EC50 is not available for a test, the 48-hour LC50 should be used in place of the desired 48-hour EC50. An EC50 or LC50 of longer than 48 hours can be used as long as the animals were not fed and the control animals were acceptable at the end of the test. An EC50 is a statistically or graphically estimated concentration that is expected to cause one or more specified effects in 50% of a group of organisms under specified conditions. An LC50 is a statistically or graphically estimated concentration that is expected to be lethal to 50% of a group of organisms under specified conditions.

2. It is preferred that the results of a test with embryos and larvae of barnacles, bivalve molluscs (clams, mussels, oysters and scallops), sea urchins, lobsters, crabs, shrimp and abalones be the 96-hour EC50 based on the percentage of organisms with incompletely developed shells plus the percentage of organisms killed. If such an EC50 is not available from a test, of the values that are available from the test, the lowest of the following should be used in place of the desired 96-hour EC50: 48- to 96-hour EC50s based on percentage of organisms with incompletely developed shells plus percentage of organisms killed, 48- to 96-hour EC50s based upon percentage of organisms with incompletely developed shells, and 48-hour to 96-hour LC50s. (Note: If the minimum acute-chronic ratio data requirements (as described in section III.B.2 of this appendix) are not met with freshwater data alone, saltwater data may be used.)

3. It is preferred that the result of tests with all other aquatic animal species and older life stages of barnacles, bivalve molluscs (clams, mussels, oysters and scallops), sea urchins, lobsters, crabs, shrimp and abalones be the 96-hour EC50 based on percentage of organisms exhibiting loss of equilibrium plus percentage of organisms immobilized plus percentage of organisms killed. If such an EC50 is not available from a test, of the values that are available from a test the lower of the following should

be used in place of the desired 96-hour EC50: the 96-hour EC50 based on percentage of organisms exhibiting loss of equilibrium plus percentage of organisms immobilized and the 96-hour LC50.

4. Tests whose results take into account the number of young produced, such as most tests with protozoans, are not considered acute tests, even if the duration was 96 hours or less.

5. If the tests were conducted properly, acute values reported as “greater than” values and those which are above the solubility of the test material should be used, because rejection of such acute values would bias the Final Acute Value by eliminating acute values for resistant species.

F. If the acute toxicity of the material to aquatic animals has been shown to be related to a water quality characteristic such as hardness or particulate matter for freshwater animals, refer to section V of this appendix.

G. The agreement of the data within and between species must be considered. Acute values that appear to be questionable in comparison with other acute and chronic data for the same species and for other species in the same genus must not be used. For example, if the acute values available for a species or genus differ by more than a factor of 10, rejection of some or all of the values would be appropriate, absent countervailing circumstances.

H. If the available data indicate that one or more life stages are at least a factor of two more resistant than one or more other life stages of the same species, the data for the more resistant life stages must not be used in the calculation of the SMAV because a species cannot be considered protected from acute toxicity if all of the life stages are not protected.

I. For each species for which at least one acute value is available, the SMAV shall be calculated as the geometric mean of the results of all acceptable flow-through acute toxicity tests in which the concentrations of test material were measured with the most sensitive tested life stage of the species. For a species for which no such result is available, the SMAV shall be calculated as the geometric mean of all acceptable acute toxicity tests with the most sensitive tested life stage, i.e., results of flow-through tests in which the concentrations were not measured and results of static and renewal tests based on initial concentrations (nominal concentrations are acceptable for most test materials if measured concentrations are not available) of test material. A renewal test is a test with aquatic organisms in which either the test solution in a test chamber is removed and replaced at least once during the test or the test organisms are transferred into a new test solution of the same composition at least once during the test. A static test is a test with aquatic organisms in which the solution ***15396** and organisms that are in a test chamber at the beginning of the test remain in the chamber until the end of the test, except for removal of dead test organisms.

Note 1: Data reported by original investigators must not be rounded off. Results of all intermediate calculations must not be rounded off to fewer than four significant digits.

Note 2: The geometric mean of N numbers is the Nth root of the product of the N numbers. Alternatively, the geometric mean can be calculated by adding the logarithms of the N numbers, dividing the sum by N, and taking the antilog of the quotient. The geometric mean of two numbers is the square root of the product of the two numbers, and the geometric mean of one number is that number. Either natural (base e) or common (base 10) logarithms can be used to calculate geometric means as long as they are used consistently within each set of data, i.e., the antilog used must match the logarithms used.

Note 3: Geometric means, rather than arithmetic means, are used here because the distributions of sensitivities of individual organisms in toxicity tests on most materials and the distributions of sensitivities of species within a genus are more likely to be lognormal than normal. Similarly, geometric means are used for ACRs because quotients are likely to be closer to lognormal than normal distributions. In addition, division of the geometric mean of a set of numerators by the geometric mean of the set of denominators will result in the geometric mean of the set of corresponding quotients.

J. For each genus for which one or more SMAVs are available, the GMAV shall be calculated as the geometric mean of the SMAVs available for the genus.

K. Order the GMAVs from high to low.

L. Assign ranks, R, to the GMAVs from "1" for the lowest to "N" for the highest. If two or more GMAVs are identical, assign them successive ranks.

M. Calculate the cumulative probability, P, for each GMAV as R/(N+1).

N. Select the four GMAVs which have cumulative probabilities closest to 0.05 (if there are fewer than 59 GMAVs, these will always be the four lowest GMAVs).

O. Using the four selected GMAVs, and Ps, calculate

Note: Natural logarithms (logarithms to base e, denoted as ln) are used herein merely because they are easier to use on some hand calculators and computers than common (base 10) logarithms. Consistent use of either will produce the same result.

P. If for a commercially or recreationally important species of the Great Lakes System the geometric mean of the acute values from flow-through tests in which the concentrations of test material were measured is lower than the calculated Final Acute Value (FAV), then that geometric mean must be used as the FAV instead of the calculated FAV.

Q. See section VI of this appendix.

V. Final Acute Equation

A. When enough data are available to show that acute toxicity to two or more species is similarly related to a water quality characteristic, the relationship shall be taken into account as described in sections V.B through V.G of this appendix or using analysis of covariance. The two methods are equivalent and produce identical results. The manual method described below provides an understanding of this application of covariance analysis, but computerized versions of covariance analysis are much more convenient for analyzing large data sets. If two or more factors affect toxicity, multiple regression analysis shall be used.

B. For each species for which comparable acute toxicity values are available at two or more different values of the water quality characteristic, perform a least squares regression of the acute toxicity values on the corresponding values of the water quality characteristic to obtain the slope and its 95 percent confidence limits for each species.

Note: Because the best documented relationship is that between hardness and acute toxicity of metals in fresh water and a log-log relationship fits these data, geometric means and natural logarithms of both toxicity and water quality are used in the rest of this section. For relationships based on other water quality characteristics, such as Ph, temperature, no transformation or a different transformation might fit the data better, and appropriate changes will be necessary throughout this section.

C. Decide whether the data for each species are relevant, taking into account the range and number of the tested values of the water quality characteristic and the degree of agreement within and between species. For example, a slope based on six data points might be of limited value if it is based only on data for a very narrow range of values of the water quality characteristic. A slope based on only two data points, however, might be useful if it is consistent with other information and if the two points cover a broad enough range of the water quality characteristic. In addition, acute values that appear to be questionable in comparison with other acute and chronic data available for the same species and for other species in the same genus should not be used. For example, if after adjustment for the water quality characteristic, the acute values available for a species or genus differ by more than a factor of 10, rejection of some or all of the values would be appropriate, absent countervailing justification. If useful slopes are not available for at least one fish and one invertebrate or if the available slopes are too dissimilar or if too

few data are available to adequately define the relationship between acute toxicity and the water quality characteristic, return to section IV.G of this appendix, using the results of tests conducted under conditions and in waters similar to those commonly used for toxicity tests with the species.

D. For each species, calculate the geometric mean of the available acute values and then divide each of the acute values for the species by the geometric mean for the species. This normalizes the acute values so that the geometric mean of the normalized values for each species individually and for any combination of species is 1.0.

E. Similarly normalize the values of the water quality characteristic for each species individually using the same procedure as above.

F. Individually for each species perform a least squares regression of the normalized ***15397** acute values of the water quality characteristic. The resulting slopes and 95 percent confidence limits will be identical to those obtained in section V.B. of this appendix. If, however, the data are actually plotted, the line of best fit for each individual species will go through the point 1,1 in the center of the graph.

G. Treat all of the normalized data as if they were all for the same species and perform a least squares regression of all of the normalized acute values on the corresponding normalized values of the water quality characteristic to obtain the pooled acute slope, V, and its 95 percent confidence limits. If all of the normalized data are actually plotted, the line of best fit will go through the point 1,1 in the center of the graph.

H. For each species calculate the geometric mean, W, of the acute toxicity values and the geometric mean, X, of the values of the water quality characteristic. (These were calculated in sections V.D and V.E of this appendix).

I. For each species, calculate the logarithm, Y, of the SMAV at a selected value, Z, of the water quality characteristic using the equation:

Y=ln WV(ln Xln Z)
J. For each species calculate the SMAV at X using the equation:

$SMAV=e^{Y}$
Note: Alternatively, the SMAVs at Z can be obtained by skipping step H above, using the equations in steps I and J to adjust each acute value individually to Z, and then calculating the geometric mean of the adjusted values for each species individually. This alternative procedure allows an examination of the range of the adjusted acute values for each species.

K. Obtain the FAV at Z by using the procedure described in sections IV.J through IV.O of this appendix.

L. If, for a commercially or recreationally important species of the Great Lakes System the geometric mean of the acute values at Z from flow-through tests in which the concentrations of the test material were measured is lower than the FAV at Z, then the geometric mean must be used as the FAV instead of the FAV.

M. The Final Acute Equation is written as:

$FAV=e^{(V[\ln(\text{water quality characteristic})]+AV[\ln Z])}$,
where:

V=pooled acute slope, and A=ln(FAV at Z).
Because V, A, and Z are known, the FAV can be calculated for any selected value of the water quality characteristic.

VI. Final Chronic Value

A. Depending on the data that are available concerning chronic toxicity to aquatic animals, the Final Chronic Value (FCV) can be calculated in the same manner as the FAV or by dividing the FAV by the Final Acute-Chronic Ratio (FACR). In some cases, it might not be possible to calculate a FCV. The FCV is (a) a calculated estimate of the concentration of a test material such that 95 percent of the genera (with which acceptable chronic toxicity tests have been conducted on the material) have higher GMCVs, or (b) the quotient of an FAV divided by an appropriate ACR, or (c) the SMCV of an important and/or critical species, if the SMCV is lower than the calculated estimate or the quotient, whichever is applicable.

Note: As the name implies, the ACR is a way of relating acute and chronic toxicities.

B. Chronic values shall be based on results of flow-through (except renewal is acceptable for daphnids) chronic tests in which the concentrations of test material in the test solutions were properly measured at appropriate times during the test. A chronic test is a comparative study in which organisms, that are subjected to different treatments, are observed for a long period or a substantial portion of their life span.

C. Results of chronic tests in which survival, growth, or reproduction in the control treatment was unacceptably low shall not be used. The limits of acceptability will depend on the species.

D. Results of chronic tests conducted in unusual dilution water, e.g., dilution water in which total organic carbon or particulate matter exceeded five mg/L, should not be used, unless a relationship is developed between chronic toxicity and organic carbon or particulate matter, or unless data show that organic carbon, particulate matter, etc., do not affect toxicity.

E. Chronic values must be based on endpoints and lengths of exposure appropriate to the species. Therefore, only results of the following kinds of chronic toxicity tests shall be used:

1. Life-cycle toxicity tests consisting of exposures of each of two or more groups of individuals of a species to a different concentration of the test material throughout a life cycle. To ensure that all life stages and life processes are exposed, tests with fish should begin with embryos or newly hatched young less than 48 hours old, continue through maturation and reproduction, and should end not less than 24 days (90 days for salmonids) after the hatching of the next generation. Tests with daphnids should begin with young less than 24 hours old and last for not less than 21 days, and for ceriodaphnids not less than seven days. For good examples of acceptable procedures see American Society for Testing and Materials (ASTM) Standard E 1193 Guide for conducting renewal life-cycle toxicity tests with Daphnia magna and ASTM Standard E 1295 Guide for conducting three-brood, renewal toxicity tests with Ceriodaphnia dubia. Tests with mysids should begin with young less than 24 hours old and continue until seven days past the median time of first brood release in the controls. For fish, data should be obtained and analyzed on survival and growth of adults and young, maturation of males and females, eggs spawned per female, embryo viability (salmonids only), and hatchability. For daphnids, data should be obtained and analyzed on survival and young per female. For mysids, data should be obtained and analyzed on survival, growth, and young per female.

2. Partial life-cycle toxicity tests consist of exposures of each of two more groups of individuals of a species of fish to a different concentration of the test material through most portions of a life cycle. Partial life-cycle tests are allowed with fish species that require more than a year to reach sexual maturity, so that all major life stages can be exposed to the test material in less than 15 months. A life-cycle test is a comparative study in which organisms, that are subjected to different treatments, are observed at least from a life stage in one generation to the same life-stage in the next generation. Exposure to the test material should begin with immature juveniles at least two months prior to active gonad development, continue through maturation and reproduction, and end not less than 24 days (90 days for salmonids) after the hatching of the next generation. Data should be obtained and

analyzed on survival and growth of adults and young, maturation of males and females, eggs spawned per female, embryo viability (salmonids only), and hatchability.

3. Early life-stage toxicity tests consisting of 28- to 32-day (60 days post hatch for salmonids) exposures of the early life stages of a species of fish from shortly after fertilization through embryonic, larval, and early juvenile development. Data should be obtained and analyzed on survival and growth.

Note: Results of an early life-stage test are used as predictions of results of life-cycle and partial life-cycle tests with the same species. Therefore, when results of a life-cycle or partial life-cycle test are available, results of an early life-stage test with the same species should not be used. Also, results of early life-stage tests in which the incidence of mortalities or abnormalities increased substantially near the end of the test shall not be used because the results of such tests are possibly not good predictions of comparable life-cycle or partial life-cycle tests.

F. A chronic value may be obtained by calculating the geometric mean of the lower and upper chronic limits from a chronic test or by analyzing chronic data using regression analysis.

1. A lower chronic limit is the highest tested concentration:

a. In an acceptable chronic test;

b. Which did not cause an unacceptable amount of adverse effect on any of the specified biological measurements; and

c. Below which no tested concentration caused an unacceptable effect.

2. An upper chronic limit is the lowest tested concentration:

a. In an acceptable chronic test;

b. Which did cause an unacceptable amount of adverse effect on one or more of the specified biological measurements; and,

c. Above which all tested concentrations also caused such an effect.

Note: Because various authors have used a variety of terms and definitions to interpret and report results of chronic tests, reported results should be reviewed carefully. The amount of effect that is considered unacceptable is often based on a statistical hypothesis test, but might also be defined in terms of a specified percent reduction from the controls. A small percent reduction (e.g., three percent) might be considered acceptable even if it is statistically significantly different from the control, whereas a large percent reduction (e.g., 30 percent) might be considered unacceptable even if it is not statistically significant.

G. If the chronic toxicity of the material to aquatic animals has been shown to be related ***15398** to a water quality characteristic such as hardness or particulate matter for freshwater animals, refer to section VII of this appendix.

H. If chronic values are available for species in eight families as described in section III.B.1 of this appendix, a SMCV shall be calculated for each species for which at least one chronic value is available by calculating the geometric mean of the results of all acceptable life-cycle and partial life-cycle toxicity tests with the species; for a species of fish for which no such result is available, the SMCV is the geometric mean of all acceptable early life-stage tests. Appropriate GMCVs shall also be calculated. A GMCV is the geometric mean of the SMCVs for the genus. The FCV shall be obtained using the procedure described in sections IV.J through IV.O of this appendix, substituting SMCV and GMCV for SMAV and GMAV respectively. See section VI.M of this appendix.

Note: Section VI.I through VI.L are for use when chronic values are not available for species in eight taxonomic families as described in section III.B.1 of this appendix.

I. For each chronic value for which at least one corresponding appropriate acute value is available, calculate an ACR, using for the numerator the geometric mean of the results of all acceptable flow-through (except static is acceptable for daphnids and midges) acute tests in the same dilution water in which the concentrations are measured. For fish, the acute test(s) should be conducted with juveniles. The acute test(s) should be part of the same study as the chronic test. If acute tests were not conducted as part of the same study, but were conducted as part of a different study in the same laboratory and dilution water, then they may be used. If no such acute tests are available, results of acute tests conducted in the same dilution water in a different laboratory may be used. If no such acute tests are available, an ACR shall not be calculated.

J. For each species, calculate the SMACR as the geometric mean of all ACRs available for that species. If the minimum ACR data requirements (as described in section III.B.2 of this appendix) are not met with freshwater data alone, saltwater data may be used along with the freshwater data.

K. For some materials, the ACR seems to be the same for all species, but for other materials the ratio seems to increase or decrease as the SMAV increases. Thus the FACR can be obtained in three ways, depending on the data available:

1. If the species mean ACR seems to increase or decrease as the SMAVs increase, the FACR shall be calculated as the geometric mean of the ACRs for species whose SMAVs are close to the FAV.

2. If no major trend is apparent and the ACRs for all species are within a factor of ten, the FACR shall be calculated as the geometric mean of all of the SMACRs.

3. If the most appropriate SMACRs are less than 2.0, and especially if they are less than 1.0, acclimation has probably occurred during the chronic test. In this situation, because continuous exposure and acclimation cannot be assured to provide adequate protection in field situations, the FACR should be assumed to be two, so that the FCV is equal to the Criterion Maximum Concentration (CMC). (See section X.B of this appendix.)

If the available SMACRs do not fit one of these cases, a FACR may not be obtained and a Tier I FCV probably cannot be calculated.

L. Calculate the FCV by dividing the FAV by the FACR.

FCV=FAV+FACR

If there is a Final Acute Equation rather than a FAV, see also section V of this appendix.
M. If the SMCV of a commercially or recreationally important species of the Great Lakes System is lower than the calculated FCV, then that SMCV must be used as the FCV instead of the calculated FCV.

N. See section VIII of this appendix.

VII. Final Chronic Equation

A. A Final Chronic Equation can be derived in two ways. The procedure described in section VII.A of this appendix will result in the chronic slope being the same as the acute slope. The procedure described in sections VII.B through N of this appendix will usually result in the chronic slope being different from the acute slope.

1. If ACRs are available for enough species at enough values of the water quality characteristic to indicate that the ACR appears to be the same for all species and appears to be independent of the water quality characteristic, calculate the FACR as the geometric mean of the available SMACRs.

2. Calculate the FCV at the selected value Z of the water quality characteristic by dividing the FAV at Z (see section V.M of this appendix) by the FACR.

3. Use V=pooled acute slope (see section V.M of this appendix), and

L=pooled chronic slope.

4. See section VII.M of this appendix.

B. When enough data are available to show that chronic toxicity to at least one species is related to a water quality characteristic, the relationship should be taken into account as described in sections C through G below or using analysis of covariance. The two methods are equivalent and produce identical results. The manual method described below provides an understanding of this application of covariance analysis, but computerized versions of covariance analysis are much more convenient for analyzing large data sets. If two or more factors affect toxicity, multiple regression analysis shall be used.

C. For each species for which comparable chronic toxicity values are available at two or more different values of the water quality characteristic, perform a least squares regression of the chronic toxicity values on the corresponding values of the water quality characteristic to obtain the slope and its 95 percent confidence limits for each species.

Note: Because the best documented relationship is that between hardness and acute toxicity of metals in fresh water and a log-log relationship fits these data, geometric means and natural logarithms of both toxicity and water quality are used in the rest of this section. For relationships based on other water quality characteristics, such as Ph, temperature, no transformation or a different transformation might fit the data better, and appropriate changes will be necessary throughout this section. It is probably preferable, but not necessary, to use the same transformation that was used with the acute values in section V of this appendix.

D. Decide whether the data for each species are relevant, taking into account the range and number of the tested values of the water quality characteristic and the degree of agreement within and between species. For example, a slope based on six data points might be of limited value if it is based only on data for a very narrow range of values of the water quality characteristic. A slope based on only two data points, however, might be more useful if it is consistent with other information and if the two points cover a broad range of the water quality characteristic. In addition, chronic values that appear to be questionable in comparison with other acute and chronic data available for the same species and for other species in the same genus in most cases should not be used. For example, if after adjustment for the water quality characteristic, the chronic values available for a species or genus differ by more than a factor of 10, rejection of some or all of the values is, in most cases, absent countervailing circumstances, appropriate. If a useful chronic slope is not available for at least one species or if the available slopes are too dissimilar or if too few data are available to adequately define the relationship between chronic toxicity and the water quality characteristic, it might be appropriate to assume that the chronic slope is the same as the acute slope, which is equivalent to assuming that the ACR is independent of the water quality characteristic. Alternatively, return to section VI.H of this appendix, using the results of tests conducted under conditions and in waters similar to those commonly used for toxicity tests with the species.

E. Individually for each species, calculate the geometric mean of the available chronic values and then divide each chronic value for a species by the mean for the species. This normalizes the chronic values so that the geometric mean of the normalized values for each species individually, and for any combination of species, is 1.0.

F. Similarly, normalize the values of the water quality characteristic for each species individually.

G. Individually for each species, perform a least squares regression of the normalized chronic toxicity values on the corresponding normalized values of the water quality characteristic. The resulting slopes and the 95 percent confidence limits will be identical to those obtained in section VII.B of this appendix. Now, however, if the data are actually plotted, the line of best fit for each individual species will go through the point 1,1 in the center of the graph.

H. Treat all of the normalized data as if they were all the same species and perform a least squares regression of all of the normalized chronic values on the corresponding normalized values of the water quality characteristic to obtain the pooled chronic slope, L, and its 95 percent confidence limits.

If all normalized data are actually plotted, the line of best fit will go through the point 1,1 in the center of the graph.

***15399** I. For each species, calculate the geometric mean, M, of the toxicity values and the geometric mean, P, of the values of the water quality characteristic. (These are calculated in sections VII.E and F of this appendix.)

J. For each species, calculate the logarithm, Q, of the SMCV at a selected value, Z, of the water quality characteristic using the equation:

$$Q=\ln M—L(\ln P\ln Z)$$

Note: Although it is not necessary, it is recommended that the same value of the water quality characteristic be used here as was used in section V of this appendix.

K. For each species, calculate a SMCV at Z using the equation:

$$SMCV=e^{Q}$$

Note: Alternatively, the SMCV at Z can be obtained by skipping section VII.J of this appendix, using the equations in sections VII.J and K of this appendix to adjust each chronic value individually to Z, and then calculating the geometric means of the adjusted values for each species individually. This alternative procedure allows an examination of the range of the adjusted chronic values for each species.

L. Obtain the FCV at Z by using the procedure described in sections IV.J through O of this appendix.

M. If the SMCV at Z of a commercially or recreationally important species of the Great Lakes System is lower than the calculated FCV at Z, then that SMCV shall be used as the FCV at Z instead of the calculated FCV.

N. The Final Chronic Equation is written as:

$$FCV=e^{(L[\ln(\text{water quality characteristic})]+\ln SL[\ln Z])}$$

Where:

L=pooled chronic slope and S = FCV at Z.
Because L, S, and Z are known, the FCV can be calculated for any selected value of the water quality characteristic.

VIII. Final Plant Value

A. A Final Plant Value (FPV) is the lowest plant value that was obtained with an important aquatic plant species in an acceptable toxicity test for which the concentrations of the test material were measured and the adverse effect was biologically important. Appropriate measures of the toxicity of the material to aquatic plants are used to compare the relative sensitivities of aquatic plants and animals. Although procedures for conducting and interpreting the results of toxicity tests with plants are not well-developed, results of tests with plants usually indicate that criteria which adequately protect aquatic animals and their uses will, in most cases, also protect aquatic plants and their uses.

B. A plant value is the result of a 96-hour test conducted with an alga or a chronic test conducted with an aquatic vascular plant.

Note: A test of the toxicity of a metal to a plant shall not be used if the medium contained an excessive amount of a complexing agent, such as EDTA, that might affect the toxicity of the metal. Concentrations of EDTA above 200 mg/L should be considered excessive.

C. The FPV shall be obtained by selecting the lowest result from a test with an important aquatic plant species in which the concentrations of test material are measured and the endpoint is biologically important.

IX. Other Data

Pertinent information that could not be used in earlier sections might be available concerning adverse effects on aquatic organisms. The most important of these are data on cumulative and delayed toxicity, reduction in survival, growth, or reproduction, or any other adverse effect that has been shown to be biologically important. Delayed toxicity is an adverse effect to an organism that results from, and occurs after the end of, its exposure to one or more test materials. Especially important are data for species for which no other data are available. Data from behavioral, biochemical, physiological, microcosm, and field studies might also be available. Data might be available from tests conducted in unusual dilution water (see sections IV.D and VI.D of this appendix), from chronic tests in which the concentrations were not measured (see section VI.B of this appendix), from tests with previously exposed organisms (see section II.F.3 of this appendix), and from tests on formulated mixtures or emulsifiable concentrates (see section II.D of this appendix). Such data might affect a criterion if the data were obtained with an important species, the test concentrations were measured, and the endpoint was biologically important.

X. Criterion

A. A criterion consists of two concentrations: the CMC and the Criterion Continuous Concentration (CCC).

B. The CMC is equal to one-half the FAV. The CMC is an estimate of the highest concentration of a material in the water column to which an aquatic community can be exposed briefly without resulting in an unacceptable effect.

C. The CCC is equal to the lowest of the FCV or the FPV (if available) unless other data (see section IX of this appendix) show that a lower value should be used. The CCC is an estimate of the highest concentration of a material in the water column to which an aquatic community can be exposed indefinitely without resulting in an unacceptable effect. If toxicity is related to a water quality characteristic, the CCC is obtained from the Final Chronic Equation or FPV (if available) that results in the lowest concentrations in the usual range of the water quality characteristic, unless other data (see section IX) show that a lower value should be used.

D. Round both the CMC and the CCC to two significant digits.

E. The criterion is stated as:

The procedures described in the Tier I methodology indicate that, except possibly where a commercially or recreationally important species is very sensitive, aquatic organisms should not be affected unacceptably if the four-day average concentration

of (1) does not exceed (2) mg/L more than once every three years on the average and if the one-hour average concentration does not exceed (3) mg/L more than once every three years on the average.

Where:

(1) = insert name of material

(2) = insert the CCC

(3) = insert the CMC

If the CMC averaging period of one hour or the CCC averaging period of four days is inappropriate for the pollutant, or if the once-in-three-year allowable excursion frequency is inappropriate for the pollutant or for the sites to which a criterion is applied, then the State may specify alternative averaging periods or frequencies. The choice of an alternative averaging period or frequency shall be justified by a scientifically defensible analysis demonstrating that the alternative values will protect the aquatic life uses of the water. Appropriate laboratory data and/or well-designed field biological surveys shall be submitted to EPA as justification for differing averaging periods and/or frequencies of exceedance.

XI. Final Review

A. The derivation of the criterion should be carefully reviewed by rechecking each step of the Guidance in this part. Items that should be especially checked are:

1. If unpublished data are used, are they well documented?

2. Are all required data available?

3. Is the range of acute values for any species greater than a factor of 10?

4. Is the range of SMAVs for any genus greater than a factor of 10?

5. Is there more than a factor of 10 difference between the four lowest GMAVs?

6. Are any of the lowest GMAVs questionable?

7. Is the FAV reasonable in comparison with the SMAVs and GMAVs?

8. For any commercially or recreationally important species of the Great Lakes System, is the geometric mean of the acute values from flow-through tests in which the concentrations of test material were measured lower than the FAV?

9. Are any of the chronic values used questionable?

10. Are any chronic values available for acutely sensitive species?

11. Is the range of acute-chronic ratios greater than a factor of 10?

12. Is the FCV reasonable in comparison with the available acute and chronic data?

13. Is the measured or predicted chronic value for any commercially or recreationally important species of the Great Lakes System below the FCV?

14. Are any of the other data important?

15. Do any data look like they might be outliers?

16. Are there any deviations from the Guidance in this part? Are they acceptable?

B. On the basis of all available pertinent laboratory and field information, determine if the criterion is consistent with sound scientific evidence. If it is not, another criterion, either higher or lower, shall be derived consistent with the Guidance in this part.

Methodology for Deriving Aquatic Life Values: Tier II

15400** ***XII. Secondary Acute Value

If all eight minimum data requirements for calculating an FAV using Tier I are not met, a Secondary Acute Value (SAV) for the waters of the Great Lakes System shall be calculated for a chemical as follows:

To calculate a SAV, the lowest GMAV in the database is divided by the Secondary Acute Factor (SAF) (Table A-1 of this appendix) corresponding to the number of satisfied minimum data requirements listed in the Tier I methodology (section III.B.1 of this appendix). (Requirements for definitions, data collection and data review, contained in sections I, II, and IV shall be applied to calculation of a SAV.) If all eight minimum data requirements are satisfied, a Tier I criterion calculation may be possible. In order to calculate a SAV, the database must contain, at a minimum, a genus mean acute value (GMAV) for one of the following three genera in the family Daphnidae—Ceriodaphnia sp., Daphnia sp., or Simocephalus sp.

If appropriate, the SAV shall be made a function of a water quality characteristic in a manner similar to that described in Tier I.

XIII. Secondary Acute-Chronic Ratio

If three or more experimentally determined ACRs, meeting the data collection and review requirements of Section VI of this appendix, are available for the chemical, determine the FACR using the procedure described in Section VI. If fewer than three acceptable experimentally determined ACRs are available, use enough assumed ACRs of 18 so that the total number of ACRs equals three. Calculate the Secondary Acute-Chronic Ratio (SACR) as the geometric mean of the three ACRs. Thus, if no experimentally determined ACRs are available, the SACR is 18.

XIV. Secondary Chronic Value

Calculate the Secondary Chronic Value (SCV) using one of the following:

If appropriate, the SCV will be made a function of a water quality characteristic in a manner similar to that described in Tier I.

XV. Commercially or Recreationally Important Species

If for a commercially or recreationally important species of the Great Lakes System the geometric mean of the acute values or chronic values from flow-through tests in which the concentrations of the test materials were measured is lower than the calculated SAV or SCV, then that geometric mean must be used as the SAV or SCV instead of the calculated SAV or SCV.

XVI. Tier II Value

A. A Tier II value shall consist of two concentrations: the Secondary Maximum Concentration (SMC) and the Secondary Continuous Concentration (SCC).

B. The SMC is equal to one-half of the SAV.

C. The SCC is equal to the lowest of the SCV or the Final Plant Value, if available, unless other data (see section IX of this appendix) show that a lower value should be used.

If toxicity is related to a water quality characteristic, the SCC is obtained from the Secondary Chronic Equation or FPV, if available, that results in the lowest concentrations in the usual range of the water quality characteristic, unless other data (See section IX of this appendix) show that a lower value should be used.

D. Round both the SMC and the SCC to two significant digits.

E. The Tier II value is stated as:

The procedures described in the Tier II methodology indicate that, except possibly where a locally important species is very sensitive, aquatic organisms should not be affected unacceptably if the four-day average concentration of (1) does not exceed (2) mg/L more than once every three years on the average and if the one-hour average concentration does not exceed (3) mg/L more than once every three years on the average.

Where:

(1) = insert name of material

(2) = insert the SCC

(3) = insert the SMC
As discussed above, States and Tribes have the discretion to specify alternative averaging periods or frequencies (see section X.E. of this appendix).

XVII. Appropriate Modifications
On the basis of all available pertinent laboratory and field information, determine if the Tier II value is consistent with sound scientific evidence. If it is not, another value, either higher or lower, shall be derived consistent with the Guidance in this part.

Table A-1.— Secondary Acute Factors

Number of minimum data requirements satisfied	Adjustment factor
1	21.9
2	13.0
3	8.0
4	7.0
5	6.1
6	5.2
7	4.3

Appendix B to Part 132—Great Lakes Water Quality Initiative

Methodology for Deriving Bioaccumulation Factors

Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) this appendix.

I. Introduction

A. The purpose of this methodology is to describe procedures for deriving bioaccumulation factors (BAFs) to be used in the calculation of Great Lakes Water Quality Guidance (Guidance) human health Tier I criteria and Tier II values and wildlife Tier I criteria. A subset of the human health BAFs are also used to identify the chemicals that are considered bioaccumulative chemicals of concern (BCCs).

B. Bioaccumulation reflects uptake of a substance by aquatic organisms exposed to the substance through all routes (i.e., ambient water and food), as would occur in nature. Bioconcentration reflects uptake of a substance by aquatic organisms exposed to the substance only through the ambient water. Both BAFs and bioconcentration factors (BCFs) are proportionality constants that describe the relationship between the concentration of a substance in aquatic organisms and its concentration in the ambient water. For the Guidance in this part, BAFs, rather than BCFs, are used to calculate Tier I criteria for human health and wildlife and Tier II values for human health because they better account for the total exposure of aquatic organisms to chemicals.

C. For organic chemicals, baseline BAFs can be derived using four methods. Measured baseline BAFs are derived from field-measured BAFs; predicted baseline BAFs are derived using biota-sediment accumulation factors (BSAFs) or are derived by multiplying a laboratory-measured or predicted BCF by a food-chain multiplier (FCM). The lipid content of the aquatic organisms is used to account for partitioning of organic chemicals within organisms so that data from different ***15401** tissues and species can be integrated. In addition, the baseline BAF is based on the concentration of freely dissolved organic chemicals in the ambient water to facilitate extrapolation from one water to another.

D. For inorganic chemicals, baseline BAFs can be derived using two of the four methods. Baseline BAFs are derived using either field-measured BAFs or by multiplying laboratory-measured BCFs by a FCM. For inorganic chemicals, BAFs are assumed to equal BCFs (i.e., the FCM is 1.0), unless chemical-specific biomagnification data support using a FCM other than 1.0.

E. Because both humans and wildlife consume fish from both trophic levels 3 and 4, two baseline BAFs are needed to calculate either a human health criterion or value or a wildlife criterion for a chemical. When appropriate, ingestion through consumption of invertebrates, plants, mammals, and birds in the diet of wildlife species to be protected may be taken into account.

II. Definitions

Baseline BAF. For organic chemicals, a BAF that is based on the concentration of freely dissolved chemical in the ambient water and takes into account the partitioning of the chemical within the organism; for inorganic chemicals, a BAF that is based on the wet weight of the tissue.

Baseline BCF. For organic chemicals, a BCF that is based on the concentration of freely dissolved chemical in the ambient water and takes into account the partitioning of the chemical within the organism; for inorganic chemicals, a BCF that is based on the wet weight of the tissue.

Bioaccumulation. The net accumulation of a substance by an organism as a result of uptake from all environmental sources.

Bioaccumulation factor (BAF). The ratio (in L/kg) of a substance's concentration in tissue of an aquatic organism to its concentration in the ambient water, in situations where both the organism and its food are exposed to and the ratio does not change substantially over time.

Bioconcentration. The net accumulation of a substance by an aquatic organism as a result of uptake directly from the ambient water through gill membranes or other external body surfaces.

Bioconcentration factor (BCF). The ratio (in L/kg) of a substance's concentration in tissue of an aquatic organism to its concentration in the ambient water, in situations where the organism is exposed through the water only and the ratio does not change substantially over time.

Biota-sediment accumulation factor (BSAF). The ratio (in kg of organic carbon/kg of lipid) of a substance's lipid-normalized concentration in tissue of an aquatic organism to its organic carbon-normalized concentration in surface sediment, in situations where the ratio does not change substantially over time, both the organism and its food are exposed, and the surface sediment is representative of average surface sediment in the vicinity of the organism.

Depuration. The loss of a substance from an organism as a result of any active or passive process.

Food-chain multiplier (FCM). The ratio of a BAF to an appropriate BCF.

Octanol-water partition coefficient (K_{OW}). The ration of the concentration of a substance in the n-octanol phase to its concentration in the aqueous phase in an equilibrated two-phase octanol-water system. For log K_{OW}, the log of the octanol-water partition coefficient is a base 10 logarithm.

Uptake. Acquisition of a substance from the environment by an organism as a result of any active or passive process.

III. Review and Selection of Data

A. Data Sources. Measured BAFs, BSAFs and BCFs are assembled from available sources including the following:

1. EPA Ambient Water Quality Criteria documents issued after January 1, 1980.

2. Published scientific literature.

3. Reports issued by EPA or other reliable sources.

4. Unpublished data.

One useful source of references is the Aquatic Toxicity Information Retrieval (AQUIRE) database.

B. Field-Measured BAFs. The following procedural and quality assurance requirements shall be met for field-measured BAFs:

1. The field studies used shall be limited to those conducted in the Great Lakes System with fish at or near the top of the aquatic food chain (i.e., in trophic levels 3 and/or 4).

2. The trophic level of the fish species shall be determined.

3. The site of the field study should not be so unique that the BAF cannot be extrapolated to other locations where the criteria and values will apply.

4. For organic chemicals, the percent lipid shall be either measured or reliably estimated for the tissue used in the determination of the BAF.

5. The concentration of the chemical in the water shall be measured in a way that can be related to particulate organic carbon (POC) and/or dissolved organic carbon (DOC) and should be relatively constant during the steady-state time period.

6. For organic chemicals with log K_{ow} greater than four, the concentrations of POC and DOC in the ambient water shall be either measured or reliably estimated.

7. For inorganic and organic chemicals, BAFs shall be used only if they are expressed on a wet weight basis; BAFs reported on a dry weight basis cannot be converted to wet weight unless a conversion factor is measured or reliably estimated for the tissue used in the determination of the BAF.

C. Field-Measured BSAFs. The following procedural and quality assurance requirements shall be met for field-measured BSAFs:

1. The field studies used shall be limited to those conducted in the Great Lakes System with fish at or near the top of the aquatic food chain (i.e., in trophic levels 3 and/or 4).

2. Samples of surface sediments (0-1 cm is ideal) shall be from locations in which there is net deposition of fine sediment and is representative of average surface sediment in the vicinity of the organism.

3. The K_{ow}s used shall be acceptable quality as described in section III.F below.

4. The site of the field study should not be so unique that the resulting BAF cannot be extrapolated to other locations where the criteria and values will apply.

5. The tropic level of the fish species shall be determined.

6. The percent lipid shall be either measured or reliably estimated for the tissue used in the determination of the BAF.

D. Laboratory-Measured BCFs. The following procedural and quality assurance requirements shall be met for laboratory-measured BCFs:

1. The test organism shall not be diseased, unhealthy, or adversely affected by the concentration of the chemical.

2. The total concentration of the chemical in the water shall be measured and should be relatively constant during the steady-state time period.

3. The organisms shall be exposed to the chemical using a flow-through or renewal procedure.

4. For organic chemicals, the percent lipid shall be either measured or reliably estimated for the tissue used in the determination of the BCF.

5. For organic chemicals with log K_{ow} greater than four, the concentrations of POC and DOC in the test solution shall be either measured or reliably estimated.

6. Laboratory-measured BCFs should be determined using fish species, but BCFs determined with molluscs and other invertebrates may be used with caution. For example, because invertebrates metabolize some chemicals less efficiently than vertebrates, a baseline BCF determined for such a chemical using invertebrates is expected to be higher than a comparable baseline BCF determined using fish.

7. If laboratory-measured BCFs increase or decrease as the concentration of the chemical increases in the test solutions in a bioconcentration test, the BCF measured at the lowest test concentration that is above concentrations existing in the control water shall be used (i.e., a BCF should be calculated from a control treatment). The concentrations of an inorganic chemical in a bioconcentration test should be greater than normal background levels and greater than levels required for normal nutrition of the test species if the chemical is a micronutrient, but below levels that adversely affect the species. Bioaccummulation of an inorganic chemical might be overestimated if concentrations are at or below normal background levels due to, for example, nutritional requirements of the test organisms.

8. For inorganic and organic chemicals, BCFs shall be used only if they are expressed on a wet weight basis. BCFs reported on a dry weight basis cannot be converted to wet weight unless a conversion factor is measured or reliably estimated for the tissue used in the determination of the BAF.

9. BCFs for organic chemicals may be based on measurement or radioactivity only when the BCF is intended to include metabolites or when there is confidence that there is no interference due to metabolites.

10. The calculation of the BCF must appropriately address growth dilution.

11. Other aspects of the methodology used should be similar to those described by ASTM (1990).

***15402** E. Predicted BCFs. The following procedural and quality assurance requirements shall be met for predicted BCFs:

1. The K_{ow} used shall be of acceptable quality as described in section III.F below.

2. The predicted baseline BCF shall be calculated using the equation: predicted baseline BCF = K_{ow}

where:

K_{ow} = octanol-water partition coefficient.

F. Octanol-Water Partition Coefficient (K_{ow}). 1. The value of K_{ow} used for an organic chemical shall be determined by giving priority to the experimental and computational techniques used as follows:

Log K_{ow} < 4:

Priority	Technique
1	Slow-stir.
1	Generator-column.
1	Shake-flask.
2	Reverse-phase liquid chromatography on C18 chromatography packing with extrapolation to zero percent solvent.
3	Reverse-phase liquid chromatography on C18 chromatography packing without extrapolation to zero percent solvent.
4	Calculated by the CLOGP program.

Log K_{ow} > 4:

Priority	Technique
1	Slow Stir.
1	Generator-column.
2	Reverse-phase liquid chromatography on C18 chromatography packing with extrapolation to zero percent solvent.
3	Reverse-phase liquid chromatography on C18 chromatography packing without extrapolation to zero percent solvent.
4	Shake-flask.
5	Calculated by the CLOGP program.

2. The CLOGP program is a computer program available from Pomona College. A value of K_{ow} that seems to be different from the others should be considered an outlier and not used. The value of K_{ow} used for an organic chemical shall be the geometric mean of the available K_{ow}s with highest priority or can be calculated from the arithmetic mean of the available log K_{ow} with the highest priority. Because it is an intermediate value in the derivation of a BAF, the value used for the K_{ow} of a chemical should not be rounded to fewer than three significant digits and a value for log K_{ow} should not be rounded to fewer than three significant digits after the decimal point.

G. This methodology provides overall guidance for the derivation of BAFs, but it cannot cover all the decisions that must be made in the review and selection of acceptable data. Professional judgment is required throughout the process. A degree of uncertainty is associated with the determination of any BAF, BSAF, BCF or K_{ow}. The amount of uncertainty in a baseline BAF depends on both the quality of data available and the method used to derive the BAF.

H. Hereinafter in this methodology, the terms BAF, BSAF, BCF and K_{ow} refer to ones that are consistent with the procedural and quality assurance requirements given above.

IV. Four Methods for Deriving Baseline BAFs

Baseline BAFs shall be derived using the following four methods, which are listed from most preferred to least preferred:

A. A measured baseline BAF for an organic or inorganic chemical derived from a field study of acceptable quality.

B. A predicted baseline BAF for an organic chemical derived using field-measured BSAFs of acceptable quality.

C. A predicted baseline BAF for an organic or inorganic chemical derived from a BCF measured in a laboratory study of acceptable quality and a FCM.

D. A predicted baseline BAF for an organic chemical derived from a K_{ow} of acceptable quality and a FCM.

For comparative purposes, baseline BAFs should be derived for each chemical by as many of the four methods as available data allow.

V. Calculation of Baseline BAFs for Organic Chemicals

A. Lipid Normalization. 1. It is assumed that BAFs and BCFs for organic chemicals can be extrapolated on the basis of percent lipid from one tissue to another and from one aquatic species to another in most cases.

2. Because BAFs and BCFs for organic chemicals are related to the percent lipid, it does not make any difference whether the tissue sample is whole body or edible portion, but both the BAF (or BCF) and the percent lipid must be determined for the same tissue. The percent lipid of the tissue should be measured during the BAF or BCF study, but in some cases it can be reliably estimated from measurements on tissue from other organisms. If percent lipid is not reported for the test organisms in the original study, it may be obtained from the author; or, in the case of a laboratory study, lipid data for the same or a comparable laboratory population of test organisms that were used in the original study may be used.

3. The lipid-normalized concentration, C_l, of a chemical in tissue is defined using the following equation:

Where:

C_B=concentration of the organic chemical in the tissue of aquatic biota (either whole organism or specified tissue) (MUg/g).

f_l=fraction of the tissue that is lipid.

B. Bioavailability. By definition, baseline BAFs and BCFs for organic chemicals, whether measured or predicted are based on the concentration of the chemical that is freely dissolved in the ambient water in order to account for bioavailability. For the purposes of this Guidance in this part, the relationship between the total concentration of the chemical in the water (i.e., that which is freely dissolved plus that which is sorbed to particulate organic carbon or to dissolved organic carbon) to the freely dissolved concentration of the chemical in the ambient water shall be calculated using the following equation:

Where:

C^{fd}_w=freely dissolved concentration of the organic chemical in the ambient water;

C^{t}_w=total concentration of the organic chemical in the ambient water;

f_{fd}=fraction of the total chemical in the ambient water that is freely dissolved.

The fraction of the total chemical in the ambient water that is freely dissolved, f_{fd}, shall be calculated using the following equation:

Where:

DOC=concentration of dissolved organic carbon, kg of dissolved organic carbon/L of water.

K_{OW}=octanol-water partition coefficient of the chemical.

POC=concentration of particulate organic carbon, kg of particulate organic carbon/L of water.

C. Food-Chain Multiplier. In the absence of a field-measured BAF or a predicted BAF derived from a BSAF, a FCM shall be used to calculate the baseline BAF for trophic levels 3 and 4 from a laboratory-measured or predicted BCF. For an organic chemical, the FCM used shall be derived from Table B-1 using the chemical's log K_{OW} and linear interpolation. A FCM greater than 1.0 applies to most organic chemicals with a log K_{OW} of four or more. The trophic level used shall take into account the age or size of the fish species consumed by the human, avian or mammalian predator because, for some species of fish, the young are in trophic level 3 whereas the adults are in trophic level 4.

D. Calculation of a Baseline BAF from a Field-Measured BAF. A baseline BAF shall be calculated from a field-measured BAF of acceptable quality using the following equation:

***15403** Where:

BAF^{t}_{T}=BAF based on total concentration in tissue and water.

f_l=fraction of the tissue that is lipid.

f_{fd}=fraction of the total chemical that is freely dissolved in the ambient water.

The trophic level to which the baseline BAF applies is the same as the trophic level of the organisms used in the determination of the field-measured BAF. For each trophic level, a species mean measured baseline BAF shall be calculated as the geometric mean if more than one measured baseline BAF is available for a given species. For each trophic level, the geometric mean of the species mean measured baseline BAFs shall be calculated. If a baseline BAF based on a measured BAF is available for either trophic level 3 or 4, but not both, a measured baseline BAF for the other trophic level shall be calculated using the ratio of the FCMs that are obtained by linear interpolation from Table B-1 for the chemical.
E. Calculation of a Baseline BAF from a Field-Measured BSAF. 1. A baseline BAF for organic chemical “i” shall be calculated from a field-measured BSAF of acceptable quality using the following equation:

Where:

$(BSAF)_i$=BSAF for chemical “i”.

$(BSAF)_r$=BSAF for the reference chemical “r”.

$(K_{OW})_i$=octanol-water partition coefficient for chemical “i”.

$(K_{OW})_r$=octanol-water partition coefficient for the reference chemical “r”.
2. A BSAF shall be calculated using the following equation:

Where:

C_t=the lipid-normalized concentration of the chemical in tissue.

C_{SOC}=the organic carbon-normalized concentration of the chemical in sediment.
3. The organic carbon-normalized concentration of a chemical in sediment, C_{SOC}, shall be calculated using the following equation:

Where:

C_S=concentration of chemical in sediment (mg/g sediment).

f_{OC}=fraction of the sediment that is organic carbon.
4. Predicting BAFs from BSAFs requires data from a steady-state (or near steady-state) condition between sediment and ambient water for both a reference chemical “r” with a field-measured BAF_l^{fd} and other chemicals “n=i” for which BSAFs are to be determined.

5. The trophic level to which the baseline BAF applies is the same as the trophic level of the organisms used in the determination of the BSAF. For each trophic level, a species mean baseline BAF shall be calculated as the geometric mean if more than one baseline BAF is predicted from BSAFs for a given species. For each trophic level, the geometric mean of the species mean baseline BAFs derived using BSAFs shall be calculated.

6. If a baseline BAF based on a measured BSAF is available for either trophic level 3 or 4, but not both, a baseline BAF for the other trophic level shall be calculated using the ratio of the FCMs that are obtained by linear interpolation from Table B-1 for the chemical.

F. Calculation of a Baseline BAF from a Laboratory-Measured BCF. A baseline BAF for trophic level 3 and a baseline BAF for trophic level 4 shall be calculated from a laboratory-measured BCF of acceptable quality and a FCM using the following equation:

Where:

$BCF^{t}T$=BCF based on total concentration in tissue and water.

fl=fraction of the tissue that is lipid.

f_{fd}=fraction of the total chemical in the test water that is freely dissolved.

FCM=the food-chain multiplier obtained from Table B-1 by linear interpolation for trophic level 3 or 4, as necessary.

For each trophic level, a species mean baseline BAF shall be calculated as the geometric mean if more than one baseline BAF is predicted from laboratory-measured BCFs for a given species. For each trophic level, the geometric mean of the species mean baseline BAFs based on laboratory-measured BCFs shall be calculated.

G. Calculation of a Baseline BAF from an Octanol-Water Partition Coefficient. A baseline BAF for trophic level 3 and a baseline BAF for trophic level 4 shall be calculated from a K_{OW} of acceptable quality and a FCM using the following equation:

Baseline BAF=(FCM) (predicted baseline BCF)=(FCM) (K_{OW})

Where:

FCM=the food-chain multiplier obtained from Table B-1 by linear interpolation for trophic level 3 or 4, as necessary.

K_{OW}=octanol-water partition coefficient.

VI. Human Health and Wildlife BAFs for Organic Chemicals

A. To calculate human health and wildlife BAFs for an organic chemical, the K_{OW} of the ***15404** y15404[chemical shall be used with a POC concentration of 0.00000004 kg/L and a DOC concentration of 0.000002 kg/L to yield the fraction freely dissolved:

B. The human health BAFs for an organic chemical shall be calculated using the following equations:

For trophic level 3:

For trophic level 4:

Where:
0.0182 and 0.0310 are the standardized fraction lipid values for trophic levels 3 and 4, respectively, that are used to derive human health criteria and values for the GLI.

C. The wildlife BAFs for an organic chemical shall be calculated using the following equations:

For trophic level 3:

For trophic level 4:

Where:
0.0646 and 0.1031 are the standardized fraction lipid values for trophic levels 3 and 4, respectively, that are used to derive wildlife criteria for the GLI.

VII. Human Health and Wildlife BAFs for Inorganic Chemicals

A. For inorganic chemicals, the baseline BAFs for trophic levels 3 and 4 are both assumed to equal the BCF determined for the chemical with fish, i.e., the FCM is assumed to be 1 for both trophic levels 3 and 4. However, a FCM greater than 1 might be applicable to some metals, such as mercury, if, for example, an organometallic form of the metal biomagnifies.

B. BAFs for Human Health Criteria and Values.

1. Measured BAFs and BCFs used to determine human health BAFs for inorganic chemicals shall be based on edible tissue (e.g., muscle) of freshwater fish unless it is demonstrated that whole-body BAFs or BCFs are similar to edible-tissue BAFs or BCFs. BCFs and BAFs based on measurements of aquatic plants and invertebrates should not be used in the derivation of human health criteria and values.

2. If one or more field-measured baseline BAFs for an inorganic chemical are available from studies conducted in the Great Lakes System with the muscle of fish:

a. For each trophic level, a species mean measured baseline BAF shall be calculated as the geometric mean if more than one measured BAF is available for a given species; and

b. For each trophic level, the geometric mean of the species mean measured baseline BAFs shall be used as the human health BAF for that chemical.

3. If an acceptable measured baseline BAF is not available for an inorganic chemical and one or more acceptable edible-portion laboratory-measured BCFs are available for the chemical, a predicted baseline BAF shall be calculated by multiplying the geometric mean of the BCFs times a FCM. The FCM will be 1.0 unless chemical-specific biomagnification data support using a multiplier other than 1.0. The predicted baseline BAF shall be used as the human health BAF for that chemical.

C. BAFs for Wildlife Criteria.

1. Measured BAFs and BCFs used to determine wildlife BAFs for inorganic chemicals shall be based on whole-body freshwater fish and invertebrate data unless it is demonstrated that edible-tissue BAFs or BCFs are similar to whole-body BAFs or BCFs.

***15405** 2. If one or more field-measured baseline BAFs for an inorganic chemical are available from studies conducted in the Great Lakes System with whole body of fish or invertebrates:

2. For each trophic level, a species mean measured baseline BAF shall be calculated as the geometric mean if more than one measured BAF is available for a given species.

b. For each trophic level, the geometric mean of the species mean measured baseline BAFs shall be used as the wildlife BAF for that chemical.

3. If an acceptable measured baseline BAF is not available for an inorganic chemical and one or more acceptable whole-body laboratory-measured BCFs are available for the chemical, a predicted baseline BAF shall be calculated by multiplying the geometric mean of the BCFs times a FCM. The FCM will be 1.0 unless chemical-specific biomagnification data support using a multiplier other than 1.0. The predicted baseline BAF shall be used as the wildlife BAF for that chemical.

VIII. Final Review

For both organic and inorganic chemicals, human health and wildlife BAFs for both trophic levels shall be reviewed for consistency with all available data concerning the bioaccumulation, bioconcentration, and metabolism of the chemical. For example, information concerning octanol-water partitioning, molecular size, or other physicochemical properties that might enhance or inhibit bioaccumulation should be considered for organic chemicals. BAFs derived in accordance with this methodology should be modified if changes are justified by available data.

***15406 Appendix C to Part 132—Great Lakes Water Quality Initiative Methodologies for Development of Human Health Criteria and Values**

Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) this appendix.

I. Introduction

Great Lakes States and Tribes shall adopt provisions consistent with this appendix C to ensure protection of human health.

A. Goal. The goal of the human health criteria for the Great Lakes System is the protection of humans from unacceptable exposure to toxicants via consumption of contaminated fish and drinking water and from ingesting water as a result of participation in water-oriented recreational activities.

B. Definitions.

Acceptable daily exposure (ADE). An estimate of the maximum daily dose of a substance which is not expected to result in adverse noncancer effects to the general human population, including sensitive subgroups.

Adverse effect. Any deleterious effect to organisms due to exposure to a substance. This includes effects which are or may become debilitating, harmful or toxic to the normal functions of the organism, but does not include non-harmful effects such as tissue discoloration alone or the induction of enzymes involved in the metabolism of the substance.

Carcinogen. A substance which causes an increased incidence of benign or malignant neoplasms, or substantially decreases the time to develop neoplasms, in animals or humans. The classification of carcinogens is discussed in section II.A of appendix C to part 132.

Human cancer criterion (HCC). A Human Cancer Value (HCV) for a pollutant that meets the minimum data requirements for Tier I specified in appendix C.

Human cancer value (HCV). The maximum ambient water concentration of a substance at which a lifetime of exposure from either: drinking the water, consuming fish from the water, and water-related recreation activities; or consuming fish from the water, and water-related recreation activities, will represent a plausible upper-bound risk of contracting cancer of one in 100,000 using the exposure assumptions specified in the Methodologies for the Development of Human Health Criteria and Values in appendix C of this part.

Human noncancer criterion (HNC). A Human Noncancer Value (HNV) for a pollutant that meets the minimum data requirements for Tier I specified in appendix C of this part.

Human noncancer value (HNV). The maximum ambient water concentration of a substance at which adverse noncancer effects are not likely to occur in the human population from lifetime exposure via either: drinking the water, consuming fish from the water, and water-related recreation activities; or consuming fish from the water, and water-related recreation activities using the Methodologies for the Development of Human Health criteria and Values in appendix C of this part.

Linearized multi-stage model. A conservative mathematical model for cancer risk assessment. This model fits linear dose-response curves to low doses. It is consistent with a no-threshold model of carcinogenesis, i.e., exposure to even a very small amount of the substance is assumed to produce a finite increased risk of cancer.

Lowest observed adverse effect level (LOAEL). The lowest tested dose or concentration of a substance which resulted in an observed adverse effect in exposed test organisms when all higher doses or concentrations resulted in the same or more severe effects.

No observed adverse effect level (NOAEL). The highest tested dose or concentration of a substance which resulted in no observed adverse effect in exposed test organisms where higher doses or concentrations resulted in an adverse effect.

Quantitative structure activity relationship (OSAR) or structure activity relationship (SAR). A mathematical relationship between a property (activity) of a chemical and a number of descriptors of the chemical. These descriptors are chemical or physical characteristics obtained experimentally or predicted from the structure of the chemical.

Relative source contribution (RSC). The factor (percentage) used in calculating an HNV or HNC to account for all sources of exposure to a contaminant. The RSC reflects the percent of total exposure which can be attributed to surface water through water intake and fish consumption.

Risk associated dose (RAD). A dose of a known or presumed carcinogenic substance in (mg/kg/day) which, over a lifetime of exposure, is estimated to be associated with a plausible upper bound incremental cancer risk equal to one in 100,000.

Slope factor. Also known as q_1*, slope factor is the incremental rate of cancer development calculated through use of a linearized multistage model or other appropriate model. It is expressed in (mg/kg/day) of exposure to the chemical in question.

Threshold effect. An effect of a substance for which there is a theoretical or empirically established dose or concentration below which the effect does not occur.

Uncertainty factor (UF). One of several numeric factors used in operationally deriving criteria from experimental data to account for the quality or quantity of the available data.

C. Level of Protection. The criteria developed shall provide a level of protection likely to be without appreciable risk of carcinogenic and/or noncarcinogenic effects. Criteria are a function of the level of designated risk or no adverse effect estimation, selection of data and exposure assumptions. Ambient criteria for single carcinogens shall not be set at a level representing a lifetime upper-bound incremental risk greater than one in 100,000 of developing cancer using the hazard assessment techniques and exposure assumptions described herein. Criteria affording protection from noncarcinogenic effects shall be established at levels that, taking into account uncertainties, are considered likely to be without an appreciable risk of adverse human health effects (i.e., acute, subchronic and chronic toxicity including reproductive and developmental effects) during a lifetime of exposure, using the risk assessment techniques and exposure assumptions described herein.

D. Two-tiered Classification. Chemical concentration levels in surface water protective of human health shall be derived based on either a Tier I or Tier II classification. The two Tiers are primarily distinguished by the amount of toxicity data available for deriving the concentration levels and the quantity and quality of data on bioaccumulation.

II. Minimum Data Requirements

The best available toxicity data on the adverse health effects of a chemical and the best data on bioaccumulation factors shall be used when developing human health Tier I criteria or Tier II values. The best available toxicity data shall include data from well ***15407** -conducted epidemiologic and/or animal studies which provide, in the case of carcinogens, an adequate weight of evidence of potential human carcinogenicity and, in the case of noncarcinogens, a dose-response relationship involving critical effects biologically relevant to humans. Such information should be obtained from the EPA Integrated Risk Information System (IRIS) database, the scientific literature, and other informational databases, studies and/or reports containing adverse health effects data of adequate quality for use in this procedure. Strong consideration shall be given to the most currently available guidance provided by IRIS in deriving criteria or values, supplemented with any recent data not incorporated into IRIS. When deviations from IRIS are anticipated or considered necessary, it is strongly recommended that such actions be communicated to the EPA Reference Dose (RfD) and/or the Cancer Risk Assessment Verification Endeavor (CRAVE) workgroup immediately. The best available bioaccumulation data shall include data from field studies and well-conducted laboratory studies.

A. Carcinogens. Tier I criteria and Tier II values shall be derived using the methodologies described in section III.A of this appendix when there is adequate evidence of potential human carcinogenic effects for a chemical. It is strongly recommended that the EPA classification system for chemical carcinogens, which is described in the 1986 EPA Guidelines for Carcinogenic Risk Assessment (U.S. EPA, 1986), or future modifications thereto, be used in determining whether adequate evidence of potential carcinogenic effects exists. Carcinogens are classified, depending on the weight of evidence, as either human carcinogens, probable human carcinogens, or possible human carcinogens. The human evidence is considered inadequate and therefore the chemical cannot be classified as a human carcinogen, if one of two conditions exists: (a) there are few pertinent data, or (b) the available studies, while showing evidence of association, do not exclude chance, bias, or confounding and therefore a casual interpretation is not credible. The animal evidence is considered inadequate, and therefore the chemical cannot

be classified as a probable or possible human carcinogen, when, because of major qualitative or quantitative limitations, the evidence cannot be interpreted as showing either the presence or absence of a carcinogenic effect.

Chemicals are described as “human carcinogens” when there is sufficient evidence from epidemiological studies to support a causal association between exposure to the chemicals and cancer. Chemicals described as “probable human carcinogens” include chemicals for which the weight of evidence of human carcinogenicity based on epidemiological studies is limited. Limited human evidence is that which indicates that a causal interpretation is credible, but that alternative explanations, such as chance, bias, or confounding, cannot adequately be excluded. Probable human carcinogens are also agents for which there is sufficient evidence from animal studies and for which there is inadequate evidence or no data from epidemiologic studies. Sufficient animal evidence is data which indicates that there is an increased incidence of malignant tumors or combined malignant and benign tumors: (a) in multiple species or strains; (b) in multiple experiments (e.g., with different routes of administration or using different dose levels); or (c) to an unusual degree in a single experiment with regard to high incidence, unusual site or type of tumor, or early age at onset. Additional evidence may be provided by data on dose-response effects, as well as information from short-term tests (such as mutagenicity/genotoxicity tests which help determine whether the chemical interacts directly with DNA) or on chemical structure, metabolism or mode of action.

“Possible human carcinogens” are chemicals with limited evidence of carcinogenicity in animals in the absence of human data. Limited animal evidence is defined as data which suggests a carcinogenic effect but are limited because: (a) The studies involve a single species, strain, or experiment and do not meet criteria for sufficient evidence (see preceding paragraph); or (b) the experiments are restricted by inadequate dosage levels, inadequate duration of exposure to the agent, inadequate period of follow-up, poor survival, too few animals, or inadequate reporting; or (c) the studies indicate an increase in the incidence of benign tumors only. More specifically, this group can include a wide variety of evidence, e.g., (a) a malignant tumor response in a single well-conducted experiment that does not meet conditions for sufficient evidence, (b) tumor response of marginal statistical significance in studies having inadequate design or reporting, (c) benign but not malignant tumors with an agent showing no response in a variety of short-term tests for mutagenicity, and (d) response of marginal statistical significance in a tissue known to have a high or variable background rate.

1. Tier I: Weight of evidence of potential human carcinogenic effects sufficient to derive a Tier I HCC shall generally include human carcinogens, probable human carcinogens and can include, on a case-by-case basis, possible human carcinogens if studies have been well-conducted albeit based on limited evidence, when compared to studies used in classifying human and probable human carcinogens. The decision to use data on a possible human carcinogen for deriving Tier I criteria shall be a case-by-case determination. In determining whether to derive a Tier I HCC, additional evidence that shall be considered includes but is not limited to available information on mode of action, such as mutagenicity/genotoxicity (determinations of whether the chemical interacts directly with DNA), structure activity, and metabolism.

2. Tier II: Weight of evidence of possible human carcinogenic effects sufficient to derive a Tier II human cancer value shall include those possible human carcinogens for which there are at a minimum, data sufficient for quantitative risk assessment, but for which data are inadequate for Tier I criterion development due to a tumor response of marginal statistical significance or inability to derive a strong dose-response relationship. In determining whether to derive Tier II human cancer values, additional evidence that shall be considered includes but is not limited to available information on mode of action such as mutagenicity/ genotoxicity (determinations of whether the chemical interacts directly with DNA), structure activity and metabolism. As with the use of data on possible human carcinogens in developing Tier I criteria, the decision to use data on possible human carcinogens to derive Tier II values shall be made on a case-by-case basis.

B. Noncarcinogens. All available toxicity data shall be evaluated considering the full range of possible health effects of a chemical, i.e., acute/subacute, chronic/subchronic and reproductive/developmental effects, in order to best describe the dose-response relationship of the chemical, and to calculate human noncancer criteria and values which will protect against the most sensitive endpoint(s) of toxicity. Although it is desirable to have an extensive database which considers a wide range of possible adverse effects, this type of data exists for a very limited number of chemicals. For many others, there is a range in quality

and quantity of data available. To assure minimum reliability of criteria and values, it is necessary to establish a minimum database with which to develop Tier I criteria or Tier II values. The following represent the minimum data sets necessary for this procedure.

1. Tier I: The minimum data set sufficient to derive a Tier I human HNC shall include at least one well-conducted epidemiologic study or animal study. A well-conducted epidemiologic study for a Tier I HNC must quantify exposure level(s) and demonstrate positive association between exposure to a chemical and adverse effect(s) in humans. A well-conducted study in animals must demonstrate a dose response relationship involving one or more critical effect(s) biologically relevant to humans. (For example, study results from an animal whose pharmacokinetics and toxicokinetics match those of a human would be considered most biologically relevant.) Ideally, the duration of a study should span multiple generations of exposed test species or at least a major portion of the lifespan of one generation. This type of data is currently very limited. By the use of uncertainty adjustments, shorter term studies (such as 90-day subchronic studies) with evaluation of more limited effect(s) may be used to extrapolate to longer exposures or to account for a variety of adverse effects. For Tier I criteria developed pursuant to this procedure, such a limited study must be conducted for at least 90 days in rodents or 10 percent of the lifespan of other appropriate test species and demonstrate a no observable adverse effect level (NOAEL). Chronic studies of one year or longer in rodents or 50 percent of the lifespan or greater in other appropriate test species that demonstrate a lowest observable adverse effect level (LOAEL) may be sufficient for use in Tier I criterion derivation if the effects observed at the LOAEL were relatively mild and reversible as compared to ***15408** effects at higher doses. This does not preclude the use of a LOAEL from a study (of chronic duration) with only one or two doses if the effects observed appear minimal when compared to effect levels observed at higher doses in other studies.

2. Tier II: When the minimum data for deriving Tier I criteria are not available to meet the Tier I data requirements, a more limited database may be considered for deriving Tier II values. As with Tier I criteria, all available data shall be considered and ideally should address a range of adverse health effects with exposure over a substantial portion of the lifespan (or multiple generations) of the test species. When such data are lacking it may be necessary to rely on less extensive data in order to establish a Tier II value. With the use of appropriate uncertainty factors to account for a less extensive database, the minimum data sufficient to derive a Tier II value shall include a NOAEL from at least one well-conducted short-term repeated dose study. This study shall be of at least 28 days duration, in animals demonstrating a dose-response, and involving effects biologically relevant to humans. Data from studies of longer duration (greater than 28 days) and LOAELs from such studies (greater than 28 days) may be more appropriate in some cases for derivation of Tier II values. Use of a LOAEL should be based on consideration of the following information: severity of effect, quality of the study and duration of the study.

C. Bioaccumulation factors (BAFs).

1. Tier I for Carcinogens and Noncarcinogens: To be considered a Tier I cancer or noncancer human health criterion, along with satisfying the minimum toxicity data requirements of sections II.A.1 and II.B.1 of this appendix, a chemical must have the following minimum bioaccumulation data. For all organic chemicals either: (a) a field-measured BAF; (b) a BAF derived using the BSAF methodology; or (c) a chemical with a BAF less than 125 regardless of how the BAF was derived. For all inorganic chemicals, including organometals such as mercury, either: (a) a field-measured BAF or (b) a laboratory-measured BCF.

2. Tier II for Carcinogens and Noncarcinogens: A chemical is considered a Tier II cancer or noncancer human health value if it does not meet either the minimum toxicity data requirements of sections II.A.1 and II.B.1 of this appendix or the minimum bioaccumulation data requirements of section II.C.1 of this appendix.

III. Principles for Development of Tier I Criteria or Tier II Values

The fundamental components of the procedure to calculate Tier I criteria or Tier II values are the same. However, certain of the aspects of the procedure designed to account for short-duration studies or other limitations in data are more likely to be relevant in deriving Tier II values than Tier I criteria.

A. Carcinogens.

1. A non-threshold mechanism of carcinogenesis shall be assumed unless biological data adequately demonstrate the existence of a threshold on a chemical-specific basis.

2. All appropriate human epidemiologic data and animal cancer bioassay data shall be considered. Data specific to an environmentally appropriate route of exposure shall be used. Oral exposure should be used preferentially over dermal and inhalation since, in most cases, the exposure routes of greatest concern are fish consumption and drinking water/incidental ingestion. The risk associated dose shall be set at a level corresponding to an incremental cancer risk of one in 100,000. If acceptable human epidemiologic data are available for a chemical, it shall be used to derive the risk associated dose. If acceptable human epidemiologic data are not available, the risk associated dose shall be derived from available animal bioassay data. Data from a species that is considered most biologically relevant to humans (i.e., responds most like humans) is preferred where all other considerations regarding quality of data are equal. In the absence of data to distinguish the most relevant species, data from the most sensitive species tested, i.e., the species showing a carcinogenic effect at the lowest administered dose, shall generally be used.

3. When animal bioassay data are used and a non-threshold mechanism of carcinogenicity is assumed, the data are fitted to a linearized multistage computer model (e.g., Global '86 or equivalent model). Global '86 is the linearized multistage model, derived by Howe, Crump and Van Landingham (1986), which EPA uses to determine cancer potencies. The upper-bound 95 percent confidence limit on risk (or, the lower 95 percent confidence limit on dose) at the one in 100,000 risk level shall be used to calculate a risk associated dose (RAD). Other models, including modifications or variations of the linear multistage model which are more appropriate to the available data may be used where scientifically justified.

4. If the duration of the study is significantly less than the natural lifespan of the test animal, the slope may be adjusted on a case-by-case basis to compensate for latent tumors which were not expressed (e.g., U.S. EPA, 1980) In the absence of alternative approaches which compensate for study durations significantly less than lifetime, the permitting authority may use the process described in the 1980 National Guidelines (see 45 FR 79352).

5. A species scaling factor shall be used to account for differences between test species and humans. It shall be assumed that milligrams per surface area per day is an equivalent dose between species (U.S. EPA, 1986). All doses presented in mg/kg bodyweight will be converted to an equivalent surface area dose by raising the mg/kg dose to the 2/3 power. However, if adequate pharmacokinetic and metabolism studies are available, these data may be factored into the adjustment for species differences on a case-by-case basis.

6. Additional data selection and adjustment decisions must also be made in the process of quantifying risk. Consideration must be given to tumor selection for modeling, e.g., pooling estimates for multiple tumor types and identifying and combining benign and malignant tumors. All doses shall be adjusted to give an average daily dose over the study duration. Adjustments in the rate of tumor response must be made for early mortality in test species. The goodness-of-fit of the model to the data must also be assessed.

7. When a linear, non-threshold dose response relationship is assumed, the RAD shall be calculated using the following equation:

Where:

RAD=risk associated dose in milligrams of toxicant per kilogram body weight per day (mg/kg/day).

0.00001 (110^{5})=incremental risk of developing cancer equal to one in 100,000.

q_1*=slope factor $(mg/kg/day)^{1}$.

8. If human epidemiologic data and/or other biological data (animal) indicate that a chemical causes cancer via a threshold mechanism, the risk associated dose may, on a case-by-case basis, be calculated using a method which assumes a threshold mechanism is operative.

B. Noncarcinogens.

1. Noncarcinogens shall generally be assumed to have a threshold dose or concentration below which no adverse effects should be observed. Therefore, the Tier I criterion or Tier II value is the maximum water concentration of a substance at or below which a lifetime exposure from drinking the water, consuming fish caught in the water, and ingesting water as a result of participating in water-related recreation activities is likely to be without appreciable risk of deleterious effects.

For some noncarcinogens, there may not be a threshold dose below which no adverse effects should be observed. Chemicals acting as genotoxic teratogens and germline mutagens are thought to possibly produce reproductive and/or developmental effects via a genetically linked mechanism which may have no threshold. Other chemicals also may not demonstrate a threshold. Criteria for these types of chemicals will be established on a case-by-case basis using appropriate assumptions reflecting the likelihood that no threshold exists.

2. All appropriate human and animal toxicologic data shall be reviewed and evaluated. To the maximum extent possible, data most specific to the environmentally relevant route of exposure shall be used. Oral exposure data should be used preferentially over dermal and inhalation since, in most cases, the exposure routes of greatest concern are fish consumption and drinking water/incidental ingestion. When acceptable human data are not available (e.g., well-conducted epidemiologic studies), animal data from species most biologically relevant to humans shall be used. In the absence of data to distinguish the most relevant species, data from the most sensitive animal species tested, i.e., the species showing a toxic effect at the lowest administered dose (given a relevant route of exposure), should generally be used.

***15409** 3. Minimum data requirements are specified in section II.B of this appendix. The experimental exposure level representing the highest level tested at which no adverse effects were demonstrated (NOAEL) from studies satisfying the provisions of section II.B of this appendix shall be used for criteria calculations. In the absence of a NOAEL, the LOAEL from studies satisfying the provisions of section II.B of this appendix may be used if it is based on relatively mild and reversible effects.

4. Uncertainty factors shall be used to account for the uncertainties in predicting acceptable dose levels for the general human population based upon experimental animal data or limited human data.

a. An uncertainty factor of 10 shall generally be used when extrapolating from valid experimental results from studies on prolonged exposure to average healthy humans. This 10-fold factor is used to protect sensitive members of the human population.

b. An uncertainty factor of 100 shall generally be used when extrapolating from valid results of long-term studies on experimental animals when results of studies of human exposure are not available or are inadequate. In comparison to a, above, this represents an additional 10-fold uncertainty factor in extrapolating data from the average animal to the average human.

c. An uncertainty factor of up to 1000 shall generally be used when extrapolating from animal studies for which the exposure duration is less than chronic, but greater than subchronic (e.g., 90 days or more in length), or when other significant deficiencies in study quality are present, and when useful long-term human data are not available. In comparison to b, above, this represents an additional UF of up to 10-fold for less than chronic, but greater than subchronic, studies.

d. An UF of up to 3000 shall generally be used when extrapolating from animal studies for which the exposure duration is less than subchronic (e.g., 28 days). In comparison to b above, this represents an additional UF of up to 30-fold for less than

subchronic studies (e.g., 28-day). The level of additional uncertainty applied for less than chronic exposures depends on the duration of the study used relative to the lifetime of the experimental animal.

e. An additional UF of between one and ten may be used when deriving a criterion from a LOAEL. This UF accounts for the lack of an identifiable NOAEL. The level of additional uncertainty applied may depend upon the severity and the incidence of the observed adverse effect.

f. An additional UF of between one and ten may be applied when there are limited effects data or incomplete sub-acute or chronic toxicity data (e.g., reproductive/developmental data). The level of quality and quantity of the experimental data available as well as structure-activity relationships may be used to determine the factor selected.

g. When deriving an UF in developing a Tier I criterion or Tier II value, the total uncertainty, as calculated following the guidance of sections 4.a through f, cited above, shall not exceed 10,000 for Tier I criteria and 30,000 for Tier II values.

5. All study results shall be converted, as necessary, to the standard unit for acceptable daily exposure of milligrams of toxicant per kilogram of body weight per day (mg/kg/day). Doses shall be adjusted for continuous exposure (i.e., seven days/week, 24 hours/day, etc.).

C. Criteria and Value Derivation.

1. Standard Exposure Assumptions. The following represent the standard exposure assumptions used to calculate Tier I criteria and Tier II values for carcinogens and noncarcinogens. Higher levels of exposure may be assumed by States and Tribes pursuant to Clean Water Act (CWA) section 510, or where appropriate in deriving site-specific criteria pursuant to procedure 1 in appendix F to part 132.

BW = body weight of an average human (BW = 70kg).

WC_d = per capita water consumption (both drinking and incidental exposure) for surface waters classified as public water supplies = two liters/day.

—or—

WC_r = per capita incidental daily water ingestion for surface waters not used as human drinking water sources = 0.01 liters/day.

FC = per capita daily consumption of regionally caught freshwater fish = 0.015kg/day (0.0036 kg/day for trophic level 3 and 0.0114 kg/day for trophic level 4).

BAF = bioaccumulation factor for trophic level 3 and trophic level 4, as derived using the BAF methodology in appendix B to part 132.

2. Carcinogens. The Tier I human cancer criteria or Tier II values shall be calculated as follows:

Where:

HCV=Human Cancer Value in milligrams per liter (mg/L).

RAD=Risk associated dose in milligrams toxicant per kilogram body weight per day (mg/kg/day) that is associated with a lifetime incremental cancer risk equal to one in 100,000.

BW=weight of an average human (BW=70 kg).

WC_d=per capita water consumption (both drinking and incidental exposure) for surface waters classified as public water supplies=two liters/day.

or

WC_r=per capita incidental daily water ingestion for surface waters not used as human drinking water sources=0.01 liters/day.

FC_{TL3}=mean consumption of trophic level 3 of regionally caught freshwater fish=0.0036 kg/day.

FC_{TL4}=mean consumption of trophic level 4 of regionally caught freshwater fish=0.0114 kg/day.

BAF^{HH}_{TL3}=bioaccumulation factor for trophic level 3 fish, as derived using the BAF methodology in appendix B to part 132.

BAF^{HH}_{TL4}=bioaccumulation factor for trophic level 4 fish, as derived using the BAF methodology in appendix B to part 132.
3. Noncarcinogens. The Tier I human noncancer criteria or Tier II values shall be calculated as follows:

Where:

HNV=Human noncancer value in milligrams per liter (mg/L).

ADE=Acceptable daily exposure in milligrams toxicant per kilogram body weight per day (mg/kg/day).

RSC=Relative source contribution factor of 0.8. An RSC derived from actual exposure data may be developed using the methodology outlined by the 1980 National Guidelines (see 45 FR 79354).

BW=weight of an average human (BW=70 kg).

WC_d=per capita water consumption (both drinking and incidental exposure) for surface waters classified as public water supplies=two liters/day.

or

WC_r=per capita incidental daily water ingestion for surface waters not used as human drinking water sources=0.01 liters/day.

***15410** FC_{TL3}=mean consumption of trophic level 3 fish by regional sport fishers of regionally caught freshwater fish=0.0036 kg/day.

FC_{TL4}=mean consumption of trophic level 4 fish by regional sport fishers of regionally caught freshwater fish=0.0114 kg/day.

BAF^{HH}_{TL3}=human health bioaccumulation factor for edible portion of trophic level 3 fish, as derived using the BAF methodology in appendix B to part 132.

BAF^{HH}_{TL4}=human health bioaccumulation factor for edible portion of trophic level 4 fish, as derived using the BAF methodology in appendix B to part 132.

Appendix D to Part 132—Great Lakes Water Quality Initiative Methodology for the Development of Wildlife Criteria

Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) this appendix.

I. Introduction

A. A Great Lakes Water Quality Wildlife Criterion (GLWC) is the concentration of a substance which is likely to, if not exceeded, protect avian and mammalian wildlife populations inhabiting the Great Lakes basin from adverse effects resulting from the ingestion of water and aquatic prey taken from surface waters of the Great Lakes System. These criteria are based on existing toxicological studies of the substance of concern and quantitative information about the exposure of wildlife species to the substance (i.e., food and water consumption rates). Since toxicological and exposure data for individual wildlife species are limited, a GLWC is derived using a methodology similar to that used to derive noncancer human health criteria (Barnes and Dourson, 1988; NAS, 1977; NAS, 1980; U.S. EPA, 1980). Separate avian and mammalian values are developed using taxonomic class-specific toxicity data and exposure data for five representative Great Lakes basin wildlife species. The wildlife species selected are representative of avian and mammalian species resident in the Great Lakes basin which are likely to experience the highest exposures to bioaccumulative contaminants through the aquatic food web; they are the bald eagle, herring gull, belted kingfisher, mink, and river otter.

B. This appendix establishes a methodology which is required when developing Tier I wildlife criteria for bioaccumulative chemicals of concern (BCCs). The use of the equation provided in the methodology is encouraged, but not required, for the development of Tier I criteria or Tier II values for pollutants other than those identified in Table 6-A for which Tier I criteria or Tier II values are determined to be necessary for the protection of wildlife in the Great Lakes basin. A discussion of the methodology for deriving Tier II values can be found in the Great Lakes Water Quality Initiative Technical Support Document for Wildlife Criteria (Wildlife TSD).

C. In the event that this methodology is used to develop criteria for pollutants other than BCCs, or in the event that the Tier II methodology described in the Wildlife TSD is used to derive Tier II values, the methodology for deriving bioaccumulation factors under appendix B to part 132 must be used in either derivation. For chemicals which do not biomagnify to the extent of BCCs, it may be appropriate to select different representative species which are better examples of species with the highest exposures for the given chemical. The equation presented in this methodology, however, is still encouraged. In addition, procedure 1 of appendix F of this part describes the procedures for calculating site-specific wildlife criteria.

D. The term “wildlife value” (WV) is used to denote the value for each representative species which results from using the equation presented below, the value obtained from averaging species values within a class, or any value derived from application of the site-specific procedure provided in procedure 1 of appendix F of this part. The WVs calculated for the representative species are used to calculate taxonomic class-specific WVs. The WV is the concentration of a substance which, if not exceeded, should better protect the taxon in question.

E. “Tier I wildlife criterion,” or “Tier I criterion” is used to denote the number derived from data meeting the Tier I minimum database requirements, and which will be protective of the two classes of wildlife. It is synonymous with the term “GLWC,” and the two are used interchangeably.

II. Calculation of Wildlife Values for Tier I Criteria

Table 4 of Part 132 and Table D-1 of this appendix contain criteria calculated by EPA using the methodology provided below.

A. Equation for Avian and Mammalian Wildlife Values. Tier I wildlife values for the pollutants designated BCCs pursuant to part 132 are to be calculated using the equation presented below.

Where:

WV=Wildlife Value in milligrams of substance per liter (mg/L).

TD=Test Dose (TD) in milligrams of substance per kilograms per day (mg/kg-d) for the test species. This shall be either a NOAEL or a LOAEL.

UF_A=Uncertainty Factor (UF) for extrapolating toxicity data across species (unitless). A species-specific UF shall be selected and applied to each representative species, consistent with the equation.

UF_S=UF for extrapolating from subchronic to chronic exposures (unitless).

UF_L=UF for LOAEL to NOAEL extrapolations (unitless).

Wt=Average weight in kilograms (kg) for the representative species.

W=Average daily volume of water consumed in liters per day (L/d) by the representative species.

F_{TLi}=Average daily amount of food consumed from trophic level i in kilograms per day (kg/d) by the representative species.

BAF^{WL}_{TLi}=Bioaccumulation factor (BAF) for wildlife food in trophic level i in liters per kilogram (L/kg), developed using the BAF methodology in appendix B to part 132, Methodology for Development of Bioaccumulation Factors. For consumption of piscivorous birds by other birds (e.g., herring gull by eagles), the BAF is derived by multiplying the trophic level 3 BAF for fish by a biomagnification factor to account for the biomagnification from fish to the consumed birds.

B. Identification of Representative Species for Protection. For bioaccumulative chemicals, piscivorous species are identified as the focus of concern for wildlife criteria development in the Great Lakes. An analysis of known or estimated exposure components for avian and mammalian wildlife species is presented in the Wildlife TSD. This analysis identifies three avian species (eagle, kingfisher and herring gull) and two mammalian species (mink and otter) as representative species for protection. The TD obtained from toxicity data for each taxonomic class is used to calculate WVs for each of the five representative species.

C. Calculation of Avian and Mammalian Wildlife Values and GLWC Derivation. The avian WV is the geometric mean of the WVs calculated for the three representative avian species. The mammalian WV is the geometric mean of the WVs calculated for the two representative mammalian species. The lower of the mammalian and avian WVs must be selected as the GLWC.

III. Parameters of the Effect Component of the Wildlife Criteria Methodology

A. Definitions. The following definitions provide additional specificity and guidance in the evaluation of toxicity data and the application of this methodology.

Acceptable endpoints. For the purpose of wildlife criteria derivation, acceptable subchronic and chronic endpoints are those which affect reproductive or developmental success, organismal viability or growth, or any other endpoint which is, or is directly related to, parameters that influence population dynamics.

***15411** Chronic effect. An adverse effect that is measured by assessing an acceptable endpoint, and results from continual exposure over several generations, or at least over a significant part of the test species' projected life span or life stage.

Lowest-observed-adverse-effect-level (LOAEL). The lowest tested dose or concentration of a substance which resulted in an observed adverse effect in exposed test organisms when all higher doses or concentrations resulted in the same or more severe effects.

No-observed-adverse-effect-level (NOAEL). The highest tested dose or concentration of a substance which resulted in no observed adverse effect in exposed test organisms where higher doses or concentrations resulted in an adverse effect.

Subchronic effect. An adverse effect, measured by assessing an acceptable endpoint, resulting from continual exposure for a period of time less than that deemed necessary for a chronic test.

B. Minimum Toxicity Database for Tier I Criteria Development. A TD value is required for criterion calculation. To derive a Tier I criterion for wildlife, the data set shall provide enough data to generate a subchronic or chronic dose-response curve for any given substance for both mammalian and avian species. In reviewing the toxicity data available which meet the minimum data requirements for each taxonomic class, the following order of preference shall be applied to select the appropriate TD to be used for calculation of individual WVs. Data from peer-reviewed field studies of wildlife species take precedence over other types of studies, where such studies are of adequate quality. An acceptable field study must be of subchronic or chronic duration, provide a defensible, chemical-specific dose-response curve in which cause and effect are clearly established, and assess acceptable endpoints as defined in this document. When acceptable wildlife field studies are not available, or determined to be of inadequate quality, the needed toxicity information may come from peer-reviewed laboratory studies. When laboratory studies are used, preference shall be given to laboratory studies with wildlife species over traditional laboratory animals to reduce uncertainties in making interspecies extrapolations. All available laboratory data and field studies shall be reviewed to corroborate the final GLWC, to assess the reasonableness of the toxicity value used, and to assess the appropriateness of any UFs which are applied. When evaluating the studies from which a test dose is derived in general, the following requirements must be met:

1. The mammalian data must come from at least one well-conducted study of 90 days or greater designed to observe subchronic or chronic effects as defined in this document.

2. The avian data must come from at least one well-conducted study of 70 days or greater designed to observe subchronic or chronic effects as defined in this document.

3. In reviewing the studies from which a TD is derived for use in calculating a WV, studies involving exposure routes other than oral may be considered only when an equivalent oral daily dose can be estimated and technically justified because the criteria calculations are based on an oral route of exposure.

4. In assessing the studies which meet the minimum data requirements, preference should be given to studies which assess effects on developmental or reproductive endpoints because, in general, these are more important endpoints in ensuring that a population's productivity is maintained. The Wildlife TSD provides additional discussion on the selection of an appropriate toxicity study.

C. Selection of TD Data. In selecting data to be used in the derivation of WVs, the evaluation of acceptable endpoints, as defined in Section III.A of this appendix, will be the primary selection criterion. All data not part of the selected subset may be used to assess the reasonableness of the toxicity value and the appropriateness of the Ufs which are applied.

1. If more than one TD value is available within a taxonomic class, based on different endpoints of toxicity, that TD, which is likely to reflect best potential impacts to wildlife populations through resultant changes in mortality or fecundity rates, shall be used for the calculation of WVs.

2. If more than one TD is available within a taxonomic class, based on the same endpoint of toxicity, the TD from the most sensitive species shall be used.

3. If more than one TD based on the same endpoint of toxicity is available for a given species, the TD for that species shall be calculated using the geometric mean of those TDs.

D. Exposure Assumptions in the Determination of the TD. 1. In those cases in which a TD is available in units other than milligrams of substance per kilograms per day (mg/kg/d), the following procedures shall be used to convert the TD to the appropriate units prior to calculating a WV.

2. If the TD is given in milligrams of toxicant per liter of water consumed by the test animals (mg/L), the TD shall be multiplied by the daily average volume of water consumed by the test animals in liters per day (L/d) and divided by the average weight of the test animals in kilograms (kg).

3. If the TD is given in milligrams of toxicant per kilogram of food consumed by the test animals (mg/kg), the TD shall be multiplied by the average amount of food in kilograms consumed daily by the test animals (kg/d) and divided by the average weight of the test animals in kilograms (kg).

E. Drinking and Feeding Rates. 1. When drinking and feeding rates and body weight are needed to express the TD in milligrams of substance per kilograms per day (mg/kg/d), they are obtained from the study from which the TD was derived. If not already determined, body weight, and drinking and feeding rates are to be converted to a wet weight basis.

2. If the study does not provide the needed values, the values shall be determined from appropriate scientific literature. For studies done with domestic laboratory animals, either the Registry of Toxic Effects of Chemical Substances (National Institute for Occupational Safety and Health, the latest edition, Cincinnati, OH), or Recommendations for and Documentation of Biological Values for Use in Risk Assessment (U.S. EPA, 1988) should be consulted. When these references do not contain exposure information for the species used in a given study, either the allometric equations from Calder and Braun (1983) and Nagy (1987), which are presented below, or the exposure estimation methods presented in Chapter 4 of the Wildlife Exposure Factors Handbook (U.S. EPA, 1993), should be applied to approximate the needed feeding or drinking rates. Additional discussion and recommendations are provided in the Wildlife TSD. The choice of the methods described above is at the discretion of the State or Tribe.

3. For mammalian species, the general allometric equations are:

a. $F = 0.0687 (Wt)^{0.82}$

Where:

F = Feeding rate of mammalian species in kilograms per day (kg/d) dry weight.

Wt = Average weight in kilograms (kg) of the test animals.

b. $W = 0.099 (Wt)^{0.90}$

Where:

W = Drinking rate of mammalian species in liters per day (L/d).

Wt = Average weight in kilograms (kg) of the test animals.
4. For avian species, the general allometric equations are:

a. $F = 0.0582 (Wt)^{0.65}$

Where:

F = Feeding rate of avian species in kilograms per day (kg/d) dry weight.

Wt = Average weight in kilograms (kg) of the test animals.
b. $W = 0.059 (Wt)^{0.67}$

Where:

W = Drinking rate of avian species in liters per day (L/d).

Wt = Average weight in kilograms (kg) of the test animals.
F. LOAEL to NOAEL Extrapolations (UF_L). In those cases in which a NOAEL is unavailable as the TD and a LOAEL is available, the LOAEL may be used to estimate the NOAEL. If used, the LOAEL shall be divided by an UF to estimate a NOAEL for use in deriving WVs. The value of the UF shall not be less than one and should not exceed 10, depending on the dose-response curve and any other available data, and is represented by UF_L in the equation expressed in Section II.A of this appendix. Guidance for selecting an appropriate UF_L, based on a review of available wildlife toxicity data, is available in the Wildlife TSD.

G. Subchronic to Chronic Extrapolations (US_S). In instances where only subchronic data are available, the TD may be derived from subchronic data. In such cases, the TD shall be divided by an UF to extrapolate from subchronic to chronic levels. The value of the UF shall not be less than one and should not exceed 10, and is represented by UF_S in the equation expressed in Section II.A of this appendix. This factor is to be used when assessing highly bioaccumulative substances where toxicokinetic considerations suggest that a bioassay of limited length ***15412** underestimates chronic effects. Guidance for selecting an appropriate UF_S, based on a review of available wildlife toxicity data, is available in the Wildlife TSD.

H. Interspecies Extrapolations (UF_A). 1. The selection of the UF_A shall be based on the available toxicological data and on available data concerning the physicochemical, toxicokinetic, and toxicodynamic properties of the substance in question and the amount and quality of available data. This value is an UF that is intended to account for differences in toxicological sensitivity among species. Guidance for selecting an appropriate UF_A, based on a review of available wildlife toxicity data, is available in the Wildlife TSD. Additional discussion of an interspecies UF located in appendix A to the Great Lakes Water Quality Initiative Technical Support Document for Human Health Criteria may be useful in determining the appropriate value for UF_A.

2. For the derivation of Tier I criteria, a UF_A shall not be less than one and should not exceed 100, and shall be applied to each of the five representative species, based on existing data and best professional judgment. The value of UF_A may differ for each of the representative species.

3. For Tier I wildlife criteria, the UF_A shall be used only for extrapolating toxicity data across species within a taxonomic class, except as provided below. The Tier I UF_A is not intended for interclass extrapolations because of the poorly defined comparative toxicokinetic and toxicodynamic parameters between mammals and birds. However, an interclass extrapolation

employing a UF_A may be used for a given chemical if it can be supported by a validated biologically-based dose-response model or by an analysis of interclass toxicological data, considering acceptable endpoints, for a chemical analog that acts under the same mode of toxic action.

IV. Parameters of the Exposure Component of the Wildlife Criteria Methodology

A. Drinking and Feeding Rates of Representative Species. The body weights (Wt), feeding rates (F_{Tli}), drinking rates (W), and trophic level dietary composition (as food ingestion rate and percent in diet) for each of the five representative species are presented in Table D-2 of this appendix. Guidance on incorporating the non-aquatic portion of the bald eagle and mink diets in the criteria calculations is available in the Wildlife TSD.

B. BAFs. The Methodology for Development of Bioaccumulation Factors is presented in appendix B to part 132. Trophic level 3 and 4 BAFs are used to derive Wvs because these are the trophic levels at which the representative species feed.

Appendix E to Part 132—Great Lakes Water Quality Initiative Antidegradation Policy

Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) appendix E to part 132.

The State or Tribe shall adopt an antidegradation standard applicable to all waters of the Great Lakes System and identify the methods for implementing such a standard. Consistent with 40 CFR 131.12, an acceptable antidegradation standard and implementation procedure are required elements of a State's or Tribe's water quality standards program. Consistent with 40 CFR 131.6, a complete water quality standards submission needs to include both an antidegradation standard and antidegradation implementation procedures. At a minimum, States and Tribes shall adopt provisions in their antidegradation standard and implementation methods consistent with sections I, II, III and IV of this appendix, applicable to pollutants identified as bioaccumulative chemicals of concern (BCCs).

I. Antidegradation Standard

This antidegradation standard shall be applicable to any action or activity by any source, point or nonpoint, of pollutants that is anticipated to result in an increased loading of BCCs to surface waters of the Great Lakes System and for which independent regulatory authority exists requiring compliance with water quality standards. Pursuant to this standard:

A. Existing instream water uses, as defined pursuant to 40 CFR 131, and the level of water quality necessary to protect existing uses shall be maintained and protected. Where designated uses of the waterbody are impaired, there shall be no lowering of the water quality with respect to the pollutant or pollutants which are causing the impairment;

B. Where, for any parameter, the quality of the waters exceed levels necessary to support the propagation of fish, shellfish, and wildlife and recreation in and on the waters, that water shall be considered high quality for that parameter consistent

with the definition of high quality water found at section II.A of this appendix and that quality ***15413** shall be maintained and protected unless the State or Tribe finds, after full satisfaction of intergovernmental coordination and public participation provisions of the State's or Tribe's continuing planning process, that allowing lower water quality is necessary to accommodate important economic or social development in the area in which the waters are located. In allowing such degradation, the State or Tribe shall assure water quality adequate to protect existing uses fully. Further, the State or Tribe shall assure that there shall be achieved the highest statutory and regulatory requirements for all new and existing point sources and all cost-effective and reasonable best management practices for nonpoint source control. The State or Tribe shall utilize the Antidegradation Implementation Procedures adopted pursuant to the requirements of this regulation in determining if any lowering of water quality will be allowed;

C. Where high quality waters constitute an outstanding national resource, such as waters of national and State parks and wildlife refuges and waters of exceptional recreational or ecological significance, that water quality shall be maintained and protected; and

D. In those cases where the potential lowering of water quality is associated with a thermal discharge, the decision to allow such degradation shall be consistent with section 316 of the Clean Water Act (CWA).

II. Antidegradation Implementation Procedures

A. Definitions.

Control Document. Any authorization issued by a State, Tribal or Federal agency to any source of pollutants to waters under its jurisdiction that specifies conditions under which the source is allowed to operate.

High quality waters. High quality waters are water bodies in which, on a parameter by parameter basis, the quality of the waters exceeds levels necessary to support propagation of fish, shellfish, and wildlife and recreation in and on the water.

Lake Superior Basin—Outstanding International Resource Waters. Those waters designated as such by a Tribe or State consistent with the September 1991 Bi-National Program to Restore and Protect the Lake Superior Basin. The purpose of such designations shall be to ensure that any new or increased discharges of Lake Superior bioaccumulative substances of immediate concern are subject to best technology in process and treatment requirements.

Lake Superior Basin—Outstanding National Resource Waters. Those waters designated as such by a Tribe or State consistent with the September 1991 Bi-National Program to Restore and Protect the Lake Superior Basin. The purpose of such designations shall be to prohibit new or increased discharges of Lake Superior bioaccumulative substances of immediate concern from point sources in these areas.

Lake Superior bioaccumulative substances of immediate concern. A list of substances identified in the September 1991 Bi-National Program to Restore and Protect the Lake Superior Basin. They include: 2, 3, 7, 8-TCDD; octachlorostyrene; hexachlorobenzene; chlordane; DDT, DDE, and other metabolites; toxaphene; PCBs; and mercury. Other chemicals may be added to the list following States' or Tribes' assessments of environmental effects and impacts and after public review and comment.

Outstanding National Resource Waters. Those waters designated as such by a Tribe or State. The State or Tribal designation shall describe the quality of such waters to serve as the benchmark of the water quality that shall be maintained and protected. Waters that may be considered for designation as Outstanding National Resource Waters include, but are not limited to, water bodies that are recognized as:

Important because of protection through official action, such as Federal or State law, Presidential or secretarial action, international treaty, or interstate compact;

Having exceptional recreational significance;

Having exceptional ecological significance;

Having other special environmental, recreational, or ecological attributes; or waters whose designation as Outstanding National Resource Waters is reasonably necessary for the protection of other waters so designated.

Significant Lowering of Water Quality. A significant lowering of water quality occurs when there is a new or increased loading of any BCC from any regulated existing or new facility, either point source or nonpoint source for which there is a control document or reviewable action, as a result of any activity including, but not limited to:

(1) Construction of a new regulated facility or modification of an existing regulated facility such that a new or modified control document is required;

(2) Modification of an existing regulated facility operating under a current control document such that the production capacity of the facility is increased;

(3) Addition of a new source of untreated or pretreated effluent containing or expected to contain any BCC to an existing wastewater treatment works, whether public or private;

(4) A request for an increased limit in an applicable control document;

(5) Other deliberate activities that, based on the information available, could be reasonably expected to result in an increased loading of any BCC to any waters of the Great Lakes System.

b. Notwithstanding the above, changes in loadings of any BCC within the existing capacity and processes, and that are covered by the existing applicable control document, are not subject to an antidegradation review. These changes include, but are not limited to:

(1) Normal operational variability;

(2) Changes in intake water pollutants;

(3) Increasing the production hours of the facility, (e.g., adding a second shift); or

(4) Increasing the rate of production.

C. Also, excluded from an antidegradation review are new effluent limits based on improved monitoring data or new water quality criteria or values that are not a result of changes in pollutant loading.

B. For all waters, the Director shall ensure that the level of water quality necessary to protect existing uses is maintained. In order to achieve this requirement, and consistent with 40 CFR 131.10, water quality standards use designations must include all existing uses. Controls shall be established as necessary on point and nonpoint sources of pollutants to ensure that the criteria applicable to the designated use are achieved in the water and that any designated use of a downstream water is protected. Where water quality does not support the designated uses of a waterbody or ambient pollutant concentrations exceed water quality criteria applicable to that waterbody, the Director shall not allow a lowering of water quality for the pollutant or pollutants preventing the attainment of such uses or exceeding such criteria.

C. For Outstanding National Resource Waters:

1. The Director shall ensure, through the application of appropriate controls on pollutant sources, that water quality is maintained and protected.

2. Exception. A short-term, temporary (i.e., weeks or months) lowering of water quality may be permitted by the Director.

D. For high quality waters, the Director shall ensure that no action resulting in a lowering of water quality occurs unless an antidegradation demonstration has been completed pursuant to section III of this appendix and the information thus provided is determined by the Director pursuant to section IV of this appendix to adequately support the lowering of water quality.

1. The Director shall establish conditions in the control document applicable to the regulated facility that prohibit the regulated facility from undertaking any deliberate action, such that there would be an increase in the rate of mass loading of any BCC, unless an antidegradation demonstration is provided to the Director and approved pursuant to section IV of this appendix prior to commencement of the action. Imposition of limits due to improved monitoring data or new water quality criteria or values, or changes in loadings of any BCC within the existing capacity and processes, and that are covered by the existing applicable control document, are not subject to an antidegradation review.

2. For BCCs known or believed to be present in a discharge, from a point or nonpoint source, a monitoring requirement shall be included in the control document. The control document shall also include a provision requiring the source to notify the Director or any increased loadings. Upon notification, the Director shall require actions as necessary to reduce or eliminate the increased loading.

3. Fact Sheets prepared pursuant to 40 CFR 124.8 and 124.56 shall reflect any conditions developed under sections II.D.1 or II.D.2 of this appendix and included in a permit.

E. Special Provisions for Lake Superior.The following conditions apply in addition to those specified in section II.B through II.C of this appendix for waters of Lake Superior so designated.

1. A State or Tribe may designate certain specified areas of the Lake Superior Basin as Lake Superior Basin—Outstanding National Resource Waters for the purpose of prohibiting the new or increased discharge of Lake Superior bioaccumulative substances of immediate concern from point sources in these areas.

2. States and Tribes may designate all waters of the Lake Superior Basin as Outstanding International Resource Waters for the purpose of restricting the increased discharge of ***15414** Lake Superior bioaccumulative substances of immediate concern from point sources consistent with the requirements of sections III.C and IV.B of this appendix.

F. Exemptions. Except as the Director may determine on a case-by-case basis that the application of these procedures is required to adequately protect water quality, or as the affected waterbody is an Outstanding National Resource Water as defined in section II.A of this appendix, the procedures in this part do not apply to:

1. Short-term, temporary (i.e., weeks or months) lowering of water quality;

2. Bypasses that are not prohibited at 40 CFR 122.41(m); and

3. Response actions pursuant to the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA), as amended, or similar Federal, State or Tribal authorities, undertaken to alleviate a release into the environment of hazardous substances, pollutants or contaminants which may pose an imminent and substantial danger to public health or welfare.

III. Antidegradation Demonstration

Any entity seeking to lower water quality in a high quality water or create a new or increased discharge of Lake Superior bioaccumulative substances of immediate concern in a Lake Superior Outstanding International Resource Water must first, as required by sections II.D or II.E.2 of this appendix, submit an antidegradation demonstration for consideration by the Director. States and Tribes should tailor the level of detail and documentation in antidegradation reviews, to the specific circumstances encountered. The antidegradation demonstration shall include the following:

A. Pollution Prevention Alternatives Analysis. Identify any cost-effective pollution prevention alternatives and techniques that are available to the entity, that would eliminate or significantly reduce the extent to which the increased loading results in a lowering of water quality.

B. Alternative or Enhanced Treatment Analysis. Identify alternative or enhanced treatment techniques that are available to the entity that would eliminate the lowering of water quality and their costs relative to the cost of treatment necessary to achieve applicable effluent limitations.

C. Lake Superior. If the States or Tribes designate the waters of Lake Superior as Outstanding International Resource Waters pursuant to section II.E.2 of this appendix, then any entity proposing a new or increased discharge of any Lake Superior bioaccumulative substance of immediate concern to the Lake Superior Basin shall identify the best technology in process and treatment to eliminate or reduce the extent of the lowering of water quality. In this case, the requirements in section III.B of this appendix do not apply.

D. Important Social or Economic Development Analysis. Identify the social or economic development and the benefits to the area in which the waters are located that will be foregone if the lowering of water quality is not allowed.

E. Special Provision for Remedial Actions. Entities proposing remedial actions pursuant to the CERCLA, as amended, corrective actions pursuant to the Resource Conservation and Recovery Act, as amended, or similar actions pursuant to other Federal or State environmental statutes may submit information to the Director that demonstrates that the action utilizes the most cost effective pollution prevention and treatment techniques available, and minimizes the necessary lowering of water quality, in lieu of the information required by sections III.B through III.D of this appendix.

IV. Antidegradation Decision

A. Once the Director determines that the information provided by the entity proposing to increase loadings is administratively complete, the Director shall use that information to determine whether or not the lowering of water quality is necessary, and, if it is necessary, whether or not the lowering of water quality will support important social and economic development in the area. If the proposed lowering of water quality is either not necessary, or will not support important social and economic development, the Director shall deny the request to lower water quality. If the lowering of water quality is necessary, and will support important social and economic development, the Director may allow all or part of the proposed lowering to occur as necessary to accommodate the important social and economic development. In no event may the decision reached under this section allow water quality to be lowered below the minimum level required to fully support existing and designated uses. The decision of the Director shall be subject to the public participation requirements of 40 CFR 25.

B. If States designate the waters of Lake Superior as Outstanding International Resource Waters pursuant to section II.E.2 of this appendix, any entity requesting to lower water quality in the Lake Superior Basin as a result of the new or increased discharge of any Lake Superior bioaccumulative substance of immediate concern shall be required to install and utilize the best technology in process and treatment as identified by the Director.

Appendix F to Part 132—Great Lakes Water Quality Initiative Implementation Procedures

Procedure 1: Site-specific Modifications to Criteria and Values

Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) this procedure.

A. Requirements for Site-specific Modifications to Criteria and Values. Criteria and values may be modified on a site-specific basis to reflect local environmental conditions as restricted by the following provisions. Any such modifications must be protective of designated uses and aquatic life, wildlife or human health and be submitted to EPA for approval. In addition, any site-specific modifications that result in less stringent criteria must be based on a sound scientific rationale and shall not be likely to jeopardize the continued existence of endangered or threatened species listed or proposed under section 4 of the Endangered Species Act (ESA) or result in the destruction or adverse modification of such species' critical habitat. More stringent modifications shall be developed to protect endangered or threatened species listed or proposed under section 4 of the ESA, where such modifications are necessary to ensure that water quality is not likely to jeopardize the continued existence of such species or result in the destruction or adverse modification of such species' critical habitat. More stringent modifications may also be developed to protect candidate (C1) species being considered by the U.S. Fish and Wildlife Service (FWS) for listing under section 4 of the ESA, where such modifications are necessary to protect such species.

1. Aquatic Life.

a. Aquatic life criteria or values may be modified on a site-specific basis to provide an additional level of protection, pursuant to authority reserved to the States and Tribes under Clean Water Act (CWA) section 510.

Guidance on developing site-specific criteria in these instances is provided in Chapter 3 of the U.S. EPA Water Quality Standards Handbook, Second Edition—Revised (1994).

b. Less stringent site-specific modifications to chronic or acute aquatic life criteria or values may be developed when:

i. The local water quality characteristics such as Ph, hardness, temperature, color, etc., alter the biological availability or toxicity of a pollutant; or

ii. The sensitivity of the aquatic organisms species that “occur at the site” differs from the species actually tested in developing the criteria. The phrase “occur at the site” includes the species, genera, families, orders, classes, and phyla that: are usually present at the site; are present at the site only seasonally due to migration; are present intermittently because they periodically return to or extend their ranges into the site; were present at the site in the past, are not currently present at the site due to degraded conditions, and are expected to return to the site when conditions improve; are present in nearby bodies of water, are not currently present at the site due to degraded conditions, and are expected to be present at the site when conditions improve. The taxa that “occur at the site” cannot be determined merely by sampling downstream and/or upstream of the site at one point in time. “Occur at the site” does not include taxa that were once present at the site but cannot exist at the site now due to permanent physical alteration of the habitat at the site resulting, for example, from dams, etc.

c. Less stringent modifications also may be developed to acute and chronic aquatic life criteria or values to reflect local physical and hydrological conditions.

Guidance on developing site-specific criteria is provided in Chapter 3 of the U.S. EPA Water Quality Standards Handbook, Second Edition—Revised (1994).

***15415** d. Any modifications to protect threatened or endangered aquatic species required by procedure 1.A of this appendix may be accomplished using either of the two following procedures:

i. If the Species Mean Acute Value (SMAV) for a listed or proposed species, or for a surrogate of such species, is lower than the calculated Final Acute Value (FAV), such lower SMAV may be used instead of the calculated FAV in developing site-specific modified criteria; or,

ii. The site-specific criteria may be calculated using the recalculation procedure for site-specific modifications described in Chapter 3 of the U.S. EPA Water Quality Standards Handbook, Second Edition—Revised (1994).

2. Wildlife.

a. Wildlife water quality criteria may be modified on a site-specific basis to provide an additional level of protection, pursuant to authority reserved to the States and Tribes under CWA section 510.

b. Less stringent site-specific modifications to wildlife water quality criteria may be developed when a site-specific bioaccumulation factor (BAF) is derived which is lower than the system-wide BAF derived under appendix B of this part. The modification must consider both the mobility of prey organisms and wildlife populations in defining the site for which criteria are developed. In addition, there must be a showing that:

i. Any increased uptake of the toxicant by prey species utilizing the site will not cause adverse effects in wildlife populations; and

ii. Wildlife populations utilizing the site or downstream waters will continue to be fully protected.

c. Any modification to protect endangered or threatened wildlife species required by procedure 1.A of this appendix must consider both the mobility of prey organisms and wildlife populations in defining the site for which criteria are developed, and may be accomplished by using the following recommended method.

i. The methodology presented in appendix D to part 132 is used, substituting appropriate species-specific toxicological, epidemiological, or exposure information, including changes to the BAF;

ii. An interspecies uncertainty factor of 1 should be used where epidemiological data are available for the species in question. If necessary, species-specific exposure parameters can be derived as presented in Appendix D of this part;

iii. An intraspecies uncertainty factor (to account for protection of individuals within a wildlife population) should be applied in the denominator of the effect part of the wildlife equation in appendix D of this part in a manner consistent with the other uncertainty factors described in appendix D of this part; and

iv. The resulting wildlife value for the species in question should be compared to the two class-specific wildlife values which were previously calculated, and the lowest of the three shall be selected as the site-specific modification.

Note: Further discussion on the use of this methodology may be found in the Great Lakes Water Quality Initiative Technical Support Document for Wildlife Criteria.

3. BAFs.

a. BAFs may be modified on a site-specific basis to larger values, pursuant to the authority reserved to the States and Tribes under CWA section 510, where reliable data show that local bioaccumulation is greater than the system-wide value.

b. BAFs may be modified on a site-specific basis to lower values, where scientifically defensible, if:

i. The fraction of the total chemical that is freely dissolved in the ambient water is different than that used to derive the system-wide BAFs (i.e., the concentrations of particulate organic carbon and the dissolved organic carbon are different than those used to derive the system-wide BAFs);

ii. Input parameters of the Gobas model, such as the structure of the aquatic food web and the disequilibrium constant, are different at the site than those used to derive the system-wide BAFs;

iii. The percent lipid of aquatic organisms that are consumed and occur at the site is different than that used to derive the system-wide BAFs; or

iv. Site-specific field-measured BAFs or biota-sediment accumulation factor (BSAFs) are determined.

If site-specific BAFs are derived, they shall be derived using the methodology in appendix B of this part.

c. Any more stringent modifications to protect threatened or endangered species required by procedure 1.A of this appendix shall be derived using procedures set forth in the methodology in appendix B of this part.

4. Human Health.

a. Human health criteria or values may be modified on a site-specific basis to provide an additional level of protection, pursuant to authority reserved to the States and Tribes under CWA section 510. Human health criteria or values shall be modified on a site-specific basis to provide additional protection appropriate for highly exposed subpopulations.

b. Less stringent site-specific modifications to human health criteria or values may be developed when:

i. local fish consumption rates are lower than the rate used in deriving human health criteria or values under appendix C of this part; and/or

ii. a site-specific BAF is derived which is lower than that used in deriving human health criteria or values under appendix C of this part.

B. Notification Requirements. When a State proposes a site-specific modification to a criterion or value as allowed in section 4.A above, the State should notify the other Great Lakes States of such a proposal and, for less stringent criteria, supply appropriate justification.

C. References.

U.S. EPA. 1984. Water Quality Standards Handbook—Revised. Chapter 3 and Appendices. U.S. Environmental Protection Agency, Office of Water Resource Center (RC-4100), 401 M Street, SW., Washington, DC 20960.

Procedure 2: Variances from Water Quality Standards for Point Sources

The Great Lakes States or Tribes may adopt water quality standards (WQS) variance procedures and may grant WQS variances for point sources pursuant to such procedures. Variance procedures shall be consistent with (as protective as) the provisions in this procedure.

A. Applicability. A State or Tribe may grant a variance to a WQS which is the basis of a water quality-based effluent limitation included in a National Pollutant Discharge Elimination System (NPDES) permit. A WQS variance applies only to the permittee requesting the variance and only to the pollutant or pollutants specified in the variance. A variance does not affect, or require the State or Tribe to modify, the corresponding water quality standard for the waterbody as a whole.

1. This provision shall not apply to new Great Lakes dischargers or recommencing dischargers.

2. A variance to a water quality standard shall not be granted that would likely jeopardize the continued existence of any endangered or threatened species listed under Section 4 of the Endangered Species Act (ESA) or result in the destruction or adverse modification of such species' critical habitat.

3. A WQS variance shall not be granted if standards will be attained by implementing effluent limits required under sections 301(b) and 306 of the Clean Water Act (CWA) and by the permittee implementing cost-effective and reasonable best management practices for nonpoint source control.

B. Maximum Timeframe for Variances. A WQS variance shall not exceed five years or the term of the NPDES permit, whichever is less. A State or Tribe shall review, and modify as necessary, WQS variances as part of each water quality standards review pursuant to section 303(c) of the CWA.

C. Conditions to Grant a Variance. A variance may be granted if:

1. The permittee demonstrates to the State or Tribe that attaining the WQS is not feasible because:

a. Naturally occurring pollutant concentrations prevent the attainment of the WQS;

b. Natural, ephemeral, intermittent or low flow conditions or water levels prevent the attainment of the WQS, unless these conditions may be compensated for by the discharge of sufficient volume of effluent to enable WQS to be met without violating State or Tribal water conservation requirements;

c. Human-caused conditions or sources of pollution prevent the attainment of the WQS and cannot be remedied, or would cause more environmental damage to correct than to leave in place;

d. Dams, diversions or other types of hydrologic modifications preclude the attainment of the WQS, and it is not feasible to restore the waterbody to its original condition or to operate such modification in a way that would result in the attainment of the WQS;

e. Physical conditions related to the natural features of the waterbody, such as the lack of a proper substrate cover, flow, depth, pools, riffles, and the like, unrelated to chemical water quality, preclude attainment of WQS; or

***15416** f. Controls more stringent than those required by sections 301(b) and 306 of the CWA would result in substantial and widespread economic and social impact.

2. In addition to the requirements of C.1, above, the permittee shall also:

a. Show that the variance requested conforms to the requirements of the State's or Tribe's antidegradation procedures; and

b. Characterize the extent of any increased risk to human health and the environment associated with granting the variance compared with compliance with WQS absent the variance, such that the State or Tribe is able to conclude that any such increased risk is consistent with the protection of the public health, safety and welfare.

D. Submittal of Variance Application. The permittee shall submit an application for a variance to the regulatory authority issuing the permit. The application shall include:

1. All relevant information demonstrating that attaining the WQS is not feasible based on one or more of the conditions in section C.1 of this procedure; and,

2. All relevant information demonstrating compliance with the conditions in section C.2 of this procedure.

E. Public Notice of Preliminary Decision. Upon receipt of a complete application for a variance, and upon making a preliminary decision regarding the variance, the State or Tribe shall public notice the request and preliminary decision for public comment pursuant to the regulatory authority's Administrative Procedures Act and shall notify the other Great Lakes States and Tribes of the preliminary decision. This public notice requirement may be satisfied by including the supporting information for the variance and the preliminary decision in the public notice of a draft NPDES permit.

F. Final Decision on Variance Request. The State or Tribe shall issue a final decision on the variance request within 90 days of the expiration of the public comment period required in section E of this procedure. If all or part of the variance is approved by the State or Tribe, the decision shall include all permit conditions needed to implement those parts of the variance so approved. Such permit conditions shall, at a minimum, require:

1. Compliance with an initial effluent limitation which, at the time the variance is granted, represents the level currently achievable by the permittee, and which is no less stringent than that achieved under the previous permit;

2. That reasonable progress be made toward attaining the water quality standards for the waterbody as a whole through appropriate conditions;

3. When the duration of a variance is shorter than the duration of a permit, compliance with an effluent limitation sufficient to meet the underlying water quality standard, upon the expiration of said variance; and

4. A provision that allows the permitting authority to reopen and modify the permit based on any State or Tribal triennial water quality standards revisions to the variance.

The State shall deny a variance request if the permittee fails to make the demonstrations required under section C of this procedure.

G. Incorporating Variance into Permit. The State or Tribe shall establish and incorporate into the permittee's NPDES permit all conditions needed to implement the variance as determined in section F of this procedure.

H. Renewal of Variance. A variance may be renewed, subject to the requirements of sections A through G of this procedure. As part of any renewal application, the permittee shall again demonstrate that attaining WQS is not feasible based on the requirements of section C of this procedure. The permittee's application shall also contain information concerning its compliance with the conditions incorporated into its permit as part of the original variance pursuant to sections F and G of this procedure. Renewal of a variance may be denied if the permittee did not comply with the conditions of the original variance.

I. EPA Approval. All variances and supporting information shall be submitted by the State or Tribe to the appropriate EPA regional office and shall include:

1. Relevant permittee applications pursuant to section D of this procedure;

2. Public comments and records of any public hearings pursuant to section E of this procedure;

3. The final decision pursuant to section F of this procedure; and,

4. NPDES permits issued pursuant to section G of this procedure.

5. Items required by sections I.1 through I.3. of this procedure shall be submitted by the State within 30 days of the date of the final variance decision. The item required by section I.4 of this procedure shall be submitted in accordance with the State or Tribe Memorandum of Agreement with the Regional Administrator pursuant to 40 CFR 123.24.
40 CFR § 123.4440 CFR § 131.21
6. EPA shall review the State or Tribe submittal for compliance with the CWA pursuant to 40 CFR 123.44, and 40 CFR 131.21.

J. State WQS Revisions. All variances shall be appended to the State or Tribe WQS rules.

Procedure 3: Total Maximum Daily Loads, Wasteload Allocations for Point Sources, Load Allocations for Nonpoint Sources, Wasteload Allocations in the Absence of a TMDL, and Preliminary Wasteload Allocations for Purposes of Determining the Need for Water Quality Based Effluent Limits

The Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) this procedure 3 for the purpose of developing Total Maximum Daily Loads (TMDLs), Wasteload Allocations (WLAs) in the Absence of TMDLs, and Preliminary Wasteload Allocations for Purposes of Determining the Need for Water Quality Based Effluent Limits (WQBELs), except as specifically provided.

A. Where a State or Tribe develops an assessment and remediation plan that the State or Tribe certifies meets the requirements of sections B through F of this procedure and public participation requirements applicable to TMDLs, and that has been approved by EPA as meeting those requirements under 40 CFR 130.6, the assessment and remediation plan may be used in lieu of a TMDL for purposes of appendix F to part 132. Assessment and remediation plans under this procedure may include, but are not limited to, Lakewide Management Plans, Remedial Action Plans, and State Water Quality Management Plans. Also, any part of an assessment and remediation plan that also satisfies one or more requirements under Clean Water Act (CWA) section 303(d) or implementing regulations may be incorporated by reference into a TMDL as appropriate. Assessment and remediation plans under this section should be tailored to the level of detail and magnitude for the watershed and pollutant being assessed.

B. General Conditions of Application. Except as provided in §132.4, the following are conditions applicable to establishing TMDLs for all pollutants and pollutant parameters in the Great Lakes System, with the exception of whole effluent toxicity, unless otherwise provided in procedure 6 of appendix F. Where specified, these conditions also apply to wasteload allocations (WLAs) calculated in the absence of TMDLs and to preliminary WLAs for purposes of determining the needs for WQBELs under procedure 5 of appendix F.

1. TMDLs Required. TMDLs shall, at a minimum, be established in accordance with the listing and priority setting process established in section 303(d) of the CWA and at 40 CFR 130.7. Where water quality standards cannot be attained immediately, TMDLs must reflect reasonable assurances that water quality standards will be attained in a reasonable period of time. Some TMDLs may be based on attaining water quality standards over a period of time, with specific controls on individual sources being implemented in stages. Determining the reasonable period of time in which water quality standards will be met is a case-specific determination considering a number of factors including, but not limited to: receiving water characteristics; persistence, behavior and ubiquity of pollutants of concern; type of remediation activities necessary; available regulatory and non-regulatory controls; and individual State or Tribal requirements for attainment of water quality standards.

2. Attainment of Water Quality Standards. A TMDL must ensure attainment of applicable water quality standards, including all numeric and narrative criteria, Tier I criteria, and Tier II values for each pollutant or pollutants for which a TMDL is established.

3. TMDL Allocations.

a. TMDLs shall include WLAs for point sources and load allocations (LAs) for nonpoint sources, including natural background, such that the sum of these allocations is not greater than the loading capacity of the water for the pollutant(s) addressed by the TMDL, minus the sum of a specified margin of safety (MOS) and any capacity reserved for future growth.

b. Nonpoint source LAs shall be based on:

i. Existing pollutant loadings if changes in loadings are not reasonably anticipated to occur;

ii. Increases in pollutant loadings that are reasonably anticipated to occur;

***15417** iii. Anticipated decreases in pollutant loadings if such decreased loadings are technically feasible and are reasonably anticipated to occur within a reasonable time period as a result of implementation of best management practices or other load reduction measures. In determining whether anticipated decreases in pollutant loadings are technically feasible and can reasonably be expected to occur within a reasonable period of time, technical and institutional factors shall be considered. These decisions are case-specific and should reflect the particular TMDL under consideration.

c. WLAs. The portion of the loading capacity not assigned to nonpoint sources including background, or to an MOS, or reserved for future growth is allocated to point sources. Upon reissuance, NPDES permits for these point sources must include effluent limitations consistent with WLAs in EPA-approved or EPA-established TMDLs.

d. Monitoring. For LAs established on the basis of subsection b.iii above, monitoring data shall be collected and analyzed in order to validate the TMDL's assumptions, to varify anticipated load reductions, to evaluate the effectiveness of controls being used to implement the TMDL, and to revise the WLAs and LAs as necessary to ensure that water quality standards will be achieved within the time-period established in the TMDL.

4. WLA Values. If separate EPA-approved or EPA-established TMDLs are prepared for different segments of the same watershed, and the separate TMDLs each include WLAs for the same pollutant for one or more of the same point sources, then WQBELs for that pollutant for the point source(s) shall be consistent with the most stringent of those WLAs in order to ensure attainment of all applicable water quality standards.

5. Margin of Safety (MOS). Each TMDL shall include a MOS sufficient to account for technical uncertainties in establishing the TMDL and shall describe the manner in which the MOS is determined and incorporated into the TMDL. The MOS may be provided by leaving a portion of the loading capacity unallocated or by using conservative modeling assumptions to establish WLAs and LAs. If a portion of the loading capacity is left unallocated to provide a MOS, the amount left unallocated shall be described. If conservative modeling assumptions are relied on to provide a MOS, the specific assumptions providing the MOS shall be identified.

6. More Stringent Requirements. States and Tribes may exercise authority reserved to them under section 510 of the CWA to develop more stringent TMDLs (including WLAs and LAs) than are required herein, provided that all LAs in such TMDLs reflect actual nonpoint source loads or those loads that can reasonably be expected to occur within a reasonable time-period as a result of implementing nonpoint source controls.

7. Accumulation in Sediments. TMDLs shall reflect, where appropriate and where sufficient data are available, contributions to the water column from sediments inside and outside of any applicable mixing zones. TMDLs shall be sufficiently stringent so as to prevent accumulation of the pollutant of concern in sediments to levels injurious to designated or existing uses, human health, wildlife and aquatic life.

8. Wet Weather Events. Notwithstanding the exception provided for the establishment of controls on wet weather point sources in §132.4(e)(1), TMDLs shall reflect, where appropriate and where sufficient data are available, discharges resulting from wet

weather events. This procedure does not provide specific procedures for considering discharges resulting from wet weather events. However, some of the provisions of procedure 3 may be deemed appropriate for considering wet weather events on a case-by-case basis.

9. Background Concentration of Pollutants. The representative background concentration of pollutants shall be established in accordance with this subsection to develop TMDLs, WLAs calculated in the absence of a TMDL, or preliminary WLAs for purposes of determining the need for WQBELs under procedure 5 of appendix F. Background loadings may be accounted for in a TMDL through an allocation to a single “background” category or through individual allocations to the various background sources.

a. Definition of Background. “Background” represents all loadings that: (1) flow from upstream waters into the specified watershed, waterbody or waterbody segment for which a TMDL, WLA in the absence of a TMDL or preliminary WLA for the purpose of determining the need for a WQBEL is being developed; (2) enter the specified watershed, waterbody or waterbody segment through atmospheric deposition or sediment release or resuspension; or (3) occur within the watershed, waterbody or waterbody segment as a result of chemical reactions.

b. Data considerations. When determining what available data are acceptable for use in calculating background, the State or Tribe should use best professional judgment, including consideration of the sampling location and the reliability of the data through comparison to reported analytical detection levels and quantification levels. When data in more than one of the data sets or categories described in section B.9.c.i through B.9.c.iii below exist, best professional judgment should be used to select the one data set that most accurately reflects or estimates background concentrations. Pollutant degradation and transport information may be considered when utilizing pollutant loading data.

c. Calculation requirements. Except as provided below, the representative background concentration for a pollutant in the specified watershed, waterbody or waterbody segment shall be established on a case-by-case basis as the geometric mean of:

i. Acceptable available water column data; or

ii. Water column concentrations estimated through use of acceptable available caged or resident fish tissue data; or

iii. Water column concentrations estimated through use of acceptable available or projected pollutant loading data.

d. Detection considerations.

i. Commonly accepted statistical techniques shall be used to evaluate data sets consisting of values both above and below the detection level.

ii. When all of the acceptable available data in a data set or category, such as water column, caged or resident fish tissue or pollutant loading data, are below the level of detection for a pollutant, then all the data for that pollutant in that data set shall be assumed to be zero.

10. Effluent Flow. If WLAs are expressed as concentrations of pollutants, the TMDL shall also indicate the point source effluent flows assumed in the analyses. Mass loading limitations established in NPDES permits must be consistent with both the WLA and assumed effluent flows used in establishing the TMDL.

11. Reserved Allocations. TMDLs may include reserved allocations of loading capacity to accommodate future growth and additional sources. Where such reserved allocations are not included in a TMDL, any increased loadings of the pollutant for which the TMDL was developed that are due to a new or expanded discharge shall not be allowed unless the TMDL is revised in accordance with these proceudres to include an allocation for the new or expanded discharge.

C. Mixing Zones for Bioaccumulative Chemicals of Concern (BCCs). The following requirements shall be applied in establishing TMDLs, WLAs in the absence of TMDLs, and preliminary WLAs for purposes of determining the need for WQBELs under procedure 5 of appendix F, for BCCs:

1. Beginning on March 23, 1997, there shall be no mixing available for new discharges of BCCs to the Great Lakes System. WLAs established through TMDLs, WLAs in the absence of TMDLs, and preliminary WLAs for purposes of determining the need for WQBELs for new discharges of BCCs shall be set equal to the most stringent applicable water quality criteria or values for the BCCs in question.

2. For purposes of section C of procedure 3 of appendix F, new discharges are defined as: (1) discharges from new Great Lakes dischargers; or (2) new or expanded discharges from an existing Great Lakes discharger. All other discharges of BCCs are defined as existing discharges.

3. Up until March 23, 2007, mixing zones for BCCs may be allowed for existing discharges to the Great Lakes System pursuant to the procedures specified in sections D and E of this procedure.

4. Except as provided in sections C.5 and C.6 of this procedure, permits issued on or after March 23, 1997 shall not authorize mixing zones for existing discharges of BCCs to the Great Lakes System after March 23, 2007. After March 23, 2007, WLAs established through TMDLs, WLAs established in the absence of TMDLs and preliminary WLAs for purposes of determining the need for WQBELs under procedure 5 of appendix F for existing dischrges of BCCs to the Great Lakes System shall be set equal to the most stringent applicable water quality criteria or values for the BCCs in question.

5. Exception for Water Conservation. States and Tribes may grant mixing zones for any existing discharge of BCCs to the Great Lakes ***15418** System beyond the dates specified in sections C.3 and C.4 of this procedure, where it can be demonstrated, on a case-by-case basis, that failure to grant a mixing zone would preclude water conservation measures that would lead to overall load reductions in BCCs, even though higher concentrations of BCCs occur in the effluent. Such mixing zones must also be consistent with sections D and E of this procedure.

6. Exception for Technical and Economic Considerations. States and Tribes may grant mixing zones beyond the dates specified in sections C.3 and C.4 of this procedure for any existing discharges of a BCC to the Great Lakes System upon the request of a discharger subject to the limited circumstances specified in sections C.6.a through C.6.d below. Such mixing zones shall also be consistent with sections D and E of this procedure.

a. The permitting authority must determine that:

i. The discharger is in compliance with and will continue to implement all applicable technology-based treatment and pretreatment requirements of CWA sections 301, 302, 304, 306, 307, 401, and 402, and is in compliance with its existing NPDES water quality-based effluent limitations, including those based on a mixing zone; and

ii. The discharger has reduced and will continue to reduce the loading of the BCC for which a mixing zone is requested to the maximum extent possible.

b. In making the determination in section C.6.a above, the State or Tribal authority should consider:

i. The availability and feasibility, including cost effectiveness, of additional controls or pollution prevention measures for reducing and ultimately eliminating BCCs for that discharger, including those used by similar dischargers;

ii. Whether the discharger or affected communities will suffer unreasonable economic effects if the mixing zone is eliminated;

iii. The extent to which the discharger will implement an ambient monitoring plan to ensure compliance with water quality criteria at the edge of any authorized mixing zone or to ensure consistency with any applicable TMDL or such other strategy consistent with section A of this procedure; and,

iv. Other information the State or Tribe deems appropriate.

c. Any exceptions to the mixing zone elimination provision for existing discharges of BCCs granted pursuant to this section shall:

i. Not result in any less stringent limitations than those existing March 23, 1997;

ii. Not likely jeopardize the continued existence of any endangered or threatened species listed under section 4 of the ESA or result in the destruction or adverse modification of such species' critical habitat;

iii. Be limited to one permit term unless the permitting authority makes a new determination in accordance with this section for each successive permit application in which a mixing zone for the BCC(s) is sought;

iv. Reflect all information relevant to the size of the mixing zone considered by the State or Tribe under subsection b above;

v. Protect all designated and existing uses of the receiving water;

vi. Meet all applicable aquatic life, wildlife and human health criteria and values at the edge of the mixing zone and, as appropriate, within the mixing zone or be consistent with any appropriate TMDL or such other strategy consistent with section A of this procedure;

vii. Ensure the discharger has developed and conducted a pollutant minimization program for the BCC(s) if required to do so under regulations adopted consistent with procedure 8 of appendix F; and

viii. Ensure that alternative means for reducing BCCs elsewhere in the watershed are evaluated.

d. For each draft NPDES permit that would allow a mixing zone for one or more BCCs after March 23, 2007, the fact sheet or statement of basis for the draft permit, required to be made available through public notice under 40 CFR 124.6(e), shall:

i. Specify the mixing provisions used in calculating the permit limits; and

ii. Identify each BCC for which a mixing zone is proposed.

D. Deriving TMDLs, WLAs, and LAs for Point and Nonpoint Sources: WLAs in the Absence of a TMDL; and Preliminary WLAs for Purposes of Determining the Need for WQBELs for OWGL. This section addresses conditions for deriving TMDLs for Open Waters of the Great Lakes (OWGL), inland lakes and other waters of the Great Lakes System with no appreciable flow relative to their volumes. State and Tribal procedures to derive TMDLs under this section must be consistent with (as protective as) the general conditions in section B of this procedure, CWA section 303(d), existing regulations (40 CFR 130.7), section C of this procedure, and sections D.1. through D.4 below. State and Tribal procedures to derive WLAs calculated in the absence of a TMDL and preliminary WLAs for purposes of determining the need for WQBELs under procedure 5 of appendix F must be consistent with sections B.9, C.1, C3 through C.6, and D. 1 through D.4 of this procedure.

1. Individual point source WLAs and preliminary WLAs for purposes of determining the need for WQBELs under procedure 5 of appendix F shall assume no greater dilution than one part effluent to 10 parts receiving water for implementation of numeric

and narrative chronic criteria and values (including, but not limited to human cancer criteria, human cancer values, human noncancer values, human noncancer criteria, wildlife criteria, and chronic aquatic life criteria and values) unless an alternative mixing zone is demonstrated as appropriate in a mixing zone demonstration conducted pursuant to section F of this procedure. In no case shall a mixing zone be granted that exceeds the area where discharge-induced mixing occurs.

2. Appropriate mixing zone assumptions to be used in calculating load allocations for nonpoint sources shall be determined, consistent with applicable State or Tribal requirements, on a case-by-case basis.

3. WLAs and preliminary WLAs based on acute aquatic life criteria or values shall not exceed the Final Acute Value (FAV), unless a mixing zone demonstration is conducted and approved pursuant to section F of this procedure. If mixing zones from two or more proximate sources interact or overlap, the combined effect must be evaluated to ensure that applicable criteria and values will be met in the area where acute mixing zones overlap.

4. In no case shall a mixing zone be granted that would likely jeopardize the continued existence of any endangered or threatened species listed under section 4 of the ESA or result in the destruction or adverse modification of such species' critical habitat.

E. Deriving TMDLs, WLAs, and LAs for Point and Nonpoint Sources; WLAs in the Absence of a TMDL; and Preliminary WLAs for the Purposes of Determining the Need for WQBELs for Great Lakes Systems Tributaries and Connecting Channels. This section describes conditions for deriving TMDLs for tributaries and connecting channels of the Great Lakes System that exhibit appreciable flows relative to their volumes. State and Tribal procedures to derive TMDLs must be consistent with the general conditions listed in section B of this procedure, section C of this procedure, existing TMDL regulations (40 CFR 130.7) and specific conditions E.1 through E.5. State and Tribal procedures to derive WLAs calculated in the absence of a TMDL, and preliminary WLAs for purposes of determining reasonable potential under procedure 5 of this appendix for discharges to tributaries and connecting channels must be consistent with sections B.9, C.1, C.3 through C.6, and E.1 through E.5 of this procedure.

1. Stream Design. These design flows must be used unless data exist to demonstrate that an alternative stream design flow is appropriate for stream-specific and pollutant-specific conditions. For purposes of calculating a TMDL, WLAs in the absence of a TMDL, or preliminary WLAs for the purposes of determining reasonable potential under procedure 5 of this appendix, using a steady-state model, the stream design flows shall be:

a. The 7-day, 10-year stream design flow (7Q10), or the 4-day, 3-year biologically-based stream design flow for chronic aquatic life criteria or values;

b. The 1-day, 10-year stream design flow (1Q10), for acute aquatic life criteria or values;

c. The harmonic mean flow for human health criteria or values;

d. The 90-day, 10-year flow (90Q10) for wildlife criteria.

e. TMDLs, WLAs in the absence of TMDLs, and preliminary WLAs for the purpose of determining the need for WQBELs calculated using dynamic modelling do not need to incorporate the stream design flows specified in sections E.1.a through E.1.d of this procedure.

2. Loading Capacity. The loading capacity is the greatest amount of loading that a water can receive without violating water quality standards. The loading capacity is initially calculated at the farthest downstream location in the watershed drainage basin. The maximum allowable loading consistent with the attainment of each applicable numeric ***15419** criterion or value for a given pollutant is determined by multiplying the applicable criterion or value by the flow at the farthest downstream location in the tributary basin at the design flow condition described above. This loading is then compared to the loadings at

sites within the basin to assure that applicable numeric criteria or values for a given pollutant are not exceeded at all applicable sites. The lowest load is then selected as the loading capacity.

3. Polluant Degradation. TMDLs, WLAs in the absence of a TMDL and preliminary WLAs for purposes of determining the need for WQBELs under procedure 5 of appendix F shall be based on the assumption that a pollutant does not degrade. However, the regulatory authority may take into account degradation of the pollutant if each of the following conditions are met.

a. Scientifically valid field studies or other relevant information demonstrate that degradation of the pollutant is expected to occur under the full range of environmental conditions expected to be encountered;

b. Scientifically valid field studies or other relevant information address other factors that affect the level of pollutants in the water column including, but not limited to, resuspension of sediments, chemical speciation, and biological and chemical transformation.

4. Acute Aquatic Life Criteria and Values. WLAs and LAs established in a TMDL, WLAs in the absence of a TMDL, and preliminary WLAs for the purpose of determining the need for WQBELs based on acute aquatic life criteria or values shall not exceed the FAV, unless a mixing zone demonstration is completed and approved pursuant to section F of this procedure. If mixing zones from two or more proximate sources interact or overlap, the combined effect must be evaluated to ensure that applicable criteria and values will be met in the area where any applicable acute mixing zones overlap. This acute WLA review shall include, but not be limited to, consideration of:

a. The expected dilution under all effluent flow and concentration conditions at stream design flow;

b. Maintenance of a zone of passage for aquatic organisms; and

c. Protection of critical aquatic habitat.

In no case shall a permitting authority grant a mixing zone that would likely jeopardize the continued existence of any endangered or threatened species listed under section 4 of the ESA or result in the destruction or adverse modification of such species' critical habitat.

5. Chronic Mixing Zones. WLAs and LAs established in a TMDL, WLAs in the absence of a TMDL, and preliminary WLAs for the purposes of determining the need for WQBELs for protection of aquatic life, wildlife and human health from chronic effects shall be calculated using a dilution fraction no greater than 25 percent of the stream design flow unless a mixing zone demonstration pursuant to section F of this procedure is conducted and approved. A demonstration for a larger mixing zone may be provided, if approved and implemented in accordance with section F of this procedure. In no case shall a permitting authority grant a mixing zone that would likely jeopardize the continued existence of any endangered or threatened species listed under section 4 of the ESA or result in the destruction or adverse modification of such species' critical habitat.

F. Mixing Zone Demonstration Requirements.

1. For purposes of establishing a mixing zone other than as specified in sections D and E above, a mixing zone demonstration must:

a. Describe the amount of dilution occurring at the boundaries of the proposed mixing zone and the size, shape, and location of the area of mixing, including the manner in which diffusion and dispersion occur;

b. For sources discharging to the open waters of the Great Lakes (OWGLs), define the location at which discharge-induced mixing ceases;

c. Document the substrate character and geomorphology within the mixing zone;

d. Show that the mixing zone does not interfere with or block passage of fish or aquatic life;

e. Show that the mixing zone will be allowed only to the extent that the level of the pollutant permitted in the waterbody would not likely jeopardize the continued existence of any endangered or threatened species listed under section 4 of the ESA or result in the destruction or adverse modification of such species' critical habitat;

f. Show that the mixing zone does not extend to drinking water intakes;

g. Show that the mixing zone would not otherwise interfere with the designated or existing uses of the receiving water or downstream waters;

h. Document background water quality concentrations;

i. Show that the mixing zone does not promote undesirable aquatic life or result in a dominance of nuisance species; and

j. Provide that by allowing additional mixing/dilution:

i. Substances will not settle to form objectionable deposits;

ii. Floating debris, oil, scum, and other matter in concentrations that form nuisances will not be produced; and

iii. Objectionable color, odor, taste or turbidity will not be produced.

2. In addition, the mixing zone demonstration shall address the following factors:

a. Whether or not adjacent mixing zones overlap;

b. Whether organisms would be attracted to the area of mixing as a result of the effluent character; and

c. Whether the habitat supports endemic or naturally occurring species.

3. The mixing zone demonstration must be submitted to EPA for approval. Following approval of a mixing zone demonstration consistent with sections F.1 and F.2, adjustment to the dilution ratio specified in section D.1 of this procedure shall be limited to the dilution available in the area where discharger-induced mixing occurs.

4. The mixing zone demonstration shall be based on the assumption that a pollutant does not degrade within the proposed mixing zone, unless:

a. Scientifically valid field studies or other relevant information demonstrate that degradation of the pollutant is expected to occur under the full range of environmental conditions expected to be encountered; and

b. Scientifically valid field studies or other relevant information address other factors that affect the level of pollutants in the water column including, but not limited to, resuspension of sediments, chemical speciation, and biological and chemical transformation.

Procedure 4: Additivity

The Great Lakes States and Tribes shall adopt additivity provisions consistent with (as protective as) this procedure.

A. The Great Lakes States and Tribes shall adopt provisions to protect human health from the potential adverse additive effects from both the noncarcinogenic and carcinogenic components of chemical mixtures in effluents. For the chlorinated dibenzo-p-dioxins (CDDs) and chlorinated dibenzofurans (CDFs) listed in Table 1, potential adverse additive effects in effluents shall be accounted for in accordance with section B of this procedure.

B. Toxicity Equivalency Factors (TEFs)/Bioaccumulation Equivalency Factors (BEFs).

1. The TEFs in Table 1 and BEFs in Table 2 shall be used when calculating a 2,3,7,8-TCDD toxicity equivalence concentration in effluent to be used when implementing both human health noncancer and cancer criteria. The chemical concentration of each CDDs and CDFs in effluent shall be converted to a 2,3,7,8-TCDD toxicity equivalence concentration in effluent by (a) multiplying the chemical concentration of each CDDs and CDFs in the effluent by the appropriate TEF in Table 1 below, (b) multiplying each product from step (a) by the BEF for each CDDs and CDFs in Table 2 below, and (c) adding all final products from step (b). The equation for calculating the 2,3,7,8-TCDD toxicity equivalence concentration in effluent is:

where:

$(TEC)_{tcdd}$=2,3,7,8-TCDD toxicity equivalence concentration in effluent

$(C)_x$=concentration of total chemical x in effluent

$(TEF)_x$=TCDD toxicity equivalency factor for x

$(BEF)_x$=TCDD bioaccumulation equivalency factor for x

2. The 2,3,7,8-TCDD toxicity equivalence concentration in effluent shall be used when developing waste load allocations under procedure 3, preliminary waste load allocations for purposes of determining reasonable potential under procedure 5, and for purposes of establishing effluent quality limits under procedure 5.

***15420 Procedure 5: Reasonable Potential To Exceed Water Quality Standards**

Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) this procedure. If a permitting authority determines that a pollutant is or may be discharged into the Great Lakes System at a level which will cause, have the reasonable potential to cause, or contribute to an excursion above any Tier I criterion or Tier II value, the permitting authority shall incorporate a water quality-based effluent limitation (WQBEL) in an NPDES permit for the discharge of that pollutant. When facility-specific effluent monitoring data are available, the permitting authority shall make this determination by developing preliminary effluent limitations (PEL) and comparing those effluent limitations to the projected effluent quality (PEQ) of the discharge in accordance with the following procedures. In all cases, the permitting authority shall use any valid, relevant, representative information that indicates a reasonable potential to exceed any Tier I criterion or Tier II value.

A. Developing Preliminary Effluent Limitations on the Discharge of a Pollutant From a Point Source.

1. The permitting authority shall develop preliminary wasteload allocations (WLAs) for the discharge of the pollutant from the point source to protect human health, wildlife, acute aquatic life, and chronic aquatic life, based upon any existing Tier I criteria. Where there is no Tier I criterion nor sufficient data to calculate a Tier I criterion, the permitting authority shall calculate a Tier II value for such pollutant for the protection of human health, and aquatic life and the preliminary WLAs shall be based upon such values. Where there is insufficient data to calculate a Tier II value, the permitting authority shall apply the procedure set forth in section C of this procedure to determine whether data must be generated to calculate a Tier II value.

2. The following provisions in procedure 3 of appendix F shall be used as the basis for determining preliminary WLAs in accordance with section 1 of this procedure: procedure 3.B.9, Background Concentrations of Pollutants; procedure 3.C, Mixing Zones for Bioaccumulative Chemicals of Concern (BCCs), procedures 3.C.1, and 3.C.3 through 3.C.6; procedure 3.D, Deriving TMDLs for Discharges to Lakes (when the receiving water is an open water of the Great Lakes (OWGL), an inland lake or other water of the Great Lakes System with no appreciable flow relative to its volume); procedure 3.E, Deriving TMDLs, WLAs and Preliminary WLAs, and load allocations (LAs) for Discharges to Great Lakes System Tributaries (when the receiving water is a tributary or connecting channel of the Great Lakes that exhibits appreciable flow relative to its volume); and procedure 3.F, Mixing Zone Demonstration Requirements.

3. The permitting authority shall develop PELs consistent with the preliminary WLAs developed pursuant to sections A.1 and A.2 of this procedure, and in accordance with existing State or Tribal procedures for converting WLAs into WQBELs. At a minimum:

a. The PELs based upon criteria and values for the protection of human health and wildlife shall be expressed as monthly limitations;

b. The PELs based upon criteria and values for the protection of aquatic life from chronic effects shall be expressed as either monthly limitations or weekly limitations; and

c. The PELs based upon the criteria and values for the protection of aquatic life from acute effects shall be expressed as daily limitations.

B. Determining Reasonable Potential Using Effluent Pollutant Concentration Data.

If representative, facility-specific effluent monitoring data samples are available for a pollutant discharged from a point source to the waters of the Great Lakes System, the permitting authority shall apply the following procedures:

1. The permitting authority shall specify the PEQ as the 95 percent confidence level of the 95th percentile based on a log-normal distribution of the effluent concentration; or the maximum observed effluent concentration, whichever is greater. In calculating the PEQ, the permitting authority shall identify the number of effluent samples and the coefficient of variation of the effluent data, obtain the appropriate multiplying factor from Table 1 of procedure 6 of appendix F, and multiply the maximum effluent

concentration by that factor. The coefficient of variation of the effluent data shall be calculated as the ratio of the standard deviation of the effluent data divided by the arithmetic average of the effluent data, except that where there are fewer than ten effluent concentration data points the coefficient of variation shall be specified as 0.6. If the PEQ exceeds any of the PELs developed in accordance with section A.3 of this procedure, the permitting authority shall establish a WQBEL in a NPDES permit for such pollutant.

2. In lieu of following the procedures under section B.1 of this procedure, the permitting authority may apply procedures consistent with the following:

a. The permitting authority shall specify the PEQ as the 95th percentile of the distribution of the projected population of daily values of the facility-specific effluent monitoring data projected using a scientifically defensible statistical method that accounts for and captures the long-term daily variability of the effluent quality, accounts for limitations associated with sparse data sets and, unless otherwise shown by the effluent data set, assumes a lognormal distribution of the facility-specific effluent data. If the PEQ exceeds the PEL based on the criteria and values for the protection of aquatic life from acute effects developed in accordance with section A.3 of this procedure, the permitting authority shall establish a WQBEL in an NPDES permit for such pollutant;

b. The permitting authority shall calculate the PEQ as the 95th percentile of the distribution of the projected population of monthly averages of the facility-specific effluent monitoring data using a scientifically defensible statistical method that accounts for and captures the long-term variability of the monthly average effluent quality, accounts for limitations associated with sparse data sets and, unless otherwise shown by the effluent data set, assumes a lognormal distribution of the facility-specific effluent data. If the PEQ exceeds the PEL based on criteria and values for the protection of aquatic life from chronic effects, human health or wildlife developed in accordance with section A.3 of this procedure, the permitting authority shall establish a WQBEL in an NPDES permit for such pollutant; and

c. The permitting authority shall calculate the PEQ as the 95th percentile of the distribution of the projected population of weekly averages of the facility-specific effluent monitoring data using a scientifically defensible statistical method that accounts for and captures the long-term variability of the weekly average effluent quality, accounts for limitations associated with sparse data sets and, unless otherwise shown by the effluent data set, assumes a lognormal distribution of the facility-specific effluent data. If the PEQ exceeds the PEL based on criteria and values to protect aquatic life from chronic effects developed in accordance with section A.3 of this procedure, the permitting ***15421** authority shall establish a WQBEL in an NPDES permit for such pollutant.

C. Developing Necessary Data to Calculate Tier II Values Where Such Data Does Not Currently Exist.
40 CFR § 122.44
1. Except as provided in sections C.2, C.4, or D of this procedure, for each pollutant listed in Table 6 of part 132 that a permittee reports as known or believed to be present in its effluent, and for which pollutant data sufficient to calculate Tier II values for non-cancer human health, acute aquatic life and chronic aquatic life do not exist, the permitting authority shall take the following actions:

a. The permitting authority shall use all available, relevant information, including Quantitative Structure Activity Relationship information and other relevant toxicity information, to estimate ambient screening values for such pollutant which will protect humans from health effects other than cancer, and aquatic life from acute and chronic effects.

b. Using the procedures specified in sections A.1 and A.2 of this procedure, the permitting authority shall develop preliminary WLAs for the discharge of the pollutant from the point source to protect human health, acute aquatic life, and chronic aquatic life, based upon the estimated ambient screening values.

c. The permitting authority shall develop PELs in accordance with section A.3 of this procedure, which are consistent with the preliminary WLAs developed in accordance with section C.1.b of this procedure.

d. The permitting authority shall compare the PEQ developed according to the procedures set forth in section B of this procedure to the PELs developed in accordance with section C.1.c of this procedure. If the PEQ exceeds any of the PELs, the permitting authority shall generate or require the permittee to generate the data necessary to derive Tier II values for noncancer human health, acute aquatic life and chronic aquatic life.

e. The data generated in accordance with section C.1.d of this procedure shall be used in calculating Tier II values as required under section A.1 of this procedure. The calculated Tier II value shall be used in calculating the preliminary WLA and PEL under section A of this procedure, for purposes of determining whether a WQBEL must be included in the permit. If the permitting authority finds that the PEQ exceeds the calculated PEL, a WQBEL for the pollutant or a permit limit on an indicator parameter consistent with 40 CFR 122.44(d)(1)(vi)(C) must be included in the permit.

2. With the exception of bioaccumulative chemicals of concern (BCCs), a permitting authority is not required to apply the procedures set forth in section C.1 of this procedure or include WQBELs to protect aquatic life for any pollutant listed in Table 6 of part 132 discharged by an existing point source into the Great Lakes System, if:

a. There is insufficient data to calculate a Tier I criterion or Tier II value for aquatic life for such pollutant;

b. The permittee has demonstrated through a biological assessment that there are no acute or chronic effects on aquatic life in the receiving water; and

c. The permittee has demonstrated in accordance with procedure 6 of this appendix that the whole effluent does not exhibit acute or chronic toxicity.

3. Nothing in sections C.1 or C.2 of this procedure shall preclude or deny the right of a permitting authority to:

a. Determine, in the absence of the data necessary to derive a Tier II value, that the discharge of the pollutant will cause, have the reasonable potential to cause, or contribute to an excursion above a narrative criterion for water quality; and

b. Incorporate a WQBEL for the pollutant into an NPDES permit.

4. If the permitting authority develops a WQBEL consistent with section C.3 of this procedure, and the permitting authority demonstrates that the WQBEL developed under section C.3 of this procedure is at least as stringent as a WQBEL that would have been based upon the Tier II value or values for that pollutant, the permitting authority shall not be obligated to generate or require the permittee to generate the data necessary to derive a Tier II value or values for that pollutant.

D. Consideration of Intake Pollutants in Determining Reasonable Potential.
40 CFR § 122.44
1. General.

a. Any procedures adopted by a State or Tribe for considering intake pollutants in water quality-based permitting shall be consistent with this section and section E.

b. The determinations under this section and section E shall be made on a pollutant-by-pollutant, outfall-by-outfall, basis.

c. This section and section E apply only in the absence of a TMDL applicable to the discharge prepared by the State or Tribe and approved by EPA, or prepared by EPA pursuant to 40 CFR 130.7(d), or in the absence of an assessment and remediation

plan submitted and approved in accordance with procedure 3.A. of appendix F. This section and section E do not alter the permitting authority's obligation under 40 CFR 122.44(d)(vii)(B) to develop effluent limitations consistent with the assumptions and requirements of any available WLA for the discharge, which is part of a TMDL prepared by the State or Tribe and approved by EPA pursuant to 40 CFR 130.7, or prepared by EPA pursuant to 40 CFR 130.7(d).

2. Definition of Same Body of Water.

a. This definition applies to this section and section E of this procedure.

b. An intake pollutant is considered to be from the same body of water as the discharge if the permitting authority finds that the intake pollutant would have reached the vicinity of the outfall point in the receiving water within a reasonable period had it not been removed by the permittee. This finding may be deemed established if:

i. The background concentration of the pollutant in the receiving water (excluding any amount of the pollutant in the facility's discharge) is similar to that in the intake water;

ii. There is a direct hydrological connection between the intake and discharge points; and

iii. Water quality characteristics (e.g., temperature, Ph, hardness) are similar in the intake and receiving waters.

c. The permitting authority may also consider other site-specific factors relevant to the transport and fate of the pollutant to make the finding in a particular case that a pollutant would or would not have reached the vicinity of the outfall point in the receiving water within a reasonable period had it not been removed by the permittee.

d. An intake pollutant from groundwater may be considered to be from the same body of water if the permitting authority determines that the pollutant would have reached the vicinity of the outfall point in the receiving water within a reasonable period had it not been removed by the permittee, except that such a pollutant is not from the same body of water if the groundwater contains the pollutant partially or entirely due to human activity, such as industrial, commercial, or municipal operations, disposed actions, or treatment processes.

e. An intake pollutant is the amount of a pollutant that is present in waters of the United States (including groundwater as provided in section D.2.d of this procedure) at the time it is withdrawn from such waters by the discharger or other facility (e.g., public water supply) supplying the discharger with intake water.

3. Reasonable Potential Determination.

a. The permitting authority may use the procedure described in this section of procedure 5 in lieu of procedures 5.A through C provided the conditions specified below are met.

b. The permitting authority may determine that there is no reasonable potential for the discharge of an identified intake pollutant or pollutant parameter to cause or contribute to an excursion above a narrative or numeric water quality criterion within an applicable water quality standard where a discharger demonstrates to the satisfaction of the permitting authority (based upon information provided in the permit application or other information deemed necessary by the permitting authority) that:

i. The facility withdraws 100 percent of the intake water containing the pollutant from the same body of water into which the discharge is made;

ii. The facility does not contribute any additional mass of the identified intake pollutant to its wastewater;

iii. The facility does not alter the identified intake pollutant chemically or physically in a manner that would cause adverse water quality impacts to occur that would not occur if the pollutants were left in-stream;

iv. The facility does not increase the identified intake pollutant concentration, as defined by the permitting authority, at the edge of the mixing zone, or at the point of discharge if a mixing zone is not allowed, as compared to the pollutant concentration in the intake water, unless the increased concentration does not cause or contribute to an excursion above an applicable water quality standard; and

v. The timing and location of the discharge would not cause adverse water quality impacts to occur that would not occur if the identified intake pollutant were left in-stream.

c. Upon a finding under section D.3.b of this procedure that a pollutant in the ***15422** discharge does not cause, have the reasonable potential to cause, or contribute to an excursion above an applicable water quality standard, the permitting authority is not required to include a WQBEL for the identified intake pollutant in the facility's permit, provided:

i. The NPDES permit fact sheet or statement of basis includes a specific determination that there is no reasonable potential for the discharge of an identified intake pollutant to cause or contribute to an excursion above an applicable narrative or numeric water quality criterion and references appropriate supporting documentation included in the administrative record;

ii. The permit requires all influent, effluent, and ambient monitoring necessary to demonstrate that the conditions in section D.3.b of this procedure are maintained during the permit term; and

iii. The permit contains a reopener clause authorizing modification or revocation and reissuance of the permit if new information indicates changes in the conditions in section D.3.b of this procedure.

d. Absent a finding under section D.3.b of this procedure that a pollutant in the discharge does not cause, have the reasonable potential to cause, or contribute to an excursion above an applicable water quality standard, the permitting authority shall use the procedures under sections 5.A through C of this procedure to determine whether a discharge causes, has the reasonable potential to cause, or contribute to an excursion above an applicable narrative or numeric water quality criterion.

E. Consideration of Intake Pollutants in Establishing WQBELs.

1. General. This section applies only when the concentration of the pollutant of concern upstream of the discharge (as determined using the provisions in procedure 3.B.9 of appendix F) exceeds the most stringent applicable water quality criterion for that pollutant.

2. The requirements of sections D.1-D.2 of this procedure shall also apply to this section.

3. Intake Pollutants from the Same Body of Water.

a. In cases where a facility meets the conditions in sections D.3.b.i and D.3.b.iii through D.3.b.v of this procedure, the permitting authority may establish effluent limitations allowing the facility to discharge a mass and concentration of the pollutant that are no greater than the mass and concentration of the pollutant identified in the facility's intake water (“no net addition limitations”). The permit shall specify how compliance with mass and concentration limitations shall be assessed. No permit may authorize “no net addition limitations” which are effective after March 23, 2007. After that date, WQBELs shall be established in accordance with procedure 5.F.2 of appendix F.

b. Where proper operation and maintenance of a facility's treatment system results in removal of a pollutant, the permitting authority may establish limitations that reflect the lower mass and/or concentration of the pollutant achieved by such treatment, taking into account the feasibility of establishing such limits.

c. For pollutants contained in intake water provided by a water system, the concentration of the intake pollutant shall be determined at the point where the raw water supply is removed from the same body of water, except that it shall be the point where the water enters the water supplier's distribution system where the water treatment system removes any of the identified pollutants from the raw water supply. Mass shall be determined by multiplying the concentration of the pollutant determined in accordance with this paragraph by the volume of the facility's intake flow received from the water system.

4. Intake Pollutants from a Different Body of Water. Where the pollutant in a facility's discharge originates from a water of the United States that is not the same body of water as the receiving water (as determined in accordance with section D.2 of this procedure), WQBELs shall be established based upon the most stringent applicable water quality criterion for that pollutant.

5. Multiple Sources of Intake Pollutants. Where a facility discharges intake pollutants that originate in part from the same body of water, and in part from a different body of water, the permitting authority may apply the procedures of sections E.3 and E.4 of this procedure to derive an effluent limitation reflecting the flow-weighted average of each source of the pollutant, provided that adequate monitoring to determine compliance can be established and is included in the permit.

F. Other Applicable Conditions.

1. In addition to the above procedures, effluent limitations shall be established to comply with all other applicable State, Tribal and Federal laws and regulations, including technology-based requirements and antidegradation policies.

2. Once the permitting authority has determined in accordance with this procedure that a WQBEL must be included in an NPDES permit, the permitting authority shall:

a. Rely upon the WLA established for the point source either as part of any TMDL prepared under procedure 3 of this appendix and approved by EPA pursuant to 40 CFR 130.7, or as part of an assessment and remediation plan developed and approved in accordance with procedure 3.A of this appendix, or, in the absence of such TMDL or plan, calculate WLAs for the protection of acute and chronic aquatic life, wildlife and human health consistent with the provisions referenced in section A.1 of this procedure for developing preliminary wasteload allocations, and

b. Develop effluent limitations consistent with these WLAs in accordance with existing State or Tribal procedures for converting WLAs into WQBELs.

3. When determining whether WQBELs are necessary, information from chemical-specific, whole effluent toxicity and biological assessments shall be considered independently.

4. If the geometric mean of a pollutant in fish tissue samples collected from a waterbody exceeds the tissue basis of a Tier I criterion or Tier II value, after consideration of the variability of the pollutant's bioconcentration and bioaccumulation in fish, each facility that discharges detectable levels of such pollutant to that water has the reasonable potential to cause or contribute to an excursion above a Tier I criteria or a Tier II value and the permitting authority shall establish a WQBEL for such pollutant in the NPDES permit for such facility.

Procedure 6: Whole Effluent Toxicity Requirements

The Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) procedure 6 of appendix F of part 132.

The following definitions apply to this part:

Acute toxic unit (TU_a). $100/LC_{50}$ where the LC_{50} is expressed as a percent effluent in the test medium of an acute whole effluent toxicity (WET) test that is statistically or graphically estimated to be lethal to 50 percent of the test organisms.

Chronic toxic unit (TU_c). 100/NOEC or $100/IC_{25}$, where the NOEC and IC_{25} are expressed as a percent effluent in the test medium.

Inhibition concentration 25 (IC_{25}). the toxicant concentration that would cause a 25 percent reduction in a non-quantal biological measurement for the test population. For example, the IC_{25} is the concentration of toxicant that would cause a 25 percent reduction in mean young per female or in growth for the test population.

No observed effect concentration (NOEC). The highest concentration of toxicant to which organisms are exposed in a full life-cycle or partial life-cycle (short-term) test, that causes no observable adverse effects on the test organisms (i.e., the highest concentration of toxicant in which the values for the observed responses are not statistically significantly different from the controls).

A. Whole Effluent Toxicity Requirements. The Great Lakes States and Tribes shall adopt whole effluent toxicity provisions consistent with the following:

1. A numeric acute WET criterion of 0.3 acute toxic units (TU_a) measured pursuant to test methods in 40 CFR part 136, or a numeric interpretation of a narrative criterion establishing that 0.3 TU_a measured pursuant to test methods in 40 CFR part 136 is necessary to protect aquatic life from acute effects of WET. At the discretion of the permitting authority, the foregoing requirement shall not apply in an acute mixing zone that is sized in accordance with EPA-approved State and Tribal methods.

2. A numeric chronic WET criterion of one chronic toxicity unit (TU_c) measured pursuant to test methods in 40 CFR part 136, or a numeric interpretation of a narrative criterion establishing that one TU_c measured pursuant to test methods in 40 CFR part 136 is necessary to protect aquatic life from the chronic effects of WET. At the discretion of the permitting authority, the foregoing requirements shall not apply within a chronic mixing zone consistent with: (a) procedures 3.D.1 and 3.D.4, for discharges to the open of the Great Lakes (OWGL), inland ***15423** lakes and other waters of the Great Lakes System with no appreciable flow relative to their volume, or (b) procedure 3.E.5 for discharges to tributaries and connecting channels of the Great Lakes System.

B. WET Test Methods. All WET tests performed to implement or ascertain compliance with this procedure shall be performed in accordance with methods established in 40 CFR part 136.

C. Permit Conditions.

40 CFR § 122.44

1. Where a permitting authority determines pursuant to section D of this procedure that the WET of an effluent is or may be discharged at a level that will cause, have the reasonable potential to cause, or contribute to an excursion above any numeric WET criterion or narrative criterion within a State's or Tribe's water quality standards, the permitting authority:

a. Shall (except as provided in section C.1.e of this procedure) establish a water quality-based effluent limitation (WQBEL) or WQBELs for WET consistent with section C.1.b of this procedure;

b. Shall calculate WQBELs pursuant to section C.1.a. of this procedure to ensure attainment of the State's or Tribe's chronic WET criteria under receiving water flow conditions described in procedures 3.E.1.a (or where applicable, with procedure 3.E.1.e) for Great Lakes System tributaries and connecting channels, and with mixing zones no larger than allowed pursuant to section A.2. of this procedure. Shall calculate WQBELs to ensure attainment of the State's or Tribe's acute WET criteria under receiving water flow conditions described in procedure 3.E.1.b (or where applicable, with procedure 3.E.1.e) for Great Lakes System

tributaries and connecting channels, with an allowance for mixing zones no greater than specified pursuant to section A.1 of this procedure.

c. May specify in the NPDES permit the conditions under which a permittee would be required to perform a toxicity reduction evaluation.

d. May allow with respect to any WQBEL established pursuant to section C.1.a of this procedure an appropriate schedule of compliance consistent with procedure 9 of appendix F; and

e. May decide on a case-by-case basis that a WQBEL for WET is not necessary if the State's or Tribe's water quality standards do not contain a numeric criterion for WET, and the permitting authority demonstrates in accordance with 40 CFR 122.44(d)(1)(v) that chemical-specific effluent limits are sufficient to ensure compliance with applicable criteria.

2. Where a permitting authority lacks sufficient information to determine pursuant to section D of this procedure whether the WET of an effluent is or may be discharged at levels that will cause, have the reasonable potential to cause, or contribute to an excursion above any numeric WET criterion or narrative criterion within a State's or Tribe's water quality standards, then the permitting authority should consider including in the NPDES permit appropriate conditions to require generation of additional data and to control toxicity if found, such as:

a. WET testing requirements to generate the data needed to adequately characterize the toxicity of the effluent to aquatic life;

b. Language requiring a permit reopener clause to establish WET limits if any toxicity testing data required pursuant to section C.2.a of this procedure indicate that the WET of an effluent is or may be discharged at levels that will cause, have the reasonable potential to cause, or contribute to an excursion above any numeric WET criterion or narrative criterion within a State's or Tribe's water quality standards.
40 CFR § 122.44
3. Where sufficient data are available for a permitting authority to determine pursuant to section D of this procedure that the WET of an effluent neither is nor may be discharged at a level that will cause, have the reasonable potential to cause, or contribute to an excursion above any numeric WET criterion or narrative criterion within a State's or Tribe's water quality standards, the permitting authority may include conditions and limitations described in section C.2 of this procedure at its discretion.

D. Reasonable Potential Determinations. The permitting authority shall take into account the factors described in 40 CFR 122.44(d)(1)(ii) and, where representative facility-specific WET effluent data are available, apply the following requirements in determining whether the WET of an effluent is or may be discharged at a level that will cause, have the reasonable potential to cause, or contribute to an excursion above any numeric WET criterion or narrative criterion within a State's or Tribe's water quality standards.

1. The permitting authority shall characterize the toxicity of the discharge by:

a. Either averaging or using the maximum of acute toxicity values collected within the same day for each species to represent one daily value. The maximum of all daily values for the most sensitive species tested is used for reasonable potential determinations;

b. Either averaging or using the maximum of chronic toxicity values collected within the same calendar month for each species to represent one monthly value. The maximum of such values, for the most sensitive species tested, is used for reasonable potential determinations:

c. Estimating the toxicity values for the missing endpoint using a default acute-chronic ratio (ACR) of 10, when data exist for either acute WET or chronic WET, but not for both endpoints.

2. The WET of an effluent is or may be discharged at a level that will cause, have the reasonable potential to cause, or contribute to an excursion above any numeric acute WET criterion or numeric interpretation of a narrative criterion within a State's or Tribe's water quality standards, when effluent-specific information demonstrates that:

(TU_a effluent) (B) (effluent flow/(Qad+effluent flow))>AC

Where TU_a effluent is the maximum measured acute toxicity of 100 percent effluent determined pursuant to section D.1.a. of this procedure, B is the multiplying factor taken from Table F6-1 of this procedure to convert the highest measured effluent toxicity value to the estimated 95th percentile toxicity value for the discharge, effluent flow is the same effluent flow used to calculate the preliminary wasteload allocations (WLAs) for individual pollutants to meet the acute criteria and values for those pollutants, AC is the numeric acute WET criterion or numeric interpretation of a narrative criterion established pursuant to section A.1 of this procedure and expressed in TU_a, and Qad is the amount of the receiving water available for dilution calculated using: (i) the specified design flow(s) for tributaries and connecting channels in section C.1.b of this procedure, or where appropriate procedure 3.E.1.e of appendix F, and using EPA-approved State and Tribal procedures for establishing acute mixing zones in tributaries and connecting channels, or (ii) the EPA-approved State and Tribal procedures for establishing acute mixing zones in OWGLs. Where there are less than 10 individual WET tests, the multiplying factor taken from Table F6-1 of this procedure shall be based on a coefficient of variation (CV) or 0.6. Where there are 10 or more individual WET tests, the multiplying factor taken from Table F6-1 shall be based on a CV calculated as the standard deviation of the acute toxicity values found in the WET tests divided by the arithmetic mean of those toxicity values.

3. The WET of an effluent is or may be discharged at a level that will cause, have the reasonable potential to cause, or contribute to an excursion above any numeric chronic WET criterion or numeric interpretation of a narrative criterion within a State's or Tribe's water quality standards, when effluent-specific information demonstrates that:

(TU_c effluent) (B) (effluent flow/Qad+effluent flow))>CC

Where TU_c effluent is the maximum measured chronic toxicity value of 100 percent effluent determined in accordance with section D.1.b. of this procedure, B is the multiplying factor taken from Table F6-1 of this procedure, effluent flow is the same effluent flow used to calculate the preliminary WLAs for individual pollutants to meet the chronic criteria and values for those pollutants, CC is the numeric chronic WET criterion or numeric interpretation of a narrative criterion established pursuant to section A.2 of this procedure and expressed in TU_c, and Qad is the amount of the receiving water available for dilution calculated using: (i) the design flow(s) for tributaries and connecting channels specified in procedure 3.E.1.a of appendix F, and where appropriate procedure 3.E.1.e of appendix F, and in accordance with the provisions of procedure 3.E.5 for chronic mixing zones, or (ii) procedures 3.D.1 and 3.D.4 for discharges to the OWGLs. Where there are less than 10 individual WET tests, the multiplying factor taken from Table F6-1 of this procedure shall be based on a CV of 0.6. Where there are 10 more individual WET tests, the multiplying factor taken from Table F6-1 of this procedure shall be based on a CV calculated as the standard deviation of the WET tests divided by the arithmetic mean of the WET tests.

Table F6-1.— Reasonable Potential Multiplying Factors: 95% Confidence Level and 95% Probability Basis

***15424 Procedure 7: Loading Limits**

The Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) this procedure.

Whenever a water quality-based effluent limitation (WQBEL) is developed, the WQBEL shall be expressed as both a concentration value and a corresponding mass loading rate.

A. Both mass and concentration limits shall be based on the same permit averaging periods such as daily, weekly, or monthly averages, or in other appropriate permit averaging periods.

B. The mass loading rates shall be calculated using effluent flow rates that are consistent with those used in establishing the WQBELs expressed in concentration.

Procedure 8: Water Quality-based Effluent Limitations Below the Quantification Level

The Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) this procedure.

When a water quality-based effluent limitation (WQBEL) for a pollutant is calculated to be less than the quantification level:

A. Permit Limits. The permitting authority shall designate as the limit in the NPDES permit the WQBEL exactly as calculated.

B. Analytical Method and Quantification Level.

1. The permitting authority shall specify in the permit the most sensitive, applicable, analytical method, specified in or approved under 40 CFR part 136, or other appropriate method if one is not available under 40 CFR part 136, to be used to monitor for the presence and amount in an effluent of the pollutant for which the WQBEL is established; and shall specify in accordance with section B.2 of this procedure, the quantification level that can be achieved by use of the specified analytical method.

2. The quantification level shall be the minimum level (ML) specified in or approved under 40 CFR part 136 for the method for that pollutant. If no such ML exists, or if the method is not specified or approved under 40 CFR part 136, the quantification level shall be the lowest quantifiable level practicable. The permitting authority may specify a higher quantification level if the permittee demonstrates that a higher quantification level is appropriate because of effluent-specific matrix interference.

3. The permit shall state that, for the purpose of compliance assessment, the analytical method specified in the permit shall be used to monitor the amount of pollutant in an effluent down to the quantification level, provided that the analyst has complied with the specified quality assurance/quality control procedures in the relevant method.

4. The permitting authority shall use applicable State and Tribal procedures to average and account for monitoring data. The permitting authority may specify in the permit the value to be used to interpret sample values below the quantification level.

C. Special Conditions. The permit shall contain a reopener clause authorizing modification or revocation and reissuance of the permit if new information generated as a result of special conditions included in the permit indicates that presence of the pollutant in the discharge at levels above the WQBEL. Special conditions that may be included in the permit include, but are not limited to, fish tissue sampling, whole effluent toxicity (WET) tests, limits and/or monitoring requirements on internal waste streams, and monitoring for surrogate parameters. Data generated as a result of special conditions can be used to reopen the permit to establish more stringent effluent limits or conditions, if necessary.

D. Pollutant Minimization Program. The permitting authority shall include a condition in the permit requiring the permittee to develop and conduct a pollutant minimization program for each pollutant with a WQBEL below the quantification level. The goal of the pollutant minimization program shall be to reduce all potential sources of the pollutant to maintain the effluent at or below the WQBEL. In addition, States and Tribes may consider cost-effectiveness when establishing the requirements of a PMP. The pollutant minimization program shall include, but is not limited to, the following:

1. An annual review and semi-annual monitoring of potential sources of the pollutant, which may include fish tissue monitoring and other bio-uptake sampling;

2. Quarterly monitoring for the pollutant in the influent to the wastewater treatment system;

3. Submittal of a control strategy designed to proceed toward the goal of maintaining all sources of the pollutant to the wastewater collection system below the WQBEL;

4. When the sources of the pollutant are discovered, appropriate cost-effective control ***15425** measures shall be implemented, consistent with the control strategy; and

5. An annual status report that shall be sent to the permitting authority including:

a. All minimization program monitoring results for the previous year;

b. A list of potential sources of the pollutant; and

c. A summary of all action taken to reduce or eliminate the identified sources of the pollutant.
40 CFR § 122.44
6. Any information generated as a result of procedure 8.D can be used to support a request for subsequent permit modifications, including revisions to (e.g., more or less frequent monitoring), or removal of the requirements of procedure 8.D, consistent with 40 CFR 122.44, 122.62 and 122.63.

Procedure 9: Compliance Schedules
The Great Lakes States and Tribes shall adopt provisions consistent with (as protective as) procedure 9 of appendix F of part 132.

A. Limitations for New Great Lakes Dischargers. When a permit issued on or after March 23, 1997 to a new Great Lakes discharger (defined in Part 132.2) contains a water quality-based effluent limitation (WQBEL), the permittee shall comply with such a limitation upon the commencement of the discharge.

B. Limitations for Existing Great Lakes Dischargers.

1. Any existing permit that is reissued or modified on or after March 23, 1997 to contain a new or more restrictive WQBEL may allow a reasonable period of time, up to five years from the date of permit issuance or modification, for the permittee to comply with that limit, provided that the Tier I criterion or whole effluent toxicity (WET) criterion was adopted (or, in the case of a narrative criterion, Tier II value, or Tier I criterion derived pursuant to the methodology in appendix A of part 132, was newly derived) after July 1, 1977.

2. When the compliance schedule established under paragraph 1 goes beyond the term of the permit, an interim permit limit effective upon the expiration date shall be included in the permit and addressed in the permit's fact sheet or statement of basis. The administrative record for the permit shall reflect the final limit and its compliance date.

3. If a permit establishes a schedule of compliance under paragraph 1 which exceeds one year from the date of permit issuance or modification, the schedule shall set forth interim requirements and dates for their achievement. The time between such interim dates may not exceed one year. If the time necessary for completion of any interim requirement is more than one year and is not readily divisible into stages for completion, the permit shall require, at a minimum, specified dates for annual submission of progress reports on the status of any interim requirements.

C. Delayed Effectiveness of Tier II Limitations for Existing Great Lakes Discharges.

1. Whenever a limit (calculated in accordance with Procedure 3) based upon a Tier II value is included in a reissued or modified permit for an existing Great Lakes discharger, the permit may provide a reasonable period of time, up to two years, in which to provide additional studies necessary to develop a Tier I criterion or to modify the Tier II value. In such cases, the permit shall require compliance with the Tier II limitation within a reasonable period of time, no later than five years after permit issuance or modification, and contain a reopener clause.

2. The reopener clause shall authorize permit modifications if specified studies have been completed by the permittee or provided by a third-party during the time allowed to conduct the specified studies, and the permittee or a third-party demonstrates, through such studies, that a revised limit is appropriate. Such a revised limit shall be incorporated through a permit modification and a reasonable time period, up to five years, shall be allowed for compliance. If incorporated prior to the compliance date of the original Tier II limitation, any such revised limit shall not be considered less-stringent for purposes of the anti-backsliding provisions of section 402(o) of the Clean Water Act.

3. If the specified studies have been completed and do not demonstrate that a revised limit is appropriate, the permitting authority may provide a reasonable additional period of time, not to exceed five years with which to achieve compliance with the original effluent limitation.

4. Where a permit is modified to include new or more stringent limitations, on a date within five years of the permit expiration date, such compliance schedules may extend beyond the term of a permit consistent with section B.2 of this procedure.

5. If future studies (other than those conducted under paragraphs 1, 2, or 3 above) result in a Tier II value being changed to a less stringent Tier II value or Tier I criterion, after the effective date of a Tier II-based limit, the existing Tier II-based limit may be revised to be less stringent if:

(a) It complies with sections 402(o) (2) and (3) of the CWA; or,

(b) In non-attainment waters, where the existing Tier II limit was based on procedure 3, the cumulative effect of revised effluent limitation based on procedure 3 of this appendix will assure compliance with water quality standards; or,

(c) In attained waters, the revised effluent limitation complies with the State or Tribes' antidegradation policy and procedures.

TECHNICAL SUPPORT DOCUMENT

For Action on the State of Oregon's New and Revised Human Health Water Quality Criteria for Toxics and Associated Implementation Provisions Submitted July 12 and 21, 2011

I. INTRODUCTION

In consideration of current information relative to fish consumption in Oregon, the Oregon Department of Environmental Quality (ODEQ) proposed revisions to Oregon's water quality standards (WQS) located in Chapter 340, Division 41 of Oregon's Administrative Rules (OAR 340-041). ODEQ proposed new and revised human health water quality criteria for toxics and associated implementation provisions on December 21, 2010. ODEQ provided a formal public comment period on the proposed revisions and held nine public hearings. The public comment period extended from December 21, 2010 through March 21, 2011. 1,075 written comments were received and responded to by ODEQ. Revisions were adopted by the Oregon Environmental Quality Commission (EQC or Commission) on June 16, 2011, and filed with Oregon Secretary of State on July 13, 2011. Oregon's submittal included a letter dated July 20, 2011, from Larry Knudsen, Assistant Attorney General, certifying that the revisions were adopted in accordance with Oregon State law. In accordance with Section 303(c) of the Clean Water Act (CWA) ODEQ submitted these revisions to EPA for review and approval on July 21, 2011.

ODEQ revised their human health criteria for iron and manganese in a separate submittal dated January 18, 2011, which EPA approved on June 9, 2011. ODEQ also revised the human health criteria for arsenic in a separate submittal dated July 12, 2011, which EPA is now approving as part of this action. ODEQ accepted public comments on these revisions from August 25 to September 30, 2010, and held public hearings in Portland and Pendleton. ODEQ also conducted further public comment on the proposed rule, including revised proposed numeric criteria from February 1 to February 23, 2011. These revisions were adopted by the EQC on April 21, 2011 and became effective under State law upon filing with the Oregon Secretary of State on June 30, 2011. ODEQ submitted the revisions to the human health criteria for arsenic to EPA for review and approval on July 12, 2011. Oregon's submittal included a letter dated July 11, 2011, from Larry Knudsen, Assistant Attorney General, certifying that the revisions were adopted in accordance with Oregon State law.

The June 16, 2011 rule package adopted by the EQC included revisions to the States' Total Maximum Daily Load (TMDL) and National Pollutant Discharge Elimination System (NPDES) permitting regulations found in OAR 340-042 and 045. These are revisions to Oregon's implementation rules and are not water quality standards. Accordingly, Oregon did not include

them in the materials submitted for review under Section 303(c) of the CWA and EPA does not address them in today's action.

Revisions addressed in today's decision can be divided into the general categories described below.

1. ***New and revised human health criteria for carcinogens and non-carcinogens at OAR 340-041-0033.***
   ODEQ adopted new and revised human health criteria for 104 toxic pollutants (48 non-carcinogens and 56 carcinogens) based on a fish consumption rate of 175 grams per day. The criteria for these toxic pollutants are consistent with EPA's 304(a) recommended criteria values[1] and were derived using the methodology presented in EPA's 2000 *Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health*[2] and EPA's 2001 Methylmercury guidance.[3] The new and revised human health criteria for toxic pollutants are contained in Table 40.

   Additional revisions related to the human health criteria include:

   - The removal of 13 pollutants consistent with EPA's removal of 304(a) recommended criteria values for these same pollutants. Most of these recommended criteria were withdrawn since EPA developed individual criteria for the most toxic of chemicals in the family of chemicals represented by those 13 pollutants.
   - Several new, revised and withdrawn footnotes to the criteria in order to provide clarification.
   - Revisions to the water quality standards provision at OAR 340-041-0033 which revise regulatory citations and table numbers referencing the human health and aquatic life criteria tables.

2. ***Revised arsenic human health criteria.***
   ODEQ adopted revised human health criteria for arsenic and submitted the revised criteria separately to EPA on July 12, 2011.

3. ***New implementation provision entitled "Site-specific background pollutant criteria" at OAR 340-041-0033(6).***
   ODEQ adopted a new provision that allows it to develop a site-specific criteria for a portion of a waterbody in the vicinity of an NPDES permitted discharge in limited instances. The criteria is only applicable for criteria addressing carcinogenic effects on

[2] EPA. 2000. *Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health*. U.S. Environmental Protection Agency, Office of Water, EPA-822-B-00-004. Available at: http://www.epa.gov/waterscience/criteria/humanhealth/method/complete.pdf
[3] EPA. 2001. *Water Quality Criterion for the Protection of Human Health: Methylmercury*. U.S. Environmental Protection Agency, Office of Water, Washington, D.C. EPA 823-R-01-001. Available at: http://www.epa.gov/waterscience/criteria/methylmercury/document.html

human health and for pollutants that are taken into a facility through their intake water and discharged to the same waterbody at an equal or lower mass. The instream criterion concentration is limited to three percent above the ambient condition and may not exceed a 10^{-4} risk level as calculated using the same input variables as used to calculate the criteria in Table 40.

4. ***Revised variance provision at OAR 340-041-0059.***
   ODEQ has removed the variance authorizing procedure found at OAR 340-041-0061(2) and replaced it with a new procedure at OAR 340-041-0059. ODEQ's objective for these revisions was to ensure that variances and their accompanying pollutant reduction plans continue to ensure progress toward meeting standards, to streamline the administration process, and to require pollutant reduction plans with specific milestones that will result in water quality improvement, and add general clarification to the rule. All variances adopted under this provision require EPA approval.

5. ***A correction to a cross-reference in the bacteria provision found at OAR 340-041-0009(10).***
   ODEQ adopted a revision to correct the cross-reference in this provision to reflect rule numbering revisions in OAR 340-041-0061.

6. ***Revised rules explaining how the mechanisms for forestry and agricultural nonpoint sources work to meet water quality standards and the total maximum daily load (TMDL) load at OAR 340-041-0007(5) and OAR 340-041-0061(9)(a)(E), (10), and (11).***
   ODEQ adopted revisions to clarify how nonpoint sources will be addressed in TMDLs and how ODEQ will interact with the Departments of Forestry and Agriculture to ensure needed programs are in place to address these sources of pollution.

II. ORGANIZATION OF DOCUMENT

This document is organized in the following manner. Part III of this document contains background on ODEQ's process to adopt new and revised human health criteria and information regarding the July 12 and 21, 2011 submittals.

Part IV contains the basis for EPA's decisions under section 303(c) of the Clean Water Act (CWA) and implementing regulations found in the Code of Federal Regulations (CFR) at 40 CFR § 131.11 to approve Oregon's new and revised human health criteria. This section includes information regarding EPA's review of Oregon's human health criteria revisions which specifically evaluates the applicability of the human health criteria to Oregon's waters along with the methodology and input variables used by Oregon for their non-carcinogenic and carcinogenic criteria. This includes an evaluation of Oregon's revised fish consumption rate of 175 grams per day used to derive the State's new and revised human health criteria. Separate subsections include the EPA's action on Oregon's new methylmercury human health criteria and revised human health criteria for arsenic. Finally, this section outlines EPA's review and action on new, revised and withdrawn footnotes, withdrawn human health criteria which were replaced by more specific criteria and the Table 40 summary language.

Part V of this document contains EPA's review and action on revisions to Oregon's narrative statement at OAR 340-041-0033.

Parts VI and VII of the document contain EPA's review and approval of two implementation procedures included in the July 21, 2011 submittal – the background pollutant criteria and the revised variance provision.

Part VIII of this document includes EPA's review and action on a minor editorial change to Oregon's bacteria provision to correct a cross-referencing error.

Part IX discusses the revised rules regarding implementation of criteria by forestry and agricultural nonpoint sources. These provisions are not WQS under the CWA and therefore EPA is taking no action on them.

III. BACKGROUND

In 1999, ODEQ initiated a Water Quality Standards Review (triennial review) to update Oregon's criteria for toxic pollutants which were based on the 1986 EPA Gold Book[4] and that were contained in OAR 340-041-0033 and Table 20 of Oregon's water quality standards. This review was completed in 2003. During this review, ODEQ made significant revisions to both their aquatic life and human health criteria based on the updated EPA methodologies and science for deriving aquatic life and human health criteria that had occurred since the Gold Book had been published. The Commission adopted these new and revised water quality standards on May 20, 2004. Upon adoption, ODEQ submitted these criteria changes along with revisions to the narrative toxics provision to EPA on July 8, 2004.

One goal of Oregon's 1999-2003 WQS review was to update its human health criteria for toxic pollutants in order to reflect the latest scientific information and EPA's most recent national CWA § 304(a) human health criteria recommendations.[5] In 2000, EPA published a revised methodology for deriving § 304(a) human health criteria recommendations titled *Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health* (hereinafter referred to as the "2000 Methodology").[6] In separate updates published in 2002 and 2003[7,8] along with 2009,[9] EPA updated the § 304(a) human health criteria recommendations to reflect this new methodology and to consider updated toxicological information in EPA's Integrated Risk Information System (IRIS).[10]

The new and revised human health criteria adopted by Oregon in 2004 were based on EPA's recommendations provided in these documents. The human health criteria were derived using a fish consumption rate of 17.5 grams per day (about 0.6 ounces per day or three 6-ounce meals per month), which represents the 90th percentile of consumption among consumers and non-consumers of fish nationwide. This is the national default fish consumption rate recommended

by EPA in the 2000 Methodology for use when local, regional or other data is not available. During the public process Oregon received comment regarding concerns that the fish consumption rate used in the criteria may not accurately represent Oregonian's consumption patterns. Following review of these comments ODEQ recommended, and in 2004 the Commission adopted, criteria derived using a fish consumption rate of 17.5 grams per day. However, in recognition of this expressed public concern, the Commission requested that ODEQ seek resources to conduct a fish consumption rate study in Oregon.

Following Oregon's 2004 adoption of these criteria, the Confederated Tribes of the Umatilla Indian Reservation (Umatilla Tribe) and other tribal governments raised objections to EPA, stating that the criteria did not protect tribal members who eat higher amounts of fish and for whom fish consumption is a critical part of their cultural tradition and religion. In response, EPA evaluated the protectiveness of the criteria in light of local and regional fish consumption data and initiated discussions with Oregon regarding this issue. Local data was available from a study conducted by the Columbia River Inter-Tribal Fish Commission (CRITFC)[11] (hereinafter referred to as the "CRITFC Study"), which included surveys of four Columbia River Tribes, two of whom reside in Oregon, the Confederated Tribes of the Umatilla Indian Reservation (CTUIR or Umatilla Tribe) and the Confederated Tribes of the Warms Springs Reservation. In addition, several regional fish consumption studies were also available.

Oregon was not able to obtain funding for a study of Oregon fish consumption rates specific to Oregon but did agree to review available literature and data in collaboration with EPA and the Umatilla Tribe. In the fall of 2006, ODEQ launched the fish consumption rate review project involving seven public workshops and two workgroups. The workgroups were charged with providing ODEQ with information relative to the available science and the potential implementation and fiscal concerns that may be associated with criteria based on a higher fish consumption rate. The Human Health Focus Group (HHFG), made up of public health professionals and toxicologists, reviewed the available data on fish consumption patterns in the Pacific Northwest and elsewhere. The group wrote a report[12] summarizing the science and made recommendations about the quality and appropriate use of the available information. ODEQ considered the HHFG's analysis and the other information obtained during this project to select a fish consumption rate they felt appropriate for use in developing criteria for Oregon's waters.

Oregon addressed several issues during the process of determining an appropriate fish consumption rate for Oregon. These included:

- Which studies should be considered when developing a fish consumption rate for Oregon?
- Should the criteria be based on a fish consumption rate that includes Oregonians who

[11] Columbia River Inter-Tribal Fish Commission (CRITFC). October 1994. *A Fish Consumption Survey of the Umatilla, Nez Perce, Yakama, and Warm Springs Tribes of the Columbia River Basin.* Technical Report 94.3. Available at: http://www.critfc.org/tech/94-3report.pdf

[12] ODEQ. June 2008. *Human Health Focus Group Report. Oregon Fish and Shellfish Consumption Rate Project.* Oregon Department of Environmental Quality. Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/HHFGFinalReportJune2008.pdf

eat large amounts of fish and shellfish for cultural, economic, health or other reasons, or a fish consumption rate reflective of Oregon's total (general) population, including people who do not eat fish or eat it rarely?

- What proportion or percentile of the population(s) should be protected by the criteria? (Within any group, whether Native-Americans, Asian-Americans, commercial fishermen or the general population, there will be some individuals who eat more than any chosen rate and some who eat less than that rate.)
- How should the consumption of salmon (an anadromous fish) and/or marine fish be considered when determining the rate to be used for freshwaters?
- Should the same rate be used for all waters of Oregon or should multiple rates be considered based on known consumption patterns?

Following review of all the information obtained during the fish consumption rate review project, ODEQ determined that a fish consumption rate of 175 grams per day was a reasonable and protective fish consumption rate to use when driving the human health criteria applicable to Oregon's surface waters. A fish consumption rate of 175 grams per day equals approximately 6.2 ounces per day (or approximately 23 8-oz fish or shellfish meals per month). This rate represents the 95th percentile value from the CRITFC study and is within the range of the 90th percentile values from various studies from the Northwest assembled by the HHFG.[13] ODEQ found the 175 grams per day rate to be consistent with the HHFG recommendation to use 90th or 95th percentile values to represent the proportion of the population the criteria should be designed to protect. ODEQ also found the rate to be consistent with HHFG recommendations to use a fish consumption rate that represents fish consumers only, rather than a rate derived from the overall population including both consumers and non-consumers of fish, and to include salmon and other marine species in the rate. Finally, ODEQ recommended that the rate be applied statewide.[14]

On October 23, 2008, ODEQ presented the EQC with a recommendation to revise Oregon's toxics criteria for human health using a FCR of 175 grams per day.[15] The Commission agreed with this recommendation and directed ODEQ to:

1. Revise Oregon's toxics criteria for human health based on a fish consumption rate of 175 grams per person per day;

[13] EPA. June 1, 2010. Technical Support Document for Action on the State of Oregon's New and Revised Human Health Water Quality Criteria for Toxics and Revisions to Narrative Toxics Provisions Submitted on July 8, 2004. [14] ODEQ. May 24, 2011. *Human Health Criteria Issue Paper.* Oregon Department of Environmental Quality. pages 8-10. Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/humanhealth/rulemaking/HumanHealthToxicCriteriaIssuePaper.pdf

[15] ODEQ. October 6, 2008. *Memo from Dick Pederson, Director ODEQ, to the Environmental Quality Commission. Agenda Item G, Action Item: Oregon's Fish Consumption Rate – For Use in Setting Water Quality Standards for Toxic Pollutants October 23, 2008 EQC Meeting.* Oregon Department of Environmental Quality. Available at: http://www.deq.state.or.us/about/eqc/agendas/attachments/2008oct/ItemG.pdf

2. Propose rule language that will allow ODEQ to implement the standards in National Pollutant Discharge Elimination System (NPDES) permits and other Clean Water Act programs in an environmentally meaningful and cost-effective manner;
3. Propose rule language or develop other implementation strategies to reduce the adverse impacts of toxic substances in Oregon's waters that are the result of non-point source (not via a pipe) discharges or other sources not subject to section 402 of the Clean Water Act;
4. Develop a proposed rule and implementation methods that carefully consider the costs and benefits of the fish consumption rate and the data and scientific analysis already compiled or that is developed as part of the rulemaking proceeding.

Pursuant to this directive, ODEQ established a Rulemaking Workgroup in December 2008. The purpose of this group was to provide input and feedback to ODEQ as it developed its proposed rulemaking to revise human health criteria using the revised fish consumption rate and to address potential issues associated with implementing the revised criteria. The workgroup met on a monthly basis from December 2008 until October 2010. In addition, to address the third element of the EQC directive, ODEQ formed other workgroups to address the reduction of toxic pollution from sources not regulated by NPDES permits and to assist in the development of a comprehensive, cross media toxics reduction strategy.[16]

On December 21, 2010, ODEQ issued a proposed rule for public comment that included new and revised human health criteria for toxic pollutants, a revision to their variance rule, a new background pollutant provision and several proposed additions and revisions to rules relating to the implementation of the NPDES program and nonpoint source programs. As detailed in Section I, ODEQ revised the proposed rule in response to comments received, presented it to the Commission for adoption on June 16, 2011, and submitted it to EPA on July 21, 2011.

On June 1, 2010, consistent with a Consent Decree entered in the U.S. District Court in the District of Oregon,[17] EPA acted on the revised human health criteria which Oregon had submitted to EPA on July 8, 2004. As part of this action, EPA disapproved all of Oregon's new and revised human health criteria that were derived using a fish consumption rate of 17.5 grams per day as well as three footnotes associated with those criteria and footnote K insofar as it applies to the "organism only" human health criterion for manganese. EPA found that these human health criteria, derived using a fish consumption rate of 17.5 grams per day, were not protective of Oregon's designated use of fishing consistent with the Commission's October 2008 directive. In the June 1, 2010 letter to ODEQ, EPA stated that it "believe[d] that Oregon's adoption of human health criteria consistent with the Commission's Directive to develop criteria using a fish consumption rate of 175 grams per day statewide would be adequate to address EPA's disapproval of the new and revised human health criteria as well as [3 of the 4] footnotes."[18] As part of the 2010 action, EPA approved the human health criteria for asbestos

Bussell, Director, Office of Water and Watersheds, EPA Region 10 to Neil Mullane, Administrator, Water Quality Division, ODEQ, *Re: EPA's Action on New and Revised Human Health Water Quality Criteria for Toxics and Revisions to Narrative Toxics Provisions in Oregon's Water Quality*

and copper since those criteria value were not derived based on a fish consumption rate, footnote K as it applies to the "water + organism criteria for iron and manganese, the withdrawal of eight human health criteria, and revisions to the narrative toxic provisions at OAR 340-041-0033(1) and (2).

A. *ODEQ'S JULY 12 AND JULY 21, 2011 SUBMITTALS*

In order to address the Commission's October 2008 directive and EPA's June 1, 2010 disapproval action, on July 21, 2011 Oregon submitted new and revised numeric human health criteria and two WQS implementation provisions to EPA for action under CWA §303(c). This submission also contained a correction to a regulatory citation in the bacteria criteria provision and several other regulatory changes that are not WQS. Revised criteria for arsenic were adopted separately by the Commission on April 21, 2011 and submitted to EPA on July 12, 2011. All of the numeric criteria adopted in these actions were derived using a fish consumption rate of 175 grams per day.

The new and revised criteria, which serve as the basis for NPDES permit limits and other regulatory decisions, are located in Oregon's WQS in a new table called Table 40. ODEQ has consolidated the human health criteria which were previously contained in Tables 20, 33A and 33B into Table 40. The adoption of the new and revised human health criteria based on a fish consumption rate of 175 grams per day is ODEQ's remedy to EPA's disapproval of ODEQ's 2004 human health criteria based on a fish consumption rate of 17.5 grams per day.

Consistent with CWA §303(c)(2)(B), in adopting these new and revised human health criteria, Oregon has adopted human health criteria for all of the priority toxic pollutants for which EPA has published criteria under CWA §304(a). Forty-eight of the 104 pollutants for which Oregon adopted new or revised human health criteria are characterized as non-carcinogens (i.e., not having the potential to cause cancer). The remaining 56 pollutants are carcinogens (i.e., having the potential to cause cancer).

The calculations that Oregon used to derive the human health criteria for non-carcinogens and carcinogens differed depending upon the primary exposure pathway appropriate to the pollutant for which the criteria were derived and are further described separately in section IV below. Oregon's criteria were adopted to protect human health from chronic (lifetime) exposure to toxic substances through drinking water and eating fish[19] obtained from surface waters. Where the criteria are derived to protect human health from exposure through both drinking water and eating fish (in combination), Oregon has adopted "water + organism" criteria. Where the criteria are derived to protect human health from exposure through eating fish alone (not in combination with drinking water), Oregon has adopted "organism only" criteria. These two sets of criteria (i.e., "water + organism" and "organism only") are reflected in the column headings of Table 40

Standards. Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/EPAHHLetter20100601.pdf
[19] As used throughout this technical support document, the term "fish" refers to finfish as well as shellfish.

in Oregon's WQS. Additional information can be found in ODEQ's Human Health Criteria Issue Paper.[20]

The criteria adopted by Oregon for methylmercury and arsenic were derived using variations to the methodology used for all other criteria. Thus, those two pollutants and the methods used to derive those criteria are addressed separately below.

Additional revisions related to the human health criteria, which are discussed below, include:

- The removal of 13 pollutants consistent with EPA's removal of 304(a) recommended criteria values for these same pollutants. Most of the previous criteria recommendations addressed families of pollutants for which the criteria recommendations were withdrawn when EPA developed criteria recommendations for the individual pollutants within each family of chemicals that present the greatest human health risk.
- Several new, revised and withdrawn footnotes to the criteria in order to provide clarification.
- Revisions to the water quality standards provision at OAR 340-041-0033 which provide narrative language explaining the human health and aquatic life criteria tables.

In response to the second, third and forth directives issued by the EQC on October 23, 2008, ODEQ also revised OAR 340-041 to include two WQS implementation provisions - a revised variance procedure and a site-specific background pollutant provision – and revised rule language addressing implementation for nonpoint sources. In addition, ODEQ adopted an intake credit rule (an NPDES permitting provision) and several changes to the TMDL rules in OAR 340-042 and 045. These latter changes were not submitted to EPA for consideration under CWA 303(c), are not WQS under the CWA, and are not addressed in this action.

[20] ODEQ. May 24, 2011. *Human Health Criteria Issue Paper.* Oregon Department of Environmental Quality. Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/humanhealth/rulemaking/HumanHealthToxicCriteriaIssuePaper.pdf

IV. ODEQ'S NEW AND REVISED HUMAN HEALTH CRITERIA

A. *EPA REVIEW OF OREGON'S HUMAN HEALTH CRITERIA REVISIONS*

This section contains the basis for EPA's decisions under section 303(c) of the CWA and implementing regulations found at 40 CFR § 131.11 to approve Oregon's new and revised human health criteria. This section includes information regarding EPA's review of Oregon's human health criteria revisions which specifically evaluates the applicability of the human health criteria to Oregon's waters along with the methodology and input variables used by Oregon for their non-carcinogenic and carcinogenic criteria. This includes an evaluation of Oregon's revised fish consumption rate of 175 grams per day. Separate subsections address EPA's action on Oregon's new methylmercury human health criteria and revised human health criteria for arsenic. Finally, this section outlines EPA's review and action on new, revised and withdrawn footnotes, withdrawn human health criteria which were replaced by more specific criteria and the Table 40 summary language.

1. Human Health Criteria Applicability to Oregon's Waters

Oregon's water quality standards designate beneficial uses for waters of the state for each basin in OAR 340-041-0101 to 0340 and Tables 101(A) through 340(A), incorporated into Oregon rule by reference. Oregon's designated uses consist of the following:

- Public Domestic Water Supply
- Private Domestic Water Supply
- Industrial Water Supply
- Irrigation
- Livestock Watering
- Fish and Aquatic Life
- Wildlife and Hunting
- Fishing
- Boating
- Water Contact Recreation
- Aesthetic Quality
- Hydro Power
- Commercial Navigation and Transportation

Oregon's human health criteria were developed to protect human health from long-term exposure to toxic pollutants in drinking water and through eating fish and shellfish containing these pollutants. Waters to be protected for drinking water are those designated as either "Public Domestic Water Supply" or "Private Domestic Water Supply." Waters to be protected for consumption of fish and shellfish are designated as "Fishing."

Oregon's "water + organism" criteria were established to limit the pollutant to levels that protect the safe consumption of drinking water and fish, including shellfish. These criteria are applied where Oregon has designated public or private domestic water supply, and fishing as beneficial uses. Table 1 below identifies those waters in Oregon that have both a fishing designated use and either a public domestic water supply or a private domestic water supply designated use. Both the "water + organism" criteria and the "organism only" criteria apply to these waters.

The "organism only" criteria apply where Oregon has designated a fishing use but not a domestic or private water supply use.[21] Table 2 below identifies those waters in Oregon that have a fishing designated use but neither a public domestic water supply nor a private domestic water supply designated use.

Table 1: Waters in Oregon that have both a fishing designated use as well as a public domestic water supply or a private domestic water supply designated use. Both the "water + organism" criteria and the "organism only" criteria apply to these waters.

300A	South Coast Basin	Estuaries and Adjacent Marine Waters
320A	Umpqua Basin	Umpqua River Estuary to Head of Tidewater and Adjacent Marine Waters

Oregon's application of human health criteria is consistent with EPA's guidance to states and the methodology inherent in developing the criteria. EPA's *Water Quality Standards Handbook* recommends that states adopt human health criteria to protect waters designated for public water supply. In addition, for waters where fish ingestion is considered an important activity, EPA recommends that the criterion applicable to fish consumption be applied to protect the use.[22] Oregon's human health criteria are applied consistent with this recommendation.

EPA has published guidelines for developing criteria that protect human health endpoints and separate criteria guidance to protect aquatic life endpoints. Consistent with the science used to derive the criteria, EPA recommends that human health criteria be applied to uses where human health could be affected by exposure from consumption of water and/or aquatic life and aquatic life criteria be applied to uses associated with the protection of aquatic life. Thus, most states, including Oregon, have adopted two sets of criteria for toxic pollutants, one to address the effects to human health and the other to address the effects to aquatic life. For some pollutants, this results in a waterbody segment having multiple criteria for a single pollutant, in which case the WQS require the attainment of all of the applicable criteria.

Oregon's human health criteria are developed pursuant to methods presented in EPA's 2000 Human Health Methodology.[23] These criteria take into consideration the cancer potency or systemic toxicity of a pollutant, the exposure related to surface water exposure and a risk characterization. The criteria generated pursuant to the 2000 Human Health Methodology protect humans from toxicological effects from chronic exposure to a pollutant through drinking water or from eating fish living in a water body to which the criteria apply.

[22] EPA. 1994. *Water Quality Standards (WQS) Handbook: Second Edition.* August 1994. United States Environmental Protection Agency, Office of Water. EPA-823-B-94-005a. page 3-15. Available at http://water.epa.gov/scitech/swguidance/standards/handbook/index.cfm

[23] EPA. 2000. *Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health*. EPA-822-B-00-004. Available at: http://www.epa.gov/waterscience/criteria/humanhealth/method/complete.pdf

EPA's guidance for developing aquatic life criteria recommends that such criteria use toxicity information for aquatic life, establishing pollutant levels necessary for protection of aquatic life from both short and long term effects of the pollutant.[24] Toxicity tests are used to evaluate pollutant effects on survival, growth and reproduction of aquatic organisms.

EPA has reviewed Oregon's new and revised human health criteria in order to assess whether they are sufficient to protect Oregon's designated uses from human health impacts associated with the pollutants for which they were adopted. Other endpoints and uses (e.g., Fish and Aquatic Life) are addressed by other provisions in Oregon's WQS and are not before the Agency for review under § 303(c)(3) of the CWA as part of this action.

2. Non-Carcinogens: Criteria Methodology and Input Variables Used by Oregon[25]

EPA's 2000 Human Health Methodology provides guidance for deriving human health criteria for toxic pollutants.[26] Pursuant to Section 304(a) of the CWA, EPA has published a table of recommended criteria for use by states in adopting and revising criteria.[27] For each pollutant, this table also identifies whether EPA recommends the methodology specific to carcinogens or non-carcinogens, based on information relative to the human health endpoints of greatest significance.[28] For criteria recommendations for non-carcinogens, the values in this table reflect criteria derived using the 'national default' values identified in the 2000 Methodology: the reference dose (RfD) contained in the Integrated Risk Information System (IRIS) at the time of publication; the use of EPA's recommended bioconcentration factors (BCFs) (as opposed to site-specific bioaccumulation factors (BAFs)); and relative source concentration factors (RSC) as provided by the latest 304(a) recommendations.

While the 2000 Methodology provides national default values, it also provides guidance necessary to adjust criteria to reflect local conditions and encourages states to use the guidance to appropriately reflect local conditions and/or protect identifiable subpopulations.[29] Numerous states have adopted criteria derived through the use of site-specific input variables instead of the national default values, thus ensuring the criteria are protective of the human health uses

[24] EPA. 1985. *Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses.* Available at: http://water.epa.gov/scitech/swguidance/standards/criteria/aqlife/upload/85guidelines.pdf
[25] For methylmercury, Oregon used an alternate approach that will be addressed in a separate section.

designated in the waters where those criteria apply.

Criteria calculated pursuant to the 2000 Methodology are derived by applying a number of pollutant-specific and general risk-assessment values to an equation that generates a criteria protective of human health uses. Where a state uses this equation to develop criteria, the protectiveness of those criteria are dependent on whether the values used for each input variable are appropriate for protection of the uses specific to a pollutant and/or waterbody. With the exception of the methylmercury criterion, Oregon has directly applied this equation when deriving the new or revised human health criteria for the non-carcinogenic pollutants included in EPA's 2009 table of 304(a) criteria recommendations.[30] A simplified version of this equation is provided in Figure A below, followed by a discussion of the variables in the equation and the values utilized by Oregon to derive their new and revised criteria, and supporting information provided by Oregon. EPA's review of the protectiveness of the criteria is contained in a later subsection.

Figure A: Simplified version of the equation used by Oregon in deriving the human health criteria for non-carcinogens.

$$AWQC = RfD \bullet RSC \bullet \frac{(BW)}{[DI + (FCR \bullet BAF)]}$$

where:

AWQC	=	Ambient Water Quality Criterion (milligrams per liter)
RfD	=	Reference dose for noncancer effects (milligrams per kilogram per day)
RSC	=	Relative source contribution factor to account for non-water sources of exposure (unitless)
BW	=	Human body weight (kilograms)
DI	=	Drinking water intake (liters per day)
FCR	=	Fish Consumption Rate (kilograms per day)
BAF	=	Bioaccumulation factor (liters per kilogram)

a) Reference Done (RfD)

For non-carcinogens, EPA's 2000 Methodology recommends deriving human health criteria using a reference dose. A reference dose is defined as "an estimate (with uncertainty spanning approximately an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without appreciable risk of deleterious effects over a lifetime."[31] In other words, individuals should not suffer from appreciable risks of deleterious effects if their exposure to a chemical is at or below the reference dose for that chemical. Thus,

[30] EPA. 2009. *EPA National Recommended Water Quality Criteria.* U.S. Environmental Protection Agency Office of Water. Office of Science and Technology. Available at: http://water.epa.gov/scitech/swguidance/standards/current/upload/nrwqc-2009.pdf

[31] EPA. 1993. *Reference Dose (RfD): Description and Use in Health Risk Assessments. Integrated Risk Information System (IRIS).* Intra-Agency Reference Dose (RfD) Work Group, Office of Health and Environmental Assessment, Environmental Criteria and Assessment Office, U.S. Environmental Protection Agency, Cincinnati, OH. Available at: http://www.epa.gov/ncea/iris/rfd.htm

the reference dose serves as a threshold level and is specific to each individual pollutant.

In deriving both the "water + organism" and "organism only" criteria for non-carcinogens, Oregon utilized the most recent reference doses recommended by EPA's current § 304(a) criteria.

b) Body Weight (BW)

Oregon used EPA's national default value of 70 kilograms for the body weight as recommended in the 2000 Methodology. The source of data for the human body weight value of 70 kilograms is the *National Health and Nutrition Examination Survey* (NHANES) conducted between 1988 and 1994 using a nationwide probability sample of over 30,000 persons. Body weights of 73 percent of those individuals included in the survey were carefully measured by survey staff (i.e., weights were not self-reported). The mean body weight value for men and women ages 18-74 years old from this survey was 75.6 kilograms. Another survey by the National Cancer Institute measured a mean body weigh value of 70.5 kilograms for adults aged 20-64 years old, and EPA's *Exposure Factors Handbook* recommends 71.8 kilograms for adults based on an earlier NHANES survey.[32] While these data are slightly higher than 70 kilograms, the derivation of cancer slope factors identified in EPA's IRIS database are based upon a body weight of 70 kilograms. Since consistency is advocated between the dose-response relationship and the exposure factors, a default value of 70 kilograms was recommended by EPA for use in deriving human health water quality criteria.[33]

c) Drinking Water Intake Rate (DI)

Oregon used EPA's national default value of two liters per day for the drinking water intake rate as recommended in the 2000 Methodology. This rate was based on the 1994-1996 *Continuing Survey of Food Intake by Individuals* (hereinafter referred to as the "CSFII survey") conducted by the U.S. Department of Agriculture. This rate represents the 86th percentile of drinking water intake data for adults collected from the CSFII survey.[34] While this rate was utilized for "water + organisms" criteria, a drinking water intake rate of zero liters per day was used for "organism only" criteria because the criteria are not intended to address human health effects from the consumption of drinking water.

d) Bioaccumulation/Bioconcentration Factor (BAF/BCF)

Bioconcentration factors (BCF) describe the uptake and retention of a pollutant by an aquatic organism from water only while bioaccumulation factors (BAF)describe the uptake and retention of a pollutant by an aquatic organism from all sources (e.g., water, ingestion, and sediment). The

magnitude of bioconcentration or bioaccumulation by aquatic organisms varies widely depending upon the pollutant but can be extremely high for some highly persistent and hydrophobic pollutants. For highly bioaccumulative pollutants, concentrations in aquatic organisms may pose unacceptable human health risks from fish consumption even when concentrations in water are too low to cause unacceptable health risks from drinking water consumption alone. EPA's 2000 Human Health Methodology recommends the use of national BAFs in the calculation of ambient water quality criteria. However, to date, EPA has only provided guidance on the calculation of national BAFs. BAF values have not been calculated for individual pollutants. EPA uses bioconcentration factors in their nationally recommended criteria. As explained below, States have the option to use these BCFs or to calculate BAFs using guidance documents published by EPA.

EPA's 2000 Human Health Methodology provides guidance on developing bioaccumulation factors for the protection of human health.[35] A subsequent technical support document to the 2000 Methodology entitled *Technical Support Document Volume 2: Development of National Bioaccumulation Factors* (2003) provides added detail to the BAF calculation procedures outlined in the Methodology.[36] In 2009, EPA published the *Technical Support Document Volume 3: Development of Site-Specific Bioaccumulation Factors.* This document provides guidance on different approaches that investigators can take to develop site-specific BAFs, and the factors that should be considered when selecting an approach for a given situation.[37]

EPA recommends that states use these methods when adopting human health criteria. Neither of the bioaccumulation technical support documents should be used alone to derive BAFs but should be used in conjunction with the 2000 Human Health Methodology. The bioaccumulation methodology documents encourage developing site-specific BAFs because EPA recognizes that BAFs vary not only between chemicals and trophic levels, but also among different ecosystems and waterbodies. National average BAF values for a given chemical and trophic level may not provide the most accurate estimate of bioaccumulation for certain water bodies in the United States. At a given location, the BAF for a chemical may be higher or lower than the national BAF, depending on the nature and extent of site-specific influences.

While EPA's 2000 Human Health Methodology recommends the use of bioaccumulation factors in deriving human health criteria, development of bioaccumulation factors is a time and resource intensive process and BAFs can vary from site-to-site. Thus, it is difficult to develop BAFs on a national or statewide scale and this has rarely been done. Therefore, until such time as

bioaccumulation factors are developed, EPA's national CWA § 304(a) human health criteria guidance values continue to be based upon the use of bioconcentration factors which reflect the uptake and retention of a pollutant by an aquatic organism from water alone. Given the lack of any Oregon-specific BAFs and consistent with EPA guidance, Oregon utilized bioconcentration factors instead of bioaccumulation factors in deriving its new and revised human health criteria. The bioconcentration factors utilized by Oregon are pollutant-specific and are consistent with the bioconcentration factors recommended by EPA in the most recent national CWA § 304(a) human health criteria recommendations.

e) Fish Consumption Rate (FC)

When establishing a single value/criterion as a regulatory endpoint, States and EPA must make several policy decisions relative to the members of the population that will be protected when using the waters for activities protected by the designated uses and the established criteria. In EPA's 2000 Human Health Methodology, EPA provides guidance to the States on the use of local and regional data to develop an appropriate fish consumption rate for the use in criteria derivation and encourages the states to use this data to determine the level of protection appropriate for State waters.

Between 2006 and 2008 Oregon conducted extensive outreach and information gathering and consulted with a group of public health experts (the Human Health Focus Group (HHFG)) in order to inform their decision-making regarding an appropriate fish consumption rate for use in developing human health criteria for Oregon. Based on the information gathered in this effort and the review of available fish consumption studies, ODEQ concluded that a fish consumption rate of 175 grams per day (about 23, 8 ounce fish meals per month) is a protective rate to use as the basis for Oregon's human health criteria. Oregon found that this rate reflected the goal of providing sufficiently clean water in the state such that people who wish to regularly eat fish for cultural, health or economic reasons may do so without risk of adverse health effects due to contaminants contained in the fish.[38]

Further detail regarding Oregon's process, information considered and the decision to use a fish consumption rate of 175 grams per day is available in Oregon's Human Health Criteria Issue Paper and the Human Health Focus Group Report and outlined in a separate EPA memo.[39]

f) Relative Source Contribution (RSC)

Criteria for pollutants that are non-carcinogens are based on a total cumulative dose over time that causes an observable effect. Because the human health water quality criteria address exposure only through drinking water and eating fish and not from other sources (e.g. skin absorption, inhalation, other foods and occupational exposure), a relative source contribution (RSC) factor is used to calculate the criteria. The RSC represents the proportion of exposure from water and fish relative to the total exposure (including water and fish - and other exposures such as air, food, dermal, etc.). This estimate allows for adjustment of the criteria value to reflect exposure from only water and fish. This is intended to make sure that the total exposure from all sources does not exceed the reference dose for lifetime exposure.

Developing an RSC value for a pollutant requires an evaluation of both the sources of potential exposure and quantifying the relative exposure from each source. EPA has derived RSC values for 17 of the pollutants with 304(a) recommended human health criteria. Most of these RSC values were developed by EPA's drinking water program under the Safe Drinking Water Act.

Oregon used 15 of the 17 RSC values recommended by EPA. These 15 RSC values are listed in table 5 below. Oregon chose to use RSC values that vary from those recommended by EPA for endrin (80% instead of 20%, discussed in more detail below) and methylmercury (a value of zero instead of 2.7×10^{-5} mg methylmercury/kg/day, discussed in the methylmercury section below).

Table 5: Criteria where Oregon applied EPA's recommended RSC values.

Pollutant	RSC Value
Antimony	40%
Chlorobenzene	20%
Chlorodibromomethane	80%
Cyanide	20%
Ethylbenzene	20%
gamma-BHC (Lindane)	20%
Hexachlorcyclopentadiene	20%
Thallium	20%
Toluene	20%
1,1,2-Trichloroethane	20%
1,1-Dichloroethylene	20%
1,2,4-Trichlorobenzene	20%
1,2-Dichlorobenzene(o)	20%
1,2-trans-Dichloroethylene	20%
1,4-Dichlorobenzene(p)	20%

RSC for Endrin

EPA's recommended RSC value of 20% for endrin was developed by the drinking water program and takes into account exposure through multiple pathways. Endrin is a pesticide that was banned under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) in the 1980s, thus limiting current sources of exposure. Following the review of available data and

information, ODEQ determined that an RSC of 80% was appropriate for use in deriving the human health criteria for endrin.[40] Oregon's rationale is described below.

Due to the chemical properties of endrin and its prohibition by FIFRA in the 1980s, ODEQ believes it is unlikely that people in Oregon would gain only 20% of their exposure from water and fish while gaining 80% of their exposure from other sources identified in the RSC calculation performed by EPA and used in EPA's recommended 304(a) criteria.[41] The 80% RSC calculation for endrin used by Oregon accounts for the two main sources of exposure which they considered to have a potential to impact human health in Oregon: (1) drinking water and (2) the bioconcentration of endrin in aquatic organisms and thus potential accumulation in fish tissue. ODEQ found that the other sources or routes of exposure to endrin considered by EPA were not expected to occur in Oregon for the following reasons:

> 1) The use of endrin has been banned in the US since the 1980s. Endrin is not mobile in soil, it volatizes into the air rapidly, and has a conservative half life estimate in soil of 14 years.
>
> 2) The U.S. Food and Drug Administration concluded in 1995 that exposure to endrin through food products was no longer a concern, thus reducing concerns regarding exposure to endrin from food sources.
>
> 3) The one possible route of exposure to endrin that was identified in the literature was at hazardous waste sites where endrin has been detected in contaminated soils; however, no such sites were identified in Oregon. [42,43]

Based on the above considerations, Oregon found that human health exposure to endrin through routes other than fish tissue and drinking water is unlikely. In addition, although endrin bioconcentrates in aquatic organisms, it is not very soluble in water and therefore is not likely to be found in drinking water sources. Since the bioconcentration factor used to derive the human health criteria is very high (3970), the endrin criteria values for "water + organism" and "organism only" are the same when rounded to significant digits.[44] Therefore, Oregon concluded that the primary routes of exposure for endrin are anticipated to be through

bioconcentration in aquatic organisms and its accumulation in fish tissue. These two exposure routes have already been accounted for through the BCF and fish consumption rate.

The purpose of the RSC is to ensure that the level of a chemical allowed by a criterion or multiple criteria, when combined with other identified sources of exposure common to the population of concern, will not result in exposures that exceed the RfD.[45] Where a state reviews exposure data and develops an alternate RSC value, EPA recommends that the RSC not be lower than 20% or higher than 80%.[46] Where it can be demonstrated that other sources and routes of exposure are not anticipated for the chemical in question (based on information about its known/anticipated uses and chemical/physical properties), EPA recommends a ceiling of 80%. This 80% ceiling is a way to provide adequate protection for those who experience exposures (from any or several sources) higher than available data may indicate.[47] Oregon adjusted the RSC value for endrin to 80% consistent with this guidance.[48]

3. Carcinogens: Criteria Methodology and Input Variables Used by Oregon[49]

As noted above, EPA's 2000 Methodology provides guidance for deriving human health criteria for toxic pollutants[50] and has published a table of recommended criteria for use by states in adopting and revising criteria.[51] For human health criteria, the values in this table reflect criteria derived using all of the 'national default' values identified in the 2000 Methodology, the reference dose (RfD) contained in the Integrated Risk Information System (IRIS) at the time of publication, the use of EPA's recommended bioconcentration factors (BCFs), relative source contribution factors (RSC) as provided by the latest 304(a) recommendations and a 10^{-6} carcinogenic risk factor. While the 2000 Methodology provides national default values, it also provides necessary guidance to adjust criteria to reflect local conditions and encourages states to use the guidance to appropriately reflect local conditions and/or protect identifiable subpopulations.[52] Numerous states have adopted criteria derived through the use of site-specific input variables or a carcinogenic risk level other than $1x10^{-6}$.

[52] EPA. 2000. *Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health*. U.S. Environmental Protection Agency, Office of Water, Washington, D.C. EPA 822-B-00-004. pages iii, 1-11. Available at: http://www.epa.gov/waterscience/criteria/humanhealth/method/complete.pdf

For carcinogens, EPA's 2000 Methodology recognizes that states have the flexibility to adopt human health criteria within a risk level range of 1×10^{-6} to 1×10^{-5}, as long as highly exposed populations would at least be protected at the 1×10^{-4} (1:10,000) risk level. Furthermore, the 2000 Methodology recognizes that states have the flexibility to adopt human health criteria that protect the general population at a more protective risk level or target the protection of a higher proportion of its population at the targeted risk level. Oregon's new and revised criteria for carcinogens (except arsenic) target the protection of high consumers at the 1×10^{-6} risk level through the use of a fish consumption rate representative of the 95th percentile consumption from a study of a highly exposed subpopulation.

EPA's 2000 Methodology describes procedures that can be used as guidance by states for deriving human health water criteria. The 2000 Methodology includes an equation that Oregon used in deriving the "water + organism" and "organism only" new and revised human health criteria for 56 carcinogens. A simplified version of this equation is provided below in Figure B. Descriptions of the variables included in these equations, and the values that Oregon utilized for each variable, are also provided below.

Figure B: Simplified version of the equation used by Oregon in deriving the human health criteria for carcinogens.

$$AWQC = \frac{(Risk\ Level \bullet BW)}{[CSF \bullet (DI + (FCR \bullet BAF))]}$$

where:

AWQC	=	Ambient Water Quality Criterion (milligrams per liter)
Risk Level	=	Risk level (unitless)
CSF	=	Cancer slope factor (milligrams per kilogram per day)
BW	=	Human body weight (kilograms)
DI	=	Drinking water intake (liters per day)
FCF	=	Fish Consumption Rate (kilograms per day)
BAF	=	Bioaccumulation factor (liters per kilogram)

a) Body Weight, Drinking Water Intake Rate, Bioaccumulation/Bioconcentration Factor and Fish Consumption Rate

Four of the input variables used by Oregon in deriving its numeric human health water quality criteria for carcinogens are the same as those used by Oregon in deriving its numeric human health water quality criteria for non-carcinogens. A body weight of 70 kilograms and a drinking water intake of two liters per day were used, consistent with the default values that EPA utilized in deriving its national CWA § 304(a) human health criteria guidance values. Oregon also used bioconcentration factors consistent with those used by EPA in deriving its national CWA § 304(a) human health criteria guidance values.

Consistent with the criteria for non-carcinogens, a fish consumption rate of 175 grams per day was used in deriving the new and revised human health criteria for carcinogens. This value was

used by Oregon following an evaluation of local and regional data (discussed in greater detail above).

b) Cancer Slope Factor

For toxic pollutants identified as carcinogens and assumed to exhibit a linear dose-response relationship at low doses, EPA derives its national CWA § 304(a) human health criteria recommendations to correspond to incremental lifetime cancer risk levels, applying a risk management policy that ensures a reasonable level of protection for the general population.[53] Accordingly, a cancer slope factor is included in the calculation. A cancer slope factor expresses incremental, lifetime risk of cancer as a function of the rate of intake of the contaminant, and is combined with exposure assumptions to express that risk in terms of an ambient water concentration. Cancer slope factors are specific to individual pollutants. In deriving both the "water + organism" and "organism only" human health criteria for carcinogens, Oregon utilized the cancer slope factors recommended by EPA.

c) Carcinogenic Risk Level

EPA has identified a risk level range of 1 x 10^{-6} (1:1,000,000) to 1 x 10^{-5} (1:100,000) to be an appropriate risk management goal for the general population. EPA characterizes this acceptable risk range as the "upper-bound estimate of excess lifetime cancer risk," ranging from one case in a population of one million to one case in a population of one hundred thousand. The nationally recommended 304(a) criteria are intended to protect the general population at a cancer risk of 1 x 10^{-6}.

EPA's 2000 Methodology states that criteria based on a 10^{-5} risk level are acceptable for the general population as long as States and authorized Tribes ensure that the risk to more highly exposed subgroups (sport fishers or subsistence fishers) does not exceed the 10^{-4} risk level. If a state does not find that the 1 x 10^{-6} risk level adequately protects highly exposed populations, it has the flexibility to adopt water quality criteria based on a more stringent risk level or at a level more representative of highly exposed population groups. This flexibility extends to all variables used to calculate the criteria. [54]

Except where specifically identified, Oregon's new and revised human health criteria for carcinogens are calculated using a risk level of 1 x 10^{-6} (1:1,000,000). As discussed earlier, these criteria include the use of a fish consumption rate of 175 grams per day, a level representative of high fish consumers in the state. Oregon's goal in adopting the criteria was to protect high end consumers (as opposed to the general population) at a risk level of 10^{-6}.

[54] EPA. 2000. *Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health*. U.S. Environmental Protection Agency, Office of Water, Washington, D.C. EPA 822-B-00-004. page 2-6. Available at: http://www.epa.gov/waterscience/criteria/humanhealth/method/complete.pdf

4. EPA Review of Input Variables for All New and Revised Human Health Criteria except Methylmercury and Arsenic[55]

As discussed above, EPA's 2000 Human Health Methodology provides guidance for deriving human health criteria for toxic pollutants. For each variable used in the criteria calculation, EPA provides a "national default value" and guidance on specific adjustments that may be necessary to reflect local conditions and/or protect identifiable subpopulations. As part of evaluating whether Oregon's criteria protect the designated uses, EPA looked at the input values used by Oregon and whether there was Oregon-specific information relative to each value that should be considered in the review.

EPA has not identified any local or regional data to indicate that the national values used by Oregon for the reference dose, relative source contribution, body weight, drinking water intake rate, or bioaccumulation factors are inappropriate for use in Oregon.

EPA's review indicates that there is local and regional fish consumption data available and that it should be considered consistent with EPA's 2000 Methodology. The 2000 Methodology recognizes the variability of fish consumption rates among population groups and by geographic region. In employing the 2000 Methodology to derive criteria, EPA urges States and Tribes to use a fish intake level derived from local or regional data instead of the national default recommendation to ensure the fish intake level chosen is protective of highly exposed subpopulations. A four preference hierarchy concerning the use of fish consumption rate data is set forth: (1) use of local data; (2) use of data reflecting similar geography/population groups; (3) use of data from national surveys; and (4) use of EPA's default intake rate.

As discussed in greater detail above, in 1996 Oregon initiated an extensive review of the fish consumption rate used for deriving its human health criteria. This process resulted in ODEQ and the Commission determining that a fish consumption rate of 175 grams per day was a reasonable and protective fish consumption rate to use as the basis for Oregon's human health criteria. EPA has reviewed the available information and the basis for ODEQ's determination and has found that Oregon has considered all relevant local and regional data, applied that data consistent with EPA's 2000 Methodology to select a fish consumption rate that would result in a level of protection consistent with that recommended by EPA in the 2000 Methodology. Thus, EPA finds that the FCR utilized to derive Oregon's criteria is consistent with EPA's recommendations in the 2000 Methodology.

B. *EPA ACTION ON ODEQ'S NEW HUMAN HEALTH CRITERIA*

ODEQ has adopted new human health criteria for 41 pollutants (excluding methylmercury which is discussed in further detail below). Previously, Oregon did not have EPA-approved values for these criteria in their WQS. These new criteria, found in Table 40 of Oregon's WQS, are

[55] Methylmercury and arsenic are addressed in sections IV.D and IV.E of this document.

consistent with EPA's current 304(a) criteria recommendations and utilize the 175 grams per day fish consumption rate.

Table 6: Oregon's new human health criteria.

EPA Approval
In accordance with its Clean Water Act authority, 33 U.S.C § 1313(c)(3) and 40 C.F.R. part 131, EPA approves Oregon's new human health toxic criteria for these 41 pollutants that are consistent with EPA's current CWA § 304(a) criteria recommendations because they are protective of Oregon's fishing and water supply designated uses.

EPA Rationale
EPA's WQS regulations at 40 C.F.R. 131 require that criteria protect the designated uses. As noted previously, Oregon's human health criteria apply to waters with fishing and water supply uses and thus must be established at a level that will protect those uses. Therefore, EPA must evaluate whether the criteria protect Oregon's human health uses.

EPA's 2000 Human Health Methodology provides guidance for deriving human health criteria for toxic pollutants. For each variable used in the criteria calculation, EPA provides a "national default value" and guidance on specific adjustments that may be necessary to reflect local conditions and/or protect identifiable subpopulations. As part of evaluating whether Oregon's criteria protect the designated uses, EPA looked at the input values used by Oregon and whether there was Oregon-specific information relative to each value that should be considered in the review. As discussed above EPA has found that ODEQ has appropriately considered local and regional data in selecting input variables for use in deriving the criteria identified in Table 6.

The 2000 Methodology document provides an extensive technical basis and justification as to how EPA's recommended human health criteria adequately protect human health uses. Oregon's new criteria were developed consistent with these recommendations, therefore, EPA has determined that Oregon's new criteria protect human health uses in accordance with 40 C.F.R. Part 131.11(a)(1).

C. *EPA ACTION ON ODEQ'S REVISED HUMAN HEALTH CRITERIA*

ODEQ has adopted revised human health criteria for 62 pollutants (excluding arsenic which is described in further detail below). These revised criteria, found in Table 40 of Oregon's WQS, are consistent with EPA's current 304(a) criteria recommendations and utilize the 175 grams per day fish consumption rate.

Table 7: Oregon's revised human health criteria.

[58] Oregon's revised human health criteria for nickel are less stringent than Oregon's previous values despite Oregon's adoption of a 175 grams per day fish consumption rate. However, the equation used to calculate the revised criteria is consistent with EPA's current 304(a) recommendations. It is unclear how ODEQ derived their previous values for nickel. Nonetheless, EPA assessed protectiveness of the revised criteria using EPA's 304(a) recommendations and Oregon's human health designated uses.

Footnote L: This criterion applies to total PCBs (e.g. determined as Aroclors or congeners).

EPA Approval

In accordance with its Clean Water Act authority, 33 U.S.C § 1313(c)(3) and 40 C.F.R. part 131, EPA approves Oregon's revised human health toxic criteria for these 62 pollutants, consistent with EPA's current CWA § 304(a) criteria recommendations, because they are protective of fishing and water supply uses.

EPA Rationale

EPA's WQS regulations require that criteria protect the designated uses. As noted previously, Oregon's human health criteria apply to waters with fishing and water supply uses and thus must be established at a level that will protect those uses. Therefore, EPA must evaluate whether the criteria protect Oregon's human health uses.

[59] Based on updates to EPA's IRIS system, the RfD value of 6.0×10^{-1} was replaced by Oregon with an RfD value of 3.0×10^{-1}. EPA. *Integrated Risk Information System (IRIS).* U.S. Environmental Protection Agency, Office of Water, Washington, D.C. Available at: www.epa.gov/iris

[60] Oregon's revised human health criteria for selenium are less stringent than Oregon's previous values despite Oregon's adoption of a 175 grams per day fish consumption rate. However, the equation used to calculate the revised criteria is consistent with EPA's current 304(a) recommendations. It is unclear how ODEQ derived their previous values for these two pollutants. Nonetheless, EPA assessed protectiveness of the revised criteria using EPA's 304(a) recommendations and Oregon's human health designated uses.

EPA's 2000 Human Health Methodology provides guidance for deriving human health criteria for toxic pollutants. For each variable used in the criteria calculation, EPA provides a "national default value" and guidance on specific adjustments that may be necessary to reflect local conditions and/or protect identifiable subpopulations. As part of evaluating whether Oregon's criteria protect the designated uses, EPA reviewed the input values used by Oregon and whether there was Oregon-specific information relative to each value that should be considered in the review. As discussed above EPA has found that ODEQ has appropriately considered local and regional data in selecting input variables for use in deriving the criteria identified in Table 7.

EPA provides an extensive technical basis and justification as to how its recommended human health criteria adequately protect human health uses in EPA's 2000 Methodology document. Oregon's revised criteria were developed consistent with these recommendations, therefore, EPA has determined that Oregon's revised criteria protect human health uses in accordance with 40 C.F.R. Part 131.11(a)(1).

D. *METHYLMERCURY CRITERION*

1. Methylmercury: Criteria Methodology and Input Variables Used by Oregon

On January 8, 2001, EPA published[61] a new national CWA § 304(a) human health criterion recommendation for methylmercury[62] which replaced EPA's previous recommendations for total mercury. The new recommendation is expressed as a fish tissue value, thus reflecting the latest science that indicates consumption of contaminated fish and shellfish is the primary human route of exposure to methylmercury.

In 1980, EPA published a water quality criterion for total mercury. The criterion was partially updated in 1997 to incorporate a change in the reference dose (RfD). Consistent with Section 304(a) of the Clean Water Act, EPA periodically revises water quality criteria to reflect the latest scientific knowledge on the type and extent of identifiable effects on human health from the presence of pollutants in a waterbody. In 2001, EPA completed a review of the water quality criterion for protection of human health for methylmercury. This criterion recommendation considered the bioaccumulation of methylmercury as well as the latest science and data regarding health effects from intake of mercury and the primary routes of exposure. The new criterion for methylmercury was derived consistent with the *Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health* (2000). The 2001 recommendation

[61] EPA. January 8, 2001. *Water Quality Criteria: Notice of Availability of Water Quality Criterion for the Protection of Human Health: Methylmercury*. U.S. Environmental Protection Agency, Office of Water, Washington, D.C. *Federal Register*, Volume: 66, Issue: 5, page: 1344 (66 FR 1344). Available at: http://www.epa.gov/fedrgstr/EPA-WATER/2001/January/Day-08/w217.htm

[62] EPA. January 2001. *Water Quality Criterion for the Protection of Human Health: Methylmercury*. U.S. Environmental Protection Agency, Office of Water, Washington, D.C. EPA 823-R-01-001. Available at: http://www.epa.gov/waterscience/criteria/methylmercury/document.html

is expressed as a fish tissue concentration for methylmercury and replaces the water column concentration for mercury that was contained in EPA's previous recommendation.[63]

As part of the 2001 reevaluation of the mercury criterion, EPA evaluated the sources and form of mercury that humans are exposed to when eating fish or consuming water from the nation's waters. It was found that humans are exposed primarily to methylmercury rather than to inorganic mercury and that the dominant exposure pathway is through consumption of contaminated fish and shellfish rather than from ambient water.[64] EPA found that if a criterion addressed the potential health effects from methylmercury, it would protect humans from the most toxic form of mercury and the primary route of exposure. Thus, in considering the fate of mercury in the environment and available toxicological data, EPA concluded that it is more appropriate to derive a water quality criterion for methylmercury rather than inorganic mercury. In addition, "EPA believes that the latest data and science on methylmercury exposure, effects, and environmental fate support the derivation of a fish tissue residue criterion," instead of a water column criterion.[65]

"Methylmercury is highly bioaccumulative and is the form of mercury that bioaccumulates most efficiently in the aquatic food web. Methylation of mercury is a key step in the entrance of mercury into food chains. The biotransformation of inorganic mercury species to methylated organic species in water bodies can occur in the sediment and the water column. Inorganic mercury can be absorbed by aquatic organisms but is generally taken up at a slower rate and with lower efficiency than is methylmercury."[66]

"Methylmercury continues to accumulate in fish as they age. Predatory organisms at the top of aquatic and terrestrial food webs generally have higher methylmercury concentrations because methylmercury is typically not completely eliminated by organisms and is transferred up the food chain when predators feed on prey; for example, when a largemouth bass feeds on a bluegill sunfish, which fed on aquatic insects and smaller fish, all of which could contain some amount of methylmercury that gets transferred to the predator. Nearly 100 percent of the mercury that bioaccumulates in upper trophic level fish (predator) tissue is methylmercury (Bloom, 1992; Akagi, 1995; Kim, 1995; Becker and Bigham, 1995.)"[67]

---

[65] EPA. January 2001. *Water Quality Criterion for the Protection of Human Health: Methylmercury*. U.S. Environmental Protection Agency, Office of Water, Washington, D.C. EPA 823-R-01-001. page 1-2. Available at: http://www.epa.gov/waterscience/criteria/methylmercury/document.html

[66] EPA. January 8, 2001. *Water Quality Criteria: Notice of Availability of Water Quality Criterion for the Protection of Human Health: Methylmercury*. U.S. Environmental Protection Agency, Office of Water, Washington, D.C. *Federal Register*, Volume: 66, Issue: 5, Page: 1344 (66 FR 1344). page 1348. Available at: http://www.epa.gov/fedrgstr/EPA-WATER/2001/January/Day-08/w217.htm

[67] EPA. January 8, 2001. *Water Quality Criteria: Notice of Availability of Water Quality Criterion for the Protection of Human Health: Methylmercury*. U.S. Environmental Protection Agency, Office of Water,

In consideration of the environmental fate of mercury, a fish tissue residue water quality criterion was found to be appropriate for many reasons. "Such a criterion integrates spatial and temporal complexity that occurs in aquatic systems and that affects methylmercury bioaccumulation. A fish tissue residue water quality criterion is more closely tied to the CWA goal of protecting the public health because it is based directly on the dominant human exposure route for methylmercury. The concentration of methylmercury is also generally easier to quantify in fish tissue than in water and is less variable over the time periods in which water quality standards are typically implemented in water quality-based. Thus, the data used in permitting activities can be based on a more consistent and measurable endpoint. A fish tissue residue criterion is also consistent with how fish advisories are issued. Fish advisories for mercury are based on the amount of methylmercury in fish tissue that is considered acceptable, although they are usually issued for a certain fish or shellfish species in terms of a meal size. A fish tissue residue water quality criterion should enhance harmonization between these two approaches for protecting the public health."[68]

Consistent with EPA's 304(a) recommendation published in 2001, Oregon has replaced its "water + organism" and "organism only" water column human health criteria for total mercury with a new fish tissue-based "organism only" human health criterion for methylmercury. Similar to the 2000 Methodology, the computation of the methylmercury criterion uses several input variables, described in Figure C below.

Figure C: Simplified version of the equation used by Oregon in deriving its new fish tissue-based "organism only" human health criterion for methylmercury.

$$TRC = \frac{(RfD - RSC) \bullet (BW)}{(FCR)}$$

where:

TRC	=	Fish Tissue Residue Criterion (milligrams per kilogram)
RfD	=	Reference dose for noncancer effects (milligrams per kilogram per day) = 0.0001mg/kg-day
RSC	=	Relative source contribution factor to account for non-water sources of exposure (milligrams per kilogram per day) = 0
BW	=	Human body weight (kilograms) = 70 kg
FCR	=	Fish Consumption Rate (kg/day) = 175 g/day

In the 2001 methylmercury criteria document, EPA strongly encourages States and authorized Tribes to consider developing a criterion using local or regional data over the default values if they believe that appropriate for protection of the target population. EPA recommends that these

---

Washington, D.C. *Federal Register*, Volume: 66, Issue: 5, Page: 1344 (66 FR 1344). page 1348. Available at: http://www.epa.gov/fedrgstr/EPA-WATER/2001/January/Day-08/w217.htm

[68] EPA. January 2001. *Water Quality Criterion for the Protection of Human Health: Methylmercury*. U.S. Environmental Protection Agency, Office of Water, Washington, D.C. EPA 823-R-01-001. page xv. Available at: http://www.epa.gov/waterscience/criteria/methylmercury/document.html

adjustments be applied consistent with the guidance provided in the 2000 Human Health Methodology.[69]

Consistent with EPA's recommendation, Oregon replaced its "water + organism" and "organism only" water column human health criteria for total mercury with a new fish tissue-based "organism only" human health criterion for methylmercury equal to 0.040 micrograms per kilogram (mg/kg). In deriving this new criterion, Oregon used the equation below and the following values for each variable: reference dose equal to 0.0001 milligrams per kilogram per day; relative source contribution of 0; body weight equal to 70 kilograms and; fish consumption rate equal to 175 grams per day. As discussed in greater detail above, the reference dose and body weight are the values recommended by EPA and the fish consumption rate was derived using local and regional data. The RSC is discussed below.

a) Relative Source Contribution (RSC) for Methylmercury

Following review of available data and information specific to the exposure pathways for methylmercury, Oregon used EPA's subtraction method to derive an RSC of zero for use in deriving the human health criterion for methylmercury.[70]

In establishing a recommended RSC value, EPA found that the most significant source of exposure to methylmercury was the ingestion of marine fish. EPA also found that the estimated exposure from ambient water, drinking water, nonfish dietary foods, air, and soil were all, on average, at least several orders of magnitude less than those from marine fish ingestion. Therefore, these later exposure pathways were not factored into EPA's recommended RSC value. An RSC of 2.7×10^{-5} mg methylmercury/kg/day is recommended by EPA as an estimated exposure from marine fish intake.[71]

EPA's above recommendation is based on the assumption that the fish consumption rate does not include fish of marine origin (as would be the case for most inland states/waters and is true of EPA's national default value for fish consumptions of 17.5 grams per day). However, as part of Oregon's reevaluation of local and regional data and the selection of a fish consumption rate of 175 grams per day, Oregon did take into consideration the consumption of salmon (an anadromous species identified as marine in the CSFII study) and regional consumption rates that included estuarine finfish and shellfish. Therefore, in reviewing this information, Oregon determined that it was not necessary to provide additional protection from ingestion of marine fish through the use of an RSC value. As a result, Oregon subtracted out the exposure related to marine fish, resulting in an RSC of zero.

---

[69] EPA. January 2001. *Water Quality Criterion for the Protection of Human Health: Methylmercury*. U.S. Environmental Protection Agency, Office of Water, Washington, D.C. EPA 823-R-01-001, page 7-2. Available at: http://www.epa.gov/waterscience/criteria/methylmercury/document.html

[70] November 3, 2000. *Federal Register*, Volume: 65, Issue: 214, pages: 66472-3 (65 FR 66472-3). Available at: http://www.epa.gov/fedrgstr/EPA-WATER/2000/November/Day-03/w27924.htm

[71] EPA. January 2001. *Water Quality Criterion for the Protection of Human Health: Methylmercury*. U.S. Environmental Protection Agency, Office of Water, Washington, D.C. EPA 823-R-01-001. page xiv. Available at: http://www.epa.gov/waterscience/criteria/methylmercury/document.html

EPA's 2000 Human Health Methodology recognizes that if States include marine fish in the fish consumption rate they may need to adjust the RSC consistent with this decision to appropriately represent overall exposure to a pollutant.

"States and Tribes need to ensure that when evaluating overall exposure to a contaminant, [and that] marine fish intake is not double-counted with the other dietary intake estimate used. Coastal States and authorized Tribes that believe accounting for total fish consumption (i.e., fresh/estuarine and marine species) is more appropriate for protecting the population of concern may do so, provided that the marine intake component is not double-counted with the RSC estimate." [72]

Oregon's use of the subtraction method for deriving the RSC for methylmercury is consistent with this guidance.

2. New human health criteria for methylmercury

Oregon has adopted the following new criterion for methylmercury:

Table 8: Oregon's criterion for methylmercury.

Pollutant	Carcinogen	Water + Organism (µg/L)	Organism Only (µg/L)
Methylmercury (mg/kg)[J]		--	0.040 (mg/kg)

Footnote J: This value is expressed as the fish tissue concentration of methylmercury. Contaminated fish and shellfish is the primary human route of exposure to methylmercury.

Oregon's new criterion of 0.040 mg/kg is expressed as a fish tissue residue concentration, not a water column concentration as all other human health criteria adopted by Oregon. Thus, when applying the criterion, ODEQ may need to consider data collected from either the water column or fish tissue or express a limitation as a water column value (e.g. provide a discharger with an effluent limit in an NPDES permit that can be measured in their effluent). Recognizing this fact, EPA has encouraged "states and authorized tribes to develop a methylmercury criterion implementation plan to ensure environmentally protective and effective administration of all water quality related programs with respect to methylmercury". Furthermore, to assist the States in this process, in April 2010 EPA published recommended methods for implementing these criteria. [73] In recognition of this need, Oregon's Human Health Criteria Issue Paper states that "…DEQ intends to develop implementation procedures similar to EPA's *Guidance for Implementing the January 2001 Methylmercury Criterion.*"[74]

3. EPA Action and Rationale Regarding Oregon's Methylmercury Criterion

EPA Action
In accordance with its Clean Water Act authority, 33 U.S.C § 1313(c)(3) and 40 C.F.R. part 131, EPA approves Oregon's new human health criterion for methylmercury, consistent with EPA's current CWA § 304(a) criteria recommendations, because it is protective of Oregon's fishing and water supply uses. EPA is also approving the first sentence of footnote J which states: *This value is expressed as the fish tissue concentration of methylmercury.*

EPA Rationale
EPA's WQS regulations require that criteria protect the designated uses. As noted previously, Oregon's human health criteria apply to waters with fishing and water supply uses and thus must be established at a level that will protect those uses. Therefore, EPA must evaluate whether the criteria protect Oregon's human health uses.

EPA's 2000 Human Health Methodology and 2001 Criteria Recommendations for Methylmercury provide guidance for deriving human health criteria for methylmercury. For each variable used in the criteria calculation, EPA provides a "national default value" and guidance on specific adjustments that may be necessary to reflect local conditions and/or protect identifiable subpopulations. As part of evaluating whether Oregon's criteria protect the designated uses, EPA reviewed the input values used by Oregon and whether there was Oregon-specific information relative to each value that should be considered in the review.

For all input variables except for the fish consumption rate and the RSC value, Oregon used EPA's recommended 304(a) national default values for calculating the methylmercury criterion. EPA has not identified any local or regional data to indicate that the national values for the reference dose, body weight, or drinking water intake rate are inappropriate for use in Oregon.

Oregon has used local and regional data to develop the fish consumption rate and RSC values used to calculate the methylmercury criterion. EPA has reviewed the information used in developing these values and has found that ODEQ appropriately considered the available data and developed input values consistent with EPA guidance.

EPA's 2001 Methylmercury Criteria document provides an extensive technical basis and justification as to how EPA's recommended criterion adequately protects human health uses. Based on Oregon's consistency with EPA's recommendations in the 2001 Methylmercury Criteria document and as discussed above, EPA has determined that Oregon's new methylmercury criterion protects human health uses in accordance with 40 C.F.R. Part 131.11(a)(1).

In addition, EPA is approving the first sentence of footnote J which states: *This value is expressed as the fish tissue concentration of methylmercury.* This sentence of the footnote provides clarification that the human health criterion for methylmercury is expressed as a fish tissue concentration rather than as a water column concentration. Oregon's new footnote

language along with the human health criterion value for methylmercury are consistent with EPA's recommended 304(a) national default values for calculating the criterion. This sentence of the footnote establishes a legally binding requirement under state law and helps describe a desired ambient condition of a waterbody to support a particular designated use and is therefore considered a WQS subject to EPA review and approval under 303(c) of the CWA. The description of the applicable expression of methylmercury is a component of the overall level of protection afforded by the criterion. Since this sentence of the footnote specifies the applicable expression of the methylmercury criterion Oregon adopted, EPA has approved this sentence of the footnote as a WQS.

EPA acknowledges the second sentence of footnote J which states: *Contaminated fish and shellfish is the primary human route of exposure to methylmercury.* This sentence of the footnote provides details on the primary route of human exposure to methylmercury, but does not establish a legally binding requirement under State law and it does not describe a desired ambient condition of a waterbody to support a particulate designated use. For this reason, this sentence of footnote J is not considered a WQS subject to EPA review and approval under 303(c) of the CWA. As a result, EPA is taking no action to approve or disapprove the second sentence of footnote J for methylmercury.

E. *INORGANIC ARSENIC CRITERIA*

1. Background

The Oregon Environmental Quality Commission directed ODEQ to revise Oregon's human health criteria for toxic pollutants based on an increased fish consumption rate of 175 grams per day as well as to carefully consider cost effective and environmentally meaningful implementation of the criteria and review the data and science behind the criteria for earth metals.[75] ODEQ reviewed the science supporting the EPA's recommended 304(a) arsenic criteria and considered the appropriateness of revising the criteria to more closely reflect the levels of arsenic that naturally occur in Oregon waters. Oregon's revised arsenic criteria, submitted to EPA on July 12, 2011 are the result of that review. Oregon's goal in reevaluating the criteria was to protect human health, reduce toxic pollutants and to achieve meaningful environmental results commensurate with the cost.[76]

Oregon made the following arsenic-related regulatory revisions (including some changes other than revisions to arsenic criteria):

---

[75] Oregon Environmental Quality Commission (OEQC). October 23, 2008. *Oregon Environmental Quality Commission Minutes of the Three Hundred and Forty-sixth Meeting.* Available at: http://www.deq.state.or.us/about/eqc/minutes/2008/2008octEQCMinutes.htm

[76] ODEQ. April 5, 2011. *Memo from Dick Pedersen, Director ODEQ, to the Environmental Quality Commission. Agenda Item E. Rule adoption: Amending water quality standards for arsenic, April 21-22, 2011EQC meeting.* Oregon Department of Environmental Quality. pages 1-2. Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/metals/EQCItemEStaffReport.pdf

- Revised the numeric criteria human health criteria for arsenic in OAR 340-04-0033 Table 20.
- Identified the form of arsenic addressed by the criteria as inorganic arsenic.
- Added footnote A which states "The arsenic criteria are expressed as total inorganic arsenic. The 'organism only' criteria are based on a risk level of approximately 1.1 x 10^{-5}, and the 'water + organism' criterion is based on a risk level of 1.1 x 10^{-4}."[77]
- Revised the drinking water M.C.L. from 0.05 mg to 10 µg/l in Table 20 and added footnote 1 which states "The arsenic value is shown here for informational purposes only and is not a water quality criterion."
- Added a new provision, OAR 340-04-0033(2)(b), that states the arsenic criteria become effective for purposes of State law and the CWA at the time of EPA approval.[78]
- Added an arsenic reduction policy under State law to address the reduction of arsenic from some anthropogenic sources in the vicinity of public drinking water intake supplies.[79]

The revised arsenic criteria were adopted through a public notice and rulemaking action separate from that used to adopt the June 16, 2011 human health criteria revisions. This separate rulemaking process is described in Section III above.

ODEQ reviewed the available scientific literature on bioaccumulation of arsenic and the ratio of inorganic arsenic to total arsenic in freshwater and marine environments. ODEQ also reviewed data specific to waters in Oregon and used the information to derive arsenic criteria for Oregon's waters.

Arsenic is a known carcinogen that may cause cancer in skin or internal organs such as the liver, kidneys, lungs and bladder. Other potential health impacts from arsenic include cardiovascular, kidney, central nervous system and hyper-pigmentation or keratosis effects.[80] In its 304(a) criteria recommendations EPA states that arsenic criteria should be based on cancer endpoints and be applied as inorganic arsenic.

Naturally-occurring arsenic in Oregon comes from geologic sources. It is typically present at natural levels in fresh surface waters at background levels that range from less than 1 microgram per liter (µg/l) to 3 µg/l. ODEQ data indicate that much higher arsenic levels (greater than 5-10 µg/l) may be present in some south central and southeastern Oregon watersheds but it is not known whether these levels represent solely natural geologic sources or are elevated due to

[77] Footnote A for arsenic was established in Table 40 in ODEQ's July 21, 2011 submittal to EPA.
[78] This language was deleted as part of ODEQ's July 21, 2011 submittal to EPA since effective dates of the criteria are addressed in OAR 340-041-0033(1), which includes arsenic.
[79] To accommodate additional revisions associated with ODEQ's submittal to EPA on July 21, 2011 ODEQ moved the location of this rule from OAR 340-041-0033(4) to OAR 340-041-0033(7). However, the rule language was not revised.
[80] EPA. 2000. *Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health*. U.S. Environmental Protection Agency, Office of Water, Washington, D.C. EPA-822-B-00-004. page 2-6. Available at: http://www.epa.gov/waterscience/criteria/humanhealth/method/complete.pdf

anthropogenic activity.[81] ODEQ's review of the scientific literature indicates natural total arsenic levels of the oceans to be in the range of 1 to 3 µg/l.[82]

EPA's current 304(a) human health criteria recommendations for arsenic, published in 1986, are derived using a fish consumption rate of 6.5 grams per day and a cancer slope factor of 1.75 and are recommended to be applied as inorganic arsenic.[83] As is the case for all pollutants, EPA's 2000 Human Health Methodology encourages states to use local and regional data when making risk management decisions inherent in developing criteria, including decisions inherent in selecting the appropriate fish consumption rate, target risk level and bioaccumulation factor.[84]

2. Numeric Criteria Revisions

Based on its review of current data and information, ODEQ found differences in the bioconcentration (BCF) of arsenic in freshwater and saltwater organisms. In addition, DEQ found the ratio of inorganic arsenic relative to total arsenic differs in the freshwater and marine environments. Based on these findings, Oregon adopted two sets of criteria, one applying to freshwater and the other to saltwater. The revised criteria and the input variables used to calculate the criteria are presented in Tables 9 and 10 below.

Oregon has adopted the following new criterion for inorganic arsenic:

Table 9: Oregon's revised arsenic criteria (as inorganic arsenic).

Pollutant	Carcinogen	Water + Organism (µg/L)	Organism Only (µg/L)
Arsenic (inorganic)[A]	✓	2.1	2.1 (freshwater) 1.0 (saltwater)

Footnote A: The arsenic criteria are expressed as total inorganic arsenic. The "organism only" criteria are based on a risk level of approximately 1.1 x 10^{-5}, and the "water + organism" criterion is based on a risk level of 1.1 x 10^{-4}.

Table 10. Input variables for Oregon's revised arsenic criteria.

	Water + organism: freshwater	Organism only: freshwater	Organism only: saltwater
Revised Criteria	2.1 µg/l	2.1 µg/l	1.0 µg/l
Input Variables	FCR=175	FCR=175	FCR=175

	BCF=14 IF=10% CSF=1.5 Risk level=$1x10^{-4}$	BCF=14 IF=10% CSF=1.5 Risk level=$1.1x10^{-5}$	BCF=26 IF=10% CSF=1.5 Risk level=$1x10^{-5}$

FCR = Fish Consumption Rate
BCF = Bioconcentration Factor
IF = Inorganic Factor
CSF = Cancer Slope Factor

Oregon's arsenic criteria revisions were adopted into Table 20 (Water Quality Criteria Summary), OAR 340-04-0033. It should be noted that in Oregon's June 16, 2011 action, all human health criteria in Table 20 were moved to Table 40. Thus, the arsenic criteria are now located in Table 40.

Oregon's revised numeric criteria for arsenic were derived using the same general methodology and equation used to calculate EPA's current 304(a) criteria for carcinogens. However, based on its review of scientific studies and Oregon specific data,[85] Oregon applied an inorganic to total arsenic ratio in the criteria calculation because the arsenic criteria are expressed in terms of inorganic arsenic, but the toxicity data used to develop EPA's BCF are reported in the form of total arsenic. Therefore, Oregon applied the inorganic to organic arsenic ratio to the criteria calculated using BCF values they derived based on state-specific data. Oregon also applied a fish consumption rate based on state-specific data. Oregon used the cancer slope factor listed in EPA's IRIS database available at the time of criteria adoption (April 2011). The input variables used by Oregon to derive their revised criteria are listed in Table 10 above.

a) Freshwater Criteria

Body weight and drinking water intake rate

Oregon used EPA's recommended national default rates for body weight and drinking water intake rates. These are the same values that Oregon used to derive all other criteria addressed in this action. Further detail on these variables was provided above.

Fish consumption rate

A fish consumption rate of 175 grams per day was used to derive the freshwater arsenic criteria. This is the same fish consumption rate that Oregon used to derive all other criteria addressed in this action. As discussed in detail above, this rate was determined by ODEQ to be appropriate for use in Oregon's human health criteria following a thorough review of local and regional data.

The fish consumption rate of 175 grams per day was selected by Oregon to ensure protection of all people in Oregon who may consume fish and shellfish from state waters including those who traditionally consume large amounts of fish for subsistence, health, economic or other reasons.[86] It reflects the 95th percentile of tribal members surveyed as part of the CRITFC Survey and the

[85] For more detail, see previous description in this document of methodology for deriving criteria for carcinogens.
[86] ODEQ. October 6, 2008. *Memo from Dick Pederson, Director ODEQ, to the Environmental Quality Commission. Agenda Item G, Action Item: Oregon's Fish Consumption Rate – For Use in Setting Water Quality Standards for Toxic Pollutants October 23, 2008 EQC Meeting.* Oregon Department of Environmental Quality. page 7. Available at: http://www.deq.state.or.us/about/eqc/agendas/attachments/2008oct/ItemG.pdf

90th percentile of subsistence consumers surveyed in regional fish consumption studies. The Human Health Focus Group formed by ODEQ to provide technical recommendations for selecting a fish consumption rate appropriate for Oregon found that fish consumers generally eat a variety of species that are the most readily available geographically and seasonally and that the range of consumption rates among fish consumers tend to be comparable regardless of the species that are available at any given time.[87] Thus, Oregon determined the rate of 175 grams per day appropriate for protection of high consumers from both freshwater and saltwater environments throughout the state.

Bioconcentration factor

Limited data are available regarding bioaccumulation (BAF) and bioconcentration (BCF) of arsenic in aquatic species. As discussed above, EPA recommends bioaccumulation data be used when available in order to take into consideration all pathways of accumulation, not merely the concentration that is received from water as reflected in bioconcentration data. EPA review of the literature found no relevant BAF data was available and thus EPA recommended that BCF data be used by Oregon to determine appropriate BCFs for use in deriving their arsenic criteria.[88]

EPA reviewed the available literature that might be relevant to recalculating a BCF specific to Oregon's waters and provided that information to ODEQ.[89] Only six published studies were identified and only four of the studies were found suitable for use in recalculating a BCF. Limitations in the data reported in two of the studies resulted in EPA determining they were not appropriate for use and thus were not used in either ODEQ's recalculations or EPA's review of the recalculated BCFs. The four studies found to be appropriate for this purpose and thus used provided data for only three species. One data set is from a test of a saltwater mollusk, the eastern oyster, and the others tested two freshwater finfish, bluegill and rainbow trout. Additional information on these studies can be found in ODEQ's April 2011 review document.[90]

Oregon determined that a BCF of 14 was appropriate for use in developing arsenic human health criteria for freshwaters of the state based on their review of the data contained in the above mentioned studies. A BCF of 14 represents the geometric mean of the data available from the studies of freshwater organisms (two publications on rainbow trout[91] and one on bluegill[92]). Oregon determined that the BCF data for the eastern oyster, a marine mollusk, was not appropriate for use in deriving a freshwater BCF because the oyster was a marine organism and available data indicate marine organisms are more likely to bioaccumulate arsenic than freshwater organisms. Furthermore, DEQ stated that they were not aware of data showing

harvesting or consumption of mollusks or other shellfish from freshwaters in Oregon and thus, freshwater mollusks were not likely to comprise a significant portion of the fish consumed from freshwaters in Oregon. Thus Oregon assumed finfish would be the primary exposure route for arsenic ingested from freshwaters and therefore, used only the data from finfish studies to calculate the freshwater BCF.[93,94] Based on this evaluation, ODEQ found that a BCF of 14 was a reasonable and protective value to use in calculating the arsenic criteria for Oregon's freshwaters.

Cancer Slope Factor

Similar to all other criteria addressed in this action, for arsenic, ODEQ used the cancer slope factor identified in EPA's Integrated Risk Information System (IRIS) data base at the time of rule adoption (April 2011). For arsenic this value is 1.5 $(mg/kg/day)^{-1}$ and was last modified in 1998.

Inorganic Proportion Factor (Inorganic to Total Arsenic Ratio)

Arsenic is present in the environment and in fish tissue in both organic and inorganic forms. Inorganic arsenic, specifically arsenite (trivalent or As III), is the form that is most toxic to humans and used to develop toxicity data for cancer and other end points. Thus, EPA recommends that human health criteria for arsenic are developed specific to inorganic arsenic and apply to the inorganic portion of arsenic in the water column. The inorganic portion may be referred to as either "inorganic arsenic" or "total inorganic arsenic". When both inorganic and organic arsenic are included, it is referred to as "total arsenic".[95]

All of the bioconcentration studies identified by EPA and used by Oregon reported arsenic as total arsenic, not inorganic arsenic. In order to address this difference in form and toxicity, Oregon multiplied the BCF by an "inorganic proportion factor" that reflects the ratio of inorganic to total arsenic likely to be present in the water. The proportion varies geographically and between fresh and marine waters so must be determined using state or local data.

Only limited data are available relative to the ratio of inorganic to total arsenic in Oregon's freshwaters. Previous studies have reported the proportion of inorganic arsenic found in fish tissue collected in the Columbia and Willamette rivers to contain an average of 6.5% inorganic arsenic while the ratios reported for individual species of fish ranged from 0.5% to 9.2% inorganic arsenic.[96] ODEQ also found several other sources of information indicating that an

inorganic proportion of 10% or less was typical of freshwater environments.[97] Based on these findings, Oregon determined that an inorganic factor of 10% was a conservative ratio and appropriate for use in deriving the arsenic criteria for Oregon's freshwaters.

To incorporate the inorganic factor (IF) into the calculation, ODEQ used the following revised equations:

$$\text{Water + fish ingestion Criterion } (\mu g/L) = 1000 \times \frac{RF \times BW}{q1^*[DW + (BCF \times FCR \times \mathbf{IF})]}$$

$$\text{Org Only Criterion } (\mu g/L) = 1000 \times \frac{RF \times BW}{q1^*[BCF \times FCR \times \mathbf{IF}]}$$

Carcinogenic Risk Level

In the 2000 Human Health Methodology EPA states that it believes States and authorized Tribes have the flexibility to adopt the carcinogenic risk level they find appropriate for protection of the designated uses as long as the general population is protected at a 10^{-5} or 10^{-6} risk level and highly exposed populations are protected at a risk level that does not exceed 10^{-4}.[98] With the exception of arsenic, Oregon has used a risk rate of 10^{-6} when developing water quality criteria for carcinogenic pollutants. However, due to the natural levels of arsenic in Oregon's waters and the exposure levels resulting from natural sources of arsenic, Oregon has chosen to use a risk level of 10^{-4} for the arsenic criteria. Oregon made this policy decision following consideration of several alternatives and consideration of public comments received on the proposed criteria. The lower level of protection afforded by the proposed criteria was clearly identified by ODEQ in the documents provided to the public during both public notice periods and in the materials presented to the EQC at the time the rule was adopted.[99] ODEQ has stated that they made this

decision because of the special circumstances associated with natural levels of arsenic but believed that the 10^{-6} risk level used to derive all other criteria continued to be appropriate.[100] In determining the acceptable risk level for the arsenic criteria, ODEQ considered the natural background levels of arsenic commonly found in Oregon and evaluated the likely risk associated with exposure to these levels for the general population and high fish consumers. As noted earlier, ODEQ found that naturally occurring arsenic in many surface waters of the state range from less than 1 µg/l up to 3 µg/l and may occur at much higher levels. Therefore, ODEQ evaluated the risks that would be associated with arsenic criteria of 2-3 µg/l.

Using the input variables identified above, Oregon determined that a freshwater water plus organism (water + org) criterion of 2.1µg/l would result in a carcinogenic risk of $1x10^{-4}$. Since this value would protect high fish consumers of the State (those consuming 175 grams of fish per day) at a 10^{-4} risk level, Oregon found this criterion would protect the human health uses in State waters at a level consistent with the risk levels recommended by EPA in the 2000 Human Health Methodology.[101] Thus, Oregon adopted an arsenic water plus organism criterion of 2.1 µg/l for freshwaters.

Oregon similarly evaluated the criterion for protection of waters where fish consumption was a designated use but drinking water was not a designated use (organism (org) only criterion). Using the same variables discussed above, Oregon determined that a criterion of 19 µg/l would protect at a $1x10^{-4}$ risk level while a criterion value of 1.9 µg/l would protect at a $1x10^{-5}$ risk level. Oregon noted that establishing the org only criterion at the same risk level as the water + org criterion would result in a criterion that was nearly an order of magnitude less stringent than the water + org criterion. Therefore, after reviewing several options Oregon established the organism only criterion at the same level as the water + org criterion (2.1 µg/l). Oregon's revised freshwater arsenic org only criterion of 2.1 µg/l represents a carcinogenic risk of 1.1 x 10^{-5} to high consumers of the State (at a fish consumption rate of 175 grams/day). Oregon found this level of protection appropriate as it was within the risk range identified in EPA's 2000 Human Health Methodology and took into consideration the natural levels of arsenic found in Oregon's waters.[102]

b) Saltwater Criteria

Oregon's objectives in developing an arsenic criterion for saltwater was to protect those who consume fish and shellfish from Oregon's marine and estuarine waters to which a criterion applies, taking into consideration the presence of naturally occurring levels of arsenic in marine waters. Uncertainties in the scientific community's current knowledge of the various species of arsenic in the saltwater environment and in marine and estuarine species also were considered in the evaluation.[103]

Oregon has not designated any saltwaters of the state as a drinking water use. Consistent with this designation, the only human health criterion applicable to and derived for saltwaters in Oregon are the organism only criteria (i.e. developed to protect humans from health effects incurred while ingesting fish and shellfish). As identified in Table 9 above, Oregon adopted an organism only criterion of 1.0 µg/l inorganic arsenic for all saltwaters of the State. The following discusses the input variables used and the conclusions reached by ODEQ in establishing this criterion.

Body weight, fish consumption rate and cancer slope factor
The input variables used for body weight, fish consumption rate and the cancer slope factor to derive Oregon's arsenic human health water quality criteria applicable to saltwater are the same as those used to derive the freshwater criteria discussed above.

Bioconcentration factor and inorganic proportion factor
Oregon's arsenic criterion for saltwater was calculated using a BCF of 26 (the geometric mean of all BCFs for fresh and saltwater species combined) and an inorganic proportion factor of 10%.

As discussed in the freshwater section above, bioconcentration data for arsenic is limited. EPA's review of the literature found only four studies appropriate for use in calculating BCFs and only one of those tested an organism from a saltwater environment (eastern oyster).[104] When ODEQ reviewed the available studies, they found a large difference in BCF values found in the study of the Eastern oyster (BCF of 350) relative to those found in the freshwater finfish studies (BCFs of 4 to 27). Given the differences in the BCFs and recognizing that people consume both mollusks and finfish from the Oregon waters where this criterion would apply, ODEQ evaluated potential options for criteria using two scenarios (see Table 11 below). The first scenario considered criterion calculated using a BCF of 26, the geometric mean of all available BCF data (both saltwater and freshwater). The second evaluated options using a BCF of 350, the geometric mean from the one study of a saltwater organism. Under both scenarios, the criteria that would result from using inorganic proportion factors of 1% and 10% were calculated. Results of the various options were compared to levels of arsenic naturally present in estuarine and marine

waters. Following analysis of the options generated under the two scenarios ODEQ evaluated the level of protection provided by each and compared the criteria to the concentrations of arsenic naturally present in estuarine and marine waters. Based on this analysis ODEQ determined that a criterion of 1.0 µg/L inorganic arsenic was appropriate for protection of the fish consumption use in Oregon's saltwaters.

Table 11. Scenarios evaluated by Oregon and/or EPA.

Scenario	**A**	**B**	**C**	**D**	**E**	**F**
Fish Consumption	175 g/day	175 g/day	175 g/day	175 g/day	175 g/day	
Bioconcentration	26	26	350	350	350	
Inorganic portion	10%	1%	1%	10%	7.3%	
Risk level	1×10^{-5}	1×10^{-6}	1×10^{-5}	1.3×10^{-5}	9.6×10^{-5}	
Natural ocean level						1 – 1.2 µg/l
Resultant Criterion	**1.0 µg/l**	**1.0 µg/l**	**0.8 µg/l**	**1.0 µg/l**	**1.0 µg/l**	**1.0 µg/l**

As part of this evaluation, ODEQ evaluated the appropriate species to be considered in deriving a BCF value, the ratio of inorganic to total arsenic in the ocean environment, and the natural level of arsenic in Oregon's salt waters. When evaluating BCF data, ODEQ found that bioconcentration of arsenic in the tissue of invertebrates tended to be higher than that for vertebrates. In particular, they found that crustaceans and mollusks tended to accumulate more inorganic arsenic in their tissue (the form toxic to humans) than anadromous or marine fish. While data specific to consumption levels of various species from Oregon's saltwaters was not available, ODEQ knew that both shellfish and finfish were harvested and consumed from saltwaters in Oregon. ODEQ's literature review also indicated that, for the general US population, estuarine and marine mollusks represent only a small percent (3-13%) of the total fish and shellfish consumption. Given the small percentage of shellfish consumption relative to fish consumption and the much higher bioconcentration rate in shellfish, ODEQ concluded that a criterion calculated using only the oyster data (BCF = 350) was likely to be overly conservative.[105]

Oregon's literature review found a growing body of literature indicating that while saltwater organisms may contain more total arsenic than freshwater fish, the predominant form of arsenic in marine species is organic arsenic (i.e. rather than inorganic arsenic).[106] One analysis of five types of ocean finfish and ocean shrimp found that inorganic arsenic in the organism's tissues was less than 0.1% of the total arsenic present in tissues.[107] Other literature reported values of less than 3% and more recent surveys report values less than 1%.[108] A summary of the data from

[108] ODEQ. April 4, 2011. *Issue Paper: Water Quality Standards Review and Recommendations: Arsenic.* Oregon

20 studies is provided below and indicates that the inorganic arsenic in tissues of marine fish and marine shellfish ranged from 0.0001% to 7.3% of the total arsenic present; anadromous fish ranged from 0.3% to 3.04% and freshwater fish tissue contained between 0.5% and 26.6% inorganic arsenic.[109]

Inorganic arsenic as a % of total arsenic in seafood measured as ng/g wet weight

	Mean	Range
Freshwater	7.2	0.5-26.6
Anadromous fish	1.1	0.03-3.04
Marine fish	1.0	0.001-6.9
Marine Crustaceans	1.3	0.001-7.3
Marine Mollusks	1.8	0.04-6.5

Based on the review of the above information, ODEQ concluded it appropriate to use an inorganic factor of 1% if used in association with a conservative BCF of 350. However, if using the less conservative BCF of 26, ODEQ used a more conservative inorganic factor of 10% in their initial scenarios. ODEQ found comparison of these scenarios was a reasonable approach to take into account the variability and uncertainty in both the BCFs and inorganic factors while not resulting in an overly conservative criterion.[110]

Natural ocean levels and complexities in the marine environment

Oregon's review of the literature found natural total arsenic levels of oceans waters to be in the range of 1 to 3 µg/l. Data cited from the Pacific Ocean indicated average concentrations of 1.1 – 1.2 µg/l.[111]

Oregon did not have any data from Oregon's marine waters where inorganic and total arsenic were measured simultaneously. Thus, they relied on the above literature for their conclusion that the natural concentrations of arsenic in Oregon salt waters contain 1.0 µg/l or more of inorganic arsenic and that a waterbody criterion of 1.0 µg/l should not present any greater human health risk than that naturally present.[112]

Carcinogenic Risk Level
For the saltwater organism only criterion of 1.0 µg/l inorganic arsenic represents a carcinogenic risk level of 10^{-5}. Since this value would protect high fish consumers of the State (those consuming 175 grams of fish per day) at a 10^{-5} risk level, Oregon found this criterion would protect the human health uses in State waters at a level consistent with the risk levels recommended by EPA in the 2000 Human Health Methodology.[113] Furthermore, ODEQ determined it was appropriate to use a different carcinogenic risk level for this criterion than that used for other criteria in the state (10^{-6}) since the resultant criterion concentration reflected that which naturally occurred in marine waters.[114] (See the discussion regarding carcinogenic risk level for the freshwater arsenic criteria for more detail regarding EPA's 2000 Human Health Methodology.)

Based on the above findings, Oregon considered the scenarios in Table 11 above when selecting an appropriate org only criterion for arsenic in Oregon's saltwaters. Based on the conservative nature of a BCF of 350, the variability in the data, the uncertainties in the scientific communities current knowledge and ODEQ's determination that "there does not appear that an unacceptable human health risk with eating fish from an unpolluted marine environment," Oregon revised the saltwater criterion for inorganic arsenic to 1.0 µg/l.

c) EPA Review of Oregon's Revised Arsenic Criteria

EPA has reviewed the information provided by Oregon regarding the literature considered during their review of the arsenic criteria. EPA determined that Oregon's review considered the relevant and available information relative to selecting appropriate input variables for deriving the arsenic criteria. EPA conducted a more detailed review of several of the variables used in deriving the criteria. This review is presented below.

(1) FRESHWATER CRITERIA

BCF for Freshwater Criteria
EPA has reviewed the literature used by Oregon to calculate a BCF and finds that all relevant studies were identified. The use of a geometric mean value from available studies is appropriate for deriving a single BCF value. As determined by Oregon, a BCF of 14 is representative of the available BCF data relative to freshwater species.

In EPA's review of the literature relative to bioaccumulation of arsenic in aquatic organisms, no BAF studies specific to bioaccumulation in Oregon or models which could readily produce

[113] ODEQ. April 5, 2011. *Memo from Dick Pedersen, Director ODEQ, to the Environmental Quality Commission. Agenda Item E. Rule adoption: Amending water quality standards for arsenic, April 21-22, 2011EQC meeting.* Oregon Department of Environmental Quality. [114] ODEQ. April 4, 2011. *Issue Paper: Water Quality Standards Review and Recommendations: Arsenic.* Oregon Department of Environmental Quality. pages 15-16 in Tanaka and Santosa. 1995 National Academy of Sciences, 1972 and EPA. 2003. Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/metals/AppEArsenicIssuePaper.pdf

bioaccumulation factors specific to Oregon's waters were found. Thus, ODEQ's use of a bioconcentration factor is appropriate in this situation.

In selecting the appropriate BCF for use in deriving freshwater criteria, Oregon reviewed the available data for both saltwater and freshwater organisms and considered whether that data was representative of organisms likely to be consumed from waters to which the criteria would apply. In evaluating the use of the data from a study of the eastern oyster, a saltwater mollusk, Oregon noted that saltwater mollusks are not present in freshwaters of Oregon and that they were "not aware of any mollusks or other shellfish harvested and consumed from Oregon's freshwaters".[115] In order to verify this assertion, EPA consulted the Oregon Department of Fish and Wildlife website.[116] According to the regulations posted on this site, Oregon prohibits the harvest or possession of all freshwater mussels or clams (except for Zebra mussels or Asian clams) except as authorized by a Scientific Take Permit.[117] Furthermore, EPA noted that no freshwater mussels or shellfish were included in the species identified in the CRITFC Fish Consumption Study. While this later fact does not speak to all mussels or shellfish from freshwaters of Oregon, it is one indication that traditional and cultural consumption of these organisms is not occurring in a large portion of Oregon. Based on this information, EPA finds the assumption made by Oregon as to type of organisms consumed from Oregon's freshwaters to be reasonable. While including BCF data from the eastern oyster in the calculations would have expanded the scope of represented species to include mollusks, it would have also contributed BCF data from a marine species into the calculation of freshwater criteria. EPA concludes that Oregon's decision not to include the BCF data from the eastern oyster was appropriate, in light of the above data with respect to the low likelihood of human consumption of freshwater mollusks in Oregon.

One commenter provided numerous comments relative to the use of a BCF instead of a site-specific BAF. In the 2000 Human Health Methodology EPA recommends using a BAF in cases where data are available. EPA's review of the literature indicates that data and models are not currently available to develop a state-specific BAF for waters in Oregon. Additional information on this topic can be found in the above description of the methodology used to develop criteria for noncarcinogens and in EPA's Response to Comments document developed in association with the recent June 1, 2010 action on Oregon's human health criteria adopted in 2004.[118] The same commenter noted that recent studies of arsenic bioaccumulation indicate use of a regression approach to developing arsenic criteria may be more appropriate than using a single criterion applicable to all waters. EPA reviewed the cited study and agrees that it is an approach that has been applied on a site-specific basis and could be applied by a state in developing criteria for arsenic. However, EPA has not developed a recommended approach for

[115] ODEQ. April 4, 2011. *Issue Paper: Water Quality Standards Review and Recommendations: Arsenic.* Oregon Department of Environmental Quality. Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/metals/AppEArsenicIssuePaper.pdf

[118] EPA. June 1, 2010. Supplemental Response to Comments Submitted by Northwest Environmental Advocates (NWEA) as They Pertain to Oregon's New and Revised Human Health Water Quality Criteria for Toxics Submitted on July 8, 2004.

incorporating this approach into a water quality criterion and no state has used it to develop a water quality criterion. Utilization of a regression approach would result in a criterion expressed as an equation for calculating a criterion concentration which varies with the ambient level of arsenic present in a waterbody in order to take into account the fact that the fraction of total arsenic that is inorganic arsenic tends to decrease as the concentration in the tissues increase. Additional questions regarding whether the criteria would more appropriately be expressed as a water column or tissue concentration would also need to be addressed. While utilizing this approach to developing a state-wide criterion would result in a site-specific criterion that may more accurately reflect the desired level of protection at any particular site (i.e. a 10^{-5} risk level), it would not necessarily provide for a greater level of protection. Given that this level of detail is not needed to protect the use and that this method has never been applied to derive a water quality criterion, EPA finds that it was reasonable for Oregon to establish a single criterion concentration and not use this new approach in this rule revision.

Inorganic Proportion Factor for Freshwater Criteria

EPA's review of available information finds that an inorganic proportion factor of 10% represents a reasonable and conservative estimate of the proportion of total arsenic present in an inorganic form in the tissue of organisms collected from freshwaters in Oregon. EPA notes that this same value was used by EPA when conducting site-specific risk assessments in the Columbia and Willamette Rivers that considered the same data set. No additional data have become available since the EPA assessments.

Level of Protection Provided by the Freshwater Criteria

Oregon's arsenic criteria for fresh waters are established at a level that protect high fish consumers in Oregon at carcinogenic risks levels of between 1×10^{-4} to 1×10^{-5} (see more detailed discussion above). EPA's 2000 Human Health Methodology states that states have the flexibility to choose an appropriate risk level for use in deriving water quality criteria as long as it protects the use to the levels recommended by EPA. Those risk levels are a 10^{-5} or 10^{-6} risk level for the general population and a risk level that does not exceed 10^{-4} for highly exposed populations.

Oregon's criteria were established using a fish consumption rate of 175 grams per day, reflective of the 95th percentile of consumption in a high-consuming subpopulation in Oregon and the 90th percentile of data from regional surveys of high consuming subpopulations. Therefore, the criteria represent the level of exposure expected to occur in highly exposed populations of Oregon. As such, Oregon's freshwater arsenic criteria protect highly exposed populations of Oregon at a level consistent with EPA's recommendations (does not exceed 10^{-4} risk level).

EPA has recommended using a fish consumption rate for the general US population of 17.5 grams per day if no local or regional data is available. There is currently no available fish consumption data specific to the general population of Oregon. If one were to evaluate the protectiveness of Oregon's arsenic criteria at EPA's default fish consumption rate of 17.5 grams per day, the result would indicate a carcinogenic risk level between $1x10^{-6}$ and $1x10^{-5}$. This risk level is consistent with that recommended by EPA. Therefore, EPA finds that ODEQ's revised arsenic criteria for freshwater are established at a level protective of both the general population and high fish consuming populations consistent with the levels recommended by EPA in the

2000 Human Health Methodology.

(2) SALTWATER CRITERIA

BCF for Saltwater Criteria

EPA has reviewed the literature used by Oregon to calculate the BCF used to derive the saltwater criterion and finds that all relevant studies were identified. EPA also found the use of a geometric mean value to be appropriate for deriving a BCF. As considered by Oregon, a BCF of 26 is representative of all available BCF data for both saltwater and freshwater species (one study of a saltwater mollusk and three studies of freshwater finfish). A BCF of 350 reflects all of the available BCF data for saltwater species (one study of a saltwater mollusk). Oregon considered both of these BCF values when evaluating the protectiveness of the revised criterion.

As noted by Oregon, there is relatively little BCF data available for arsenic and only one study that addresses saltwater species. Given the limited data and the differences in BCF between the finfish and mollusk data, EPA finds Oregon's approach of comparing the outcomes of scenarios for both a BCF of 26 and a BCF of 350 in terms of protectiveness to be reasonable. (See Table 11 above). Given the limited data and the variability in the available data, EPA believes that evaluating the level of protection provided by a range of inorganic proportion factors in association with the different BCF values is also appropriate. EPA's evaluation of whether the criteria derived using these input values is protective of the use is provided below.

Inorganic Proportion Factor for Saltwater Criterion

EPA's review of the literature relative to the ratio of inorganic to total arsenic in the tissue of saltwater organisms indicated that ODEQ reviewed the available information on this subject. EPA concurs that the information is limited, especially specific to Oregon waters, but it does indicate that the ratio of inorganic to total arsenic in tissues of saltwater organisms is typically lower than that found in freshwater organisms. Thus, using the 10% inorganic ratio that is also used in the freshwater criteria serves to provide a conservative estimate of the ratio—i.e., one that is larger than the mean ratio values found in various studies (1 to 3%). Given the variability in these factors and in the BCF values discussed above, EPA believes it was appropriate for ODEQ to have considered several different exposure scenarios when developing this criterion and that ODEQ's use of inorganic factors of 10% and 1% in the scenarios was also reasonable. EPA's evaluation of whether the criteria derived using these input values is protective of the use is provided below.

Level of Protection Provided by the Saltwater Criteria

Oregon adopted a saltwater criterion of 1 µg/l and relied on multiple lines of evidence in determining it is protective of Oregon's human health uses. Consistent with Oregon's approach at evaluating scenarios, EPA has evaluated the level of protection provided by each scenario presented. As illustrated in Table 11 above, when the more conservative BCF (350) was paired with the less conservative inorganic proportion factor (1%), a criterion of 1.0 µg/L was found to protect high fish consuming populations (175 g/day) at a 1.3×10^{-5} risk level. When the less conservative BCF (26) was paired with the more conservative inorganic proportion factor (10%), a criterion of 1.0 µg/l was found to protect high consumers (175 g/day) at a 1.0×10^{-5} risk level. Both of these scenarios provide a level of protection consistent with that recommended by EPA

in the 2000 Human Health Methodology. However, when EPA evaluated the level of protection that would be provided using the more conservative of both factors (BCF of 350 and inorganic proportion factor of 10%), a criterion of 1.0 µg/l resulted in a 1.3 x 10^{-4} risk level. This level is a higher risk than that recommended by EPA in the 2000 Human Health Methodology. EPA notes that the highest ratio of inorganic to total arsenic in fish tissue of saltwater organisms identified by ODEQ was 7.3%. ODEQ used 10% as a conservative inorganic proportion value for marine criteria (incorporating data from freshwater species) but EPA believes 7.3% is also a conservative estimate for marine organisms as it is the highest data value reported. Combining an inorganic factor of 7.3% (not as conservative a value as selected by Oregon but still sufficiently conservative based on a reasonable assessment of the available data) with a BCF of 350 (more conservative than the value ultimately selected by Oregon), EPA calculated that a criterion of 1.0 µg/L would protect high fish consuming populations at a risk level of 9.6 x 10^{-5}. Thus, a criterion of 1.0 µg/l calculated using a conservative inorganic proportion factor of 7.3% would protect high fish consumers in Oregon at a level consistent with that recommended by EPA in the 2000 Human Health methodology.

Oregon has presented a reasonable scientific basis to not rely solely on the BCF from the eastern oyster (350) in calculating the saltwater criterion, and instead rely on a BCF that incorporates data from other species (26).[119] Furthermore, the percentage of total arsenic that occurs in an inorganic form that Oregon paired with this BCF (10%) was more than sufficiently conservative based on the available data. Based on the calculations discussed in the paragraph above and these additional considerations, EPA believes that Oregon's saltwater criterion for arsenic will protect human health consistent with the level recommended by EPA.

(3) GENERAL CONSIDERATIONS

Risk level applied to arsenic criteria relative to that applied to other criteria

EPA reviewed the information provided by Oregon related to establishing criteria for arsenic at a level different than that used for all other criteria in the State. EPA notes that ODEQ stated that they were addressing arsenic as a special case and clearly stated their reasons for evaluating risk management decisions relative to this pollutant. The public notice, memorandum presenting recommendations to the EQC and ODEQ's document presenting its review and recommendations for the arsenic criteria all clearly identify that the criteria recommendations were established at a level providing less protection than for other pollutants in Oregon. Thus, the Commission was made aware of the policy decision inherent in their decision to adopt the recommended criteria. Thus, EPA finds that Oregon was reasonably exercising its discretion when establishing an alternate risk level for the arsenic criteria.

Cancer Slope Factor

One commenter noted that a cancer slope factor of 1.75$(mg/kg/day)^{-1}$ was used by EPA to develop the current 304(a) criteria recommendation while another stated that EPA was currently

[119] Mollusks tend to accumulate arsenic to a greater extent than other species and mollusks represent only a small percent (3-13%) of the U.S. general population's total fish and shellfish consumption. A marine BCF that is only based on mollusk data is therefore not ideally representative of marine species overall. EPA concludes that it was reasonable for Oregon to incorporate data from non-mollusk species to arrive at a more representative BCF, even though those non-mollusk species were not marine species.

reviewing the science behind the cancer slope factor. Both of these assertions are correct. EPA's 304(a) criteria recommendations for arsenic were first published in 1986 and uses a cancer slope factor of $1.75(mg/kg/day)^{-1}$. This recommendation has not been updated to reflect the latest value identified in the IRIS database, in part because the science behind that number is currently under review. A draft document was circulated for public comment and peer review by the Science Advisory Board in 2010.[120] EPA is currently reviewing these comments and has yet to make a final determination on potential revisions to the cancer slope factor for arsenic. Thus, EPA does not believe it appropriate for ODEQ to use the draft value in revising these criteria. EPA expects to coordinate with ODEQ regarding the potential need for reevaluation of the criteria if a new value is established in IRIS and/or changes are made to EPA's 304(a) criteria recommendations for arsenic.

3. EPA Action and Rationale Regarding Oregon's Arsenic Criteria

EPA Action
In accordance with its Clean Water Act authority, 33 U.S.C § 1313(c)(3) and 40 C.F.R. part 131, EPA approves Oregon's revised human health toxic criteria for inorganic arsenic because they are protective of Oregon's fishing and water supply uses. EPA is also approving footnote A which states: *The arsenic criteria are expressed as total inorganic arsenic. The "organism only" criteria are based on a risk level of approximately 1.1 x 10^{-5}, and the "water + organism" criterion is based on a risk level of 1.1 x 10^{-4}.*

EPA Rationale
EPA's WQS regulations require that criteria protect the designated uses. As noted previously, Oregon's human health criteria apply to waters with fishing and water supply uses and thus must be established at a level that will protect those uses. Therefore, EPA must evaluate whether the criteria protect Oregon's human health uses.

As discussed in detail above, EPA has found that Oregon considered the available and relevant literature in revising Oregon's arsenic criteria. Oregon provided a reasonable basis for the decisions made in developing the criteria. All three of the criteria adopted by ODEQ were found to protect human health uses consistent with recommendations provided in EPA's 2000 Human Health Methodology.

Inorganic Arsenic and Footnote A in Table 40
EPA's current 304(a) human health criteria recommendations are specifically identified as criteria for inorganic arsenic. As noted above, inorganic arsenic is the form most toxic to humans. As such, EPA's recommendations relative to this criteria and the associated risk assessment input variables are expressed as inorganic arsenic. In this revision, Oregon specifically identified that the criteria as inorganic arsenic in Table 40 by placing the word "inorganic" in parentheses.

[120] February 19, 2010. *Federal Register*, Volume: 75, No.: 33, page: 7477 (78 FR 7477). Available at: http://www.gpo.gov/fdsys/pkg/FR-2010-02-19/pdf/FR-2010-02-19.pdf

In addition, EPA is approving footnote A to the arsenic criteria in Table 40 which states: *The arsenic criteria are expressed as total inorganic arsenic. The "organism only" criteria are based on a risk level of approximately 1.1 x 10^{-5}, and the "water + organism" criterion is based on a risk level of 1.1 x 10^{-4}.*

The first sentence of the footnote provides clarification that the human health criterion for arsenic is expressed as total inorganic. This new footnote language for arsenic is consistent with EPA's recommended 304(a) national default expression for the arsenic criterion. The second sentence of the footnote clearly articulates the input variables regarding risk levels that were used to derive the arsenic criteria. This footnote establishes a legally binding requirement under State law and helps describe a desired ambient condition of a waterbody to support a particular designated use and is therefore considered a WQS subject to EPA review and approval under 303(c) of the CWA. The description of the applicable expression of arsenic associated risk level is a component of the overall level of protection afforded by the arsenic criteria. Therefore, EPA approves this footnote as a WQS.

Acknowledgement of Maximum Contaminant Level (MCL) in Table 20
ODEQ revised the drinking water MCL for arsenic from 0.05 mg to 10 µg/l in Table 20 and added footnote 1 which states: *The arsenic value is shown here for informational purposes only and is not a water quality criterion.*

Drinking water standards are regulations that EPA sets to control the level of contaminants in the nation's drinking water. In most cases, the standard is a MCL**,** the maximum permissible level of a contaminant in water which is delivered to any user of a public water system. The Safe Drinking Water Act gives individual states and tribes the opportunity to set and enforce their own drinking water standards if the standards are at least as stringent as EPA's national standards. When making a determination to regulate, the Safe Drinking Water Act requires consideration of these three criteria:

- the potential adverse effects of the contaminant on the health of humans;
- the frequency and level of contaminant occurrence in public drinking water systems; and
- whether regulation of the contaminant presents a meaningful opportunity for reducing public health risks.

ODEQ revised their MCL value for arsenic from 0.05 mg to 10 µg/l in Table 20. This revision reflects the current level set under the Safe Drinking Water Act and is consistent with EPA recommended drinking water MCL.[121] ODEQ also added a clarifying footnote which explains that the MCL value is not a water quality criterion.

[121] January 22, 2001. *Federal Register*, Volume: 66, No.: 14, page: 6976 (66 FR 6976). *Arsenic and Clarifications to Compliance and New Source Contaminants Monitoring Final Rule.* Available at: http://www.epa.gov/fedrgstr/EPA-WATER/2001/January/Day-22/w1668.htm
March 25, 2003. *Federal Register*, Volume: 68, No.: 57, page: 14501 (68 FR 14501). *Minor Clarification of National Primary Drinking Water Regulation for Arsenic; Final Rule.* Available at: http://www.gpo.gov/fdsys/pkg/FR-2003-03-25/html/03-7048.htm

Since Oregon has not adopted the arsenic MCL value as a water quality criterion, is not considered WQS under the CWA. Instead, the MCL is a value that the State uses to set the maximum permissible level of arsenic in drinking water delivered to the tap (after treatment) consistent with the Safe Drinking Water Act, not a value that surface waters of the State must meet. MCLs are enforceable standards under the Safe Drinking Water Act, and are not required under the Clean Water Act unless determined by the State to be needed to protect the designated uses. For these reasons, EPA is taking no action to approve or disapprove the revised MCL value for arsenic.

Based on the above, EPA has determined that Oregon's MCL value for arsenic is not a WQS subject to EPA review and approval under Section 303(c) of the CWA. As a result, EPA is taking no action to approve or disapprove this MCL value.

Provision Establishing the Effective Date for Arsenic at OAR 340-041-0033(2)(b)
The following language was added to Oregon's WQS at OAR340-041-0033 – Toxic Substances as part of Oregon's April 21, 2011 rule revisions submitted to EPA on July 12, 2011:

OAR 340-041-0033(2)(b) The arsenic criteria in Table 20 established by this rule do not become applicable for purposes of ORS chapter 468B or the federal Clean Water Act unless and until they are approved by EPA pursuant to 40 CFR 131.21 (4/27/2000).

As part of Oregon's subsequent June 16, 2011 rule revisions submitted to EPA on July 21, 2011, Oregon removed and renumbered the provision cited above language at OAR 340-041-0033(3)(b) when it reformatted the toxics criteria tables, thus moving the arsenic criteria to Table 40. Since the deleted language was submitted to EPA as part of the June 16, 2011 rule revisions, the provision is no longer applicable under state law and there is no requirement for EPA to act on the provision under Section 303(c) of the CWA.
~~*OAR 340-041-0033(3)(b) The arsenic criteria in Table 20 established by this rule do not become applicable for purposes of ORS chapter 468B or the federal Clean Water Act unless and until they are approved by EPA pursuant to 40 CFR 131.21 (4/27/2000).*~~

Since ODEQ deleted the language l as part of the July 21, 2011 submittal to EPA, the provision is not applicable under State law and there is no requirement for EPA to evaluate the provision under Section 303(c) of the CWA.

In the July 21, 2011 submittal, ODEQ addressed the effective dates of the criteria, including arsenic, in the associated revisions at OAR 340-041-0033(1) which describe the dates when the toxics criteria in Tables 20, 33A, 33B and 40 become effective under State law and the Clean Water Act. EPA's rationale for approval of OAR 340-041-0033(1) is explained in section V of this document.

Acknowledgement of the Arsenic Reduction Policy at OAR 340-041-0033(7)
In conjunction with this rule and in recognition that the revised criteria provide a lower level of protection than other human health criteria in Oregon, an Arsenic Reduction Policy was adopted under State law at OAR 340-041-033(4). To accommodate additional revisions associated with the rulemaking submitted to EPA on July 21, ODEQ reorganized the location of the rule and

moved the arsenic reduction policy section to OAR 340-041-0033(7). However, ODEQ did not revise any of the rule language that was previously adopted. The policy was included in Oregon's WQS regulation in the same section as the arsenic criteria to help ensure it was applied where applicable. The policy requires that, in situations where water bodies have background levels below the arsenic criteria, dischargers with the potential to affect a drinking water supply develop an arsenic reduction plan and take feasible steps to reduce arsenic loading.

The new policy does not establish a legally binding ambient condition for a waterbody to support a particular designated use. Nor does it establish a binding process whereby the State would establish an alternate ambient condition for a waterbody following a public process. Rather, this policy outlines permitting requirements that the State will place on selected dischargers (those located in a surface water drinking water protection area as delineated under the Safe Drinking Water Act). These permitting requirements are not tied to what is necessary to protect the designated uses of Oregon's waters, but rather to what measures are "feasible" to reduce arsenic loading. The permitting requirements are to be used in association with other implementation tools to encourage further arsenic reductions below the established criteria, but they do not modify those criteria.

In the Response to Comments, ODEQ states that the arsenic reduction policy is an important component of Oregon's WQS but that the intent of the policy is not to alter the numeric criteria. Furthermore, ODEQ specifies that the policy applies to specific sources and circumstances and requires that feasible reduction steps be taken.[122]
Based on the above, EPA has determined that this policy is not a WQS subject to EPA review and approval under Section 303(c) of the CWA. As a result, EPA is taking no action to approve or disapprove this provision.

F. *NEW, REVISED AND WITHDRAWN FOOTNOTES*

As part of the July 21, 2011 submittal, ODEQ added, revised and withdrew several footnotes. In addition to footnote J (for methylmercury) and footnote A (for arsenic) which are discussed separately above with those individual criteria, these changed footnotes are described in further detail below.

1. New Footnotes

ODEQ has added new footnotes for the following three pollutants: barium, cyanide, and PCBs.

Footnote C: Barium
The human health criterion for barium is the same as originally published in the 1976 EPA Red Book which predates the 1980 methodology and did not utilize the fish ingestion BCF approach. This same criterion value was also published in the 1986 EPA Gold Book. Human health risks are primarily from drinking water, therefore no "organism only" criterion was developed. The

[122] ODEQ. March 2011. *Summary of Public Comment and Agency Response. Amending Oregon's Water Quality Standards: Revising Human Health Criteria for Arsenic.* Oregon Department of Environmental Quality. page 26. Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/metals/AttCArsenicPublicComment.pdf

"water + organism" criterion is based on the Maximum Contaminant Level (MCL) established under the Safe Drinking Water Act.

Footnote G: Cyanide
The cyanide criterion is expressed as total cyanide (CN)/L.

Footnote L: PCBs
This criterion applies to total PCBs (e.g. determined as Aroclors or congeners).

Acknowledgement of Barium Footnote C
The new footnote C for barium clarifies the source of information upon which the criterion is based. However, the footnote does not establish a legally binding requirement under State law nor does it describe a desired ambient condition of a waterbody to support a particular designated use. Therefore this footnote is not considered a WQS subject to EPA review and approval under 303(c) of the CWA. As a result, EPA is taking no action to approve or disapprove the new footnote for barium. The underlying criterion for barium was unrevised and therefore EPA is not reviewing the underlying criterion as part of this action.

EPA acknowledges that the footnote provides accurate information respecting the human health criterion development for barium. The new footnote for barium explains that the criterion is based upon a Safe Drinking Water MCL value along with the rationale for why an "organism only" criterion does not exist. The human health criterion for barium was not derived using EPA's 2000 Methodology, but instead was based upon EPA's national 304(a) criteria recommendations in EPA's 1986 Gold Book.

EPA Approval of Footnotes for Cyanide (footnote G) and PCBs (footnote L)
In accordance with its Clean Water Act authority, 33 U.S.C § 1313(c)(3) and 40 C.F.R. part 131, EPA approves Oregon's addition of the two footnotes, Footnote G for cyanide and Footnote L for PCBs, as consistent with EPA's current CWA § 304(a) criteria recommendations.

EPA Rationale Regarding Footnotes for Cyanide (footnote G) and PCBs (footnote L)
Oregon's new footnote G for cyanide explains that the criterion is expressed as total cyanide (CN)/L. EPA has reviewed this footnote language and the 304(a) criteria recommendation, which states that the "recommended water quality criterion is expressed as total cyanide, even though the IRIS RfD used to derive the criterion is based on free cyanide. The multiple forms of cyanide that are present in ambient water have significant differences in toxicity due to their differing abilities to liberate the CN-moiety. Some complex cyanides require even more extreme conditions than refluxing with sulfuric acid to liberate the CN-moiety. Thus, these complex cyanides are expected to have little or no 'bioavailability' to humans. If a substantial fraction of the cyanide present in a water body is present in a complex form (e.g., $Fe_4[Fe(CN)_6]_3$), this criterion may be over conservative."[123] Oregon's new footnote language along with the human

[123] EPA. *National Recommend Ambient Water Quality Criteria for the Protection of Aquatic Life and Human Health.* Published pursuant to section 304(a) of the Clean Water Act. Footnote jj. Available at: http://www.epa.gov/waterscience/criteria/wqctable/index.html

health criterion values for cyanide are consistent with EPA's recommended 304(a) national default values for calculating the criterion.

This footnote establishes a legally binding requirement under state law and helps describe a desired ambient condition of a waterbody to support a particular designated use and is therefore considered a WQS subject to EPA review and approval under 303(c) of the CWA. The description of the applicable form of cyanide is a component of the overall description of the level of protection afforded by the criterion. Since this footnote specifies the applicable form of the cyanide criterion Oregon adopted, EPA approves this footnote as a WQS. EPA is approving the associated numeric criteria for cyanide as discussed above in section IV.

Oregon's new footnote L for PCBs explains that the criterion applies to total PCBs. EPA has reviewed this footnote language and the 304(a) criteria recommendations, which states that the "criterion applies to total PCBs, (e.g., the sum of all congener or all isomer or homolog or Aroclor analyses.)"[124] Oregon's new footnote language along with the human health criterion values for PCBs are consistent with EPA's recommended 304(a) national default values for calculating the criterion.

This footnote establishes a legally binding requirement under state law and helps describe a desired ambient condition of a waterbody to support a particular designated use and is therefore considered a WQS subject to EPA review and approval under 303(c) of the CWA. The description of the applicable form of PCBs is a component of the overall description of the level of protection afforded by the criterion. Since this footnote specifies the applicable form of the PCB criterion Oregon adopted, EPA approves this footnote as a WQS. EPA is approving the associated numeric criteria for PCBs as discussed above in section IV.

2. Revised Footnotes

ODEQ has revised the footnotes below for the following six pollutants: footnote B: asbestos, footnote D: chlorophenoxy herbicide (2,4,5,-TP), footnote E: chlorophenoxy herbicide (2,4,-D), footnote F: copper, footnote I: methoxychlor, and footnote K: nitrates.

Table 12: Revised Footnotes.

Id.	Pollutant	Previous Footnote	New Footnote
B	Asbestos	*Human health criteria for carcinogens reported for three risk levels. Value presented is the 10-6 risk level, which means the probability of one cancer case per million people at the stated concentration.*	*The human health risks from asbestos are primarily from drinking water, therefore no "organism only" criterion was developed. The "water + organism" criterion is based on the Maximum Contaminant Level (MCL) established under the Safe Drinking Water Act.*
D	Chlorophenoxy Herbicide (2,4,5,-TP)	*This value is based on a Drinking Water regulation.*	*The Chlorophenoxy Herbicide (2,4,5,-TP)criterion is the same as originally*

[124] EPA. *National Recommend Ambient Water Quality Criteria for the Protection of Aquatic Life and Human Health.* Published pursuant to section 304(a) of the Clean Water Act. Footnote N. Available at: http://www.epa.gov/waterscience/criteria/wqctable/index.html

			published in the 1976 EPA Red Book which predates the 1980 methodology and did not utilize the fish ingestion BCF approach. This same criterion value was also published in the 1986 EPA Gold Book. Human health risks are primarily from drinking water, therefore no "organism only" criterion was developed. The "water + organism" criterion is based on the Maximum Contaminant Level (MCL) established under the Safe Drinking Water Act.
E	Chlorophenoxy Herbicide (2,4,-D)	*This value is based on a Drinking Water regulation.*	*The Chlorophenoxy Herbicide (2,4,-D) criterion is the same as originally published in the 1976 EPA Red Book which predates the 1980 methodology and did not utilize the fish ingestion BCF approach. This same criterion value was also published in the 1986 EPA Gold Book. Human health risks are primarily from drinking water, therefore no "organism only" criterion was developed. The "water + organism" criterion is based on the Maximum Contaminant Level (MCL) established under the Safe Drinking Water Act.*
F	Copper	*This value is based on a Drinking Water regulation.*	*Human health risks from copper are primarily from drinking water, therefore no "organism only" criterion was developed. The "water + organism" criterion is based on the Maximum Contaminant Level (MCL) established under the Safe Drinking Water Act.*
I	Methoxychlor	*No BCF was available; therefore, this value is based on that published in the 1986 EPA Gold Book.*	*The human health criterion for methoxychlor is the same as originally published in the 1976 EPA Red Book which predates the 1980 methodology and did not utilize the fish ingestion BCF approach. This same criterion value was also published in the 1986 EPA Gold Book. Human health risks are primarily from drinking water, therefore no "organism only" criterion was developed. The "water + organism" criterion is based on the Maximum Contaminant Level (MCL) established under the Safe Drinking Water Act.*
K	Nitrates	*No BCF was available; therefore, this value is based on that published in the 1986 EPA Gold Book.*	*The human health criterion for nitrates is the same as originally published in the 1976 EPA Red Book which predates the 1980 methodology and did not utilize the fish ingestion BCF approach. This same criterion value was also published in the 1986 EPA Gold Book. Human health risks are primarily from drinking water, therefore no "organism only" criterion was developed. The "water +*

			organism" criterion is based on the Maximum Contaminant Level (MCL) established under the Safe Drinking Water Act.

EPA Review
All six of these revised footnotes clarify the sources of information upon which the criteria are based. The footnotes are not considered water quality standards because they do not establish legally binding requirements under State law and do not describe a desired ambient condition of a waterbody to support a particular designated use. Therefore they are not water quality standards subject to EPA review and approval under 303(c) of the CWA. As a result, EPA is taking no action to approve or disapprove the revised footnotes for these six pollutants.

The revised footnotes identified above explain in more detail than the previous footnotes that the criteria are based upon a Safe Drinking Water MCL value in addition to an explanation concerning the rationale for why an "organism only" criterion does not exist. These human health criteria were not derived using EPA's 2000 Methodology, but instead were based upon EPA's national 304(a) criteria recommendations in EPA's 1986 Gold Book and developed under the Safe Drinking Water Act. EPA has reviewed these footnotes and found them to be accurate regarding the human health criteria development for these six pollutants. The underlying toxics criteria for asbestos and copper were approved by EPA on June 1, 2010. The underlying toxics criteria for chlorophenoxy herbicide (2,4,5,-TP), chlorophenoxy herbicide (2,4,-D), methoxychlor, and nitrates have not been revised and thus are not addressed in this action. These values remain consistent with EPA's current 304(a) criteria recommendations.

3. Withdrawn Footnotes

ODEQ has removed the footnote below for the three pollutants to which it applied: hexachlorocyclo-hexane-technical, nitrosamines, and nitrosodiethylamine, N:
No BCF was available; therefore, this value is based on that published in the 1986 Gold Book.

EPA Review
EPA's current CWA 304(a) criteria recommendations include the following BCF values for these three pollutants:

- Hexachlorocyclo-hexane-technical: BCF value = 130
- Nitrosamines: BCF value = 0.20
- Nitrosodiethylamine, N: BCF value = 0.20

At the time of Oregon's previous adoption of human health criteria for these three pollutants, EPA's 304(a) criteria recommendations were not derived using a methodology that accounted for bioconcentration through the use of a BCF. EPA now recommends the use of the BCF values listed above. Consistent with EPA's recommended 304(a) national default values for calculating the human health criteria, ODEQ has updated the criteria for these three pollutants to include EPA's recommended BCF values and therefore the three footnotes are no longer accurate or relevant. EPA is approving Oregon's human health criteria for hexachlorocyclo-hexane-

technical, nitrosamines, and nitrosodiethylamine, N as discussed above in section IV as consistent with EPA's 304(a) guidance.

Therefore, as a result of updating the human health criteria for these three pollutants, the footnotes are no longer accurate and relevant and removing them is appropriate. Furthermore, these three footnotes were not water quality standards because they did not establish legally binding requirements under state law and they did not describe a desired ambient condition of a waterbody to support a particulate designated use. Rather, the footnotes clarified the source of information, EPA's 1986 Gold Book, upon which the criteria were based. For this reason, the footnotes were not considered WQS subject to EPA review and approval under 303(c) of the CWA. As a result, EPA is taking no action to approve or disapprove the removal of the footnote as applied to hexachlorocyclo-hexane-technical, nitrosamines, and nitrosodiethylamine, N.

G. *WITHDRAWN HUMAN HEALTH CRITERIA WHICH WERE REPLACED BY MORE SPECIFIC CRITERIA*

During this rule revision, Oregon updated its numeric human health toxics criteria to reflect EPA's most recent science and refinements as published in EPA's current CWA § 304(a) criteria recommendations. Included in the refinements recommended by EPA was the removal of 13 general human health criteria developed for families of pollutants and the replacement of these criteria by other criteria that address the specific chemical(s) of concern for human health protection. The 13 chemicals that ODEQ has removed and replaced with criteria for specific chemical compounds are consistent with EPA's current 304(a) criteria recommendations. They are listed and explained in Table 13 below.

Table 13: Withdrawn human health criteria replaced with more specific criteria.

No.	Withdrawn Criteria	Replacement Criteria	Explanation[125]
1	Dinitrotoluene	*Dinitrotoluene 2,4*	More specific and more stringent of the two compounds was retained.
2	Dinitro-o-Cresol 2,4	Dinitrophenol 2,4; Dinitrophenols	Alternative compounds, including a synonym, in the same family identified.
3	Diphenylhydrazine	Diphenylhydrazine 1,2	More specific compound in the same family identified.
4	Endosulfan	Endosulfan Alpha; Endosulfan Beta; Endosulfan Sulfate	More specific compounds in the same family identified.
5	Halomethanes	Chlorodibromomethane; Dichlorobromomethane; Bromoform; *Chloroform*	More specific compounds in the same family identified.
6	Monochlorobenzene	Chlorobenzene	Identical compound, the two criteria names are synonyms.

[125] Explanations in the table were developed with information from EPA's "Gold Book". EPA. May 1, 1986. *Quality Criteria for Water*. U.S. Environmental Protection Agency, Office of Water. 440/5-86-001. Available at: https://owpubauthor.epa.gov/scitech/swguidance/standards/upload/2009_01_13_criteria_goldbook.pdf

7	Polynuclear Aromatic Hydrocarbons	Acenaphthene; Anthracene; Fluorene; *Fluoranthene;* Pyrene; Chyrsene; Dibenzo(a,h)anthracene; Benzo(a)anthracene; Benzo(a)pyrene; Benzo(b)fluorantehene 3,4; Benzo(k)fluoranthene; Indeno(1,2,3-cd)pyrene	More specific compounds in the same family identified.
8	Chlorinated Benzenes	Chlorobenzene	More specific compound in the same family identified.
9	DDT	DDD 4,4'; DDE 4,4'; DDT 4,4'	More specific compounds in the same family identified.
10	Dichlorobenzenes	*Dichlorobenzene(m) 1,3*; Dichlorobenzene(o)1,2; Dichlorobenzene(p) 1,4	More specific compounds in the same family identified.
11	Dichloroethylenes	Dichloroethylene 1,1; Dichloroethylene trans 1,2	More specific compounds in the same family identified.
12	Dichlorobenzidine	*Dichlorobenzidine 3,3'*	More specific and more sensitive of the two compounds was retained.
13	Dichloropropene	*Dichloropropene 1,3*	More specific and more sensitive of the two compounds was retained.

Note: Chemicals listed in *italics* are criteria that Oregon had previously adopted and which EPA had previously approved. EPA is taking no action on these criteria. All other pollutants listed in the replacement criteria column, new criteria have been adopted by Oregon and are approved by EPA as part of this action.

EPA Review

In 2000 and 2003 EPA refined its "priority" list of toxic pollutants and 304(a) human health criteria recommendations specific to a number of pollutants on that list.[126] The criteria for the 13 pollutants listed above have been refined in three ways:

1. EPA previously had established recommended criteria for large chemical families of pollutants. Advances in scientific information have allowed EPA to refine its criteria recommendations by developing criteria for specific chemical forms (i.e. isomers or congeners) of a pollutant within the larger chemical family. For example, while the *Gold Book* published only a single criterion for DDT, subsequent revisions (see EPA's 2004 *National Recommended Water Quality Criteria*) have resulted in multiple criteria for DDT and two metabolites: 4,4' DDT, 4,4' DDE and 4,4' DDD. Similarly, while the *Gold Book* recommended a single criterion for dichlorobenzenes in the *Gold Book,* EPA's 2004 *National Recommended Water Quality Criteria*, recommends criteria for 1,2-dichlorobenzene, 1,3-dichlorobenzene, and 1,4-dichlorobenezene;

[126] November 3, 2000. *Federal Register*, Volume: 65, Issue: 214, page: 66443 (65 FR 66443). Available at: http://www.epa.gov/fedrgstr/EPA-WATER/2000/November/Day-03/w27924.htm
December 31, 2003. *Federal Register*, Volume: 68, Issue: 250, page: 75507 (68 FR 75507). Available at: http://edocket.access.gpo.gov/2003/pdf/03-32211.pdf

2. EPA has replaced some of the toxic pollutant names with synonyms for specific chemicals.[127] For example, while the *Gold Book* contained criteria for hexachlorocyclohexane-alpha, hexachlorocyclohexane-beta, and hexachlorocyclohexane-gamma, these criteria are now listed under the synonyms alpha BHC, beta BHC and gamma BHC in EPA's *National Recommended Water Quality Criteria*; and
3. EPA has condensed certain pollutants from several chemical forms of a given compound into a single compound, such as recommending criteria for total arsenic in EPA's 2004 *National Recommended Water Quality Criteria* to replace the previously recommended criteria for arsenic (tri) and arsenic (pent) as published in the *Gold Book*.

In updating its numeric toxics human health criteria, Oregon revised the criteria consistent with EPA's most recent CWA § 304(a) criteria recommendations, including withdrawing and/or revising the criteria as recommended by the above changes. The criteria withdrawn based on these refinements in chemical names are identified in Table 13 above. The table further identifies the pollutants for which Oregon has adopted new criteria to address the human health impacts associated with these pollutants. EPA action on the new criteria were addressed previously as part of EPA's action on Oregon's new criteria in section IV.B.

EPA Approval

In accordance with its Clean Water Act authority, 33 U.S.C § 1313(c)(3) and 40 C.F.R. part 131, EPA approves the withdrawal of Oregon's human health criteria for the 13 pollutants identified in Table 13, coupled with EPA's approval of new criteria (in section IV.B), as protective of human health. These changes are consistent with EPA's current CWA § 304(a) criteria recommendations to replace the specified criteria with more specific criteria for associated pollutants consistent with the latest science. EPA has approved the more specific pollutant replacement criteria above as consistent with 40 C.F.R. part 131. Since these new criteria address the same human health affects as the withdrawn criteria, EPA finds the criteria for the 13 pollutants identified above are not necessary to protect Oregon's fishing and water supply uses.

EPA Rationale

The CWA requires that, whenever a state or authorized tribe revises or adopts new WQS, it adopt criteria for all toxic pollutants listed pursuant to CWA § 307(a)(1) for which EPA has developed recommended criteria under CWA § 304(a), the discharge or presence of which in the affected waters could reasonably be expected to interfere with the adopted designated uses (CWA § 303(c)(2)(B)). As noted above, Oregon has refined the list of criteria for which it has established human health criteria to reflect recent science incorporated by EPA into the § 304(a)

[127] In addition, the following pollutant names were modified by ODEQ from their previous human health criteria for consistency with EPA terminology. These compounds are synonyms.

1. Dibutylphthalate was changed to Di-n-butyl Phthalate
2. Di-2-ethylhexyl phthalate was changed to Ethylhexyl phthalate bis 2
3. Hexachlorocyclohexane-alpha was changed to BHC alpha
4. Hexachlorocyclohexane-beta was changed to BHC beta
5. Hexachlorocyclohexane-gamma was changed to BHC gamma (Lindane)

human health criteria recommendations, including the removal of several pollutants representing chemical families and replacing them with criteria for more specific chemical compounds within the same general family. As such, the changes in the pollutant names listed above and the criteria adopted for these pollutants represent a refinement of criteria for individual chemicals within families, not withdrawals of criteria identified for pollutants in CWA § 307(a). Therefore, Oregon's withdrawal of its previous human health water quality criteria for these 13 pollutants is consistent with CWA § 303(c)(2)(B).

As stated above, Oregon's removal of these 13 pollutants and the associated criteria is consistent with EPA's removal of 304(a) criteria recommendations. Although the criteria for these 13 pollutants have been withdrawn, Oregon has developed individual criteria for the most toxic of chemicals in that family or retained the more specific criteria or a synonym for the chemical compounds. Therefore, while withdrawing the criteria for these 13 pollutants, Oregon has adopted new criteria to protect the same human health endpoints which these criteria were originally developed to protect. Therefore, EPA has determined that the withdrawal of these criteria coupled with the adoption of new criteria for similar pollutants (approved above in section IV.B) will protect Oregon's human health uses in accordance with 40 C.F.R. part 131.11(a)(1).

H. *TABLE 40 HUMAN HEALTH CRITERIA SUMMARY*

Oregon has added the following summary language prior to the human health criteria in Table 40 which explains the purpose of the criteria, criteria derivation and the format of the table.

TABLE 40: Human Health Water Quality Criteria for Toxic Pollutants

Human Health Criteria Summary
The concentration for each pollutant listed in Table 40 was derived to protect Oregonians from potential adverse health impacts associated with long-term exposure to toxic substances associated with consumption of fish, shellfish, and water. The "organism only" criteria are established to protect fish and shellfish consumption and apply to waters of the state designated for fishing. The "water + organism" criteria are established to protect the consumption of drinking water, fish, and shellfish, and apply where both fishing and domestic water supply (public and private) are designated uses. All criteria are expressed as micrograms per liter (µg/L), unless otherwise noted. Pollutants are listed in alphabetical order. Additional information includes the Chemical Abstract Service (CAS) number, whether the criterion is based on carcinogenic effects (can cause cancer in humans), and whether there is an aquatic life criterion for the pollutant (i.e. "y"= yes, "n" = no). All the human health criteria were calculated using a fish consumption rate of 175 grams per day unless otherwise noted. A fish consumption rate of 175 grams per day is approximately equal to 23 8-ounce fish meals per month. For pollutants categorized as carcinogens, values represent a cancer risk of one additional case of cancer in one million people (i.e. 10-6), unless otherwise noted. All metals criteria are for total metal concentration, unless otherwise noted. Italicized pollutants represent non-priority pollutants. The human health criteria revisions established by OAR 340-041-0033

and shown in Table 40 do not become applicable for purposes of ORS chapter 468B or the federal Clean Water Act until approved by EPA pursuant to 40 CFR 131.21 (4/27/2000).

Acknowledgement of Table 40 Summary Language

The new introductory summary language for Table 40 explains the purpose of the criteria, criteria derivation and the format of the table. However, this language does not establish a legally binding requirement under State law and it does not describe a desired ambient condition of a waterbody to support a particular designated use it is not considered a WQS subject to EPA review and approval under 303(c) of the CWA. EPA has addressed the new and revised underlying human health criteria in Table 40 and the narrative language at OAR 340-041-0033(4) in this technical support document. This summary language further explains how the state derived the criteria values in Table 40. EPA incorporated the explanatory information provided in this summary into its analysis of the individual criteria values in Table 40. But because this summary does not operate as an independent water quality standard, in isolation from the criteria values in Table 40 and the narrative language at OAR 340-041-0033(4) (which EPA acted on individually), EPA is taking no action to approve or disapprove this summary language.

V. NARRATIVE STATEMENT

Oregon's revisions to its narrative toxics provisions found at OAR 340-041-033(1), (3) and (4) are shown in underline/strikeout format below. Underlined text represents added text, while text with a line through the middle (strikeout) represents deleted text. Non-revised words are also provided below for context. Additionally, Oregon reorganized sections of OAR 340-041-0033, thus renumbering several of the provisions without substantively changing any of the regulatory language.

340-041-0033
Toxic Substances
(1) Amendments to sections (4) and (6) of this rule (OAR 340-041-0033) and associated revisions to Tables 20, 33A, 33B and 40 do not become applicable for purposes of ORS chapter 468B or the federal Clean Water Act unless and until EPA approves the provisions it identifies as water quality standards pursuant to 40 CFR 131.21 (4/27/2000).

(3) Aquatic Life Criteria. Levels of toxic substances in waters of the state may not exceed the applicable aquatic life criteria listed in Tables 20, 33A, and 33B. Tables 33A and 33B, adopted on May 20, 2004, update Table 20 as described in this section.

EPA Action
In accordance with its Clean Water Act authority, 33 U.S.C § 1313(c)(3) and 40 C.F.R. part 131, EPA approves the new and revised language at OAR 340-041-0033(1) and (3).

EPA Rationale
The new and revised provisions at OAR 340-041-0033(1) and (3) describe dates when the toxics criteria in Tables 20, 33A, 33B and 40 become effective under state law and the Clean Water Act. The effective date of WQS provisions under the CWA is determined by the date of EPA approval. These timing provisions are WQS that provide for the new and revised criteria to be immediately in effect at the time of EPA's approval action. EPA has addressed the new and revised underlying human health criteria in this technical support document. OAR 340-041-0033(3) clarifies that only aquatic life criteria remain in Tables 20, 33A and 33B. EPA will address the aquatic life criteria in these tables and their corresponding footnotes in a separate action.

(4) Human Health Criteria. The criteria for waters of the state listed in Table 40 are established to protect Oregonians from potential adverse health effects associated with long-term exposure to toxic substances associated with consumption of fish, shellfish, and water.

EPA Action
In accordance with its Clean Water Act authority, 33 U.S.C § 1313(c)(3) and 40 C.F.R. part 131, EPA approves the new language at OAR 340-041-0033(4).

EPA Rationale

The new provision at OAR 340-041-0033(4) adopts the human health criteria in Table 40. EPA approves this language which adopts the criteria and describes the intent of the criteria to protect human health uses in Oregon. This language explains the purpose of the human health criteria and describes that the criteria in Table 40 are established to protect Oregonians from potential adverse health effects association with long-term exposure to toxic substances associated with fish, shellfish and water consumption. EPA's action on each individual criterion in Table 40 is described in detail above.

VI. BACKGROUND POLLUTANT CRITERIA PROVISION

A. *BACKGROUND*

As previously discussed, in October 2008, the Oregon Environmental Quality Commission directed ODEQ to revise the State's human health criteria to incorporate a fish consumption rate of 175 grams per day. The fish consumption rate of 175 grams per day was selected by Oregon to ensure protection of all people in Oregon who may consume fish and shellfish from State waters including those who traditionally consume high amounts of fish for subsistence, health, economic or other reasons.[128] The rate reflects the 95th percentile of tribal members surveyed as part of the CRITFC Survey[129] and the 90th percentile of subsistence consumers surveyed in regional fish consumption studies. When providing this direction, the Commission also directed ODEQ to "propose rule language that would allow [O]DEQ to implement the standards in NPDES permits and other Clean Water Act programs in an environmentally meaningful and cost-effective manner" and to carefully consider the costs and benefits associated with elements of the new rule. This latter directive came following testimony from several stakeholders regarding potential implementation difficulties and economic burden of adopting the more stringent criteria.[130]

In response to this direction, ODEQ not only revised the human health criteria but also developed several new and revised rules addressing the implementation of the revised criteria. Each revised implementation rule targeted specific situations raised as potential concerns by ODEQ staff and stakeholders. The adoption of a new site-specific background pollutant criterion provision and the revisions to the variance provision (discussed in previous section) were submitted to EPA for action under Section 303(c) of the CWA while other rules were adopted pursuant to state law and were not submitted to EPA. All revisions are addressed separately in this document.

Oregon developed an *Issue Paper: Implementing Water Quality Standards for Toxic Pollutants in NPDES Permits, Human Health Toxics Rulemaking*[131] that discusses how ODEQ will implement the revised criteria in NPDES permits. Section IV.3 of this paper speaks directly to the site-specific background pollutant criterion provision and provides greater detail on its purpose, development and content as well as providing some discussion of how the resultant

criterion would be applied to NPDES permits.[132] Other issue papers were developed to address implementation of the criteria outside of the NPDES program including papers that address nonpoint sources, antidegradation and source control.[133]

One situation identified during the workgroup process as potentially problematic to dischargers as well as ODEQ when issuing NPDES permits as a result of the revised human health criteria is when a NPDES discharger takes in water from and discharges to the same waterbody, which contains pollutants from upstream sources over which the discharger has little to no control. ODEQ adopted an intake credit provision at OAR 340-045-0105 that does not hold facilities accountable for removing these upstream pollutants if the concentration of the pollutant does not exceed the water quality criteria, the facility does not chemically or physically modify the pollutant and several other conditions described in the rule are met.

However, facilities that concentrate pollutants in their discharge above the levels in the intake water are not eligible for the intake credit rule. For example, such an increase in concentration may occur when a facility's process involves evaporation (e.g. non-contact cooling water), and the facility recycles water, thus resulting in the same mass of the pollutant but a lower volume of water. If the upstream concentration of the pollutant in the waterbody exceeds the underlying criterion, a permit limit is established such that the criterion is met at the end of the discharge pipe and the facility would need to treat the water prior to discharge regardless of the upstream concentration.[134]

ODEQ discussed numerous options for addressing this type of situation with the objective for providing an approach that:

- protects human health;
- establishes reasonable implementation of the revised water quality standards for facilities in the situation described above;
- allocates limited State resources efficiently; and

- ensures that regulatory requirements and costs for a facility are commensurate with the environmental threat they pose.[135]

Oregon proposed a draft rule and accepted public comment on that rule during the public process described above for all other elements of this action submitted by Oregon on July 21, 2011. In EPA's public comments to ODEQ on March 21, 2011 regarding the previous version of the background pollutant criteria provision proposed for public comment, EPA stated that ODEQ could:

- Implement the criterion on a site specific basis and submit each application to EPA for evaluation on a case by case basis; or
- Revise the provision consistent with a performance-based approach as a viable alternative to submitting each revision to EPA on a site specific basis. If ODEQ were to choose this option, sufficiently detailed implementation procedures would need to be adopted directly into the WQS regulations which establish a framework that is binding, clear, predictable and transparent.

Following consideration of the comments received, ODEQ adopted a performance-based water quality standard that can be used to adopt site-specific criteria for human health carcinogens where all of the following conditions apply:

- The criterion at issue is a human health criterion, for a pollutant identified as a carcinogen.
- The discharge does not increase the mass load of the pollutant in the receiving water. The mass load of the pollutant discharged to a waterbody may not exceed the mass load of the pollutant taken in from the same waterbody or a hydrologically connected water.
- The pollutant concentration in the receiving water is not increased by more than 3% above the upstream ambient concentration.
- The water body concentration does not exceed a calculated value that represents the human health criterion calculated at a risk level of 10^{-4}.
- The discharger uses any feasible pollutant reduction measures known and available to minimize the pollutant concentration in their discharge.
- The criterion must be evaluated and revised, if appropriate, when the permit is reissued.
- No TMDL has been developed for the waterbody and pollutant at issue.[136]

The provision authorizes ODEQ to develop a site-specific criterion for the waterbody in the vicinity of a discharge and use that criterion to develop an effluent limit for the pollutant if all conditions of the rule are met. The criterion established would be based upon the most stringent of 1) the instream concentration following receipt of the current level of discharge from the

Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/humanhealth/rulemaking/NPDESIssuePaper.pdf

facility, 2) a 3% increase in the ambient instream concentration of the pollutant, or 3) a concentration value that represents a 1×10^{-4} risk level. In addition, the criterion could not be established at a level that would allow the facility to increase the mass load of the pollutant from that in their intake water.[137]

A site-specific background pollutant criterion may only be developed under this provision if the waterbody serves as the receiving water for a NPDES discharge and the effluent discharged meets certain requirements. Oregon's rule limits the criteria developed under this rule by requiring the criteria be established at the most stringent of several options that are based on applying certain limitations on the effluent from the facility and on the resultant instream criteria. Therefore, the process outlined in Oregon's rule uses the same type of calculations made in establishing NPDES permit limits to calculate the resultant instream concentration at various effluent conditions. Once a site-specific criterion is adopted, it is to be used to develop permit effluent limits in the same manner as any other criteria.[138]

In order to provide further guidance to their permit writers ODEQ will be developing an Internal Management Directive (IMD) within 180 days of EPA's approval action.[139] This is one of several items identified by ODEQ as actions necessary to assist ODEQ staff and the public in implementing the provisions approved in this action.

B. *ODEQ'S JULY 21, 2011 SUBMITTAL*

ODEQ has added a new provision which establishes a site-specific background pollutant criteria at OAR 340-041-0033(6). This provision is a performance-based water quality standard that results in site-specific human health water quality criteria under the conditions and procedures specified within the rule. It addresses existing permitted discharges of a pollutant removed from the same body of water, as defined in the provision.

Below is Oregon's background pollutant criteria provision, found at OAR 340-041-0033(6).

340-041-0033(6)

Establishing Site-Specific Background Pollutant Criteria: This provision is a performance-based water quality standard that results in site-specific human health water quality criteria under the conditions and procedures specified in this rule section. It addresses existing permitted discharges of a pollutant

removed from the same body of water. For waterbodies where a discharge does not increase the pollutant's mass and does not increase the pollutant concentration by more than 3%, and where the water body meets a pollutant concentration associated with a risk level of $1x10^{-4}$, DEQ concludes that the pollutant concentration continues to protect human health.

(a) Definitions: For the purpose of this section [OAR 340-041-0033(6)]:

(A) "Background pollutant concentration" means the ambient water body concentration immediately upstream of the discharge, regardless of whether those pollutants are natural or result from upstream human activity.

(B) An "intake pollutant" is the amount of a pollutant that is present in public waters (including groundwater) as provided in subsection (C), below, at the time it is withdrawn from such waters by the discharger or other facility supplying the discharger with intake water.

(C) "Same body of water": An intake pollutant is considered to be from the "same body of water" as the discharge if the department finds that the intake pollutant would have reached the vicinity of the outfall point in the receiving water within a reasonable period had it not been removed by the permittee. This finding may be deemed established if:

(i) The background concentration of the pollutant in the receiving water (excluding any amount of the pollutant in the facility's discharge) is similar to that in the intake water;

(ii) There is a direct hydrological connection between the intake and discharge points; and

(I) The department may also consider other site-specific factors relevant to the transport and fate of the pollutant to make the finding in a particular case that a pollutant would or would not have reached the vicinity of the outfall point in the receiving water within a reasonable period had it not been removed by the permittee.

(II) An intake pollutant from groundwater may be considered to be from the "same body of water" if the department determines that the pollutant would have reached the vicinity of the outfall point in the receiving water within a reasonable period had it not been removed by the permittee, except that such a pollutant is not from the same body of water if the groundwater contains the pollutant partially or entirely due to past or present human activity, such as industrial, commercial, or municipal operations, disposal actions, or treatment processes.

(iii) Water quality characteristics (e.g., temperature, pH, hardness) are similar in the intake and receiving waters.

(b) Applicability

(A) Site-specific criteria may be established under this rule section only for carcinogenic pollutants.

(B) Site-specific criteria established under this rule section apply in the vicinity of the discharge

for purposes of establishing permit limits for the specified permittee.
(C) The underlying waterbody criteria continue to apply for all other Clean Water Act programs.

(D) The site-specific background pollutant criterion will be effective upon department issuance of the permit for the specified permittee.

(E) Any site-specific criteria developed under this procedure will be re-evaluated upon permit renewal.

(c) A site-specific background pollutant criterion may be established where all of the following conditions are met:

(A) The discharger has a currently effective NPDES permit;

(B) The mass of the pollutant discharged to the receiving waterbody does not exceed the mass of the intake pollutant from the same body of water, as defined in section 6(a)(C) above, and, therefore, does not increase the total mass load of the pollutant in the receiving water body;

(C) The discharger has not been assigned a TMDL wasteload allocation for the pollutant in question;

(D) The permittee uses any feasible pollutant reduction measures available and known to minimize the pollutant concentration in their discharge;

(E) The pollutant discharge has not been chemically or physically altered in a manner that causes adverse water quality impacts that would not occur if the intake pollutants were left in-stream; and,

(F) The timing and location of the pollutant discharge would not cause adverse water quality impacts that would not occur if the intake pollutant were left in-stream.

(d) The site-specific background pollutant criterion must be the most conservative of the following four values. The procedures deriving these values are described in the sections (6)(e) of this rule.

(A) The projected in-stream pollutant concentration resulting from the current discharge concentration and any feasible pollutant reduction measures under (c)(D) above, after mixing with the receiving stream.

(B) The projected in-stream pollutant concentration resulting from the portion of the current discharge concentration associated with the intake pollutant mass after mixing with the receiving stream. This analysis ensures that there will be no increase in the mass of the intake pollutant in the receiving water body as required by condition (c)(B) above.

(C) The projected in-stream pollutant concentration associated with a 3% increase above the background pollutant concentration as calculated:

(i) For the mainstem Willamette and Columbia Rivers, using 25% of the harmonic mean flow of the waterbody.

(ii) For all other waters, using 100% of the harmonic mean flow or similar critical flow

value of the waterbody.

(D) A criterion concentration value representing a human health risk level of 1×10^{-4}. This value is calculated using EPA's human health criteria derivation equation for carcinogens (EPA 2000), a risk level of 1×10^{-4}, and the same values for the remaining calculation variables that were used to derive the underlying human health criterion.

(e) Procedure to derive a site-specific human health water quality criterion to address a background pollutant:

(A) The department will develop a flow-weighted characterization of the relevant flows and pollutant concentrations of the receiving waterbody, effluent and all facility intake pollutant sources to determine the fate and transport of the pollutant mass.

(i) The pollutant mass in the effluent discharged to a receiving waterbody may not exceed the mass of the intake pollutant from the same body of water.

(ii) Where a facility discharges intake pollutants from multiple sources that originate from the receiving waterbody and from other waterbodies, the department will calculate the flow-weighted amount of each source of the pollutant in the characterization.

(iii) Where intake water for a facility is provided by a municipal water supply system and the supplier provides treatment of the raw water that removes an intake water pollutant, the concentration and mass of the intake water pollutant shall be determined at the point where the water enters the water supplier's distribution system.

(B) Using the flow weighted characterization developed in Section (6)(e)(A), the department will calculate the in-stream pollutant concentration following mixing of the discharge into the receiving water. The resultant concentration will be used to determine the conditions in Section (6)(d)(A) and (B).

(C) Using the flow weighted characterization, the department will calculate the in-stream pollutant concentration based on an increase of 3% above background pollutant concentration. The resultant concentration will be used to determine the condition in Section (6)(d)(C).

(i) For the mainstem Willamette and Columbia Rivers, 25% of the harmonic mean flow of the waterbody will be used.

(ii) For all other waters, 100% of the harmonic mean flow or similar critical flow value of the waterbody will be used.

(D) The department will select the most conservative of the following values as the site-specific water quality criterion.

(i) The projected in-stream pollutant concentration described in Section 6(e)(B);

(ii) The in-stream pollutant concentration based on an increase of 3% above background described in Section 6(e)(C); or

(iii) A water quality criterion based on a risk level of 1×10^{-4}.

(f) Calculation of water quality based effluent limits based on a site-specific background pollutant criterion:

> *(A) For discharges to receiving waters with a site-specific background pollutant criterion, the department will use the site-specific criterion in the calculation of a numeric water quality based effluent limit.*
>
> *(B) The department will compare the calculated water quality based effluent limits to any applicable aquatic toxicity or technology based effluent limits and select the most conservative for inclusion in the permit conditions.*

(g) In addition to the water quality based effluent limits described in Section (6)(f), the department will calculate a mass-based limit where necessary to ensure that the condition described in Section (6)(c)(B) is met. Where mass-based limits are included, the permit shall specify how compliance with mass-based effluent limitations will be assessed.

(h) The permit shall include a provision requiring the department to consider the re-opening of the permit and reevaluation of the site-specific background pollutant criterion if new information shows the discharger no longer meets the conditions described in subsections (6)(c) and (e).

(i) Public Notification Requirements.

> *(A) If the department proposes to grant a site-specific background pollutant criterion, it must provide public notice of the proposal and hold a public hearing. The public notice may be included in the public notification of a draft NPDES permit or other draft regulatory decision that would rely on the criterion and will also be published on the water quality standards website;*
>
> *(B) The department will publish a list of all site-specific background pollutant criteria approved pursuant to this rule. A criterion will be added to this list within 30 days of its effective date. The list will identify: the permittee; the site-specific background pollutant criterion and the associated risk level; the waterbody to which the criterion applies; the allowable pollutant effluent limit; and how to obtain additional information about the criterion.*

C. *EPA ACTION ON ODEQ'S NEW BACKGROUND POLLUTANT CRITERIA PROVISION*

EPA Action

In accordance with its CWA authority, 33 U.S.C § 1313(c)(3) and 40 C.F.R. part 131, EPA approves Oregon's new background pollutant criteria provision at OAR 340-041-0033(6), as detailed below, because it is consistent with the Clean Water Act and the implementing Federal water quality standards regulations governing EPA's review and approval or disapproval of new or revised water quality standards as required in 40 C.F.R. part 131. In EPA's review of Oregon's background pollutant criteria provision, the Agency considered information submitted on July 21, 2011 including ODEQ's NPDES Implementation Issue Paper[140] and Response to

[140] ODEQ. May 24, 2011. *Issue Paper: Implementing Water Quality Standards for Toxic Pollutants in NPDES Permits, Human Health Toxics Rulemaking.* Oregon Department of Environmental Quality. Available at:

Comments document.[141]

In its review and action on the background pollutant provision, EPA also considered the following three key elements:

- Whether the site-specific human health criteria to be generated under the provision are sufficient to protect Oregon's human health uses, as required under 40 CFR 131.6.
- Whether the site-specific human health criteria to be generated under the provision are consistent with EPA's regulatory specifications for criteria at 40 CFR 131.11.
- Whether this implementation procedure contains sufficient detail, and suitable safeguards, such that additional § 303(c) review of individual criteria generated under the provision would be redundant.

As described in further detail below, EPA has concluded that the site-specific background pollutant provision adequately addresses all three of these elements and thus is consistent with CWA § 303(c) and its implementing regulations.

EPA Rationale

The provision establishes site-specific human health criteria at a level to protect Oregon's human health uses

Oregon's site-specific background pollutant provision contains a binding restriction that any site-specific criterion to be generated under the provision must be established at the most conservative (stringent) of the conditions specified in OAR 340-041-033(6)(d) and reflect no net addition of the pollutant from the discharger to the waterbody segment. In no case may a criterion developed under this provision represent a carcinogenic human health risk level greater than 1.0 x10^{-4}, however, it may be more stringent. Since the least stringent scenario for a site-specific criterion generated under the provision (i.e., one generated based on a 10^{-4} risk level) is itself within EPA's recommended range of risk levels protective of human health designated uses, EPA concludes that a criterion developed using Oregon's site-specific background pollutant provision would be protective of Oregon's human health uses.

EPA's Human Health Methodology recognizes that States and Tribes have discretion in selecting appropriate risk ranges and recommends that states adopt criteria for carcinogens based on either a 1 x 10^{-6} or 1 x 10^{-5} risk level to protect the general population, as long as highly exposed populations do not exceed a 1 x 10^{-4} risk level.[142] Consistent with the flexibility accorded to States in developing risk ranges for carcinogenic pollutants, Oregon has chosen to exercise this discretion by allowing the risk level for carcinogens in waters in the vicinity of certain NPDES discharges not to exceed 10^{-4}. As discussed previously, Oregon used a fish consumption rate reflective of highly exposed consumers and a risk level of 1 x 10^{-6} for deriving their human

[141] ODEQ. May 2011. *Response to Comments: Proposed Water Quality Standards for Human Health and Water Quality Standards Implementation Policies.* Oregon Department of Environmental Quality. page 21. Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/humanhealth/rulemaking/ResponseToComments.pdf

[142] EPA. 2000. *Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health*. U.S. Environmental Protection Agency, Office of Water, EPA-822-B-00-004. page 2-6. Available at: http://www.epa.gov/waterscience/criteria/humanhealth/method/complete.pdf

health criteria. In this case, the site specific criteria would continue to protect the highly exposed consumer but at a risk level between 1 x 10^{-6} and 1 x 10^{-4}. Thus, EPA concludes that any site-specific criterion calculated based on a 1 x 10^{-4} risk level would be consistent with EPA's guidance with respect to highly exposed populations, since the fish consumption rate already reflects highly exposed populations. EPA has recommended using a fish consumption rate for the general US population of 17.5 grams per day if no local or regional data is available. There is currently no available fish consumption data specific to the general population of Oregon. If one were to evaluate the protectiveness of a site-specific criterion developed under this provision at a 10^{-4} risk level but using EPA's default fish consumption rate of 17.5 grams per day, the result would protect at a carcinogenic risk level of 1 x 10^{-5}. This risk level is consistent with that recommended by EPA by EPA in the 2000 Human Health Methodology. Therefore, EPA finds that criteria established under this provision would be established at a level protective of both the general population and high fish consuming populations consistent with the levels recommended by EPA in the 2000 Human Health Methodology.

In response to several comments regarding the use of a 1 x 10^{-4} risk level, ODEQ affirmed that the criterion would be established at "the most protective of the following results: the current ambient pollutant concentration after discharge; the background concentration plus three percent; or the criteria value calculated at a 1 x 10^{-4} risk level" (emphasis added)).[143] In several other responses to comments as well as at several places in the Issue Paper, ODEQ has also stated that a 1 x 10^{-4} risk would be the greatest possible risk allowed under the criterion and that other conditions within the provision would often limit the criterion further.[144] ODEQ also specifies this fact in their July 21, 2011 letter to EPA requesting the review and approval of these rules.[145] In ODEQ's response to comments, they explained why they found this additional level of risk to be protective in this site-specific situation. They note that several restrictions have been included in the rule in order to limit any additional risk to the human health use.

- First, the rule requires that the pollutant be from the "same body of water" and that the mass of the pollutant associated with the facility may not be increased from its intake water to the effluent water. These requirements ensure that any discharge limits based on the site specific criterion would not add any additional mass to the waterbody, although the discharger may slightly increase the pollutant concentration relative to background (up to a maximum of three percent). In other words, the pollutant present in the

[145] ODEQ. July 21, 2011. Letter from Neil Mullane, Water Quality Division Administrator, to Michael Bussell, Office of Water and Watersheds, EPA Region 10. *Re: Oregon Submission of Revised State Water Quality Standards for Toxic Pollutants, Including a New Background Pollutant Provision and a Revised Variance Rule for EPA Review and Approval.*

waterbody segment to which the criteria will apply would have reached the vicinity of the outfall point had it not been intercepted by the discharger and there is no addition of pollutants by the facility.[146]

- Second, the application of the criterion is limited to the sole purpose of accommodating existing discharges from an existing NPDES discharger. In no case could a criterion decrease in stringency such that the current discharge concentration to a water body would be allowed to increase as a result of the revision.[147]
- Third, the underlying water quality criterion will remain in effect for all other CWA purposes including 303(d) listing and TMDL development. (as explained above)
- Finally, the rule requires that the criterion be re-evaluated upon permit renewal (OAR 340-041-0033(6)(b)(E)), thus making the criterion effective only for the duration of the permit and requiring that the site-specific criterion be reevaluated and revised, if appropriate, upon permit renewal using current ambient and effluent data in situations where all the prerequisite conditions continue to be present.[148] As noted above, if a TMDL was established prior to this renewal, a site-specific criterion could not be obtained under this rule and the facility's effluent limit must be consistent with the WLA in the TMDL.

ODEQ therefore determined that the relative increase in ambient concentration does not result in a significant change to human health risk[149] and that the criterion developed under this provision would be protective of the beneficial uses of that waterbody.[150]

Since this provision establishes a process for developing individual site-specific criteria, the exact location of each application cannot be specified in advance. However, the provision does specify criteria location relative to the pertinent discharger ("in the vicinity of the discharge for purposes of establishing permit limits for the specified permittee"). (OAR 340-041-0033(6)(b)). Thus, dischargers other than the specified permittee would not be able to use the site-specific criterion in permit calculations.[151] For the specified permitee, a site-specific criterion

corresponding to a risk level of 1 x 10^{-4} or safer would be applicable to the water in the vicinity of the discharge.[152] Since the site-specific conditions are themselves predicated on the characteristics of the discharger, an appropriate matching of the criterion to discharger is an adequate specification of where the site-specific criteria will apply.

EPA notes that one commenter was concerned that the approach in the proposed rule introduced an inconsistency into Oregon's water quality criteria. The commenter questioned whether it was consistent with the Clean Water Act for Oregon to determine that a single risk target is both protective (where site-specific criteria apply) and non-protective (where site-specific criteria do not apply) of human health uses. ODEQ addressed this comment by adding additional detail in the final rule. In addition, EPA evaluated this concern relative to the final rule in light of the fact that Oregon already had the discretion, consistent with EPA's Human Health Methodology, to adopt criteria based on a risk range between 1 x 10^{-6} and 1 x 10^{-4} (in conjunction with a fish consumption rate that reflects high-consuming populations). If Oregon had adopted state-wide criteria reflecting a risk range less stringent than 1 x 10^{-6}, Oregon could have exercised its discretion, based on its own policy priorities and consistent with CWA § 510, to apply *more stringent* site-specific criteria where it deemed appropriate. Under these circumstances, a single risk target would be both protective (where site-specific criteria do not apply) and non-protective (where site-specific criteria apply). The only practical distinction between this scenario and the one raised in public comments is which risk level is treated as the normative baseline, and which is treated as site-specific departure from the baseline.

Since multiple risk levels for carcinogenic pollutants are within the range identified as acceptable in EPA's Human Health Methodology, and States/Tribes have the ability to define "local conditions" when establishing site specific criteria, EPA concludes that Oregon has discretion to apply both one risk level as a generally applicable value and other risk levels on a site-specific basis (i.e., as "site-specific conditions" under 40 CFR 131.11(b)). While the target risk level is combined with other values (based on a scientific rationale) to generate a criterion value for a carcinogenic pollutant, site-specific variation in the target risk level itself is based on Oregon's risk management judgment. In order for the overall site-specific criterion to be "based on sound scientific rationale," under 40 CFR 131.11(a)(1), it is sufficient that Oregon has clearly identified the rationale for the site-specific criteria as a policy decision within its discretion and consistent with EPA's Human Health Methodology.

EPA also notes that one commenter expressed concern about the interaction between the proposed background pollutant provision and Oregon's existing mixing zone policy. EPA acknowledges that, as with other Oregon criteria, the site specific criteria generated under the background pollutant provision would be used in developing water quality based effluent limits for the NPDES permit discharging to the waterbody. EPA also acknowledges that, in certain instances, Oregon's current mixing zone policy may be applied when developing such limits. In

---

Quality Standards Implementation Policies. Oregon Department of Environmental Quality. page 56. Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/humanhealth/rulemaking/ResponseToComments.pdf

[152] As discussed below, Oregon's existing mixing zone policy would still affect the calculation of effluent limits based on the criterion. Nevertheless, the applicable criterion in the receiving water is constrained, by OAR 340-041-0033(6)(D), to be at least as stringent as the value calculated based on a risk level of 1x10^{-4}.

the Issue Paper ODEQ states that once the site-specific background pollutant criterion has been determined, the criterion will be used to establish a numeric permit effluent limit using the same procedures and guidance used for establishing permit limits for any human health criteria.[153] Furthermore, ODEQ's response to comments specifies that any mixing will be determined based on the guidance provided in [O]DEQ's Reasonable Potential Internal Management Directive (IMD) and that [O]DEQ's published guidelines (Regulated Mixing Zones IMD) would govern the siting and sizing of any zones of mixing.[154] Any mixing zone allowed would be required under the CWA to comply with the all requirements of the State's mixing zone provision prior to a mixing zone being authorized. In certain circumstances it is possible that a mixing zone for a site-specific criterion generated under this provision (or any other human health criterion for a carcinogen) may allow a limited area of the waterbody in which the cancer risk associated with the pollutant concentration would exceed 1×10^{-4}. However, EPA does not therefore conclude that the criterion is inconsistent with its Human Health Methodology. The potential for criteria to be implemented in concert with an EPA-approved state mixing zone policy is a background assumption of EPA's Human Health Methodology, not an additional factor that would weigh in favor of further limiting states' risk management discretion.

Furthermore, the language of OAR 340-041-0033(6)(d)(A) and (B) that speaks to the projected instream concentration "after mixing with the receiving stream" addresses the calculation of a projected instream value under specified effluent conditions. It does not establish a new mixing zone policy. EPA finds it appropriate that ODEQ utilize calculations similar to those used to develop permits when projecting this instream value as this allows the results of applying limitations to the effluent to be expressed as an insteam concentration and thus to be directly compared to the options limited by instream concentration. Furthermore, it provides that, for purposes of the stringency analysis, all options are expressed in the same units as the final criterion value. A similar practice is commonly used when EPA and States determine whether a discharge needs a water quality based effluent limit (see, e.g., 40 CFR 122.44(d)(1)(ii) "When determining whether a discharge causes, has the reasonable potential to cause, or contributes to an in-stream excursion above a narrative or numeric water quality standard, the permitting authority shall use procedures which account for … where appropriate, the dilution of the effluent in the receiving water." (emphasis added)).

EPA considered whether implementation of the background pollutant provision is consistent

with the requirements of 40 CFR 131.10. For the following reasons, EPA concludes that it is. Oregon has expressly stated that a criterion based on a higher risk level, established pursuant to the provision, "continues to protect human health." OAR 340-041-0033(6). Thus, the background pollutant provision does not represent the revision of a human health use, but rather the articulation (within the range of the state's discretion) of the risk range the State considers protective of human health uses in this site-specific situation. The revision of criteria within the State's range of discretion for a designated use does not represent the removal or impairment of such a designated use. In conclusion, the provision contains a clear, predictable and transparent restriction that any site-specific criterion to be generated under the background pollutant provision must not correspond to a human health risk level of less stringent than 1×10^{-4}.[155] This minimum risk level is the most critical of the restrictions contained in the provision since it sets the least stringent criterion possible under the procedure. The least stringent criterion possible under the procedure is protective of Oregon's human health uses and is consistent with EPA's Human Health Methodology. Thus, EPA's approval of the provision may also serve as the Clean Water Act § 303(c)(3) approval of the individual site-specific criteria to be generated under the provision.

The provision generates site-specific human health criteria consistent with 40 CFR 131.11

EPA's regulations at 40 CFR 131.11 require States to adopt water quality criteria that protect the designated use and must be that are based on sound scientific rationale. It also allows States to modify criteria in order to reflect site-specific situations.[156] In OAR 340-041-0033(6) Oregon establishes a procedure to develop a site-specific human health criterion for carcinogens in a limited number of site-specific situations when developed consistent with the procedures specified in the rule.

Oregon has restricted the use of the site-specific background pollutant criteria provision to waterbodies where an existing NPDES discharger withdraws water from a waterbody and returns it to the same waterbody without adding any mass to the pollutant of concern. It is further limited to carcinogenic pollutants[157] and utilizes information about the discharge to limit the criterion. The rule provides a structured framework for developing a site-specific criterion which is limited by a number of factors, including a requirement that the criterion never exceed a criterion calculated at a 1×10^{-4} risk level. Further limitations are derived based on the pre-existing quantity and quality of the discharge into the receiving water, no greater than a three percent increase in instream concentration and no increase in mass load of the pollutant from the discharger. In no case will the criteria allow greater than a 10^{-4} carcinogenic risk level (as established using the same methodology used for all other human health criteria addressed in this action).

EPA has reviewed whether Oregon had supplied appropriate grounds to derive a site-specific human health criterion for carcinogens, consistent with 40 CFR 131.11. EPA's water quality standards regulations provide that water quality criteria "must be based on sound scientific

[155] OAR 340-041-0033(6)(d)
[156] 40 CFR 131.11 (A)(1); 40 CFR 131.11(b)(1)(ii)
[157] OAR 340-041-0033(6)(b)(A)

rationale,"[158] and contemplate that a State may adopt site-specific criteria, and provide that these site-specific criteria "should . . . reflect site-specific conditions."[159] EPA's Human Health Methodology further clarifies a State's flexibility to derive site-specific criteria for human health criteria. Human health criteria may be modified to reflect, in a justifiable manner, "local environmental conditions." Local conditions may be those which prevail over a particular river reach, an entire river, regionally, or Statewide.[160] In other guidance, EPA has acknowledged that *less stringent* site specific modifications to human health criteria may be appropriate (in that case, either based on local variation in fish consumption rates or applicable bioaccumulation factors).[161] Thus, EPA finds that the criteria are based on a sound scientific rationale, will reflect site-specific conditions and, as discussed above, are established at a level that will protect Oregon's human health uses.

The provision establishes site-specific human health criteria using the performance-based criterion approach

Finally, EPA reviewed whether the background pollutant provision contains sufficient detail, and suitable safeguards, that EPA's approval of the provision may also serve as the Clean Water Act § 303(c)(3) approval of the individual site-specific criteria to be generated under the provision**.**

EPA's water quality standard regulations at 40 CFR 131.21 provide that a state water quality standard adopted after May 30, 2000 is not applicable for Clean Water Act purposes until "EPA approves that water quality standard [under § 303(c)(3) of the CWA]." However, when EPA promulgated this regulation it made clear that states have the option to streamline this process by pursuing a "performance-based" approach whereby the state adopts a "process (i.e., a criterion derivation methodology) rather than a specific outcome (i.e., concentration limit for a pollutant) consistent with 40 CFR 131.11 and 131.13."[162] Under the performance-based approach, EPA conducts a CWA § 303(c)(3) review of the procedure and the criteria that would be generated under that procedure. EPA approval of the provision can encompass approval of the individual criteria to be generated under the provision where the procedure is "sufficiently detailed and has suitable safeguards to ensure predictable and repeatable outcomes." To this end, the procedure should establish a "structure or decision-making framework that is binding, clear, predictable, and transparent." [163] EPA further specified that the performance-based approach is particularly well suited to the derivation of site-specific numeric criteria where the proper construction and implementation of such an approach can result in defensible site-specific adjustments to numeric ambient water quality criteria.[164]

Oregon's site-specific background pollutant criterion provision was adopted as a performance-based approach to develop site-specific human health criteria for carcinogens under the conditions and procedures specified in their rule.[165] Oregon's July 21, 2011 submission letter specifically states that the provision was "adopted [as] a new performance-based water quality standard" and that it "establishes the procedure by which a site-specific criterion may be developed for a limited portion of the waterbody".[166] ODEQ's staff report EQC at the time of rule adoption indicates a clear intent for the rule to be adopted as a procedure by which, when approved by EPA, could be used to develop site-specific criteria that will not need subsequent approval by EPA.[167]

A performance-based approach relies on the State to specify methodologies and decision thresholds in their water quality standards regulations so that a structure or decision-making framework that is binding, clear, predictable and transparent is established. As with all other modifications to state water quality standards, EPA requires that the state provide opportunity for the public to comment on this rule and that the regulation be adopted consistent with state law. Oregon's site-specific pollutant criterion provision has been promulgated in OAR 340-041-0033(6) of Oregon's Water Quality Standards, has undergone public review and hearing through the process used for all other revisions adopted by the State on June 16, 2011, and has been certified as having been adopted pursuant to State law.[168] Therefore, EPA finds that this provision provides a regulatory framework for decision-making (i.e. criteria development) that is binding, predictable and transparent and that the public has had the opportunity to provide comment on the proposed rule.

EPA's guidance further notes that a performance-based "approach is particularly useful for criteria which are heavily influenced by site-specific factors."[169] In this case, Oregon has restricted the use of this provision to waterbodies where a waterbody contains a pollutant upstream of a water supply source and a NPDES discharger withdraws water from the waterbody and returns it to the same waterbody without adding any mass to the pollutant of concern. Additionally, the background pollutant provision specifies that it only applies to carcinogenic pollutants, OAR 340-041-0033(6)(b)(A), and utilizes information about the discharge to limit the criterion. Thus, EPA believes it is appropriate that such criterion be developed on a site-specific basis.

[168] Oregon Department of Justice. General Counsel Division. July 20, 2011. Letter from Larry Knudsen, Assistant Attorney General, Natural Resources Section, to Michael Bussell, EPA Region 10. *Re: Certification of Water Quality Standard Amendment (Fish Consumption Rate).*
[169] April 27, 2000. *Federal Register*, Volume: 65, No.: 82, page: 24648 (65 FR 24648). Available at: http://www.gpo.gov/fdsys/pkg/FR-2000-04-27/pdf/00-8536.pdf

Finally, EPA's guidance specifies that such procedures "must include a public participation step to provide all stake-holders and the public an opportunity to review the data and calculations supporting the site-specific application of the implementation procedures." The State would also need to maintain a publically available, comprehensive list of all site-by-site decisions made

using the procedures.[170] Oregon's WQS regulation at OAR 340-041-0033(6)(i) establishes the public notification requirements for any criterion to be adopted under this provision. It specifically requires ODEQ to provide public notice of the proposal and hold a public hearing. In addition to other public notification procedures in place by the State, ODEQ will publish the proposal on their WQS website. Furthermore, the provision requires ODEQ to publish a list of all criteria approved pursuant to the rule within 30 days of its effective date and identifies the minimum elements to be contained in this list. EPA believes that the public process required by Oregon within OAR 340-041-0033(6)(i) is consistent with that described in EPA's guidance and required by 40 CFR 131.11.

In order to provide further guidance to ODEQ staff and to ensure consistent implementation of the provision, ODEQ will develop an Internal Management Directive (guidance document) within 180 days of EPA's action on this provision.[171] This document will be available on ODEQ's website and thus facilitate even greater clarity and transparency for the public.

In consideration of the above factors, EPA concludes that the provision contains a binding, clear, predictable, and transparent framework such that any site-specific criterion generated under the provision must not result in a human health risk level of greater than 1×10^{-4} and will protect the human health uses of Oregon's waters. Therefore, any additional oversight by EPA would be redundant. Thus, the provision contains sufficient detail, and suitable safeguards, that EPA's approval of the provision serves as the Clean Water Act § 303(c)(3) approval of the individual site-specific criteria to be generated under the provision. Since this procedure is adopted into State regulation and Oregon is bound by the decision-making framework contained therein, any criteria which are not derived in accordance with the approved procedures would need separate approval from EPA to be applicable under the CWA.

When EPA reviews the results of Oregon's triennial review, EPA expects to evaluate a representative subset of the site-specific decisions to ensure that Oregon is adhering to the EPA-approved procedure. Finally, EPA notes that if Oregon fails to follow these procedures and does not obtain separate CWA § 303(c)(3) approval for the site-specific criterion, this would provide EPA with a basis to object to an NPDES permit for not deriving from or complying with the applicable standards.[172]

VII. VARIANCE PROVISION

A. *BACKGROUND*

EPA's regulations at 40 C.F.R. Part 131.13, provides that states may, at their discretion, include in state water quality standards policies generally affecting the application and implementation of water quality standards, such as general policies for variances. If a state chooses to adopt such a variance policy, the regulation specifies that such policies are required to be submitted to EPA for review and approval.

The objective of the Clean Water Act is to restore and maintain the chemical, physical and biological integrity of the Nation's waters. The CWA further specifies an interim goal that, "wherever attainable," water quality provides for the protection and propagation of fish, shellfish, and wildlife and provides for recreation in and on the water.

40 C.F.R. Part 131.10(g) specifies the factors a state may use to determine that a designated use, which is not an existing use, is not ultimately attainable. These factors are:

1. Naturally occurring pollutant concentrations prevent the attainment of the use; or
2. Natural, ephemeral, intermittent or low flow conditions or water levels prevent the attainment of the use, unless these conditions may be compensated for by the discharge of sufficient volume of effluent discharges without violating state water conservation requirements to enable uses to be met; or
3. Human caused conditions or sources of pollution prevent the attainment of the use and cannot be remedied or would cause more environmental damage to correct than to leave in place; or
4. Dams, diversions or other types of hydrologic modifications preclude the attainment of the use, and it is not feasible to restore the water body to its original condition or to operate such modification in a way that would result in the attainment of the use; or
5. Physical conditions related to the natural features of the water body, such as the lack of a proper substrate, cover, flow, depth, pools, riffles, and the like, unrelated to water quality, preclude attainment of aquatic life protection uses; or
6. Controls more stringent than those required by sections 301(b) and 306 of the Act would result in substantial and widespread economic and social impact.

In 1977, an Office of General Counsel legal opinion[173] considered the practice of temporarily downgrading the designated use and criteria, as it applies to a specific discharger rather than permanently[174] downgrading an entire water body or water body segment and determined that

[173] EPA. March 29, 1977. *Office of General Counsel on Matters of Law Pursuant to 40 CFR Section 125.36(m). No. 58.* U.S. Environmental Protection Agency. Washington, D.C. Available at: http://water.epa.gov/scitech/swguidance/standards/upload/2008_08_04_standards_section40cfr3.pdf

[174] "Permanent" used in the context of a designated use is intended solely to differentiate from a time-limited variance. EPA's regulations at 131.20 require states to review uses that do not include those specified in CWA section 101(a)(2) and to revise standards accordingly if information becomes available to indicate such uses are attainable.

such a practice is acceptable as long as it is adopted consistent with the substantive requirements for permanently downgrading a designated use. EPA continued to articulate this position in its *Water Quality Standards Handbook* (Section 5.3) specifically stating:

> *Variance procedures involve the same substantive and procedural requirements as removing a designated use , but unlike use removal, variances are both discharger and pollutant specific, are time limited, and do not forego the currently designated use*.

Thus, the six 131.10(g) factors, which are used to justify a designated use change through a use attainability analysis, consistent with 131.10(g), are the same factors that must be evaluated when justifying a variance.

Variances allow for a more site-specific and time-limited consideration of attainability than a permanent designated use revision. They encourage states to maintain the underlying designated uses and criteria as goals instead of declaring them unattainable prematurely when they may be attainable in the long term. For example, technology improvements could lower treatment costs in the future such that attaining the designated use and criteria would no longer cause substantial and widespread economic and social impact. Variances are typically specific to a pollutant(s) and either apply to specific permittees or geographic areas. Variances only apply to the pollutants, permittees and geographic areas for which they were written; all other applicable standards remain in place.

Variances must be of a limited or temporary duration for a fixed term.[175] Variances are time-limited designated uses and associated criteria and are thus considered water quality standards. As such, any variances granted by the state must be submitted to EPA for review and approval or disapproval under CWA section 303(c). The preamble to EPA's 1983 regulation[176] states that EPA has approved state-adopted variances in the past and will continue to do so if each individual variance is adopted as a water quality standard and subject to the same public review as other changes in the water quality standards. EPA's *Water Quality Standards Handbook*[177] reiterates the 1983 Preamble as did EPA's Advanced Notice of Proposed Rulemaking (ANPRM), in 1998, seeking comments on possible revisions to the Water Quality Standards Regulation.[178]

EPA's *Water Quality Standards Handbook* also specifies that EPA has approved state-adopted variances in the past and will continue to do so if:

[176] November 8, 1983. *Federal Register*, Volume: 48, No.: 217, page 51403 (48 FR 51403). Available at: http://nepis.epa.gov/Exe/ZyPURL.cgi?Dockey=20003ZVR.txt

[177] EPA. 1994. *Water Quality Standards (WQS) Handbook: Second Edition.* August 1994. United States Environmental Protection Agency, Office of Water. EPA-823-B-94-005a. page 5-12. Available at http://water.epa.gov/scitech/swguidance/standards/handbook/index.cfm

[178] July 7, 1998. *Federal Register*, Volume: 63, No.: 129, page: 36759 (63 FR 36759). Available at: http://water.epa.gov/scitech/swguidance/standards/handbook/upload/1998_07_07_1998_July_Day-07_w17513.pdf

- The State includes the individual variance as part of the water quality standard.
- The state demonstrates that meeting the standard is unattainable based on one or more of the factors in 131.10(g).
- The justification submitted includes documentation that treatment more advanced than that required by sections 301(b)(1)(b) and 306 of the Clean Water Act has been carefully considered and that alternative effluent control strategies have been evaluated.
- The more stringent State criterion is maintained and is binding upon all other dischargers on the stream or stream segment.
- The discharger who is given a variance for one particular constituent is required to meet the applicable criteria for other constituents.
- The variance was granted for a specific period of time.
- The discharger either must meet the standard upon the expiration of this time period or must make a new demonstration of "unattainability."
- Reasonable progress is being made toward meeting the water quality standards.
- The variance was subjected to public notice and opportunity for comment.

In summary, states have the discretion to include variance policies in their water quality standards regulation. Such policies are subject to EPA review and approval. In addition, if a state chooses to revise standards by granting a variance, states must adopt such variances pursuant to state law and each individual variance is subject to public review, consistent with EPA's regulations. Variances are not effective for Clean Water Act purposes until approved by EPA.

B. *ODEQ'S JULY 21, 2011 SUBMITTAL*

ODEQ has removed the variance language found at OAR 340-041-0061(2) and replaced it with new language at OAR 340-041-0059. Oregon's revised variance provision lays out the necessary process for obtaining a variance, the conditions under which a variance will be granted, and the requirements during a variance. DEQ's objective for these revisions is to ensure that variances and their accompanying pollutant reduction plans continue to ensure progress toward meeting standards, to streamline the administration process, to require pollutant reduction plans with specific milestones that will result in water quality improvement, and to add general clarification to the rule.[179]

Below is ODEQ's revised variance provision, found at OAR 340-041-0059.

OAR 340-041-0059
Variances

This rule (OAR 340-041-0059) does not become applicable for purposes of ORS chapter 468B or the federal Clean Water Act unless and until EPA approves the provisions it identifies as water quality

[179] ODEQ. May 24, 2011. *Issue Paper: Implementing Water Quality Standards for Toxic Pollutants in NPDES Permits, Human Health Toxics Rulemaking.* Oregon Department of Environmental Quality. Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/humanhealth/rulemaking/NPDESIssuePaper.pdf

standards pursuant to 40 CFR 131.21 (4/27/2000).

(1) Applicability. Subject to the requirements and limitations set out in sections (2) through (7) below, a point source may request a water quality standards variance where it is demonstrated that the source cannot feasibly meet effluent limits sufficient to meet water quality standards. The director of the department will determine whether to issue a variance for a source covered by an existing NPDES permit. The commission will determine whether to issue a variance for a discharger that does not have a currently effective NPDES permit.

(a) The variance applies only to the specified point source permit and pollutant(s); the underlying water quality standard(s) otherwise remains in effect.

(b) The department or commission may not grant a variance if:

(A) The effluent limit sufficient to meet the underlying water quality standard can be attained by implementing technology-based effluent limits required under sections 301(b) and 306 of the federal Clean Water Act, and by implementing cost-effective and reasonable best management practices for nonpoint sources under the control of the discharger; or

(B) The variance would likely jeopardize the continued existence of any threatened or endangered species listed under section 4 of the Endangered Species Act or result in the destruction or adverse modification of such species' critical habitat; or

(C) The conditions allowed by the variance would result in an unreasonable risk to human health; or

(D) A point source does not have a currently effective NPDES permit, unless the variance is necessary to:

(i) Prevent or mitigate a threat to public health or welfare;

(ii) Allow a water quality or habitat restoration project that may cause short term water quality standards exceedances, but will result in long term water quality or habitat improvement that enhances the support of aquatic life uses;
(iii) Provide benefits that outweigh the environmental costs of lowering water quality. This analysis is comparable to that required under the antidegradation regulation contained in OAR-041-0004(6)(b); or

(E) The information and demonstration submitted in accordance with section (4) below does not allow the department or commission to conclude that a condition in section (2) has been met.

(2) Conditions to Grant a Variance. Before the commission or department may grant a variance, it must determine that:

(a) No existing use will be impaired or removed as a result of granting the variance and

(b) Attaining the water quality standard during the term of the variance is not feasible for one or

more of the following reasons:

(A) Naturally occurring pollutant concentrations prevent the attainment of the use;

(B) Natural, ephemeral, intermittent, or low flow conditions or water levels prevent the attainment of the use, unless these conditions may be compensated for by the discharge of sufficient volume of effluent discharges to enable uses to be met without violating state water conservation requirements;

(C) Human-caused conditions or sources of pollution prevent the attainment of the use and cannot be remedied or would cause more environmental damage to correct than to leave in place;

(D) Dams, diversions, or other types of hydrologic modifications preclude the attainment of the use, and it is not feasible to restore the waterbody to its original condition or to operate such modification in a way which would result in the attainment of the use;

(E) Physical conditions related to the natural features of the waterbody, such as the lack of a proper substrate, cover, flow, depth, pools, riffles, and unrelated to water quality preclude attainment of aquatic life protection uses; or

(F) Controls more stringent than those required by sections 301(b) and 306 of the federal Clean Water Act would result in substantial and widespread economic and social impact.

(3) Variance Duration.

(a) The duration of a variance must not exceed the term of the NPDES permit. If the permit is administratively extended, the permit effluent limits and any other requirements based on the variance and associated pollutant reduction plan will continue to be in effect during the period of the administrative extension. The department will give priority to NPDES permit renewals for permits containing variances and where a renewal application has been submitted to the director at least one hundred eighty days prior to the NPDES permit expiration date.

(b) When the duration of the variance is less than the term of a NPDES permit, the permittee must be in compliance with the specified effluent limitation sufficient to meet the underlying water quality standard upon the expiration of the variance.

(c) A variance is effective only after EPA approval. The effective date and duration of the variance will be specified in a NPDES permit or order of the commission or department.

(4) Variance Submittal Requirements. To request a variance, a permittee must submit the following information to the department:

(a) A demonstration that attaining the water quality standard for a specific pollutant is not feasible for the requested duration of the variance based on one or more of the conditions found in section (2)(b) of this rule;

(b) A description of treatment or alternative options considered to meet limits based on the applicable underlying water quality standard, and a description of why these options are not technically, economically, or otherwise feasible;

(c) Sufficient water quality data and analyses to characterize ambient and discharge water pollutant concentrations;

(d) Any cost-effective and reasonable best management practices for nonpoint sources under the control of the discharger that addresses the pollutant the variance is based upon;

(e) A proposed pollutant reduction plan that includes any actions to be taken by the permittee that would result in reasonable progress toward meeting the underlying water quality standard. Such actions may include proposed pollutant offsets or trading or other proposed pollutant reduction activities, and associated milestones for implementing these measures. Pollutant reduction plans will be tailored to address the specific circumstances of each facility and to the extent pollutant reduction can be achieved; and

(f) If the discharger is a publicly owned treatment works, a demonstration of the jurisdiction's legal authority (such as a sewer use ordinance) to regulate the pollutant for which the variance is sought. The jurisdiction's legal authority must be sufficient to control potential sources of that pollutant that discharge into the jurisdiction's sewer collection system.

(5) Variance Permit Conditions. Effluent limits in the discharger's permit will be based on the variance and not the underlying water quality standard, so long as the variance remains effective. The department must establish and incorporate into the discharger's NPDES permit all conditions necessary to implement and enforce an approved variance and associated pollutant reduction plan. The permit must include, at a minimum, the following requirements:

(a) An interim concentration based permit limit or requirement representing the best achievable effluent quality based on discharge monitoring data and that is no less stringent than that achieved under the previous permit. For a new discharger, the permit limit will be calculated based on best achievable technology;

(b) A requirement to implement any pollutant reduction actions approved as part of a pollutant reduction plan submitted in accordance with section (4)(e) above and to make reasonable progress toward attaining the underlying water quality standard(s);

(c) Any studies, effluent monitoring, or other monitoring necessary to ensure compliance with the conditions of the variance; and

(d) An annual progress report to the department describing the results of any required studies or monitoring during the reporting year and identifying any impediments to reaching any specific milestones stated in the variance.

(6) Public Notification Requirements.

(a) If the department proposes to grant a variance, it must provide public notice of the proposal and hold a public hearing. The public notice may be included in the public notification of a draft NPDES permit or other draft regulatory decision that would rely on the variance;

(b) The department will publish a list of all variances approved pursuant to this rule. Newly approved variances will be added to this list within 30 days of their effective date. The list will identify: the discharger; the underlying water quality standard addressed by the variance; the waters of the state to which the variance applies; the effective date and duration of the variance;

the allowable pollutant effluent limit granted under the variance; and how to obtain additional information about the variance.

(7) Variance Renewals.

(a) A variance may be renewed if:

(A) The permittee makes a renewed demonstration pursuant to section (2) of this rule that attaining the water quality standard continues to be infeasible,

(B) The permittee submits any new or updated information pertaining to any of the requirements of section 4,

(C) The department determines that all conditions and requirements of the previous variance and actions contained in the pollutant reduction plan pursuant to section (5) have been met, unless reasons outside the control of the discharger prevented meeting any condition or requirement, and

(D) All other requirements of this rule have been met.

(b) A variance renewal must be approved by the department director and by EPA.

C. *EPA ACTION ON ODEQ'S REVISED VARIANCE PROVISION*

EPA Action

In accordance with its CWA authority, 33 U.S.C § 1313(c)(3) and 40 C.F.R. part 131, EPA approves certain sections of Oregon's revised variance provision at OAR 340-041-0059, as detailed below, because they are consistent with the Clean Water Act and the implementing Federal water quality standards regulations governing EPA's review and approval or disapproval of new or revised water quality standards as required in 40 C.F.R. part 131. These federal regulations as well as EPA's guidance, to date, on variances are detailed above. EPA outlines below the sections of the provision it is approving as water quality standards pursuant to CWA section 303(c) and the sections of the provision which are not water quality standards under CWA section 303(c) and therefore upon which EPA is taking no action. Oregon may use the full variance provision (both those sections approved as WQS and those identified as not being WQS) when developing and implementing any individual variance. Each individual variance the State adopts consistent with the regulations at OAR 340-041-0059, must be submitted to EPA for review and approval prior to its use in a NPDES permit or other CWA action. In EPA's review of Oregon's revised variance provision, the Agency considered information submitted on July 21, 2011 including ODEQ's NPDES Implementation Issue Paper[180] and Response to Comments document.[181]

[180] ODEQ. May 24, 2011. *Issue Paper: Implementing Water Quality Standards for Toxic Pollutants in NPDES Permits, Human Health Toxics Rulemaking.* Oregon Department of Environmental Quality. Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/humanhealth/rulemaking/NPDESIssuePaper.pdf

[181] ODEQ. May 2011. *Response to Comments: Proposed Water Quality Standards for Human Health and Water Quality Standards Implementation Policies.* Oregon Department of Environmental Quality. page 21. Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/humanhealth/rulemaking/ResponseToComments.pdf

EPA Rationale
EPA has reviewed the provision at OAR 340-041-0059 in Oregon's water quality standards regulations, entitled, "Variances". EPA previously approved Oregon's existing variance provision at OAR 350-041-0061(2).

Oregon's revised variance provision adds more definition to what was required in OAR 350-041-0061(2) and requires the applicant to develop a schedule for improvements by implementing a pollution reduction plan. These revisions will assist in meeting the goal of facilitating water quality improvements and attaining the underlying criteria.

EPA is approving the specified sections of Oregon's variance regulation explained below as a "general policy" under §131.13. ODEQ is still required to submit each individual variance to EPA for review and action before it is effective for purposes of the CWA because the variances themselves are also water quality standards. Accordingly, each variance submitted for EPA's review must include the Attorney General's certification and be consistent with the CWA and EPA's implementing regulations, including all applicable public participation requirements. Thus, EPA's review of Oregon's variance authorizing provision need not evaluate each hypothetical variance the State may issue under OAR 340-041-0059 and consider whether such a variance would be consistent with the CWA and EPA's implementing regulation. EPA's approval of Oregon's variance provision at OAR 340-041-0059 is not an automatic approval of any future variance the State wishes to grant pursuant to these provisions.

Below, EPA outlines the sections it is approving as water quality standards pursuant to CWA section 303(c) and the sections upon which EPA is taking no action. EPA's approval reflects EPA's determination that the specific section adopted at OAR 340-041-0059 is consistent with the Clean Water Act and the implementing Federal water quality standards regulations in 40 C.F.R. part 131.

Introductory Language to OAR 340-041-0059
EPA is approving the introductory language which states, "This rule (OAR 340-041-0059) does not become applicable for purposes of ORS chapter 468B or the federal Clean Water Act unless and until EPA approves the provisions it identifies as water quality standards pursuant to 40 CFR 131.21 (4/27/2000)."

In accordance with its Clean Water Act authority, 33 U.S.C § 1313(c)(3) and 40 C.F.R. part 131, EPA approves this new language. This language describes when Oregon's revised variance provision becomes effective under state law and the Clean Water Act. The effective date of water quality standards provisions under the CWA is determined by the date of EPA approval. This language regarding timing is a water quality standard that provides for the sections of the revised variance provision to be immediately in effect at the time of EPA's approval action.

OAR 340-041-0059(1) "Applicability"
EPA is approving OAR 340-041-0059(1) "Applicability" and OAR 340-041-0059(1)(a) which reflects that the variance only applies to the specified point source and pollutant; the underlying water quality standards remain in effect. This scope of applicability is consistent with EPA interpretive Guidance and the 1977 Office of General Counsel legal opinion discussing

variances.

Moreover, EPA is approving OAR 340-041-0059(1)(b) and (1)(b)(A) as they are consistent with 131.10(h)(2) which prohibits a State's removal of a designated uses where "[s]uch uses will be attained…by implementing cost-effective and reasonable best management practices for nonpoint source control." EPA has concluded that Oregon's language at (1)(b)(A) that prohibits the State from issuing a variance where *"effluent limitations sufficient to meet the underlying water quality standards can be attained by…implementing cost-effective and reasonable best management practices for nonpoint sources under the control of the discharger,"* is consistent with 131.10(h)(2) because Oregon's variance authorizing provision only allows the State to issue discharger-specific variances.[182] Given this scope of Oregon's variance authorizing provision, EPA believes it is reasonable for the State to limit the prohibition in (1)(b)(A) to those cost-effective and reasonable best management practices for nonpoint sources to those practices under the control of the discharger.[183]

EPA is approving OAR 340-041-0059(1)(b)(B)-(E) because these sections are not inconsistent with the CWA and EPA's implementing regulations. While OAR 340-041-0059(1)(b)(D) does not categorically prohibit the issuance of a variance to a new discharger, neither do the CWA or EPA's implementing regulations. While 40 CFR 122.4(i) limits discharges from "a new source or a new discharger" that "will cause or contribute to the violation of water quality standards," a variance is a revision to the water quality standard itself, and therefore 122.4(i) is not relevant. EPA notes, however, that the circumstances in which a new discharger will be able to meet the other requirements for a variance (e.g., a demonstration that [a]ttaining the water quality standard during the term of the variance is not feasible,") are likely to be significantly more limited for a new discharger than an existing discharger. EPA acknowledges that granting a variance to a new discharger may be appropriate under very specific and limited circumstances. It will review the appropriateness of particular circumstances on an individual variance basis.

---

[182] OAR 340-041-0059(1)(a) provides that the "variance applies only to the specified point source permit and pollutant(s); the underlying water quality standard(s) otherwise remain in effect."

[183] EPA disagrees with the contrary contention, made in public comments, that the BMP requirements of 40 C.F.R. § 131.10(h)(2) must apply to "all nonpoint sources in the consideration of a variance application, not just those under the control of the applicant." Northwest Environmental Advocates (NWEA). March 17, 2011. Letter from Nina Bell, Executive Director, NWEA to Andrea Matzke, ODEQ, *Re: Proposed Revised Water Quality Standards for Human Health Toxic Pollutants and Revised Water Quality Standards Implementation Policies.* page 32. In support of this proposition, the commenter cites a 1994 EPA interpretive memorandum ("Tudor Davies memo") and a 1995 EPA economic guidance document. The Tudor Davies memo discusses how the requirements of 40 CFR 131.12(a)(2) apply to antidegradation policies, not the applicability of 40 CFR 131.10(h)(2) to variances. The citation to the 1995 Interim Economic Guidance for Water Quality Standards is similarly inapposite. This guidance addresses how an economic analysis under 131.10(g)(6) should be conducted to demonstrate that a variance is needed. Sections 40 C.F.R. 131.10(d) and (h)(2) are independent requirements from 131.10(g). EPA recognizes that the introduction section of the guidance document states that polluting entities can be point or nonpoint sources of pollution and that attainment of water quality standards is not limited to controls placed on point sources. However, this statement should be viewed in context of the stated scope of the guidance, which is to address economic factors considered under 131.10(g) and 131.12. Even if this statement could be read to apply to 131.10(d) and (h)(2), Oregon's provision at OAR 340-041-0059(1)(b)(A) is consistent with EPA's 1995 economic guidance document because the guidance contemplates that financial impacts are determined by the costs the entity itself would face by implementing the necessary pollution controls.

OAR 340-041-0059(2) "Conditions to Grant a Variance"

EPA is approving OAR 340-041-0059(2), (2)(a) and (2)(b) "Conditions to Grant a Variance" because it is consistent with the substantive requirements of permanently changing designated uses at §131.10, specifically §131.10(g).

OAR 340-041-0059(2)(a) requires the state to determine that "[n]o existing use will be impaired or removed as a result of granting the variance." One commenter argues that this section is inconsistent with EPA's regulations because it "does not explicitly require variances to meet the antidegradation policy[,]…falls short of full protection of existing uses[,]… [and] makes no reference to the water quality that is required to maintain and protect existing uses."[184] EPA disagrees that OAR 340-041-0059(2)(a) is inconsistent with EPA regulations. OAR 340-041-0059(2)(a) is consistent with 131.10(h)(1) and (g) which both prohibit a state from removing the protection for an existing use. While a state's adoption of new or revised water quality standards is not itself subject to antidegradation review, EPA notes that OAR 340-041-0059(2)(a) is also consistent with 131.12(a)(1): requiring the that "[e]xisting instream water uses and the level of water quality necessary to protect the existing uses shall be maintained and protected." EPA believes that prohibiting the impairment or removal of an existing use will achieve the goals of "maintain[ing] and protect[ing]" the "level of water quality necessary to protect the existing use."

Section OAR 340-041-0059(2)(b) is consistent with the substantive requirements at §131.10(g).

OAR 340-041-0059(3) "Variance Duration"

EPA is approving OAR 340-041-0059(3) and the first sentence of OAR 340-041-0059(3)(a) "Variance Duration" as a water quality standard that states "The duration of a variance must not exceed the term of the NPDES permit." EPA understands this section to mean that each variance will expire five years after the State adopts the variance, the maximum length of a NPDES permit consistent with federal regulations and OAR 340-045-0035(8), or the variance will specify a specific expiration date of less than five years after the variance was adopted into state regulation. As discussed earlier, the 1977 Office of General Counsel legal opinion explains that time-limited revisions to the designated use and criteria are environmentally preferable as compared with the permanent removal of a designated use because the more stringent standards apply to all other dischargers not covered by the variance. EPA is approving this sentence as it states the specific time limit for which the designated use and criteria have been determined to be "unattainable" consistent with §131.10(g).

EPA is taking no action on the last two sentences of OAR 340-041-0059(3)(a) "Variance Duration" that states "If the permit is administratively extended, the permit effluent limits and any other requirements based on the variance and associated pollutant reduction plan will continue to be in effect during the period of the administrative extension. The department will give priority to NPDES permit renewals for permits containing variances and where a renewal application has been submitted to the director at least one hundred eighty days prior to the

[184] Northwest Environmental Advocates (NWEA). March 17, 2011. Letter from Nina Bell, Executive Director, NWEA to Andrea Matzke, ODEQ, *Re: Proposed Revised Water Quality Standards for Human Health Toxic Pollutants and Revised Water Quality Standards Implementation Policies.* page 39.

NPDES permit expiration date." These sections are NPDES permitting requirements because they describe the permitting process for handling situations where there is a delay in reissuing a permit. Such language does not affect how long the variance applies as the approved water quality standard and the administrative extension of a permit is not subject to EPA WQS approval or disapproval.

EPA is also taking no action on OAR 340-041-0059(3)(b) "Variance Duration" because that section of the provision reiterates the permitting provisions at §122.44(d)(vii) requiring the NPDES permit limit to derive from and comply with the applicable water quality standards once the variance expires. Therefore, EPA does not consider this section to be a water quality standard.

EPA is approving OAR 340-041-0039(3)(c) "Variance Duration" as a water quality standard because it clearly states that the variance is not effective for CWA section 402 permitting purposes until EPA approves it, consistent with §131.21(c). EPA notes that once an individual variance has been approved, it is a water quality standard applicable for CWA section 402 permitting purposes (see 40 CFR 131.21) and thus becomes subject to the triennial review requirements at 40 C.F.R. 131.20.

OAR 340-041-0059(4) "Variance Submittal Requirements"
EPA is approving OAR 340-041-0059(4) "Variance Submittal Requirements" and OAR 340-041-0059(4)(a) consistent with §131.10(g) because it requires a demonstration that one of EPA's regulatory factors precludes attainment of the use. EPA is also approving OAR 340-041-0059(4)(b)-(f) because these sections provide substantive requirements for what the applicant must submit to the State to obtain a variance, and are not inconsistent with the requirements of the CWA and EPA's regulations.

OAR 340-041-0059(5) "Variance Permit Conditions"
EPA is approving OAR 340-041-0059(5), (5)(a) and (5)(b) "Variance Permit Conditions" because these sections establish the water quality requirements during a variance. While those requirements might typically be presented in the form of instream water quality criteria, EPA considers the requirement for a permit limit to include the best achievable effluent quality to be a surrogate for identifying the instream water quality criteria at the highest attainable condition. Thus, EPA is approving sections 5(a) and 5(b) because they describe the resulting instream concentration and together act as a surrogate for interim criterion applicable during a variance. Based on Oregon's regulatory language in this section, the best achievable effluent quality will be appropriately determined on a case-by-case basis.

EPA is not taking action on OAR 340-041-0059(5)(c) and (5)(d) because they are monitoring and reporting requirements applicable to a discharger's NPDES permit. These requirements are not considered WQS under CWA section 303(c) or addressed in EPA's water quality standards regulations because they are NPDES permitting requirements.

OAR 340-041-0059(6) "Public Notice Requirements"
EPA is approving OAR 340-041-0059(6) "Public Notice Requirements" and OAR 340-041-0059(6)(a) and 0059(6)(b) because they address the requirements for public notice of a variance

consistent with §131.20(b), and explain what information will be provided to the public. EPA notes that this section states that public notification for a variance can be included in the public notification of a draft NPDES permit or draft regulatory decision that would rely on the variance. In addition, EPA must approve the variance before it can be implemented and thus the State cannot finalize the NPDES permit with a limit that reflects a variance until EPA has approved the variance.

OAR 340-041-0059(7) "Variance Renewals"

EPA is approving OAR 340-041-0059(7) "Variance Renewals". EPA is approving OAR 340-041-0059(7)(a)(A) as consistent with 131.10(g) as it requires the permittee to demonstrate that attaining water quality standards during the term of the variance is still not feasible based on factors consistent with 131.10(g)(1)-(6). EPA is approving all other language in OAR 340-041-0059(7) because this regulatory language is not inconsistent with the CWA or EPA's implementing regulations. EPA notes that since variances are water quality standards, the state will need to include variances in the applicable water quality standards that the state reviews during its triennial review processes under §131.20(a). EPA understands that OAR 340-041-0059(7)(D) ("[a]ll other requirements of this rule have been met.") will require a new round of public notice, comporting with the requirements of OAR 340-041-0059(6), and all other requirements in OAR 340-041-0059 to be met when any variance is renewed.

VIII. BACTERIA

Oregon's revisions to its bacteria provision found at OAR 340-041-0009(10) are shown in underline/strikeout format below. Underlined text represents added text, while text with a line through the middle (strikeout) represents deleted text. The revised text corrects a citation based on renumbering in OAR 340-041-0061.

(10) Water Quality Limited for Bacteria: In those water bodies, or segments of water bodies identified by the Department as exceeding the relevant numeric criteria for bacteria in the basin standards and designated as water-quality limited under section 303(d) of the Clean Water Act, the requirements specified in section 11 of this rule and in OAR 340-041-0061(11~~2~~) must apply.

EPA Action
In accordance with its CWA authority, 33 U.S.C § 1313(c)(3) and 40 C.F.R. part 131, EPA approves this minor editorial change as a non-substantive revision to water quality standards at OAR 340-041-0009.

EPA Rationale
The minor editorial change in this provision to correct the citation due to a renumbering revision in OAR 340-041-0061(12) does not alter the underlying provision that EPA previously approved and EPA is not acting on the underlying provision. EPA approves this non-substantive revision to Oregon's WQS under section 303(c) of the CWA and the implementing regulations at 40 CFR Part 131.

IX. REVISED RULES REGARDING IMPLEMENTAIN FOR NONPOINT SOURCES

A. *STATEWIDE NARRATIVE CRITERIA*

Oregon's revisions to OAR 340-041-0007(5) are shown in underline/strikeout format below. Underlined text represents added text, while text with a line through the middle (strikeout) represents deleted text. The revised rule clarifies the state regulatory mechanisms for water quality control applicable to forest management activities.

(5) Logging and forest management activities must be conducted in accordance with the ~~Oregon~~ rules established by the Environmental Quality Commission and must not cause violation of water quality standards. Nonpoint sources of pollution from forest operations on state and private forest lands are subject to best management practices and other control measures established by the Oregon Board of Forestry as provided in ORS 527.765 and 527.770. Forest ~~Practices~~ operations conducted in good faith compliance with the best management practices and control measures established under the Forest Practices Act ~~to minimize adverse effects on water quality~~ are generally deemed not to cause violations of water quality standards as provided in ORS 527.770. Forest operations are subject to load allocations established under ORS 468B.110 and OAR Division 340-042 to the extent needed to implement the federal Clean Water Act.

Acknowledgement of OAR 340-041-0007(5)
EPA acknowledges the revised language contained in OAR 340-041-0007(5). ODEQ has revised their regulations to explain how the control measures applicable to forestry nonpoint sources under the Forest Practices Act are presumed to meet water quality standards and that forest operations are subject to load allocations in TMDLs.[185] Furthermore, the rule clarifies the water quality regulatory requirements for forest management activities in Oregon.

This rule states that certain activities related to logging and forest management are generally deemed not to cause violations of water quality standards if best management practices and control measures under the Forest Practices Act are followed. The CWA requires NPDES permits for discharges from point sources and compliance with that permit, but does not require that states develop enforceable regulatory programs for nonpoint sources. Whether a State chooses to make water quality standards directly enforceable for nonpoint sources is solely a matter of state law and the State has discretion as to how it enforces its laws. This provision is applicable only to nonpoint sources and their compliance with water quality standards and TMDL load allocations. As such EPA does not consider this provision to be a water quality standard under section 303(c) of the CWA. Water quality standards are provisions of State or Federal law which consist of a designated use or uses for waters of the United States, and water quality criteria necessary to protect the uses (40 CFR 131.3(i)).

[185] ODEQ. June 7, 2011. *Executive Summary. Human Health Toxics Rulemaking.* Oregon Department of Environmental Quality. page 9. Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/humanhealth/rulemaking/ExecSummary.pdf

In addition, this provision does not include language that has the effect of changing the level of protection provided by Oregon's water quality criteria and therefore does not constitute a new or revised water quality standard. The provision defines how logging and forest management nonpoint sources activities must control their discharges in order to comply with Oregon's water quality standards, but it does not establish or revise any of the components of the water quality standards themselves.

Therefore, this provision is not considered a water quality standard subject to EPA review and approval and EPA is taking no action to approve or disapprove this provision.

B. *OTHER IMPLEMENTATION OF WATER QUALITY*

Oregon's revisions to implementation provisions found at OAR 340-041-0061(9)(a)(E), (10), and (11) are shown in underline/strikeout format below. Underlined text represents added text, while text with a line through the middle (strikeout) represents deleted text. The revised rule at (9)(a)(E) corrects an error to the cross-reference to the antidegradation policy. The revised rules in (10) and (11) explain how the mechanisms for forestry and agricultural nonpoint sources work to meet water quality standards and the total maximum daily load (TMDL) load allocations under the Forest Practices Act and Agriculture Water Quality Management Act.[186] Finally, the revised rule contains revised paragraph numbers for subsections (2) through (16) as the variance rule in section (2) was moved to OAR 340-041-0059.

(9)(a)(E) Mass loads assigned as described in paragraphs (B) and (C) of this subsection will not be subject to OAR 340-041-0004(~~9~~7);

Acknowledgement of OAR 340-041-0061(9)(a)(E)
EPA acknowledges the changed cross-reference located in OAR 340-041-0061(9)(a)(E) Other Implementation of Water Quality Criteria. Water quality standards are provisions of State or Federal law which consist of a designated use or uses for waters of the United States, and water quality criteria necessary to protect the uses (40 CFR 131.3(i)). EPA has determined this provision is not a WQS. Instead, the provision at section (9)(a)(E) is a NPDES permitting implementation provision and corrects an error to a regulatory citation to the antidegradation policy.

*(10) Forestry on state and private lands. ~~For~~ Nonpoint sources of pollution from forest operations on state or private lands~~, water quality standards~~ are ~~intended to be attained and are implemented through~~ subject to best management practices and other control ~~mechanisms~~ measures established ~~under the Forest Practices Act (ORS 527.610 to 527.992) and rules thereunder, administered~~ by the Oregon Department of Forestry~~. Therefore,~~ under the Forest Practices Act, (ORS 527.610 to 527.992) Such forest operations ~~that are~~ when conducted in good faith compliance with the Forest Practices Act requirements are ~~(except for the limits set out in ORS 527.770) deemed in compliance with this division. DEQ will work with the Oregon~~

[186] ODEQ. June 7, 2011. *Executive Summary. Human Health Toxics Rulemaking.* Oregon Department of Environmental Quality. page 9. Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/humanhealth/rulemaking/ExecSummary.pdf

~~*Department of Forestry to revise the Forest Practices program to attain water quality standards.*~~ *generally deemed not to cause violations of water quality standards as provided in ORS 527.770. Forest operations on state and private lands are subject to load allocations under ORS 468.110 and OAR 340, Division 42, to the extent necessary to implement the federal Clean Water Act.*

(11) ~~*Agricultural water quality management plans to reduce agricultural nonpoint source pollution are developed and implemented by the Oregon Department of Agriculture (ODA) through a cooperative agreement with the department to implement applicable provisions of ORS 568.900 to 568.933 and 561.191. If the department has reason to believe that agricultural discharges or activities are contributing to water quality problems resulting in water quality standards violations, the department may consult ODA. If water quality impacts are likely from agricultural sources and the department determines that a water quality management plan is necessary, the director may write a letter to the director of the ODA requesting that such a management plan be prepared and implemented to reduce pollutant loads and achieve the water quality criteria.*~~ *In areas subject to the Agricultural Water Quality Management Act, the Oregon Department of Agriculture (ODA) under ORS 568.900 to 568.933 and 561.191 develops and implements agricultural water quality management area plans and rules to prevent and control water pollution from agricultural activities and soil erosion on agricultural and rural lands. Area plans and rules must be designed to achieve and maintain water quality standards. If the department determines that the area plan and rules are not adequate to achieve and maintain water quality standards, the department will provide ODA with comments on what would be sufficient to meet WQS or TMDL load allocations. If a resolution cannot be agreed upon, the department will request the Environmental Quality Commission (EQC) to petition ODA for a review of part or all of water quality management area plan and rules. If a person subject to an ODA area plan and implementing rules causes or contributes to water quality standards violations, the department will refer the activity to ODA for further evaluation and potential requirements.*

Acknowledgement of OAR 340-041-0061(10) and (11)

EPA acknowledges the revised language in OAR 340-041-0061(10) and (11) Other Implementation of Water Quality Criteria. The revised rules in (10) and (11) explain how state rules for forestry and agricultural nonpoint sources are to be implemented consistent with water quality standards and the total maximum daily load (TMDL) load allocations.[187] These provisions set forth the extent to which Oregon requires nonpoint sources of pollution from forest operations under the Forest Practices Act and agricultural activities under the Agricultural Water Quality Management Act to control their discharges in order to protect water quality.

These rules state that forest operations and agricultural activities generally will not be deemed to cause violations of water quality standards if best management practices and control measures under the Forest Practices Act and water quality management area plans under the Agricultural Water Quality Management Act are followed and identify the process to be used when water quality concerns arise. Thus, the rule clarifies mechanisms for WQS implementation and

[187] ODEQ. June 7, 2011. *Executive Summary. Human Health Toxics Rulemaking.* Oregon Department of Environmental Quality. page 9. Available at: http://www.deq.state.or.us/wq/standards/docs/toxics/humanhealth/rulemaking/ExecSummary.pdf

compliance.

Whether a State chooses to make water quality standards directly enforceable for nonpoint sources is solely a matter of state law. The CWA requires NPDES permits for discharges from point sources and compliance with that permit, but does not require that states develop enforceable regulatory programs for nonpoint sources. These provisions are applicable only to nonpoint sources and how they comply with water quality standards and TMDL load allocations and as such are not water quality standards under section 303(c) of the CWA. Water quality standards are provisions of State or Federal law which consist of a designated use or uses for waters of the United States, and water quality criteria necessary to protect the uses (40 CFR 131.3(i)).

In addition, these provisions do not include language that has the effect of changing the level of protection provided by Oregon's water quality criteria and therefore do not constitute new or revised water quality standards. The provisions define the extent to which forest operations and agricultural operations that result in nonpoint source discharges must control their discharges in order to comply with Oregon's water quality standards, but they do not establish or revise any of the components of the water quality standards themselves.

Therefore, these provisions are not considered water quality standards subject to EPA review and approval and EPA is taking no action to approve or disapprove the provisions.

Acknowledgment of Section Renumbering in OAR 340-041-0061(2)-(16)
The revised rule contains revised paragraph numbers for subsections OAR 340-041-0061(2) through (16) as the variance rule in section (2) was moved to OAR 340-041-0059. EPA acknowledges the renumbering for subsections that were previously approved by EPA under 303(c) of the CWA as a non-substantive formatting change which does not require EPA action.

RESPONSES TO PUBLIC COMMENTS RELATING TO MAINE'S JANUARY 14, 2013, SUBMISSION TO EPA FOR APPROVAL OF CERTAIN OF THE STATE'S NEW AND REVISED WATER QUALITY STANDARDS (WQS) THAT WOULD APPLY IN WATERS THROUGHOUT MAINE, INCLUDING WITHIN INDIAN TERRITORIES OR LANDS

January 30, 2015

INTRODUCTION

This document contains responses to the significant comments EPA received concerning Maine's January 14, 2013, submittal to EPA Region 1, in which Maine proposed certain revisions to its surface water quality standards (WQS or standards) pursuant to section 303(c) of the federal Clean Water Act (CWA). EPA Region 1 solicited comments from the public specifically relating to the aspect of Maine's request that EPA approve the State's WQS revisions to apply in waters within Indian territories or lands (hereinafter referred to as "Indian lands") located in Maine. It is important to note that, in the Agency's judgment, the public comments EPA received in relation to Maine's January 14, 2013, submission raised both significant legal and technical questions, which extend equally to the EPA's decisions addressed in its letter approving and disapproving certain of Maine's standards in waters within Indian lands. EPA's responses to the comments below will be presented in the context of Maine's January 14, 2013, submittal, but EPA applied the principles articulated in this document to our decision on all the WQS the State has asked the Agency to approve for waters in Indian lands.

Maine's 2013 submittal specifically included a request that EPA approve the WQS revisions as applying to all waters throughout the State of Maine, including to waters within Indian lands located within the State. Neither the CWA (and its implementing regulations), nor the federal Administrative Procedure Act (APA), specify any notice and comment requirements that EPA must satisfy before approving or disapproving a state's new or revised WQS submittal. EPA's longstanding position has been that it is sufficient for EPA to review the adequacy of a submitting state's public process for revisions to its WQS and to rely on that process if it adequately notified and involved the public. See 40 C.F.R. §§ 131.5(a)(3), 131.6(e), and 131.20(b) and 40 CFR part 25 for public participation requirements relevant to state adoption of WQS. The State of Maine's Department of Environmental Protection (ME DEP) provided public notice and an opportunity to comment (including a public hearing), at the state level, on the WQS revisions included in the State's January 14, 2013, submittal to EPA.

However, while ME DEP provided public notice of the substance of the WQS revisions as they would apply generally in the State, the State's notice may not have sufficiently informed the public that ME DEP intended to seek EPA's approval of these revisions to apply in waters within Indian lands. To ensure adequate public participation and development of a complete administrative record for EPA's subsequent decisions, EPA decided to seek further comment due to the possibility that the State's notice may not have been sufficiently clear to some members of the public about the State's intent to apply its WQS revisions to waters in

Indian lands. Accordingly, in August of 2013, EPA solicited additional comment on the approvability of these WQS for waters in Indian lands. In particular, EPA sought comments regarding the State's legal authority to establish WQS in waters in Indian lands under the Maine Implementing Act (MIA, 30 M.R.S.A § 6401, et seq.) as ratified by the Maine Indian Claims Settlement Act (MICSA, 25 U.S.C. § 1721, et seq.) and on whether these WQS revisions would adequately protect water quality in Indian lands.

This responses to comments (RTC) document contains EPA's responses to the significant comments EPA received. We reiterate that EPA lawfully used its discretion to seek additional public input to better inform its approval/disapproval decision and to ensure that any potential flaws in the State's public process are remedied. There is no legal prohibition in the CWA, the Administrative Procedure Act, or any other applicable legal requirement that precludes EPA from seeking such comment to better inform its decision when the administrative record before it is potentially incomplete. Adequate public participation in the context of a federal agency's decision-making process, where regulatory decisions are being made that potentially impact the public or where there is significant public interest, is a fundamental aspect of administrative law in our system of government. Furthermore, we emphasize that EPA's having sought public comment in this one instance, in addition to the State's public participation process, does not in any way set a legal or policy precedent that could in any way be used by any person in the future to require EPA to solicit public comment on any State's WQS submission for EPA review and approval or disapproval. As explained throughout EPA's RTC document and Decision Support Document related to EPA's decision on Maine's WQS submissions, the Agency has been presented with a unique set of circumstances due to the highly atypical legal framework that MIA and MICSA establish for Indian lands in Maine; circumstances which do not exist in other areas of the United States.

The WQS revisions in Maine's 2013 submittal include five new or revised WQS criteria, including three human health criteria (HHC) for the allowable levels or concentrations in surface waters for three toxic pollutants: arsenic, acrolein, and phenol. For arsenic, ME DEP changed the cancer risk level, fish consumption rate, and percentage of inorganic arsenic (relative to organic arsenic) used in calculating the criteria for *inorganic* arsenic, which is the form of arsenic that is harmful to human health. For acrolein and phenol, ME DEP updated its ambient water quality criteria consistent with updates EPA has made to its recommended criteria for those two pollutants based on newly published reference doses.

This RTC document is a source of information about EPA's decision on Maine's submissions, and should be read in conjunction with EPA's letter communicating its decision on these and other WQS to Maine DEP and with the accompanying Decision Support Document; the latter focusing specifically on, among other things, the question whether Maine has adequate legal authority to establish WQS in waters located in Indian lands and on whether Maine's standards meet the requirements of the CWA. This RTC document incorporates the terminology and reasoning presented in those other two documents, while expanding on it in certain respects to address the more specific individual comments EPA received. This responsiveness summary digests and organizes the significant comments received. Opposing comments concerning each issue were grouped together where EPA received comments on both sides of an issue. We received

comments from the State of Maine's Office of the Attorney General, the Commissioner of the ME DEP, and from three of the four federally recognized Indian Tribes in Maine – the Penobscot Nation, the Houlton Band of Maliseet Indians, and the Aroostook Band of Micmacs; no other parties provided comments to EPA.

The particular language used in the summary of each issue presented below may derive primarily from one set of comments. But this does not mean that EPA has not considered each of the comments received on the issue in question. EPA did not limit its analysis of the comments submitted to the digest presented below, and we have reviewed each comment in its entirety. This outline and its digest of the comments are simply designed to structure our responses and make them more accessible to the interested public, while addressing the substantive content of all of the significant comments received.

Comments and Responses to Comments on EPA's 2003 NPDES Program Approval

Some of the key issues relevant to Maine's WQS submission were also the subject of public comments EPA received in the context of EPA's 2003 action on Maine's National Pollution Discharge Elimination System (NPDES) program application. In fact, the Penobscot Nation and the Houlton Band of Maliseet Indians specifically incorporated by reference into their comments on Maine's WQS submission those Tribes' earlier comments on Maine's NPDES program application. Consequently, EPA's responses today to some of those same issues, or at least to certain aspects of those same issues, parallel EPA's earlier responses to comments received on Maine's NPDES program application. For completeness and efficiency, rather than repeat in this RTC document all of EPA's responses to the Tribes' comments on Maine's NPDES program, EPA hereby incorporates by reference its responses to public comments received on Maine's NPDES program application, but only to the extent those earlier responses are consistent with, and are not superseded by, the First Circuit's decision in *Maine v. Johnson*, 498 F.3d 37 (1st Cir. 2007), and the responses expressly articulated in this document and in EPA's accompanying Decision Support Document.

Federal Indian Common law cited by Maine Indian Tribes and Protecting the Tribes' Sustenance Fishing

As discussed in detail below in EPA's specific responses to specific public comments, many of the Maine Tribes' (primarily the Penobscot Nation's) legal arguments opposing Maine's jurisdiction to establish WQS in waters within Indian lands included citations to federal case law. EPA addresses that case law in more detail later in this RTC document. Many of the Tribes' comments rely heavily on the case law. It is therefore worth noting here in summary, for purposes of orienting the reader to what follows, that EPA found many of those cited cases compelling from the standpoint of supporting the proposition that the CWA requires protection of the quality of the water that supports the Maine Tribes' sustenance fishing practices, culture and lifestyle. The cases cited also represent a strong collection of federal Indian common law on subjects such as the federal government's trust responsibility to Indian tribes, the sovereign status of Indian tribes in

the United States, and the canons of statutory construction used by the federal courts to interpret treaties and statutes addressing the rights of Indian tribes.

With one very important and dispositive exception that arises due to the unique nature and jurisdictional provisions of the settlement acts[1], EPA does not disagree that the cases cited by the Maine Tribes articulate valid and accurate general principles of federal Indian common law. In EPA's view, however, none of these cases answers or is dispositive of the question whether Maine has legal jurisdiction to establish WQS in waters within Indian lands in Maine, but that is precisely the argument that the Maine Tribes frequently assert is supported by those cases. As EPA explains in this RTC document and in its Decision Support Document, the settlement acts clearly undermine the Maine Tribes' use of those cases to oppose Maine's assertion of jurisdiction. Moreover, EPA reads the vast majority of the Maine Tribes' comments as taking the position that protection of their sustenance fishing practices and a legal conclusion that Maine has jurisdiction to establish WQS in waters within Indian lands in Maine are mutually exclusive. The inaccuracy of that position is demonstrated by EPA's Decision Support Document. That is, EPA has determined that Maine has jurisdiction to establish WQS in waters within Indian lands in Maine and that EPA has no discretion to find otherwise given the settlement acts. At the same time, however, EPA has also disapproved certain of Maine's WQS as not being adequately protective of the applicable CWA designated uses, which encompass the Maine Tribes' sustenance fishing practices. Consequently, the jurisdictional scheme embodied in the settlement acts renders those cases inapposite to EPA's decision. In addition, to the extent that the Maine Tribes cite

---

[1] Settlement Acts in Maine

MIA and MICSA

In 1980, Congress passed the Maine Indian Claims Settlement Act (MICSA), which resolved litigation in which the Southern Tribes asserted land claims to a large portion of the State of Maine. 25 U.S.C. §§ 1721, et seq. MICSA ratified a state statute passed in 1979, the Maine Implementing Act (MIA), which was designed to embody the agreement reached between the State and the Southern Tribes. 30 M.R.S. §§ 6201, et seq. In 1981, MIA was amended to include provisions for land to be taken into trust for the Houlton Band of Maliseet Indians, as provided for in MICSA. 30 M.R.S. § 6205-A, 25 U.S.C. § 1724(d)(1). Since it is Congress that has plenary authority as to federally recognized Indian Tribes, MIA's provisions concerning jurisdiction and the status of the Tribes are effective as a result of, and consistent with, the Congressional ratification in MICSA.

MSA and ABMSA

In 1989, the Maine legislature passed the Micmac Settlement Act (MSA) to embody an agreement as to the status of the Aroostook Band of Micmacs. 30 M.R.S. §§ 7201, et seq. In 1991, Congress passed the Aroostook Band of Micmacs Settlement Act (ABMSA), which ratified the MSA. 25 U.S.C. § 1721, Act Nov. 26, 1991, P.L. 102-171, 105 Stat. 1143. One principal purpose of both statutes was to give the Micmacs the same settlement that had been provided to the Maliseets in MICSA. See ABMSA § 2(a)(4) and (5). In 2007, the Federal Court of Appeals for the First Circuit confirmed that the Micmacs and Maliseets are subject to the same jurisdictional provisions in MICSA. Aroostook Band of Micmacs v. Ryan, 484 F.3d 41 (1st Cir. 2007).

Where appropriate, this document will refer to the combination of MICSA, MIA, ABMSA, and MSA as the "settlement acts."

to the First Circuit's opinions interpreting MIA and MICSA, EPA's RTC document explains why those cases also do not support the Tribes' assertion that Maine does not have jurisdiction.

Two examples illustrate this general point. While EPA agrees that *U.S. v. Adair*, 723 F. 2d 1394 (9th Cir. 1984); *Winters v. United States*, 207 U.S. 564 (1908); and *Washington v. Washington State Commercial Passenger Fishing Ass'n*, 443 U.S. 658 (1979), may be cited in support of arguments that address tribal sustenance fishing practices and the associated quantity and/or quality of the waters that support those fishing practices, nothing in those cases does or can supersede or affect the jurisdictional arrangement embodied in the settlement acts. Similarly, while *Wisconsin v. E.P.A.*, 266 F. 3d 741 (7th Cir. 2001); *State of Washington, Dep't of Ecology v. U.S.E.P.A.* 725 F. 2d 1465 (9th Cir. 1985); *Merrion v. Jicarilla Apache Tribe*, 455 U.S. 130 (1982); *New Mexico v. Mescalero Apache Tribe*, 462 U.S. 324 (1983); *Oklahoma Tax Comm'n v Sac & Fox Nation*, 508 U.S. 114 (1993); and *Three Affiliated Tribes of Ft. Berthold v. Wold Eng'g*, 476 U.S. 877 (1986), may each stand for or support in some manner the proposition that states generally lack jurisdiction in Indian reservations absent express authorization by Congress, those cases cannot properly be cited to support an argument that Maine has no jurisdiction to apply state law in Indian lands in Maine, because Congress expressly granted Maine such authority in the settlement acts.

EPA's Specific Responses

I. Maine's legal authority or jurisdiction to establish WQS in Indian waters.

A central issue raised by Maine's WQS submission is whether Maine has the necessary legal authority, or jurisdiction, to establish WQS applicable to surface waters (both reservation and trust land waters) situated in Indian lands located within the exterior boundaries of the State of Maine. EPA received many comments about this legal issue from three of the Maine Indian Tribes and from the State of Maine.

EPA's Decision Support Document contains, among other things, a legal analysis of the specific statutory provisions of the settlement acts and their respective legislative histories. That analysis supports EPA's legal determination that Maine has the necessary legal authority to establish WQS in surface waters located in Indian lands in Maine. While the legal analysis constitutes EPA's reading of the language and legislative history of the statutes themselves, it does not always address directly the way in which the Maine Tribes' articulated their jurisdictional arguments opposing Maine's legal authority to establish WQS in waters in Indian lands in Maine.

The reason for that is that the Tribes' public comments on the jurisdictional question rely, to a great extent, on two concepts derived from principles of

federal Indian common law, i.e., the federal government's trust relationship to Indian tribes generally and the concept of inherent tribal sovereignty. It is for that reason that EPA's responses below to the Maine Tribes' public comments on the jurisdictional question principally are organized around the way in which the Tribes specifically crafted their jurisdictional arguments, i.e., primarily in terms of the federal trust responsibility and the concept of inherent tribal sovereignty. After addressing those comments from the Tribes, EPA's responses also address the State of Maine's comments on the federal trust responsibility and tribal sovereignty.

A. Does the federal trust responsibility affect or determine whether Maine has jurisdiction to establish WQS in waters within Indian lands?

Many of the Tribes' comments relating to whether Maine has jurisdiction focused on the federal trust responsibility to the Maine Indian Tribes. The Tribes asserted that the EPA's trust responsibility obligates EPA to conclude that Maine does not have jurisdiction. Examples of those comments are identified below first, followed by examples of the State of Maine's comments about the trust. EPA's responses to the comments are provided after the listed representative examples received from the parties who commented.

Representative examples of comments from Maine's Indian Tribes

1. EPA's federal trust responsibility and duties under the CWA preclude EPA from finding that Maine has jurisdiction to promulgate WQS applicable to waters in Indian lands.

2. EPA's Constitutionally-based trust responsibility and federal Indian common law require EPA to reject Maine's WQS application as to waters within Indian lands.

3. EPA's trust responsibility requires it to protect the Tribes' natural resources and sovereign authority against state encroachment.

4. Approval of Maine's WQS in waters within Indian lands would be an unlawful abdication of EPA's trust responsibility because it would empower Maine to control tribal resources when Maine does not even recognize the existence of the Penobscot Nation's sustenance fishery.

5. The authority to establish WQS under the CWA applicable to the Southern Tribes' sustenance fishery established under MIA and MICSA must reside with EPA in the first instance, as the Tribes' trustee, or, eventually with the Penobscot Nation.

6. Congress acquired the Houlton Band of Maliseet Indians' trust lands for the purpose of preserving the Tribe's riverine culture, including traditional fishing, hunting and gathering activities. EPA therefore has a trust responsibility to protect the quality of the waters in the Tribes' lands.

Representative examples of comments from the State of Maine

1. The concept of a federal "trust responsibility" to Indian tribes does not apply under the CWA because there are no substantive or procedural requirements written into the CWA that anyone may review to assess whether a particular action that EPA takes complies with a "trust responsibility." EPA cannot establish procedural or substantive requirements, pursuant to a trust responsibility, that are not already embodied in the CWA. The federal trust responsibility toward Indian tribes in Maine is fully and exclusively expressed through the substance of the statutes and regulations that an agency is charged with administering.

2. Even if the concept of a federal "trust responsibility" otherwise would apply toward the Maine Indian Tribes under the CWA, Title 25 U.S.C. section 1725(h) of MICSA makes clear that federal Indian law that would otherwise affect or preempt the jurisdiction of Maine relating to "environmental matters" has no effect in Maine.

3. Reservation lands in Maine are not held in trust by the federal government.

EPA's responses to comments concerning the general nature of the federal trust responsibility to the Maine Tribes in this case and the extent to which that trust responsibility is relevant or dispositive to the question whether Maine has adequate legal authority or jurisdiction to establish WQS for surface waters within Indian lands located in Maine

As EPA previously noted in its responses to public comments received on Maine's NPDES program application in 2003, the commenters' arguments (on both sides) regarding the federal government's trust responsibility to the Maine Indian Tribes do not accurately articulate the scope of the trust responsibility as relevant to EPA's decisions in this matter; and, more specifically, do not accurately articulate the scope of the trust responsibility to the Maine Indian Tribes as EPA exercises its authorities under the CWA.

First, it is important to note that the existence, operation and extent of the federal trust responsibility to the Maine Indian Tribes under the United States Constitution and

applicable federal statutory and common law cannot be determined in isolation from the allocation of legal jurisdiction among the tribal, State, and federal governments under the the settlement acts. For example, the jurisdictional framework set forth in the MIA was ratified by Congress in MICSA, and it is well-established law that Congress has plenary authority to legislate in the area of Indian affairs. EPA does not have the legal authority to alter the jurisdictional arrangement ratified by Congress in the settlement acts, either pursuant to the trust responsibility to the Maine Indian Tribes in relation to the CWA or pursuant to any other law.

At the same time, however, EPA still must consider the trust responsibility toward the Maine Indian Tribes when implementing the CWA, but must do so within the bounds of the jurisdictional scheme that Congress ratified in the settlement acts and the requirements of the CWA. It is for this reason that the federal trust cases cited by the Penobscot Nation in its comments are inapposite, i.e., none of these cases discusses the federal trust obligation against the backdrop of statutes such as the settlement acts, and they cannot properly be cited for the proposition that the trust obligation should or does override Congress' jurisdictional arrangement in those settlement acts such that Maine cannot establish WQS in waters in Indian lands in Maine. The cases cited by the Tribe include, e.g., *HRI, Inc. v. E.P.A.*, 198 F.3d 1224 (10th Cir. 2000); *Cherokee Nation v. State of Georgia*, 30 U.S. 1 (1831); *United States v. Mitchell (Mitchell II)*, 463 U.S. 206 (1983); *Seminole Nation v. United States*, 316 U.S. 286 (1942).

As EPA earlier explained in its responses to public comments on EPA's proposed approval of Maine's NPDES program, the trust responsibility towards the Maine Indian Tribes continues to operate in Maine in relation to the CWA, even under the settlement acts, but that the trust's reach and effect are more limited than might typically be the case in other states. In other words, the settlement acts significantly revise in Maine the jurisdictional arrangement that more typically exists elsewhere in the United States among Indian tribes, a state, and the federal government. EPA notes that the Penobscot Nation's comments cite to a number of federal court opinions that address the trust. See for example, *Worcester v. Georgia*, 31 U.S. 515 (1832); *Oneida County v. Oneida Indian Nation*, 470 U.S. 226 (1985); and *State of Washington, Dep't of Ecology v. U.S. E.P.A.*, 752 F.2d 1465 (9th Cir. 1985); *HRI, Inc. v. E.P.A.* 198 F.3d 1224 (10th Cir. 2000); *Cherokee Nation v. State of Georgia*, 30 U.S. 1 (1831); *United States v. Mitchell (Mitchell II)*, 463 U.S. 206 (1983); *Seminole Nation v. United States*, 316 U.S. 286 (1942). These cases and others of their kind, which may have addressed the federal trust, are not relevant to the analysis of whether Maine has jurisdiction to establish WQS in waters within Indian lands in Maine because the courts in those cases were not confronted with statutes like the settlement acts which, as EPA said above, alters the typical framework within which the trust operates.

The trust and federal Indian common law

As a threshold matter, when delving into the meaning of the settlement acts, EPA is employing, and always has employed, where appropriate, the interpretive canons of federal Indian common law that derive from the general trust responsibility. For

example, we agree that any ambiguity in the meaning of statutory provisions that attempt to limit tribal sovereignty must be narrowly construed and that such ambiguities must be resolved in favor of the tribes. EPA also agrees that the federal government's general trust responsibility charges the Agency with a responsibility to protect the tribes' inherent sovereignty from unwarranted state encroachment. Adhering to these basic common law elements of the trust doctrine does not run afoul of the settlement acts. They do not result in any alteration of the jurisdictional arrangement ratified in the settlement acts and simply require the Agency to consider the Maine Indian Tribes' interests and welfare consistent with Maine's authority, when EPA implements the CWA. In so doing, we are not thereby affecting or preempting Maine's jurisdiction, but merely applying the law which provides that jurisdiction to the State, and analyzing how that grant of authority from Congress affects EPA's CWA decisions in relation to the Maine Indian Tribes. We note that the First Circuit, without much comment, has invoked the general trust in support of the idea that ambiguities in MICSA should be interpreted in favor of the Tribes where possible. *Penobscot Nation v. Fellencer*, 164 F.3d 706 (1st Cir. 1999).

Consistent with the discussion above, the settlement acts do not create a complete barrier to the application of the federal common law concerning the federal government's trust responsibility in Maine. For one example, MICSA itself provides for certain lands and natural resources to be held in trust for the Penobscot Nation and the Passamaquoddy Tribe (hereinafter referred to for convenience as the "Southern Tribes") and the Houlton Band of Maliseet Indians. 25 U.S.C. § 1724. (Also for convenience, the Houlton Band of Maliseet Indians and the Aroostook Band of Micmacs will hereinafter be referred to as the "Northern Tribes," where appropriate). So the mechanism of having the federal government serve as a trustee for tribal resources operates expressly under MICSA. The trust relationship is also evident elsewhere in the statute, albeit in a more inchoate form. MICSA clearly establishes that the Houlton Band of Maliseet Indians and the two Southern Tribes are federally recognized and it specifically charges them to document how their governments are structured. 25 U.S.C. §§ 1721(a) (3), (4), and (5), 1722(a), (h) and (k), and 1726. The Aroostook Band of Micmacs Settlement Act, Pub. L. 102-171, Nov. 26, 1991, 105 Stat. 143, contains similar provisions at Sec. 2(a)(1) and Sec. 3(1) and Sec. 7.[2] These various provisions are perfectly consistent with EPA's work with the Tribes on a government-to-government basis consistent with a trust relationship with the federal government. In addition, MICSA and MIA combine to explicitly reserve to the Southern Tribes the right to take fish for their individual sustenance within their reservations and to manage their lands and natural resources more generally. 30 M.R.S.A. § 6207(4); 25 U.S.C. § 1724(h); see also 25 U.S.C. § 1724(g)(3) for provisions relating to management of natural resources for the Southern Tribes and for the Houlton Band of Maliseet Indians. In addition, Pub. L. 102-171, Nov. 26, 1991, 105 Stat. 143, contains similar provisions at Sec. 5(b)(3) for the Aroostook Band of Micmacs. The Southern Tribes' statutorily reserved sustenance fishing right establishes an interest that the Southern Tribes have in the protection of specific natural resources, the fish that may

[2] In 1989, the Maine legislature passed the Micmac Settlement Act (MSA) to embody an agreement as to status of the Aroostook Band of Micmacs. 30 M.R.S. §§ 7201 et seq. In 1991, Congress passed the Aroostook Band of Micmacs Settlement Act (ABMSA), which ratified the MSA. 25 U.S.C. § 1721, Act Nov. 26, 1991, P.L. 102-171, 105 Stat. 1143.

sustain them and the water quality on which the quality of that fishing right depends. In addition, as articulated in EPA's Decision Support Document, EPA has determined that Congress's intent in the settlement acts was to establish a land base for the four federally recognized Maine Tribes permitting them to sustain their unique culture and lifestyle practices. The legislative record regarding the trust land provisions in MIA, MICSA, MSA and ABMSA demonstrate Congress's intent to provide the Tribes with the opportunity to exercise their sustenance life ways, including sustenance fishing in waters of tribal trust lands. For additional discussion relevant to the Maine Tribes' sustenance fishing practices, see EPA's Decision Support Document and the Department of the Interior's (DOI) January 30, 2015 letter to EPA. In sum, it is relatively easy to conclude that all the elements of a trust relationship exist under the settlement acts for the four federally recognized Maine Tribes, consistent with the trust doctrine as it has been developed in the federal common law. The Tribes are federally recognized; the Tribes have an interest in specific natural resources which the CWA charges EPA to protect; and the federal government, including EPA, has a responsibility to consider the Tribes' interests, consistent with applicable law.

As stated earlier, however, the existence of this trust relationship does not and cannot legally alter the jurisdictional arrangement Congress ratified in the settlement acts. The trust by itself does not and cannot compel, or constitute an independent basis for, EPA to disapprove Maine's surface WQS as applied in waters within Indian lands in Maine on the grounds that the State does not have jurisdiction to do so where, in fact, the settlement acts and their jurisdictional provisions actually *do* provide Maine with the requisite legal authority. Accordingly, EPA disagrees with the Penobscot Nation's comments that cite to and characterize several of the First Circuit's legal opinions as providing a basis for applying the full suite of federal Indian common law principles and the trust *prior to* analyzing MIA and MICSA.. See Page 11 of the Penobscot Nation's comments, citing *Pènobscot Nation v. Fellencer*, 164 F.3d 706 (1st Cir. 1999) and *State of Rhode Island v. Narragansett Indian Tribe*, 19 F.3d 685 (1st. Cir. 1994).

Tribal comments that the trust obligates EPA to find that Maine does not have jurisdiction because the trust requires EPA to protect the Tribes from state encroachment

Outside Maine, EPA has typically excluded Indian country from EPA-approved state environmental programs based on the absence of state jurisdiction in Indian country. See, e.g., *HRI, Inc. v. EPA*, 198 F.3d 1224, 1247 (2000). By contrast, in Maine, the jurisdictional provisions of the settlement acts provide the State jurisdiction to administer WQS in waters in Indian lands. Moreover, MICSA's savings clauses (see more detailed discussion in EPA's Decision Support Document), in effect, prevent any federal law applicable to Indians from rewriting those jurisdictional provisions (*i.e.*, from preempting or affecting the application of Maine law) without explicit Congressional action made specifically applicable in Maine. Therefore, as discussed above in this RTC document, EPA has carefully considered how the trust operates consistent with MIA, MICSA and the CWA in the context of Maine's surface WQS submission. EPA is not relying on the trust to determine whether Maine has jurisdiction to establish water quality standards for waters in Indian lands. As discussed elsewhere in this RTC document, the jurisdictional

scheme established in the settlement acts bears on how the Agency implements our decision consistent with the trust responsibility.

However, notwithstanding that Maine does have jurisdiction to establish surface WQS that apply in waters within Indian lands in Maine, EPA's implementation role under the CWA and the trust responsibility to the Tribes nonetheless require EPA to consider the effects that Maine's WQS would have on the Maine Indian Tribes' interests and welfare as we exercise our existing CWA authority. This is not different in kind from the way in which the CWA generally obligates EPA to consider and comply with the requirements of the CWA in assessing impacts of state and EPA decisions on the interests and welfare (in this instance human health, specifically) of persons in light of the goals of the CWA. In other words, EPA must evaluate the adequacy of Maine's WQS as they apply to waters within Indian lands using a standard or methodology that is consistent with the requirements of the CWA. The trust responsibility to the Maine Indian Tribes together with the Agency's authorized means of implementing the CWA require EPA to consider impacts on the Tribes in relation to protections of tribal resources that are addressed by the settlement acts and the CWA. See e.g., the discussion in EPA's Decision Support Document regarding the "designated use" of sustenance fishing and its protection under the CWA.

In addition, as we will discuss further below, the CWA assigns EPA a very important role in overseeing state surface WQS programs. Therefore, EPA's decision finding that Maine has the authority to establish WQS for waters within Indian lands will not prevent EPA from continuing to work with the Tribes and will not prevent EPA from communicating with all interested parties to improve coordination in protecting water quality in the surface waters in question. In fact, EPA's decision letter to ME DEP is a concrete example and manifestation of how CWA requirements provide for EPA's protection of the Maine Indian Tribes' interests and welfare in a way that is consistent with the jurisdictional framework established by Congress in Maine through the settlement acts and with the trust responsibility to the Tribes.

Maine's comments about the trust

As EPA earlier articulated in its responses to comments on Maine's NPDES program application in 2003, EPA disagrees with Maine's assertion that the federal government has no trust relationship or responsibility with respect to the Southern Tribes' reservations. While it is true that Congress curtails the applicability of the Non-Intercourse Act to the Penobscot Nation and the Passamaquoddy Tribe in MICSA Section 1724(g)(1), Congress also created similar responsibilities in Sections 1724(g)(2) and (3) that apply post-MICSA. Section 1724(g)(3) requires the approval of the Secretary of the Interior for six specific types of land transfers within the Southern Tribes' "territories,"

which have been defined, in MIA,[1] to include the reservations.[2] See 25 U.S.C. §1724(g)(3). Section 1724(g)(2) states that "any transfer of land or natural resources within Passamaquoddy Indian Territory or Penobscot Indian Territory ... shall be void ab initio and without any validity in law or equity." 25 U.S.C. §1724(g)(2). This language is very similar to that of the Non-Intercourse Act which states that no transfer of land or title to land from any Indian nation or Tribe "shall be of any validity in law or equity, unless the same be made by treaty or convention entered into pursuant to the Constitution." 25 U.S.C. §177. More importantly, Congress intended for these MICSA sections to replace the Non-Intercourse Act as a source of federal trust responsibility. Both houses of Congress, in responding to concerns about federal protection of the Southern Tribes, acknowledged that "[o]ne of the most important federal protections is the restriction against alienation of Indian lands without federal consent. [The sections that eventually became Sections 1724(g)(2) and (3)] specifically provide] for such a restriction and, as was made clear during the hearings, this provision is comparable to the Indian Non-Intercourse Act, 25 U.S.C. §177." H.R. DOC. NO. 96-1653, at 15 (1980); S.R. DOC. NO. 96-957 at 15(1980). As Congress confirms, Sections 1724(g)(2) and (3) essentially replace the Non-Intercourse Act as a source of federal trust responsibility. Reading MICSA as Congress intended would mean that the reservations are subject to a federal trust responsibility by nature of their inclusion as delineated parts of Penobscot Indian Territory and Passamaquoddy Indian Territory. See 25 U.S.C. §§1724(g)(2) and (3); 30 M.R.S.A. §6205.

Additionally, there are other sources of the federal trust relationship with respect to the reservations, as well as to the Southern and Northern Tribes' trust lands. It is obvious that the reservation lands are central to federally protected rights reserved for the Penobscot Nation and the Passamaquoddy Tribe. MICSA federally recognizes the Passamaquoddy Tribe, the Penobscot Nation, and the Houlton Band of Maliseet Indians. 25 U.S.C. §1721. The Aroostook Band of Micmacs Settlement Act, Pub. L. 102-171, Nov. 26, 1991, 105 Stat. 143, contains a similar provision at Sec. 2 (a)(1). In addition, MIA reserves, for the Southern Tribes, hunting and fishing rights within their reservations. 30 M.R.S.A. §6207(4). Both the House and Senate Committee reports relating to MICSA confirm that Congress intended for the Southern Tribes to have "the permanent right to control hunting and fishing ... within their reservations" according to the terms set out in MIA. H.R. DOC. NO. 96-1653, at 17 (1980); S.R. DOC. NO. 96-957 at 16 (1980). MICSA also reserves, for the Penobscot Nation and the Passamaquoddy Tribe, the right to manage their natural resources. 25 U.S.C. §1724(h). See also 25 U.S.C. § 1724(g)(3) for provisions relating to management of natural resources for the Southern Tribes and for the Houlton Band of Maliseet Indians. In addition, Pub. L. 102-171, Nov. 26, 1991, 105 Stat. 143, contains similar provisions at Sec. 5(b)(3) for the Aroostook Band of Micmacs. Therefore, it is reasonable to conclude that Congress reserved the trust lands in order to preserve the Maine Tribes' cultural activities, in

---

[1]The Maine statute that is ratified by MICSA. See 30 M.R.S.A. §6205.

[2]The First Circuit has recognized that the necessity of the signature of the Secretary of the Interior implicates a federal trust responsibility. See Key Bank 112 F.3d. 538 at 553.

particular sustenance fishing, and intended that there be some federal responsibility to protect these activities consistent with the trust responsibility and the requirements of the CWA. For additional discussion relevant to the Maine Tribes' sustenance fishing practices, see EPA's Decision Support Document and DOI's January 30, 2015 letter to EPA.

Ultimately, the CWA provides the relevant authority for EPA to approve or disapprove Maine's surface WQS. 33 U.S.C. §1251 et. seq. As mentioned before, MIA, in 30 M.R.S.A. Section 6207(4), reserves for the Penobscot Nation and the Passamaquoddy Tribe, a sustenance fishing right within their reservations. MICSA, in 25 U.S.C. Section 1724(h), reserves for these Tribes, the right to manage their natural resources. See also 25 U.S.C. § 1724(g)(3) for provisions relating to management of natural resources for the Southern Tribes and for the Houlton Band of Maliseet Indians. In addition, Pub. L. 102-171, Nov. 26, 1991, 105 Stat. 143, contains similar provisions at Sec. 5(b)(3) for the Aroostook Band of Micmacs. Federal common law principles, and Congressional intent, support the position that the Tribes have the ability to practice sustenance fishing in their reservation and trust land waters. Section 303(c) of the CWA specifically gives EPA the authority to ensure that states adopt WQS that are protective of human health and the environment. 33 U.S.C. § 1313(c). EPA is the federal body charged with protecting the very resource that is reserved for Maine's federally recognized tribes, and the CWA gives EPA the authority to oversee state WQS. EPA should account for tribal resources, such as their fishing rights, in exercising that oversight authority, as required by the CWA and consistent with CWA authority and the trust relationship.

Moreover, it is clear that the State of Maine itself contemplated that sustenance fishing practices for the Maine Tribes would be part of the settlement embodied in MIA and subsequently ratified by Congress through MICSA. MIA section 6207(1) provides that "[i]n addition to the authority provided in this subsection, the Passamaquoddy Tribe and the Penobscot Nation, subject to the limitations of subsection 6, may exercise within their respective Indian territories all the rights incident to ownership of land under the laws of the State." The legislative history to MIA clearly indicates that both reservation lands and lands acquired pursuant to MIA after its enactment (trust lands) would enjoy riparian or littoral rights under state law and/or principles of common law.

> The boundaries of the Reservations are limited to those areas described in the bill, but include any riparian or littoral rights expressly reserved by the original treaties with Massachusetts or by operation of state law. Any lands acquired by purchase or trade may include riparian or littoral rights to the extent they are covered by the selling party or included by general principles of law. State of Maine, Maine Legislature, Joint Select Committee on the Indian Land Claims, Report of the Joint Select Committee on Indian Land Claims Relating to LD 2037 "AN ACT to provide for Implementation of the Settlement of Claims by Indians in the State of Maine and to Create the Passamaquoddy Indian Territory and Penobscot Indian Territory." Paragraph 14. 1980.

In support of the State's assertion that no trust relationship exists with respect to the reservations, Maine cites in its comments to a letter from DOI in which that Agency, according to Maine, stated that "fee title to the islands in the Penobscot River was held by Maine in trust for the benefit of the Penobscot Nation" and also cited to *Bangor Hydro-Electric Co.*, 83 FERC ¶ 61,037, 1998 WL292768 (F.E.R.C.). Bangor is a Federal Energy Regulatory Commission (FERC) case regarding the licensing of a hydro-electric project under the Federal Power Act (FPA). 16 U.S.C. §§797, 808. The Penobscot Nation and DOI intervened regarding parts of the Penobscot Nation's lands that were inundated when the project was originally built. Both Bangor and the case upon which it relies, *Federal Power Comm'n v. Tuscarora Indian Nation*, 362 U.S. 99,115 (1960), recognized that the narrow definition of "reservations," which relies on a strictly property oriented understanding of the term, is confined to the FPA. Bangor at 10. Tuscarora plainly says that "the national 'paternal interest' in the welfare and protection of the Indians is not the 'interests in lands owned by the United States' required, as an element of 'reservations' by § 3(2) of the Federal Power Act." Tuscarora, at 115. FERC's assertion in Bangor that "no trust relationship exists" with respect to aboriginal lands, should therefore be understood in this limited capacity, that "no trust relationship exists" for the purposes of the FPA, which requires an interest in lands owned by the United States. Bangor is therefore irrelevant in determining whether there is a federal trust responsibility with respect to the reservations outside the context of the FPA, and therefore does not establish or constitute precedent for the trust responsibility in the context of EPA's implementation of under the CWA.

Tuscarora, however, highlights the difference between 1) a narrow trust responsibility relating to lands "held in trust" and 2) a more general interest in the welfare and protection of the Indians, which points to a general federal trust responsibility, a distinction which is important to this discussion. In federal Indian law, the federal government's general trust responsibility derives from the United States Constitution as further developed by the Supreme Court and other federal courts of the United States, and has become a key aspect of federal Indian common law. The general trust responsibility includes the notion that the federal government has a responsibility, as a general matter, to consider and protect Indian tribes' interests when implementing federal statutes or evaluating decisions that may affect tribes. The federal government's attention to the Indian law canons of statutory construction that have evolved in the common law is an element of this general trust responsibility. The general trust responsibility does not, however, create or establish substantive obligations on the part of the federal government.

The specific trust on the other hand derives from substantive rights established in statutes or regulations that are implemented by the federal government on behalf of Indian tribes. The specific trust is sometimes referred to as an obligation that entails fiduciary duties on the part of the federal government to protect specified tribal rights. As noted in Cohen's Handbook of Federal Indian Law, "[t]he concept of a federal trust responsibility to Indians evolved from early treaties with tribes; statutes, particularly the Trade and Intercourse Acts; and the opinions of the Supreme Court." Cohen explains that the Supreme Court played a major role in defining the relationship between the federal government and Indian tribes. The Court's cases established principles, among others,

such as tribes' right to own land and to set land use policies for those subject to tribal authority, as a federal duty to protect tribal rights including tribal property rights, and as a rationale for canons of construction of various legal documents in light of the federal government's obligation to protect tribal sovereignty and property. See generally section 5.04[3][a] of Cohen's Handbook. In this case, EPA has attended to the general trust responsibility to the Maine Tribes by consulting with them about and understanding their interests in the decisions we are making regarding Maine's WQS in tribal waters, and by implementing the requirements of the CWA that apply to the WQS program. The substance of EPA's review of those WQS is governed by the generally applicable requirements of the CWA that guide EPA's implementation, not by any authority that creates a specific fiduciary obligation to any particular tribe in Maine.

We note that Maine also argues that CWA Section 518, a provision that allows Indian tribes to apply for treatment in the same manner as a state ("treatment as a state" or "TAS") status for purposes of certain CWA programs, is not available to the Tribes in Maine. Accordingly, says Maine, that fact is another reason why EPA has no trust responsibility to the Maine Tribes. EPA responds that its decision on Maine's WQS submissions relates to *Maine's* submission regarding WQS for waters in Indian lands, which is governed by EPA's CWA authorities and responsibilities, and which is unaffected by the separate issue of potential tribal roles under Section 518.[3] Even assuming, only for purposes of responding to Maine's specific comment, that none of the Maine Tribes could qualify for TAS status under CWA Section 518, EPA strongly disagrees that such fact, even if true, would mean that no trust responsibility exists to the Maine Tribes. This RTC document and EPA's Decision Support Document each address and demonstrate EPA's exercise of its CWA authority consistent with the trust responsibility to the Maine Tribes notwithstanding EPA's determination that Maine has adequate legal authority to establish WQS for waters within Indian lands. Maine's comment about CWA section 518 is not relevant to the question of whether a federal trust responsibility exists in Maine under the settlement acts and the CWA.

From the perspective of EPA's earlier description of the general and specific trust responsibilities, and for all of the other reasons discussed above, a federal trust relationship clearly does exist with respect to the Penobscot Nation and Passamaquoddy Tribes' reservations as well as with respect to the Southern and Northern Tribes' trust lands. In summary, although MICSA Section 1724(g)(1) negates the application of the Non-Intercourse Act (a statute often identified as a source of the federal government's specific, as opposed to general, trust responsibility) to these Indians, Congress intentionally included modern non-intercourse provisions in MICSA Section 1724(g)(2) and (3), thereby continuing a federal trust responsibility to the Tribes, and more specifically to their reservations. In addition to these non-intercourse provisions and the common law sources of the federal government's general trust responsibility, the CWA

[3] EPA notes that on October 8, 2014, the Penobscot Nation submitted to EPA an application "to administer water quality standards program and for federal approval of the standards" covering the Maine Stem of the Penobscot River from Indian Island north to the confluence of the east and west branches of the river. Included in the Nation's submission was a TAS application. EPA has not commenced a formal review of the Nation's application, wanting first to address Maine's submissions.

gives EPA the authority to review the State's WQS for consistency with the statute and thereby to utilize its existing authority to protect the reservations and trust lands and the practices and rights associated with them. The relevant settlement acts established trust lands for the Northern and the Southern Maine Tribes, and specifically defined those holdings to include "land or natural resources," which in turn specifically includes "fishing and fishing rights." The settlement acts contain provisions about the potential disposition and management of those resources. The relevant statutory provisions have been cited earlier in this RTC document. So in utilizing our existing CWA authority to protect the Maine Tribes' interests and welfare in relation to the reservations and trust lands, EPA is acting consistently with the settlement acts in Maine and the trust responsibility.

The State also cites in its comments to the First Circuit's opinion in *Nulankeyutmonen Nkihttaqmikon v. Impson*, 503 F.3d 18, 31 (1st Cir. 2007) in support of its contention that EPA has no trust responsibility to the Maine Indians Tribes in making decisions under the CWA. Maine claims that the CWA contains no set of written standards that anyone may review to assess whether a particular implementation decision EPA may render complies with its trust obligation under the CWA. Thus, Maine asserts, an EPA decision that breathes substantive or procedural requirements into the CWA pursuant to its trust relationship, but independent of the CWA, would be arbitrary and capricious, citing to *Michigan v. EPA*, 268 F.3d 1075, 1085 (D.C. Circuit 2001).

EPA agrees with Maine's assertion that any specific requirements that flow from a specific trust relationship must derive their content from and are the product of applicable law, whether treaties, statutes, or regulations. See *Shoshone-Bannock Tribes v. Reno*, 56 F.3d 1482 (D.C. Cir. 1995); *State of California v. Watt*, 668 F.3d 1290, 1324 (D.C. Cir. 1981). However, EPA disagrees with Maine to the extent the State argues that EPA may not, in exercising our existing authority and discretion under the CWA, be informed by our consideration of tribal interests consistent with the general trust relationship. The CWA includes requirements for how EPA must review the adequacy of WQS, and EPA must apply those requirements to Maine's WQS in Indian waters. In considering the impacts of Maine's WQS on the water quality-related interests and welfare of the Indian Tribes in Maine, and most notably on the tribal sustenance fishing practices associated with Indian land waters, EPA is exercising its CWA authority consistent with the trust relationship, the requirements of the CWA, and the settlement acts. EPA's decision that Maine's human health criteria are not sufficiently protective of the CWA "designated uses" that apply to waters in Indian lands is directly tied to a fundamental requirement of the CWA, *i.e.* that WQS must protect designated uses. See EPA's Decision Support Document for a more detailed discussion. In this regard, EPA's decision to disapprove certain of Maine's WQS is entirely consistent with the holding in *Nulankeyutmonen Nkihttaqmikon v. Impson* in the sense that EPA's decision is derived from CWA requirements, provisions in the settlement acts, and Congress's intent to preserve the Tribes' sustenance fishing practices, culture, and lifestyle.

B. Many comments from the Maine Tribes relating to the question of Maine's jurisdiction focused on the concept of the Tribes' inherent sovereignty, and/or the concept of "internal tribal matters" as an explicit expression in MIA/MICSA of the Southern Tribes' retained inherent sovereign status. Maine submitted comments along the lines that MIA/MICSA provide the State with jurisdiction, at least implying that these concepts raised by the Tribes do not function to alter that outcome.

Examples of the Tribes' comments

1. Establishing an appropriate fish consumption rate (FCR) and cancer risk level (CRL) for use in establishing WQS under the CWA are each an "expressly retained sovereign activity."

2. Setting CRLs and FCRs amounts to regulation of the Tribes' sustenance fishing right, which the State is not authorized to do under MIA and MICSA.

3. Establishing WQS under the CWA is an inherent sovereign right and is an internal tribal matter.

4. If the Indian Tribes, as opposed to the State, were establishing WQS in Indian waters, the Tribes would not be regulating any non-tribal members.

5. An Indian Tribe's inherent authority or tribal sovereignty cannot be divested unless Congress expressly acts to do so.

6. Water quality in Indian waters is something that may directly threaten the "health or welfare of the tribe." Water rights and governmental jurisdiction are "critical elements necessary for tribal sovereignty."

7. Congress did not "unequivocally abrogate the Tribe's inherent authority to protect the sustenance fishery."

8. The legislative history to MICSA indicates that MICSA's sustenance fishing right is an example of an "expressly retained sovereign activity."

9. Inherent sovereignty applies in this context and allows Indian tribes to protect subsistence practices embodying cultural, spiritual, and physical elements.

10. Inherent sovereignty precludes Maine from regulating in this way. Sustenance fishing is an aboriginal right.

11. The notion that establishing WQS in Indian waters is an internal tribal matter is supported by federal and State governments' adoption of principles in the United Nations declaration on the Rights of Indigenous Peoples.

12. Determining a CRL that tribal members will be subjected to is an internal tribal matter. Maine is asking EPA to approve Maine's policy judgment about the level of risk the Tribes should face, which is inappropriate and inconsistent with the Tribes' inherent sovereignty.

13. Protection of tribal health and welfare is an internal tribal matter over which the State may not exercise jurisdiction, and includes environmental regulation.

Examples of the State's comments

1. The CWA and MIA/MICSA provide Maine with the authority to establish WQS in waters within Indian lands in Maine.

2. MICSA's savings clauses would preclude the Maine Indian Tribes from implementing a WQS program in Maine.

EPA's responses to comments concerning principles of inherent tribal sovereignty (and MIA's and MICSA's internal tribal matters provision) and its effect on Maine's legal authority to establish WQS for waters within Indian lands

Basic tenets or principles of federal Indian common law as they relate to tribal sovereignty

EPA agrees with the comments that set forth the basic tenets of federal Indian common law supporting the idea that Indian tribes have retained their inherent powers as sovereign entities (unless expressly abrogated by Congressional action), that such sovereign status has existed since long before contact with European nations, and that Indian tribes' sovereignty it is not something that was delegated or granted to the tribes by Congress. EPA has consistently sought to uphold the inherent sovereignty of Indian tribes wherever applicable. See, e.g., EPA's 1984 Indian Policy.

Many of the federal court opinions cited by the Penobscot Nation in its comments reflect or discuss certain aspects of these common law principles of federal Indian law. See, e.g., *Wisconsin v. E.P.A.*, 266 F. 3d 741 (7th Cir. 2001); *State of Washington, Dep't of Ecology v. U.S.E.P.A.* 725 F. 2d 1465 (9th Cir. 1985); *Merrion v. Jicarilla Apache Tribe*, 455 U.S. 130 (1982); *New Mexico v. Mescalero Apache Tribe*, 462 U.S. 324 (1983); *Oklahoma Tax Comm'n v Sac & Fox Nation*, 508 U.S. 114 (1993); *Three Affiliated Tribes of Ft. Berthold v. Wold Eng'g*, 476 U.S. 877 (1986); *Kiowa Tribe of Oklahoma v. Mfg techs, Inc.* 523 U.S. 751 (1998); *Santa Clara Pueblo v. Martinez*, 436 U.S. 49 (1978); *Williams v. Lee*, 358 U.S. 217 (1959); *Aroostook Band of Micmacs v. Ryan*, 404 F.3d 48 (1st Cir. 2005); *Montana v. United States*, 450 U.S. 544 (1981); *City of Albuquerque v. Browner*, 97 F. 3d 415 (10th Cir. 1996).

These general principles of Indian common law cited by the Penobscot Nation, however, are not dispositive of and do not directly answer the fundamental jurisdictional question before EPA in this matter: what effect do the settlement acts have on the jurisdictional relationship among the Southern and Northern Tribes, the State of Maine, and the federal government when implementing the CWA WQS program applicable to Indian waters within Indian lands in Maine? The cases cited by the Penobscot Nation were not decided against the backdrop of statutes like MIA and MICSA which, as EPA has explained throughout this RTC document, alter in certain important respects the Maine Indian Tribes' inherent sovereign status as compared to the more typical situation that exists in parts of the United States that do not have statutes like MIA and MICSA.[4]

EPA recognizes the fundamental principles of federal Indian law relating to inherent tribal sovereignty, and is aware that Congress has plenary power over Indian affairs as established in the Indian commerce clause of the Constitution. *Santa Clara Pueblo v. Martinez*, 436 U.S. 49, 56 (1978). As a result, only Congress may change the jurisdictional relationships in Indian country by expanding or contracting state, tribal and federal jurisdiction. If Congress takes any action to limit a tribe's sovereignty, it must do so expressly and any ambiguities must be resolved in the tribe's favor. Congress may provide for state law to apply in Indian country, but it must do so expressly. *See California v. Cabazon Band of Mission Indians*, 480 U.S. 202, 207 (1987).

In this matter, EPA is applying the Congressional grant of legal authority to Maine in the Southern and Northern Tribes' Indian lands which is adequate to support the State's assertion of legal authority to implement a CWA WQS program applicable to waters in Indian lands located in Maine. See EPA's Decision Support Document for a more detailed discussion and analysis. Both MIA and MICSA, as further elucidated in MIA's and MICSA's legislative histories, embody a jurisdictional framework that serves as a compromise in settlement of the land claims that gave rise to these statutes. The Senate Report accompanying MICSA specifically addressed concerns about the impact of these

[4] The Penobscot Nation also cites to *Aroostook Band of Micmacs v. Ryan*, 404 F.3d 48 (1st Cir. 2005) as a First Circuit opinion that addresses tribal sovereignty "absent their divestment by the federal government." See Page 14 of the Penobscot Nation's comments. This case, however, like the others cited by the Tribe, does not stand for the proposition that MICSA did not give Maine the legal authority to establish WQS in waters within Indian lands.

two statutes on the Penobscot and Passamaquoddy Tribes' sovereign rights and jurisdiction. "While the settlement represents a compromise in which State authority is extended over Indian territory to the extent provided in the Maine Implementing Act, in keeping with [certain legal precedent] the settlement provides that henceforth the Tribes will be free from State interference in the exercise of their internal affairs. Thus, rather than destroying the sovereignty of the Tribes, by recognizing their power to control their internal affairs and by withdrawing the power which Maine previously claimed to interfere in such matters, the settlement strengthens the sovereignty of the Maine Tribes." Page 14, Special Issues. The Senate Report goes on to describe other ways in which the Tribes' sovereignty is protected, including, but not limited to, the hunting and sustenance fishing right provisions in the statutes and the provisions granting to the Southern Tribes state constitutional status of municipalities. However, the nature of this compromise in retaining certain aspects or elements of the Tribes' sovereignty does not override or conflict with the fact that Congress in MICSA ratified a jurisdictional relationship among the Tribes and the State that gave Maine the authority to apply state law to those matters not falling within either:1) the internal tribal matters provision in the statute; 2) the Southern Tribes' reservation hunting and fishing rights or 3) certain other matters specifically reserved by the statutes to the Tribes.[5] EPA's conclusion that Maine has the legal authority to establish WQS in waters within Indian lands is consistent with MIA and MICSA because, as discussed below in more detail, doing so is not an internal tribal matter and does not alter or regulate the Southern Tribes' right to take fish within their reservations for their individual sustenance. In fact, EPA's Decision Support Document explains that the Southern and Northern Tribes' fishing rights are being protected under the CWA notwithstanding Maine's authority to establish WQS in waters within Indian lands.

Consistent with the analysis above of the Maine Tribes' sovereign status, as expressed in MICSA, which ratifies MIA, the federal Indian common law cases cited by the Penobscot Nation are generally inapposite here. The vast majority of the cases did not address the scope of the sovereign status of an Indian tribe under statutes similar to MIA and MICSA. See e.g., *Kiowa Tribe of Oklahoma v. Mfg techs, Inc.* 523 U.S. 751 (1998); *New Mexico v. Mescalero Apache Tribe*, 462 U.S. 324 (1983); *Santa Clara Pueblo v. Martinez*, 436 U.S. 49 (1978); *Williams v. Lee*, 358 U.S. 217 (1959); *Goodyear Atomic Corp. v. Miller*, 486 U.S. 174 (1988); *Montana v. United States*, 450 U.S. 544 (1981); *Wisconsin v. E.P.A.*, 266 F. 3d 741 (7th Cir. 2001); *City of Albuquerque v. Browner*, 97 F. 3d 415 (10th Cir. 1996). In addition, although the Penobscot Nation also cites to several First Circuit cases discussing some aspects of inherent tribal sovereignty generally, none of those cases held that Maine law did not generally apply to the Maine Indian Tribes under MIA section 6204 and MICSA sections 1725(a) and 1725(b)(1) on the basis of the Tribes' inherent sovereign status. See, e.g., *Akins v. Penobscot Nation*, 130 F. 3d 482 (1st Cir. 1997); *Penobscot Nation v. Fellencer*, 164 F. 3d 706 (1st Cir. 1999); *Bottomly v. Passamaquoddy Tribe*, 599 F. 2d 1061 (1st Cir. 19179); and *Aroostook Band of Micmacs v. Ryan*, 404 F.3d 48 (1st Cir. 2005).

[5] The other matters referenced here are not pertinent to EPAs decision.

The effect of the settlement acts on federal Indian common law as they relate to tribal sovereignty

The settlement acts clearly represent a substantial revision to the relationship between state and Indian jurisdiction that would apply in Maine absent the settlement acts. Virtually every court that has reviewed the statutes has emphasized that it is impossible in Maine to simply apply federal Indian common law without first starting with the settlement acts. See, e.g. *Akins v. Penobscot Nation*, 130 F.3d 482, 484 (1st Cir. 1997); *Penobscot Nation v. Fellencer*, 164 F.3d 706, 708 (1st Cir. 1999), cert. denied 527 U.S. 1022 (1999); *Penobscot Nation v. Georgia-Pacific*, 254 F.3d 317, 320 (1st Cir. 2001), cert. denied 534 U.S. 1127 (2002); *Penobscot Nation v. Stilphen*, 461 A.2d 478, 482 (Me. 1983), app. dismissed 464 U.S. 923 (1983); *Great Northern Paper Inc. v. Penobscot Nation*, 770 A.2d 574, 580 (Me. 2001), cert. denied -- U.S. –, 122 S.Ct. 543 (2001); *Maine v. Johnson*, 498 F.3d 37, 42 (1st Cir. 2007). For example, the settlement acts create a status for the Northern and Southern Tribes (although there are statutory differences for each of the two groups) that is unique in the nation, and extends state authority over the Tribes to an unusual extent. Therefore, to say simply that federal Indian common law applies to the Maine Tribes (without any qualification) understates the critical role the settlement acts play in revising the customary formula for gauging Indian sovereignty.

On the other hand, it overstates the effect of the settlement acts to say that federal Indian law is irrelevant to interpreting how the settlement acts apply in Maine. As a threshold matter, for example, MICSA is a federal statute that modifies tribal jurisdiction, and therefore is subject to the interpretive doctrines in federal common law giving the tribes the benefit of the doubt where the statute is ambiguous. *Fellencer*, 164 F.3d at 709. Additionally, MICSA ratified the jurisdictional formulation in MIA for the Southern Tribes, and MIA specifically preserves "internal tribal matters" from state regulation. When analyzing the scope of "internal tribal matters," the First Circuit has twice referred to general principles of federal Indian law, both common law (*Akins*, 130 F.3d at 489-90) and statutory provisions (*Fellencer*, 164 F.3d at 711), to help understand the extent of that term. MICSA and its legislative history make it clear that "internal tribal matters" is not a reservation of the Southern Tribes' full inherent sovereignty that predated passage of MICSA. But the term nevertheless protects key elements of the Southern Tribes' inherent sovereignty from state regulation. Therefore, when confronted with MICSA, courts have looked to the body of federal Indian law to better understand how a tribe's inherent sovereignty works in the customary case. In EPA's decision on Maine's WQS submission, EPA has similarly filtered the body of general federal Indian common law through the lens of MICSA, recognizing its unique requirements, while understanding at the same time that the statute operates against the backdrop of federal Indian common law.

EPA would disagree with any assertion that the Southern or Northern Tribes are no longer sovereigns, notwithstanding that the Southern and Northern Tribes are treated differently by the settlement acts in certain respects. Congress specifically recognized the tribal governments of the Southern and Northern Tribes. 25 U.S.C. §§ 1721(a) (3),

(4), and (5), 1722(a), (h) and (k); Aroostook Band of Micmacs Settlement Act, Pub. L. 102-171, Nov. 26, 1991, 105 Stat. 143, at Sec. 2 (a)(1) and Sec. 3(1). Congress charged the Tribes with developing written instruments to govern their affairs when acting in a governmental capacity. 25 U.S.C. § 1726 and Aroostook Band of Micmacs Settlement Act, Pub. L. 102-171, Nov. 26, 1991, 105 Stat. 143, at Sec. 7. It is explicitly clear in MIA and MICSA that the Southern Tribes exercise sovereignty in the sense of having governmental authority over their internal affairs and may take fish for their individual sustenance within their reservations. Using the term sovereignty when referring to the activities of these tribal governments is completely consistent with, indeed is compelled by, the terms of MICSA and The Aroostook Band of Micmacs Settlement Act. But the focus of this matter is the extent of the State's authority in relation to that which may be reserved to the Southern and Northern Tribes, and simply embracing or banishing the term "sovereignty" (without any qualifications or more nuanced explanations) contributes little to answering that question.

Penobscot Nation's sovereignty argument in relation to MIA section 6204

The Penobscot Nation asserts that the Tribe's full aboriginal inherent sovereignty was intended by Congress to be retained in MICSA. The Penobscot Nation argues this is true notwithstanding the language in MIA section 6204 generally subjecting all Indian Tribes in Maine to the laws of the State and to the civil and criminal jurisdiction of the courts of the State to the same extent as any other person or lands or other natural resources therein. The Penobscot Nation argues that section 6204 "merely confirms that the Nation will adopt Maine law as its own, but it does not expressly impose any form of State regulatory authority upon the Tribe or its natural resources." The Tribe cited to *Wauneka v. Campbell*, 22 Ariz. App. 287, 526 P. 2d 1085 (C.A. 1974), a case included in one section of MICSA's legislative history.

Although the Tribe's comment doesn't refer to MIA section 6202, "Legislative findings and declaration of policy," EPA notes that this language may also be relevant to the Tribe's argument:

> The foregoing agreement between the Indian claimants and the State also represents a good faith effort by the Indian claimants and the State to achieve a just and fair resolution of their disagreement over jurisdiction on the present Passamaquoddy and Penobscot Indian reservations and in the claimed areas. To that end, the Passamaquoddy Tribe and the Penobscot Nation have agreed to adopt the laws of the State as their own to the extent provided in this Act. The Houlton Band of Maliseet Indians and its lands will be wholly subject to the laws of the State.

As part of this overall argument in support of the Tribe's assertion of full aboriginal inherent sovereignty, the Tribe also references certain passages from MICSA's legislative history and federal case law. For a number of reasons, EPA disagrees that this particular argument, either on its own, or in conjunction with the Tribe's other arguments about

inherent tribal sovereignty, results in a legal conclusion that Maine is precluded by MIA and MICSA from establishing WQS in waters within Indian lands in Maine.

First, as set forth in EPA's Decision Support Document, and as explained in various other portions of this RTC document, the statutory provisions of MIA and MICSA and those statutes' legislative histories, very clearly establish that state law applies to the Penobscot Nation and the Passamaquoddy Tribe (and the other Maine Tribes) in the context of environmental regulation. Moreover, as the First Circuit said in *Maine v. Johnson*:

> In our view, the Settlement Acts make ordinary Maine law apply, even if only tribal members and tribal lands are affected in the particular case, *unless* the internal affairs exemption applies; and the scope of that exemption is determined by the character of the subject matter. Discharging pollutants into navigable waters is not of the same character as tribal elections, tribal membership or other exemplars that relate to the structure of Indian government or the distribution of tribal property. [*Maine v. Johnson*, 498 F. 3d 37, 46.]
>
> In addition to Maine's explicit authority over tribal lands and natural resources, the Settlement Acts expressly divested the Maine Tribes of sovereign immunity, *25 U.S.C. § 1725(d)*, and with limited exceptions, made the Maine Tribes subject to the general criminal and civil law of Maine even with respect to activities carried out on tribal lands. *25 U.S.C. § 1725(a), (c)*; *30 M.R.S.A. § 6204*. [*Maine v. Johnson*, 498 F. 3d 37, 42-43.]
>
> [T]he question here is whether *Maine* has adequate authority to implement permitting as to the tribes' lands, and *section 6204* on its face is about as explicit in conferring such authority as is possible. [*Maine v. Johnson*, 498 F. 3d 37, 43.]

Each of these passages from *Maine v. Johnson* directly conflicts with the Tribe's argument that MIA and MICSA did not intend to provide Maine with the legal authority to regulate the Penobscot Nation under state law because the Settlement Acts intended to preserve the Maine Tribes' full aboriginal inherent sovereignty. Indeed, every time the U.S. Court of Appeals for the First Circuit has adjudicated the extent of Maine's jurisdiction in Indian territories, it is clear the court held that MICSA applies the laws of the State to the Southern Tribes.

Five different First Circuit cases adjudicating the application of state law in the Southern Tribes' territories have never hinted at the idea that state law applies to the Tribes as anything other than state law. *Passamaquoddy Tribe v. Maine*, 75 F.3d at 789, n. 1 (1st Cir. 1996) ("Among other things, the Gaming Act, if it applied, would preempt various provisions of Maine's criminal law, including 17–A Me. Rev. Stat. Ann. §§ 953–954."); *Akins v. Penobscot Nation*, 130 F.3d 482 (1st Cir. 1997) ("This case turns on whether the issuance of stumpage permits is an 'internal tribal matter.' If this is an internal tribal matter, then under both Settlement Act and the Implementing Act, Maine law does not apply and no claims arise under the Maine Constitution or under the Maine

Administrative Procedure Act. Thus no claim arises under state law warranting the exercise of diversity jurisdiction." 130 F.3d at 485); *Penobscot Nation v. Fellencer*, 164 F.3d 706 (1st Cir. 1999), cert. denied, 527 U.S. 1022, 119 S. Ct. 2367, 144 L. Ed. 2d 771 (1999) (Maine state law did not apply only because the decision whether to employ a tribal member or a non-tribal member as a community nurse fell within the "internal tribal matter" exception to the applicability of state law under MIA and MICSA); *Penobscot Nation v. Georgia Pacific Corporation*, 254 F. 3d 317 (1st Cir. 2001) (Company demanded documents from Maine Tribes based on Maine's Freedom of Access Act. "Under Maine law, the Tribes are regulated in certain respects as municipalities, and municipalities are covered by the Access Act." 254 F.3d at 318.); *Maine v. Johnson*, 498 F.3d 37, 43 (1st Cir. 2007) ("The Southern tribes say that state authority over land and water resources can coexist with tribal authority, pointing to certain provisions of the Settlement Acts that explicitly make state authority 'exclusive.' So, the tribes say, the existence of Maine's authority does not automatically negate concurrent tribal authority over the same subject matter. But the question here is whether Maine has adequate authority to implement permitting as to the tribes' lands, and section 6204 on its face is about as explicit in conferring such authority as is possible. What the tribes might do if Maine did not legislate is beside the point. The Southern tribes' concurrency argument would have bite only if their own 'concurrent' regulatory authority, if it existed, took priority over enacted Maine law. But this would turn on its head the explicit language of the Settlement Acts giving Maine authority over land and water resources in the tribes' territories. If there is 'concurrent' jurisdiction at all, it is subordinate to Maine's overriding authority to act within the scope of section 6204, which clearly includes Maine's power to regulate discharge permitting consistent with the Clean Water Act.") And none of these cases held that the reference to W*auneka v. Campbell*, 22 Ariz. App. 287, 526 P. 2d 1085 (C.A. 1974), in MICSA's legislative history, supports the proposition that Maine state law does not apply as state law to the Southern Tribes under MIA section 6204.

MIA's internal tribal matters provision

In this subsection of EPA's RTC document, EPA provides a legal analysis of the "internal tribal matters" provision in MIA, as ratified by MICSA, as well as a discussion of how the First Circuit has construed the provision in its decisions to date. As explained below, EPA concludes that establishing WQS in waters within Indian lands is not an internal tribal matter. That conclusion is well-supported by First Circuit precedent, which strongly suggested that the balancing factors from *Akins* and *Fellencer*, that should be used in circumstances that constitute close questions of the applicability of the internal tribal matters provision, would be *inappropriate* if applied to the question of Maine's authority to establish WQS in waters within Indian lands. *Maine v. Johnson,* at 46. Nevertheless, because of the prominence of the concept of internal tribal matters in the Penobscot Nation's comments, EPA analyzes the concept below in detail. EPA even analyzes the balancing factors from *Akins* and *Fellencer* as applied to the WQS question to demonstrate that, even if it were appropriate to apply the factors, the analysis shows that Maine has authority to establish WQS in waters in Indian lands and that such

authority is not inconsistent with and does not run afoul of the internal tribal matters provision in MIA.

EPA recognizes the importance of the "internal tribal matters" provisions in MIA section 6206(1), as ratified by MICSA section 1725(b)(1), which by its terms only applies to the two Southern Tribes. We agree that, to the extent a subject is an internal tribal matter, the State is precluded from regulating that subject and that it falls beyond the reach of the grant of state authority in MIA section 6204, as ratified by Congress. Therefore, the scope of the internal tribal matters concept essentially defines the boundary of the State's jurisdiction and the State's ability to regulate activities in the Southern Tribes' territories.[6]

The internal tribal matters provision in MIA and MICSA is a reservation of authority to the Southern Tribes based on their inherent sovereignty that predates MICSA. Congress did not intend, however, to reserve through MICSA the *full scope* of the Southern Tribes' inherent sovereignty which the federal courts had recently recognized prior to MICSA. *Bottomly v. Passamaquoddy Tribe*, 599 F.2d 1061, 1065-66 (1st Cir. 1979); *Joint Trib. Coun. of Passamaquoddy Tribe v. Morton*, 528 F.2d 370, 379 (1st Cir. 1975). That interpretation would cause the exception of internal tribal matters to swallow the rule Congress created, which is that state law generally applies to the Maine Tribes and their lands. But as we discuss further below, the common law generally interpreting Indian Tribes' inherent sovereignty is relevant to assessing the scope of internal tribal matters, at least as a threshold test. If a subject matter would be beyond the reach of any Indian Tribe's inherent sovereignty, it could not qualify as an internal tribal matter under MICSA. If a subject matter is generally within the inherent authority of a Tribe to govern (and one decides it is appropriate to undertake an internal tribal matters analysis), EPA concludes that the next step in the analysis consists of using the factors that the First Circuit has derived in analyzing the provisions of MIA and MICSA. In short, EPA has concluded that "internal tribal matters" under MICSA is a subset of the inherent authority Indian Tribes generally retain as reflected in the general principles of federal Indian common law.

In addition, we note that it would be difficult to reconcile the unique wording of MICSA section 1725(f) with the interpretation that internal tribal matters reserves the Southern Tribes' unimpaired inherent sovereignty. This section provides:

> The Passamaquoddy Tribe and the Penobscot Nation are hereby authorized to exercise jurisdiction, separate and distinct from the civil and criminal jurisdiction of the State of Maine, *to the extent authorized by the Maine Implementing Act, and any subsequent amendments thereto.*

25 U.S.C. § 1725(f) (emphasis added). These provisions of MICSA show that the jurisdictional arrangement Congress ratified in MICSA results in an atypical scope for the Southern Tribes' inherent authority. That is because an Indian Tribe's inherent

[6] MIA and MICSA also identify areas of jurisdiction specifically reserved to the Southern Tribes, but those provisions are not relevant to this WQS analysis under the CWA. See e.g. sections 6209-A and 6209-B.

sovereignty typically is not dependent on or subject to definition by state law in the United States, and it requires no affirmative grant of authority from Congress for a Tribe to assert its inherent sovereignty in relation to state law. See *Merrion v. Jicarilla Apache Tribe*, 455 U.S. 130, 148 n. 14 (1982) ("[N]either the Tribe's Constitution nor the Federal Constitution is the font of any sovereign power of the Indian tribes."], see also id. at 168 ("Tribal sovereignty is neither derived from nor protected by the Constitution. Indian tribes have, however, retained many of the powers of self-government that they possessed at the time of their incorporation into the United States." (Stevens, J. dissenting; footnote omitted)). But Congress has plenary authority to alter the scope of an Indian tribe's inherent sovereign authority.

Congress understood that MIA had essentially flipped the presumption against state law applying in Indian country, and the wording of section 1725(f) therefore makes sense. Faced with ratifying a state statute that included an aggressive extension of state authority over the Southern Tribes and their territories, using sweeping language creating a presumption that state law applies, Congress was being careful to point out that the Southern Tribes still exercised independent jurisdictional authority for certain purposes under the terms of the MIA. The wording of section 1725(f) is fully consistent when we conclude that internal tribal matters reserved some subset of the Southern Tribes' inherent sovereignty, and that Congress was expressly confirming that residual authority. MICSA, however, also ratifies a substantial grant of authority to the State, which includes adequate authority to establish WQS in waters in Indian lands. Normally, outside Maine, establishing WQS in Indian lands would fall outside state jurisdiction. Here, MIA and MICSA provide that authority to the State.

Consistent with the discussion above regarding the scope and limitations of the internal tribal matters provision, the portion of MICSA's legislative history which specifically speaks to the States' authority to regulate the *environment* in the Southern Tribes' territories is direct and compelling. Most notably, when discussing the specific section of MICSA that ratifies MIA's jurisdictional arrangement for the Southern Tribes, the Senate Report concludes:

> . . . State law, including but not limited to laws regulating land use or management, conservation and environmental protection, are fully applicable as provided in this Section and Section 6204 of the Maine Implementing Act. That the regulation of land or natural resources may diminish or restrict maximization of income or value is not considered a financial encumbrance and is not barred from application under this Act.

S. Rep. at 27(emphasis added).

The only other place in the Congressional Committee Reports that speaks directly to regulation by the State of environmental matters in Indian lands is the discussion of the first savings clause in MICSA, section 1725(h). This provision makes federal Indian law up to 1980 generally applicable in Maine, but only if that law does not affect or preempt state jurisdiction:

> Except as other wise [sic] provided in this subchapter, the laws and regulations of the United States which are generally applicable to Indians, Indian nations, or tribes or bands of Indians or to lands owned by or held in trust for [them] shall be applicable in the State of Maine, except that no law or regulation of the United States (1) which accords or relates to a special status or right of or to any Indian, Indian nation, tribe or band of Indians, Indian lands, Indian reservations, Indian country, Indian territory or land held in trust for Indians, and also (2) which affects or preempts the civil, criminal, or regulatory jurisdiction of the State of Maine, including, without limitation, laws of the State relating to land use or environmental matters, shall apply within the State.

25 U.S.C. § 1725(h)(emphasis added). This provision does not control what jurisdiction Maine received under MICSA; it simply protects the jurisdiction granted to the State elsewhere in MICSA from inadvertent intrusion by general federal Indian law. As a structural matter, however, it is notable that Congress specifically identified "environmental matters" as an area of state law to be protected, strongly supporting our conclusion that environmental regulation was included in the grant of authority to the State. The Senate Report confirms this conclusion:

> It is also the intent of this subsection, however, to provide that federal laws according special status or rights to Indian [sic] or Indian Tribes would not apply within Maine if they conflict with the general civil, criminal, or regulatory laws or regulations of the State. Thus, for example, although the federal Clean Air Act, 42 U.S.C. § 7474, accords special rights to Indian Tribes and Indian lands, such rights will not apply in Maine because otherwise they would interfere with State air quality laws which will be applicable to the lands held by or for the benefit of the Maine Tribes. This would also be true of police power laws on such matters as safety, public health, environmental regulations or land use.

S. Rep. at 31; see also H.R. Rep. at 29. This passage makes it very clear that Congress understood it was making state environmental law applicable to Indian lands.

As noted earlier, the First Circuit's precedent interpreting MIA and MICSA is consistent with Congress' intent to make Maine environmental law apply to Indian lands. And establishing WQS is, in character, much more akin to discharging pollutants into navigable waters than it is to such matters as tribal elections, tribal membership or other exemplars that relate to the structure of Indian government or the distribution of tribal property.

First Circuit precedent interpreting MIA's and MICSA's internal tribal matters provision, including an analysis of the *Akins* and *Fellencer* factors

In its decision in *Maine* v. *Johnson*, the First Circuit squarely addressed the "internal tribal matters" provision in MIA, ratified by MICSA. In *Maine* v. *Johnson,* the Court noted that its decisions in *Akins* and *Fellencer* were the only two in which the Court had

directly construed the phrase "internal tribal matters" as applied to the Maine Tribes. The Court clearly distinguished both of those prior cases from the CWA NPDES program case before it, noting, among other things, that in each of *Akins* and *Fellencer*, the State disclaimed any interest in regulation or superintendence over the activities in question. The Court noted further that the Settlement Act's jurisdictional provisions clearly affirmed Maine's asserted power in the context of regulating discharges of pollutants into navigable waters, even for facilities located on tribal lands discharging into tribal waters. The Court stated that "[i]f the internal affairs exemption negated so specific a ground of state authority, it is hard to see what would be left of the compromise restoration of Maine's jurisdiction." *Maine* v. *Johnson,* at 45. The Court subsequently noted that "[i]n our view, the Settlement Acts make ordinary Maine law apply, even if only tribal members and tribal lands are affected in the particular case, *unless* the internal affairs exemption applies," finding that discharging pollutants into navigable waters is not of the same character as the enumerated examples of internal tribal matters contained in the MIA. *Id.* At 46. The Court clearly rejected EPA's use of the "balancing test" that the Agency stated was consistent with the Court's analysis in *Akins* and *Fellencer*, noting that "discharging pollutants into navigable waters is not a borderline case in which balancing . . . or ambiguity canons . . . can alter the result." *Id.* At 46.

As noted above, in *Maine* v. *Johnson* the First Circuit suggested that EPA's application of the balancing factors and method of analysis derived from *Akins* and *Fellencer* was misplaced in an area of regulatory authority so clearly reserved to the State under MIA and MICSA. It therefore behooves EPA first to ask the question whether the facts and surrounding circumstances pertinent to Maine's WQS submissions are more akin to the circumstances present in *Maine v Johnson* or to those present in *Akins* and *Fellencer*. That is, is Maine's request to apply its WQS to waters within Indian lands clearly within its regulatory authority under MIA and MICSA in the way that the Court in *Maine v. Johnson* viewed regulating discharges of pollutants into navigable waters (where Maine expressed a strong interest in doing so)? Or does the WQS context before EPA now involve circumstances and relative tribal and state interests more akin to a dispute over whether non-tribal members have timber rights in Indian territory (where the State had disclaimed an interest in regulating the issue), or to a situation in which a tribe wanted the ability and right to determine who, as between a tribal member and non-tribal member, could work as a community nurse (and where the State disclaimed any interest in applying its anti-discrimination laws to that decision)?

Upon examination, the factual circumstances and relative tribal and state interests presented by Maine's establishment of WQS in tribal waters are clearly are more analogous and pertinent to those at issue in *Maine v. Johnson* than they are to those in *Akins* and *Fellencer*. Maine's WQS program falls within a broad area of environmental regulation; Maine has expressed a strong desire to exercise regulatory authority in this area; and there potentially would be non-trivial impacts on non-tribal members outside of tribal lands were EPA to find that MIA and MICSA preclude Maine from applying its WQS in waters in Indian land. Following the First Circuit's reasoning then, it would not even be appropriate for EPA to apply the balancing factors from *Akins* and *Fellencer* to determine whether Maine has jurisdiction to establish WQS for waters in Indian lands.

The Court found that the circumstances present in *Akins* and *Fellencer* were much closer legal questions as to whether the internal tribal matters provisions of MIA and MICSA applied, as compared to whether those provisions applied to the question whether Maine had authority to implement an NPDES program in Indian lands. Two critical factors that informed the Court's holding were the potential effects of a tribal NPDES program on non-members outside of Indian territories and the State's strongly expressed desire to implement such program itself throughout the State, including in waters within Indian lands. The Court's holding is consistent with the idea that the jurisdictional provisions of MICSA establish a presumption that Maine was provided with regulatory authority over a particular activity absent a finding that the internal tribal matter exception applied (and absent a showing that other explicitly reserved areas of tribal jurisdiction, clearly not relevant to the WQS context, applied).

Thus, the Penobscot Nation's use in its public comments of the *Akins* and *Fellencer* balancing factors as a basis of its jurisdictional analysis would be rejected by the First Circuit. Of central importance to the First Circuit's analysis of the internal tribal matters provision in MICSA is that its scope is *not* defined by the idea that the concept is intended to cover any and all matters that a sovereign government would typically have authority to regulate, but, rather, under MIA and MICSA the *character* of the activity at issue must be so internal to *tribal* government that it does not impact the State's authority in a way that affects non-tribal members or that is contrary to the State's interest in exercising its authority consistent with the atypical allocation of state jurisdiction under MIA and MICSA. At bottom, it is hard to discern how, given the potential effects of a tribal CWA WQS program on non-member upstream dischargers and on the application of State law, in an area of regulation where the State has expressed a strong desire that its standards apply throughout the State, that the First Circuit would decide that Maine did not have adequate jurisdiction to set WQS for waters in Indian lands. See EPA's Decision Support Document for additional discussion.

A direct comparison of the various factors, dynamics, and impacts described above in relation to a WQS program, with the factors considered by the First Circuit in its decision that Maine has jurisdiction under MIA and MICSA to issue NPDES permits to tribally-owned facilities located on tribal land and which discharge only to tribal waters, compels a legal conclusion that Maine has jurisdiction to establish WQS in waters within Indian lands. As discussed elsewhere in this document and in EPA's Decision Support Document, however, the State's authority and discretion to set such standards is not unbounded and must still comply with CWA requirements, including those that would protect the designated use of sustenance fishing in waters in Indian lands.

Nonetheless, EPA would like to respond fully and comprehensively to the Penobscot Nation's comments. Consequently, EPA provides below specific responses to the Penobscot Nation's internal tribal matters argument, even though the logic of the First Circuit's analysis in *Maine v. Johnson* suggests that these factors are not appropriately applied to the facts presented by Maine's WQS submission.

Before delving into the specifics of the Penobscot Nation's comments on this issue, we note that federal Indian common law plays a limited role in our interpretation of the internal tribal matters exception. The First Circuit has stated that:

> We stress that we do not read the reference by Congress to Santa Clara Pueblo in the legislative history of the Settlement Act as invoking all of prior Indian law . . . . But we also do not agree that reference to such law is never helpful in defining what is an internal tribal matter. Congress was explicitly aware of such law, and explicitly made existing general federal Indian law applicable to the Penobscot Nation in the Settlement Act. In other areas, courts have long presumed that Congress acts against the background of prior law.

Akins, at 489. Insofar as federal Indian common law provides insight into the sorts of activities that Congress and the courts considered to be matters of inherent tribal sovereignty, and thus what rights Congress may have reserved under the settlement acts, it is a useful aid for determining whether water quality regulation is an internal tribal matter. The First Circuit directs us to examine that common law. The court does say that federal Indian common law defines the scope of internal tribal matters. The internal tribal matter exception under MICSA is essentially a reservation of some elements of inherent tribal sovereignty. *Akins*, at 489. Therefore, in order to qualify as an internal tribal matter, an activity must, as a threshold matter, qualify as a matter of inherent tribal sovereignty. However, concluding that a matter would be treated as part of a tribe's inherent tribal sovereignty under federal Indian common law does not end the inquiry. The First Circuit then provides us a series of factors to determine whether the issue or activity is an internal tribal matter under MICSA.

EPA's responses to the Penobscot Nation's *Akins* and *Fellencer* factors analysis

Factors:

a. Does the activity regulate only tribal members?

Tribal comment: There would only be an indirect effect on non-tribal members. Non-tribal members are not being regulated directly.

EPA's response:

To the extent that the *Akins* and *Fellencer* balancing factors are analyzed, the degree to which an activity may affect non-tribal members has been a primary consideration for the First Circuit. A finding that Maine does not have authority to establish WQS for waters in Indian lands, and the corresponding finding that the Maine Indian Tribes do have that authority for those waters, could have a non-trivial effect on non-member facilities in Maine subject to effluent limitations in NPDES permits that must ensure compliance with WQS. *See*, e.g., *City of Albuquerque v. Browner*, 97 F. 3d 415 (10th Cir. 1996), *cert. denied*, 522 U.S. 965 (1997). In *City of Albuquerque v. Browner*, the City of Albuquerque challenged EPA's approval of the Isleta Pueblo's water quality standards on

a number of grounds, including that certain of the Tribe's standards were allegedly unattainable because they were too stringent, and would have an adverse effect on an upstream discharger located outside of Indian Country. The Tenth Circuit upheld the district court's opinion affirming EPA's approval of the Tribe's WQS. Under the First Circuit's analysis in *Akins* and *Fellencer*, the *potential* for impacts on non-members of a tribal CWA WQS program weighs heavily against finding that Maine does not have authority under MIA and MICSA to establish WQS in waters in Indian lands under the concept of internal tribal matters.

b. Does the activity relate to lands that define the Tribes' territories, particularly to the commercial use of tribal lands?

Tribal comment: The matter at hand concerns the harvesting or deriving of value from tribal resources.

The second factor in the *Akins* and *Fellencer* analysis concerns a tribe's ability to decide how to use its own resources to protect the interests of its members. The First Circuit found that the Tribe's decisions regarding commercial use of "the very land that defines the territory of the Nation" fell within the realm of internal tribal matters. Id. at 487, 488. This factor is not necessarily limited to commercial use of land, however. Rather, it has to do with resources within the tribe's territory that have a direct effect on tribal well-being. In *Fellencer*, the court analogized control of natural resources on tribal land to control of human resources on tribal land. *Fellencer*, 164 F.3d at 710. The particular "human resource" at issue was a community nurse who was not a tribal member, but who practiced on the Penobscot reservation serving tribal members, and whose practice had a direct effect on the health of tribal members. In this case, the court recognized that "Indian tribes may 'retain inherent power to exercise civil authority over the conduct of non-Indians on fee lands within its reservation when that conduct threatens or has some direct effect on the ... health or welfare of the tribe.' " Id., quoting *Montana v. United States*, 450 U.S. at 566.

Fellencer confirms that in order to protect tribal health and welfare, tribes may control activities of non-members *within* Indian territory. However, tribes do not generally have authority to control such activities outside of Indian territory. *Montana v. United States*, 450 U.S. at 565-66. Here, many of the waters in question, *e.g.*, the Penobscot River, and the fish in those waters, are resources used by Maine, its citizens, and the Maine Tribes. The First Circuit's holdings in *Akins* and *Fellencer* do not provide EPA with any grounds to deny the state jurisdiction over setting WQS in any waters within Indian lands, and even more certainly not for waters and resources that are used by tribal and non-tribal members. Again, however, it is important to note that notwithstanding Maine's jurisdictional authority, EPA has the authority under the CWA to protect the Maine Tribes' sustenance fishing practices provided for under the settlement acts by ensuring that WQS applicable to waters in Indian lands protect the quality of water necessary to support those sustenance fishing practices.

c. Does the activity affect the Tribes' ability to regulate their natural resources?

Tribal comment: The matter concerns the regulation or conservation of tribal resources.

EPA's response

The First Circuit has held that an activity predominantly affecting a tribe's ability to control the use of its own resources is likely to be an internal tribal matter. *Akins* in particular examined an example of natural resource regulation, stumpage permits, which it determined was an internal tribal matter. However, the *Akins* holding is a narrow one. Under *Akins*, the test is not whether the assertion of state law interferes with the tribe's regulation of its natural resources, but whether the assertion of *tribal authority* over such resources interferes with *state* regulation. The court emphasized that "[b]y its own terms, the Implementing Act, § 6204, makes State laws regulating land use or management, conservation and environmental protection applicable to tribal lands. The absence of an assertion that any such [State] laws are involved here is telling." *Akins*, 130 F.3d at 488. The deciding element in the court's analysis of this factor seems to be that the stumpage permit system, "involving tribal lands, appears to have no significant impact on Maine's environmental or other interests." Id.

Also important in the First Circuit's consideration was the geographic component of inherent tribal sovereignty. Id. at 489. The court determined that timber permitting qualified as an internal tribal matter in part because "the policy concerns the harvesting of a natural resource from [land that defines Indian territory]." Id. at 487. The timber subject to the disputed permitting system was located entirely on the Penobscot Nation's territory. Because the resource was confined to Indian territory, the associated permitting system did not impair the State's ability to regulate its own natural resources.

The issue we face today is vastly more complicated than in *Akins* because many of the rivers and streams that are tribal waters flow through and touch both tribal and non-tribal lands. In addition, the WQS regulations at issue involve potential impacts to discharging facilities that operate inside and outside Indian territories. Following the First Circuit's analysis of MICSA, EPA begins with the assumption that the State's laws are generally applicable in all waters. See 25 U.S.C. § 1725(b)(1). Certain activities may be excluded from state regulation as internal tribal matters, but the general presumption is that state laws apply to all water bodies in Maine.

Based on this factor, the State has clear jurisdiction to establish WQS that may have the potential to affect the effluent limitations contained in NPDES permits issued to facilities that are largely located and operate outside of tribal territories and, under the reasoning in

Maine v. Johnson, even to sources that are on tribal lands and owned by tribal members and which have no measurable impact on non-members.[7]

d. Does the activity implicate or impair an interest of the State of Maine?

Tribal comment: The State's only interest in establishing WQS is in subverting sustenance fishing.

EPA response

Another important factor in the First Circuit's prior consideration of internal tribal matters was whether the State had asserted any interest in regulating the matter at issue. The *Akins* court noted at the outset that "[t]his is not a dispute between Maine and the Nation over the attempted enforcement of Maine's laws" and that the tribe's regulation of its own timber resources was "not of central concern to ... Maine." *Akins*, at 487, 488. In *Fellencer*, the court clarified that a general state interest in regulating a matter such as employment discrimination was not sufficient to remove the matter from the scope of internal tribal matters. But because the State expressly disavowed an interest in regulating *tribal* governmental employment decisions, the court found that tribal regulation of its own employees did not impair any *state* interest. *Fellencer*, at 710-11.

In its WQS submission, Maine has vigorously asserted its interest in regulating water quality throughout the State, including within waters located in Indian lands. That is a very different dynamic between the State and the Indian Tribes than the one that existed in the *Fellencer* and *Akins* disputes. Id., *Akins*, 130 F.3d at 488 ("This is ... a question of allocation of jurisdiction among different fora and allocation of substantive law to a dispute between tribal members where neither the Congress nor the Maine Legislature has expressed a particular interest."). In *Maine v. Johnson*, 498 F.3d 37, 45, the First Circuit stated:

> In both those cases, unlike this case, Maine disclaimed any interest in regulation or superintendence. *Akins*, 130 F.3d at 488; *Fellencer*, 164 F.3d at 710-11. By contrast, in the present case, Maine affirmatively asserts authority as to both tribal and non-tribal land to regulate discharges into navigable waters. The Settlement Act provisions just quoted affirm that power. If the internal affairs exemption negated so specific a ground of state authority, it is hard to see what would be left of the compromise restoration of Maine's jurisdiction.

[7] As discussed below, EPA is requiring the State to consider impacts on tribal resources and amend its WQS accordingly. However, the State is not required to cede regulatory authority simply because its activities have an impact on tribal resources.

e. Is defining the activity as an "internal tribal matter" consistent with prior legal understandings?

Tribal comment: Under federal Indian common law principles, the matter at hand involves the inherent authority of an Indian tribe, which must be free from undermining by a state.

EPA's response:

As explained earlier, Maine's jurisdiction to establish WQS in Indian lands is consistent with the First Circuit's analysis of MIA and MICSA and its holdings in *Maine v. Johnson, Akins* and *Fellencer* and, to the extent applicable given MIA and MICSA's unique jurisdictional arrangement, other federal Indian common law.

In order to understand the internal tribal matters exception, we must recognize that MICSA, while legislated against the backdrop of federal Indian common law, altered the operation of that common law in Maine. Under federal Indian common law, Indian tribes may have a paramount interest in regulating their own water quality that supersedes that of the state in which the tribes' territory is located. However, as discussed earlier and below, federal Indian common law may aid us in interpreting MICSA but cannot change the statute's general provision for state jurisdiction over natural resources. We must look carefully at what Congress and the courts have said regarding the extent of the internal tribal matters exception to state jurisdiction.

Following the First Circuit's example, we look first to the legislative history of MICSA, and then to federal Indian common law for prior legal understandings of internal tribal matters. As mentioned earlier, we rely largely on the Senate Report, which the House Report "accepts as its own" in part. H.R. Rep. at 20; *Garcia v. United States*, 469 U.S. 70, 76 (1984) (committee reports are an authoritative source for determining legislative consent), cited by *Akins*, at 489. The few references that the Senate Report makes to natural resource regulation are telling. In its discussion of the application of state environmental law under section 1725(b)(1), the provision of MICSA ratifying the MIA and its jurisdictional provisions, the Senate Report states:

> State law, including but not limited to laws regulating land use or management, conservation and environmental protection, are fully applicable as provided in this Section and Section 6204 of the Maine Implementing Act. That the regulation of land or natural resources may diminish or restrict maximization of income or value is not considered a financial encumbrance and is not barred from application under this Act.

S. Rep. at 27.

In addition, when explaining the operation of the savings clauses discussed earlier, the Senate Report provides a specific example of a federal environmental law that would be

excluded from operating in Maine Indian Country to avoid interfering with state environmental law. Although the example in this passage focuses on the provision in the Clean Air Act that allows Indian tribes to redesignate their lands to a new air quality classification under the prevention of significant deterioration (PSD) air permitting program, the passage ends by emphasizing that this exclusion would also operate more generally as to "police power laws on such matters as . . . environmental regulation."

> It is also the intent of this subsection, however, to provide that federal laws according special status or rights to Indian [sic] or Indian Tribes would not apply within Maine if they conflict with the general civil, criminal, or regulatory laws or regulations of the State. Thus, for example, although the federal Clean Air Act, 42 U.S.C. § 7474, accords special rights to Indian Tribes and Indian lands, such rights will not apply in Maine because otherwise they would interfere with State air quality laws which will be applicable to the lands held by or for the benefit of the Maine Tribes. This would also be true of police power laws on such matters as safety, public health, environmental regulations or land use.

S. Rep. at 31; see also H.R. Rep. at 29. In addition, this passage makes clear that Congress was not limiting the application of federal Indian law in Maine solely to avoid any interference with state environmental regulation as it applies to lands outside Indian territories. The report specifically discusses Congress's intent to protect the application of state air quality laws which will be applicable to land held "for the benefit of the Maine Tribes." Again, this discussion would be pointless if Congress did not specifically intend to make state environmental regulation applicable in the Southern Tribes' territory.

This passage in MICSA's legislative history is telling in the context of analyzing the State's authority to set WQS under the CWA. The Clean Air Act provision cited by the Senate report refers to the authority tribes have outside Maine to redesignate the air quality classification for their territory so that PSD permits for upwind facilities must include emission limits that protect the air quality consistent with the tribe's chosen classification of its territory. This example is strikingly similar to the function of the WQS program in the context of the CWA. Both programs involve the authority of non-federal sovereigns to determine the level of environmental quality that must be maintained within their territories, and that determination has the effect of controlling the content of permits issued to facilities that might impact those territories. Indeed, the "Area Redesignation" provisions in section 164 of the Clean Air Act are about as direct a cognate to the WQS program in the CWA as one could find in federal environmental law. It is reasonable then, for EPA to conclude, that Congress intended its grant of jurisdiction to the State to include a program like the CWA WQS.

Our inquiry does not end here. *Akins* opens the possibility that even in the area of natural resource regulation, activities may fit within the internal tribal matters exception and be free of state regulation. Here we turn to the federal Indian common law to help us define the contours of inherent tribal sovereignty, which in turn form the basis for internal tribal matters. The analysis of federal Indian common law in *Akins* draws a clear distinction

between inherent tribal authority over the activities of members and non-members. Tribes generally have authority over their own members. In some circumstances, federal Indian common law has found that tribal authority extends to non-member conduct on tribal territory, but not to non-member conduct outside of tribal territory. See *Akins*, at 490. MICSA constricted the common law understanding of inherent tribal sovereignty by establishing the general presumption that state law applies even within tribal territories. 33 U.S.C. § 1725(b)(1). Therefore, the fact that an activity takes place on or off reservation no longer answers the question. Instead, the relative involvement of tribal members and non-members becomes decisive.

Of course, *Akins* and *Fellencer* themselves form part of our prior legal understanding of internal tribal matters. However, these cases provide little more than an analytical framework for considering the issue. Neither case offers a definitive interpretation of the scope of internal tribal matters. To the contrary, the First Circuit emphasized that "[w]e tread cautiously and write narrowly, for the problems and conflicting interests presented by this case will not be the same as the problems and interests presented in the next case." *Akins*, 130 F.3d at 487. *Akins*, while recognizing one example of natural resource regulation as an internal tribal matter, was narrowly drawn to address only stumpage permits where state legal requirements were not at issue. Overall, *Fellencer* went somewhat further in addressing impacts on non-members, holding that a tribe could regulate the activities of a non-member who was acting on tribal territory, serving tribal members, and whose activities had a direct impact on tribal health and welfare. It is tempting to read these cases together to say that natural resource management decisions having a direct impact on tribal health and welfare are an internal tribal matter. But these holdings, as discussed earlier, are not so broad. *Akins* emphasized that tribal authority extended to activities of tribal members, and in some case non-members, *within* tribal territory. *Akins*, 130 F.3d at 489. *Fellencer* relied heavily on its understanding of employment discrimination law as a major source of support for its decision that tribal employment decisions are internal tribal matters. The law surrounding the employment issue indicated quite clearly that tribal governmental employment decisions were retained as an element of inherent tribal sovereignty under MICSA.

Although the situation outside Maine may be quite different, under MICSA EPA has concluded that establishing WQS in Indian water in Indian lands in Maine is not an internal tribal matter. Tribal comments have suggested that under *Fellencer*, tribes may regulate non-member activities that have a direct effect on tribal health and welfare. This reading, however, stretches the First Circuit's decision far past its boundaries. In finding that the Tribe could exercise authority over a non-member to protect tribal health and welfare, the *Fellencer* court emphasized the minimal effects on non-members versus the significant effect on tribal members, as well as the clear statutory basis for the Tribe's control over its governmental employment decision. Here, tribal WQS under the CWA potentially could impact non-tribal members. EPA cannot extend the results of these cases to such vastly different circumstances, particularly when the reasoning of the cases counsels us to do the opposite.

Tribal government as an element of internal tribal matters, including establishing cancer risk levels and fish consumption rates as a matter of tribal policy judgments.

The Tribes argue that establishing cancer risk levels and fish consumption rates are matters of tribal government policy that are part of a distinctly governmental function, that of establishing WQS under the CWA. The Tribes assert that this should lead EPA to conclude that as a legal matter Maine does not have jurisdictional authority to set such standards.

EPA's response

EPA agrees that Maine's fishing designated uses and the Northern and Southern Tribes' trust land and reservation land sustenance fishing practices require adequate protection under the CWA. However, that fact, as important as it is to the Tribes' physical, spiritual and cultural existence, does not alter the jurisdictional framework embodied in the settlement acts. Those vital interests and cultural practices of the Tribes, as critical elements of their survival and well-being may still be protected to the extent authorized under the CWA, and EPA's disapproval of Maine's HHC as they would apply to waters within Indian lands demonstrates that very important point. As the First Circuit has stated, not every matter that might fall within the notion of a governmental function necessarily constitutes an internal tribal matter under MIA and MICSA. "That a tribe attempts to govern a matter does not render it an internal tribal matter." *Akins* at 486.

We agree with the comments from the Tribes' advocates that water quality regulation is of central importance to these Tribes and is a critical issue in maintaining their culture and way of life. We also understand the Tribes' desire to exercise as direct a control over that water quality as possible. Outside the context of the settlement acts, we agree with the Tribes that water quality management is a core governmental function, and therefore that it should generally be reserved to tribal governments. EPA cannot agree, however, that MIA's reference to "tribal government" as one of the examples of internal tribal matters sweeps into that concept all the attributes generally associated with Indian self-governance outside Maine.

C. Tribes commented that EPA will be unable to protect tribal resources if EPA determines Maine has authority to establish WQS in waters within Indian lands.

EPA's response

Certain comments from the Tribes generally raised concerns about the protection of tribal resources if EPA determines Maine has authority to establish WQS in waters within Indian lands. EPA recognizes that if Maine is the standard-setting authority, the State will have the first opportunity to make the judgment calls involved in implementing the WQS program. However, the State's WQS must still meet CWA requirements, which include establishing water quality criteria that assure uses are protected. As demonstrated

by EPA's decision to disapprove certain of Maine's WQS on the basis that they do not adequately protect tribal sustenance fishing practices, EPA's oversight of the State's program through authority established in the CWA plays an important role in protecting water quality in Indian lands notwithstanding the jurisdictional arrangement established by the settlement acts.

Notwithstanding the Tribes' concerns, the practical realities of how a state's WQS program operates do not suffice as a basis for ignoring the jurisdictional arrangement in the settlement acts. As discussed extensively above, Congress has revised that customary jurisdictional formula in Maine. So, pursuant to the settlement acts and the CWA, EPA must acknowledge that the State has the authority to establish WQS applicable to Indian lands, just as the First Circuit has already determined that Maine has the authority to issue federal NPDES permits in Indian lands.

EPA does not agree that finding Maine has authority to implement the WQS program in Indian lands constitutes some sort of delegation to the State of the trust responsibility. As already explained in this RTC document, EPA has discussed the proper interpretation of the trust responsibility to the Maine Tribes generally, and in this matter specifically. EPA has also explained its continuing role in CWA program oversight, in which the trust plays a role. The Agency's continuing role in program oversight does provide adequate tools under the CWA for protecting the Maine Tribes' interests. But before discussing those oversight mechanisms, it is important to understand the context within which EPA's oversight authority operates and how that relates to MICSA's provisions. There are various provisions in the CWA that assign EPA the task of reviewing a state's decisions in implementing the CWA. The Act expresses this authority in various ways, but essentially EPA is either charged with intervening or provided the opportunity to intervene when state decisions do not comply with the requirements of the CWA.[8]

Maine's comments suggest that MICSA's provisions, especially the savings clauses, prevent EPA from exercising its CWA oversight authorities on behalf of the Tribes consistent with the trust responsibility. In EPA's view, Maine inaccurately characterizes EPA's oversight in this matter as "apply[ing] heightened scrutiny to Maine's WQS before approving them as to Indian Territory." See page 10 of Maine's September 13, 2013 WQS comments. EPA is not applying heightened scrutiny to Maine's WQS, but rather is exercising its responsibility as required under the CWA, and consistent with the settlement acts, to protect the Maine Tribes' sustenance fishing practices. See EPA's Decision Support Document. In so doing, EPA is at the same time acting consistently with the trust responsibility to the Tribes. The implication embedded within Maine's comment is that such a decision by EPA would accord the Tribes a special status and that intervening in a state regulatory decision under the CWA would affect or preempt the

[8] See e.g., 33 U.S.C. § 1342(d)(2)(when objecting to a proposed State NPDES permit, EPA shall provide a State with "a statement of the reasons for such objection and the effluent limitations and conditions which such permit would include if it were issued by the Administrator") and 40 CFR 123.44(c), or 33 U.S.C. § 1313(c)(4)(B)(EPA shall promulgate a water quality standard "if a revised or new water quality standard submitted by such State . . . is determined by the Administrator not to be consistent with the applicable requirements of this chapter").

State's jurisdiction to make that decision, which would run afoul of MIA and MICSA. Ultimately, the CWA establishes EPA's relevant authority, which EPA is exercising consistent with the federal trust responsibility. 33 U.S.C. §1251 et. seq. As mentioned before, MIA, in 30 M.R.S.A. Section 6207(4), reserves for the Penobscot Nation and the Passamaquoddy Tribe a right to take fish for their individual sustenance within their reservations. MICSA, in 25 U.S.C. Section 1724(h), reserves for these Indians the right to manage their natural resources. The CWA specifically gives EPA the authority to administer the statute to protect surface waters. 33 U.S.C. § 1251 et. seq. More specifically, the CWA gives EPA certain authority to oversee state water quality standards to ensure that they adequately protect human health and the environment. 33 U.S.C. § 1313. And EPA is exercising that authority to protect the resource uses that are here of interest to the Tribes -- the sustenance fishing uses of those waters -- consistent with the trust relationship and the requirements of the CWA.

EPA does not agree with Maine's interpretation of the effect of MICSA's savings clauses on the trust, because the Agency's disapproval of Maine's HHC as they would apply to waters within Indian lands is grounded in the requirements of both the CWA and the settlement acts. No state in the nation has "jurisdiction" to establish WQS contrary to the requirements of the CWA, at least in the sense that states cannot do so without running the risk that EPA will disapprove them. Therefore, the savings clauses in MICSA do not shield Maine from EPA's oversight under the CWA when EPA bases its objections on CWA requirements, for such objections do not affect any authority or jurisdiction that Maine has.

D. EPA must protect a broad range of cultural, spiritual, and physical aspects of the Tribes' lifestyles and associated resources. Sustenance fishing touches on all of these aspects of the Tribes' existence and culture.

EPA's response

EPA fully recognizes, respects and appreciates the broad range of cultural, spiritual, and physical aspects of the Tribes' lifestyles and associated resources, and the ways in which a sustenance fishing lifestyle touches on all of these aspects of the Tribes' existence and culture. EPA's disapproval of Maine's HHC as they would apply to waters within Indian lands reflects the extent to which, under the CWA, EPA has the authority to ensure that Maine's WQS adequately protect the Tribes' sustenance fishing practices in relation to the Tribes' fish consumption and therefore their health. EPA notes, however, that notwithstanding EPA's recognition of and respect for the multi-faceted nature of the Tribes' sustenance fishing lifestyle and the various ways in which the Tribes' existence and culture depends on that practice, the focus of EPA's decision to disapprove certain of Maine's WQS in Indian lands necessarily is specific to the physical health-related fish consumption practices of the Tribes. That focus is necessary pursuant to the authority

provided by Congress to EPA under the CWA and the WQS program when human health criteria are established.[9]

However, EPA recognizes that in so protecting the Maine Tribes' sustenance fishing practices, through a focus on human health impacts, other cultural and spiritual aspects of grave importance to the Tribes may also be protected. This does not mean that EPA is overreaching or extending its authority under the CWA; it simply means that there are collateral benefits that arise due to the fact that protecting the Tribes' health through protection of their sustenance fishing practices has implications for other important aspects of their lifestyle and culture.

E. Tribal comment: Maine's regulatory actions and expressed legal positions demonstrate that the Maine Tribes' subsistence practices will not be protected by Maine.

EPA's response

As explained earlier in this RTC document, the accuracy or inaccuracy of factual statements such as this one is not a factor that can affect the jurisdictional arrangement established by the settlement acts. EPA's earlier explanation in this document about its ability and obligation to ensure that the Maine Tribes' sustenance fishing practices are protected under Maine's WQS program shows how the Tribes' concerns about Maine's future intentions are being addressed by EPA in accordance with CWA requirements. See EPA's Decision Support Document for a more detailed discussion.

II. Tribal comment: Even if EPA approves Maine's WQS to apply in waters in Indian Territory, EPA should ensure that the Tribes have a "decisive role in decision-making that affects its waters."

EPA's response

Prior to EPA's decision today to approve and to disapprove certain of Maine's WQS, EPA complied with its obligations to consult with the Maine Indian Tribes about Maine's WQS submissions. EPA carefully considered the Tribes' views, interests, and policy and legal arguments, along with all other pertinent information, including public comments and other sources of information in the administrative record, in reaching its decision to approve and to disapprove certain of Maine's WQS for waters in Indian lands. EPA will continue to act within the confines of the CWA consistent with the trust responsibility in reviewing any future new or revised WQS by Maine that would affect tribal waters and

[9] Tribes have argued that in addition to fishing for their individual consumption, the definition of sustenance traditionally incorporated other components, including but not limited to barter and exchange. Commission Saltwater Fisheries Report, at p. 22-33. EPA is not deciding in its approval and disapproval of certain of Maine's new and revised WQS whether any of these other components, beyond the Tribes' individual consumption of fish, are properly part of the definition of the term "sustenance" as those other components are not, in any event, relevant to development of human heath criteria under the CWA.

uses. EPA will ensure that the Maine Tribes remain involved in any such matters through the government-to-government consultation process EPA is committed to follow.

III. Tribal comment: Even if EPA approves Maine's WQS to apply in waters in Indian Territory EPA should put written procedures in place to moderate between the State and Tribes.

EPA's response

See response to comment immediately above. In addition, EPA agrees that such written procedures would be very helpful, and EPA is prepared to facilitate discussions among the Maine Tribes and Maine. However, EPA notes that there is no legal basis for EPA to *demand* that such written procedures exist as a precondition to the State exercising its jurisdiction to establish WQS in waters in Indian lands.

IV. Tribal comment: EPA must ensure that "designated uses" are protected.

EPA's response

EPA's disapproval of certain of Maine's WQS demonstrates that EPA is fulfilling its CWA obligation to ensure that designated uses under the CWA are protected by water quality criteria. See EPA's Decision Support Document for a detailed discussion and explanation.

V. Tribal comment: A fundamental Congressional purpose in creating the Southern Tribes' reservations was to protect the sustenance fishery.

EPA's response

EPA agrees that a fundamental purpose behind creation of the Southern Tribes' reservations was to protect the sustenance fishery. As discussed earlier in this document, and in greater detail in EPA's Decision Support Document, this Congressional purpose supports EPA's decision to insist on criteria that protect the sustenance fishing rights associated with waters in the Southern Tribes' reservations in Maine. At the same time, however, this Congressional purpose does not function to alter the jurisdictional arrangement among the State, the federal government, and the Maine Tribes, established by Congress in MICSA.

VI. Tribal comment: MICSA sets forth a sustenance fishing right reserved to Southern Tribes (not abrogated by any provisions of MICSA).

EPA's response

EPA agrees that MICSA sets forth a sustenance fishing right reserved to Southern Tribes that has not been abrogated by any provisions of MICSA or any other federal law. As discussed earlier in this document, and in greater detail in EPA's Decision Support Document, this fact supports EPA's decision to insist on criteria that protect the sustenance fishing use associated with the Southern Tribes' reservations. At the same time, however, the sustenance fishing right reserved to the Southern Tribes does not function to alter the jurisdictional arrangement among the State, federal government, and the Maine Tribes, established by Congress in MICSA.

VII. Tribal comment: Maine fails to recognize the Maine Tribes as separate sovereigns, for purposes of downstream water quality protection.

EPA's response

EPA has addressed earlier in this RTC document the question of the sovereign status of the Maine Tribes and the extent to which that factor does or does not play a part in EPA's analysis of whether Maine has jurisdiction to establish WQS in Indian lands and how EPA views the general trust responsibility to the Maine Tribes.

Further, as noted earlier in relation to a similar comment about Maine's interactions with the Maine Tribes, the accuracy of factual statements such as this one is not a factor that can affect the jurisdictional arrangement established by MIA and MICSA. EPA's earlier explanation in this document about its ability and obligation to protect the Maine Tribes' fishing practices under the CWA, as demonstrated by EPA's disapproval of Maine's HHC as they would apply to waters within Indian lands, shows how the Tribes' concerns about Maine's future intentions with regard to their sustenance fishing practices under the CWA are being addressed by EPA in compliance with CWA requirements.

Additionally, any NPDES permits issued by Maine must ensure adequate protection of WQS that may apply in tribal waters. Thus, if Maine or EPA were to promulgate more stringent WQS applicable to waters in Indian lands in Maine, in response to EPA's disapproval of Maine's HHC, any NPDES permits issued by Maine must ensure adequate protection of such WQS.

VIII. Maine's comments (not already responded to earlier in this RTC document).

1. **Maine's comment: Under the operative statutes Maine has authority and responsibility to establish WQS for all state waters, including waters near or within Indian territories.**

EPA's response

EPA's letter to Maine in response to its WQS submissions indicates that EPA agrees that Maine has adequate legal authority to establish WQS for all state waters, including waters in Indian lands. See EPA's Decision Support Document for a more detailed discussion.

2. **Maine's comment: The applicable statutes don't permit EPA or the Tribes to establish WQS in the State's stead.**

EPA's response

Today, EPA is affirming that Maine has the legal authority to set WQS for waters in Indian lands. Maine's assertion that the Tribes and EPA do not have the legal authority to establish such standards instead of Maine no longer is pertinent given EPA's determination that Maine has such authority. However, if Maine does not address in a timely manner under the CWA the WQS deficiencies EPA's decision letter has identified, the CWA *requires* EPA to promulgate such standards in the State's stead. Furthermore, as noted earlier in this RTC document in relation to Maine's assertion that the Maine Indian Tribes are not eligible for TAS status under CWA section 518, EPA's decision is not addressing whether the Tribes separately have such authority.

3. **Maine's comment: EPA must make a formal finding that the State lacks jurisdiction before it can assert federal jurisdiction, which EPA cannot do under MIA and MICSA and *Maine v. Johnson*.**

EPA's response

Today, EPA is affirming that Maine has such legal authority but has found that certain of Maine's WQS are not approvable under the CWA. In addition, Maine's assertion that EPA does not have the legal authority at this time to establish such standards is no longer pertinent given EPA's determination that Maine has such authority. However, if Maine does not address in a timely manner under the CWA the WQS deficiencies EPA's decision letter has identified, the CWA *requires* EPA to promulgate such standards in the State's stead.

4. **Maine's comment: EPA approved many WQS submissions, some including in the Penobscot River, without mentioning jurisdictional issues, and also approved designated uses that do not mention anything about tribal interests or sustenance fishing. EPA's NPDES record belies EPA's own legal position.**

EPA's response

See EPA's Decision Support Document for a partial response to and discussion of the issues raised by this comment.

In addition, as of 2004, EPA's letters to Maine responding to the State's proposed new and revised water quality standards expressly stated that EPA's decision to approve or disapprove did not apply to waters within Indian Country. Consequently, there would not have been a reason for EPA to address in those letters tribal interests in waters in Indian lands, including sustenance fishing. Moreover, the fact that ME DEP may have issued NPDES permits to facilities that discharged directly or indirectly into the Penobscot River, and that EPA may not have offered any comments about those permits, does not constitute an acknowledgment by EPA that Maine's WQS had been approved by EPA to apply in waters in Indian lands.

As to NPDES permits that EPA issued to the Penobscot Nation's POTW, EPA included language that indicated, not that Maine's WQS directly applied to such discharges as a legal matter, but that as a practical matter Maine's WQS provided some guidance as to how the NPDES permit's effluent limits for pollutants should be written or determined. When EPA recited that those permits met Maine WQS that applied "in the proximity" of the discharge, the Agency very consciously used a formulation that did not recite that Maine's WQS applied at the point of discharge. Basically, EPA looked to the nearest approved WQS as guidance for the discharge limits in those permits. The State's WQS approved outside Indian lands provided that guidance. In the absence of federal, state or Indian WQS applicable under the CWA at the point of discharge, this course of action makes abundant practical sense.

5. **Maine's comment: The State has asked EPA to explain its legal basis for not applying State WQS in Indian Territory and EPA has never responded.**

EPA's response

Whether or not the State's comment is accurate is no longer a relevant point because EPA's decision today has answered that question. In addition, EPA notes that a lack of a response before its decision today would, in any event, not be able to affect the outcome of a legal analysis dictated by the settlement acts and the CWA.

6. **Maine's comment: The "trust responsibility" only applies to trust lands, not reservation lands in Maine (which are not held in trust).**

EPA's response

See discussion above beginning at page 11.

7. **Maine's comment: MICSA's savings clauses render the "the trust obligation" inapplicable in Maine.**

EPA's response

See discussion above beginning at page 38.

8. **Maine's comment: Indian Tribes in Maine are not eligible for TAS status under CWA Section 518.**

EPA's response

See discussion above beginning at page 15.

9. **Maine's comment: Maine asserts that there is no basis for EPA to treat waters within Indian territories any differently than the waters in Maine outside of Indian territories.**

EPA's response

EPA's Decision Support Document demonstrates the inaccuracy of Maine's comment and discusses in detail the reasons why EPA has determined that there is a significant difference between such waters and their uses for purposes of the CWA.

10. **Maine's comment: EPA's current review is unlawful and unnecessary.**

    a. **Statute gives EPA 90 days to act and require changes to submitted WQS. EPA did not require changes within 90 days, so EPA cannot require changes now.**

EPA's response

EPA disagrees with Maine's reading of the CWA provisions at issue. As described by the United States Department of Justice in legal pleadings filed in Maine's case filed against EPA, State of Maine, et. al. v. McCarthy et. al., Civil Action No. 1:14cv264, (United States District Court for the District of Maine 2014), no provision of the CWA or its implementing regulations preclude EPA from disapproving a state's WQS on the basis that EPA did not inform such state within 90 days of its WQS submission to EPA that

changes to the state's proposed WQS are necessary. The following description of the relevant CWA authorities sets forth the correct sequence of events in relation to a state's WQS submission and EPA's review.

States must hold public hearings for the purpose of reviewing their WQS, and, as appropriate, modifying and adopting standards, at least once every three years beginning with October 18, 1972. 33 U.S.C. § 1313(c)(1). This review and revision process is commonly referred to as the triennial review process. Any new or revised WQS adopted by a state must be submitted to EPA for a determination of whether it meets the CWA's requirements. 33 U.S.C. § 1313(c)(1) and (3); 40 C.F.R. §§ 131.5, 131.6 and 131.20. EPA's review of such WQS involves the application of EPA's legal, scientific and policy expertise. *See* 40 C.F.R. § 131.5. If EPA determines that the new or revised WQS is consistent with the CWA, then EPA shall so notify the relevant state within 60 days from the date of submission. 33 U.S.C. § 1313(c)(3); 40 C.F.R. § 131.21(a)(1).

If EPA determines that the new or revised WQS is not consistent with the CWA, EPA shall notify the state within 90 days from the date the WQS is submitted that it is disapproved, and must specify necessary changes. 33 U.S.C. § 1313(c)(3); 40 C.F.R. § 131.21(a)(2). If the state then fails to adopt the specified changes within 90 days of EPA's notice, EPA must "promptly" propose a federal WQS for the waters involved. 33 U.S.C. § 1313(c)(4)(A); 40 C.F.R. § 131.22(a). Then, unless the state revises its WQS and EPA approves that revision, EPA must proceed to promulgate the WQS itself. 33 U.S.C. § 1313(c)(4)(A).

In the context of its CWA citizen suit claim, Maine asserted that EPA has waived its authority to disapprove Maine's outstanding WQS, that EPA is barred from disapproving such WQS, and that EPA is required to approve such WQS, apparently on the theory that EPA loses its authority to disapprove WQS when it misses the statutory deadline to do so. Congress provided EPA with authority to approve or disapprove new or revised WQS regardless of whether EPA has met the statutory deadline for doing so under CWA section 303(c)(3).
As discussed above, new and revised WQS must be submitted to EPA for review. 33 U.S.C. § 1313(c)(2)(A). *If* EPA determines that the new or revised WQS meets the requirements of the CWA, EPA shall approve the WQS within 60 days. *Id.* at § 1313(c)(3). *If* EPA determines that the new or revised WQS is not consistent with the requirements of the CWA, EPA shall within 90 days of submission disapprove the WQS and specify necessary changes. *Id.* "On its face, this language plainly supports . . . that Congress did not intend new or revised state standards to be effective until after EPA had reviewed and approved them." *Alaska Clean Water Alliance v. Clarke*, 1997 WL 446499 * 3 (W.D. Wash. July 8, 1997). Indeed, the CWA does not even remotely suggest that Congress intended for EPA to lose its authority to approve or disapprove a WQS, or that the WQS must automatically be deemed approved, if EPA fails to act by the 60 or 90-day statutory deadlines. *See* 33 U.S.C. § 1313(c)(2)(A); *United States v. James Daniel Good Real Property*, 510 U.S. 43, 63 (1993) ("[I]f a statute does not specify a consequence for noncompliance with statutory timing provisions, the federal courts will not in the ordinary course impose their own coercive sanction.").

Moreover, to the extent the CWA is ambiguous on this point, EPA has explained in the context of a CWA rulemaking that "the concept of a default approval of state and tribal WQS submissions is not consistent with section 303 of the CWA [because] [s]ection 303(c)(3) requires EPA to make an affirmative finding that the standards revisions submitted to EPA are consistent with the CWA." 65 Fed. Reg. 24,641, 24,646 (Apr. 27, 2000). EPA's interpretation of CWA section 303(c) as not providing for automatic approvals or disapprovals of WQS if EPA does not act within the 60 or 90 day windows of that section is entitled to deference. *See Chevron U.S.A., Inc. v. Natural Res. Def. Council, Inc.*, 467 U.S. 837, 842-43 (1984). In addition, Congress has expressly provided a remedy when EPA fails to timely respond to a WQS submission. The CWA citizen suit provision provides the district courts with jurisdiction to order EPA to perform its mandatory duty to approve or disapprove a new or revised WQS when EPA has failed to timely respond. 33 U.S.C. § 1365(a). As the Supreme Court has explained, "[w]hen, as here, there are less drastic remedies available for failure to meet a statutory deadline, courts should not assume that Congress intended the agency to lose its power to act." *Brock v. Pierce County*, 476 U.S. 253, 260 (1986).

b. Maine's comment: There is no basis for separate federal notice and comment.

EPA's response

See EPA's introduction to this RTC document for a response to this comment.

c. Maine's comment: The Maine Tribes were well aware and participated in the State's action.

EPA's response

EPA reviewed Maine's notice to the public and the public's comments on Maine's proposed WQS revisions. In the first instance, while the Tribes in Maine participated in the State's public process, their comments focused entirely on the adequacy of the state standards and whether they would protect sustenance fishing. The Tribes' comments did not focus on the State's authority to set standards for waters in the Tribes' lands. It is reasonable to assume that the Tribes were concerned about how Maine's WQS might impact sustenance fishing opportunities in waters outside Indian lands. It was not clear that Maine's notice alerted the public and the Tribes to the State's assertion of jurisdiction to set WQS for waters in the Tribes' lands.

Ultimately, EPA determined that, in light of the great deal of interest in the jurisdictional and technical issues involved in Maine's proposal, it would be prudent to err on the side of caution by taking additional steps to ensure that the Maine Tribes and other members of the public had clear notice of the implications of Maine's proposed WQS revisions.

EPA had never before approved or disapproved in Maine WQS revisions to be applied to waters within Indian lands. Moreover, EPA received additional comments from the Maine Tribes and from the ME DEP and the Maine Office of the Attorney General that were not part of Maine's administrative record for its WQS revisions at the state level; and to that extent the record before EPA is now more complete.

d. Maine's comment: Maine accuses EPA of bad faith, "creating" jurisdictional controversy where there is none.

EPA's response

As set forth in great detail in EPA's Decision Support Document, EPA's decision has two essential components, a legal jurisdictional component and a scientific/technical component. The latter required a complex assessment by EPA of the adequacy of Maine's criteria in relation to the designated uses of the waters in Indian lands, once EPA determined that Maine had jurisdiction. The complexity of the issues with which EPA was confronted, demonstrated by the content of its decision documents both as to the jurisdictional analysis and technical determinations, shows that EPA was not creating a jurisdictional controversy where there was none. In fact, it is a significant mischaracterization of the issues confronting EPA, and of EPA's deliberative process, to portray EPA's activities and process as nothing more than "creating" a jurisdictional controversy.

In the end, EPA concluded that there is no valid legal basis to distinguish or depart from the First Circuit's reasoning and decision in *Maine v. Johnson* that Maine has jurisdiction to implement the CWA NPDES program in Indian lands. A careful analysis was warranted, however, due to the arguable differences between the NPDES and WQS programs, and due to the copious substantive comments EPA received from the State and Maine Tribes on the jurisdictional question. For EPA not to have ensured that its decision had the benefit of the full explanation of the State's and the Tribes' views on this question could have led to a decision for which there was an incomplete and possibly flawed administrative record.

11. Maine's comment: Maine's submitted WQS are approvable and there is no basis upon which EPA may disapprove them.

EPA's response

EPA's Decision Support Document explains in detail the bases upon which EPA has decided to disapprove Maine's HHC for waters in Indian lands. EPA disagrees with Maine's assertion that "there is no basis upon which EPA may disapprove" any of Maine's WQS. In summary, EPA's disapproval of Maine's HHC for waters in Indian lands is based on the fact that Maine did not use a fish consumption rate that results in criteria that are sufficient to protect the designated use of sustenance fishing in those waters. EPA's Decision Support Document also contains an explanation of EPA's

identification of the sustenance fishing designated uses for waters in Indian lands that derives from Congress's purpose in confirming and establishing, through the settlement acts, sustenance fishing in the Southern Tribes' reservations and in the trust land waters of the Southern and Northern Tribes. We refer the reader to EPA's Decision Support Document for more detailed information relevant to Maine's comment.

12. Maine's comment: Maine's WQS protect sensitive subpopulations that engage in sustenance fishing.

EPA's response

EPA's Decision Support Document discusses EPA's determination, consistent with the requirements of the CWA, that Maine's HHC do not adequately protect the Maine Tribes' health given the Tribes' sustenance fishing practices and the designated use of sustenance fishing in waters in Indian lands. EPA also disagrees with Maine's characterization of the Maine Tribes as "sensitive subpopulations" of the State's general population. EPA's Decision Support Document explains that the Maine Tribes constitute their own *general* population in the geographic areas defined by their reservations and trust lands and that it would therefore be inappropriate to treat the Tribes merely as a "sensitive subpopulation" of Maine's general population in waters located within Indian lands. We refer the reader to EPA's Decision Support Document for more detailed information relevant to Maine's comment.

13. Maine's comment: Maine's WQS are based on technically sound and objective data and analysis regarding cancer risk, fish consumption rates and bioconcentration.

EPA's response

EPA has approved many of Maine's WQS as being technically sound regarding cancer risk, fish consumption rates and bioconcentration. However, for the reasons set forth in EPA's Decision Support Document, EPA does not agree that Maine's HHC meet CWA requirements as applied in waters within Indian lands in Maine, because the fish consumption rate on which they are based is not representative of the Tribes' sustenance fishing. See also EPA's responses to comments VIII. 10 and 11 above, regarding fish consumption rates used by Maine and the fact that it would not be consistent with the requirements of the CWA, as informed by the settlement acts, to treat the Maine Indian Tribes as a "sensitive subpopulation" of Maine's general population.

14. Maine's comment: EPA has used in the past some of this data (meaning the data used in establishing the WQS submitted to EPA in January 2013).

EPA's response

EPA has never "used" the data Maine refers to in its comment for purposes of determining whether Maine's WQS meet CWA requirements in waters within Indian lands in Maine. The fact that EPA may have considered this data in the past to approve Maine's HHC in waters outside Indian lands, including whether such criteria are protective of highly exposed subpopulations fishing in waters outside of Indian lands, is not relevant to the question whether Maine's WQS meet CWA requirements for the target population of tribal members engaged in sustenance fishing in waters located in Indian lands.

15. Maine's comment: Maine's human health criteria are grounded in the empirical, local population-specific data that EPA prefers.

EPA's response

EPA acknowledges that Maine's HHC are based in part on local, population-specific fish consumption data, and EPA has approved those criteria for waters outside of Indian lands. However, as discussed in EPA's Decision Support Document and summarized briefly in earlier responses above to some of Maine's other comments, EPA has determined that the localized data are not representative of unsuppressed tribal sustenance fish consumption in waters in Indian lands, and therefore the HHC that are based on the localized data are not adequate to protect the sustenance fishing use in those waters. Maine must use fish consumption data that are representative of unsuppressed tribal sustenance fish consumption in waters in Indian lands, such as the data from the Wabanaki Cultural Lifeways Exposure Scenario ("Wabanaki Study"), which was completed in 2009, rather than the 1990 study conducted by McLaren/Hart – ChemRisk, of Portland, Maine (the "ChemRisk Study"[10]) that was actually used by Maine. See also EPA's responses above relating to Maine's calculation of a fish consumption rate and the fact that the Maine Tribes are the general population to which HHC should be targeted for waters in Indian lands.

[10] ChemRisk, A Division of McLaren Hart, and HBRS, Inc., *Consumption of Freshwater Fish by Maine Anglers,* as revised, July 24, 1992. See also Ebert, E.S., N.W. Harrington, K.J. Boyle, J.W. Knight, R.E. Keenan, *Estimating Consumption of Freshwater Fish among Maine Anglers,* North American Journal of Fisheries Management, 13:4, 737-745 (1993); http://dx.doi.org/10.1577/1548-8675(1993)013<0737:ECOFFA>2.3.CO;2

IX. Maine Tribes' comments regarding the adequacy of Maine's WQS

1. **Tribal comment: Apart from the jurisdictional question, Maine's WQS for arsenic, phenol and acrolein are scientifically and legally flawed, and are arbitrary and capricious.**

EPA's response

EPA's Decision Support Document explains in detail the bases of EPA's decision to disapprove the three HHC identified in the comment, along with the rest of Maine's HHC, as applied to waters within Indian lands. We therefore refer the reader to that document. See also EPA's responses to comments VIII. 10, 11 and 12 above, regarding fish consumption rates used by Maine and the fact that it is not consistent with the requirements of the CWA to treat the Maine Indian Tribes as a "sensitive subpopulation" of the general population in Maine.

2. **Tribal comment: As to arsenic, EPA received comments from the Maine Tribes that Maine's arsenic standard failed to consider other exposure routes and synergistic effects; that the ChemRisk Study used by Maine to establish a fish consumption rate is flawed for a number of reasons; that unscientific manipulation of variables used by Maine to calculate in-stream criteria shouldn't be accepted by EPA; and that the fish consumption rate and cancer risk level used for arsenic by Maine are unacceptable.**

EPA's response

EPA's Decision Support Document sets forth in detail the bases for EPA's disapproval of Maine's arsenic standard as it would apply to waters within Indian lands in Maine. While EPA's decision was not based on all of the objections raised by the Maine Tribes' comments, EPA agrees that Maine's arsenic criteria are not approvable under the CWA for waters in Indian lands. See also EPA's responses to comments VIII. 10, 11 and 12 above, regarding fish consumption rates used by Maine and the fact that it is not consistent with the requirements of the CWA to treat the Maine Indian Tribes as a "sensitive subpopulation" of the general population in Maine.

3. **Tribal comment: Using inconsistent fish consumption rates and cancer risk levels for different WQS is arbitrary and capricious.**

EPA's response

EPA's Decision Support Document sets forth in detail the bases for EPA's disapproval of Maine's HHC as they would apply to waters within Indian lands in Maine. Because EPA is disapproving all of the HHC for waters in Indian lands due to an inadequate fish

consumption rate, it is not necessary at this time to consider the extent to which differing fish consumption rates or cancer risk levels for different criteria might be approvable for those waters.

4. **Tribal comment: The arsenic in-stream concentration is increasing as compared to Maine's prior in-stream concentration for arsenic, which imposes increased risks to tribal members.**

EPA's response

EPA's Decision Support Document sets forth in detail the bases for EPA's disapproval of Maine's HHC, including arsenic, as they would apply to waters within Indian lands in Maine. Because EPA is disapproving Maine's arsenic criteria as it would apply to waters in Indian lands, it is premature to address how Maine's arsenic HHC for waters in Indian lands will compare with the prior criterion.

5. **Tribal comment: The Penobscot Nation comments that the Wabanaki study contains "site specific" data, and that the CWA does not preclude the use of site-specific data from any particular time period in establishing WQS.**

EPA's response

EPA's Decision Support Document sets forth in detail the bases for EPA's disapproval of Maine's HHC as they would apply to waters within Indian lands in Maine. EPA agrees with the Penobscot Nation that, based on the data and information available at this time, fish consumption data from the Wabanaki Study is the best available representative data and thus, barring any better data being collected, must be used in establishing HHC for waters in Indian lands in Maine. See also EPA's responses to comments VIII. 10, 11 and 12 above, regarding fish consumption rates used by Maine and the fact that it is not consistent with the requirements of the CWA to treat the Maine Indian Tribes as a "sensitive subpopulation" of the general population in Maine.

6. **Tribal comment: The Penobscot Nation comments that its sustenance fishing right is an "existing use" and a "designated use" as those terms are used in the CWA. The Tribe further comments that Maine's human health WQS submission shows that these uses will not be protected in waters within Indian lands.**

EPA's response

EPA's Decision Support Document sets forth in detail the bases for EPA's disapproval of Maine's HHC as they would apply to waters within Indian lands in Maine. Included in the Decision Support Document is EPA's explanation of its identification of the designated use of sustenance fishing for waters within Indian lands and its relationship

both to CWA requirements and to Congress's purpose in establishing the Maine Tribes' reservations and trust lands under the settlement acts. EPA agrees that Maine's current HHC are not adequate to protect the designated use of sustenance fishing that applies to waters in Indian lands and therefore has disapproved those criteria. See also EPA's responses to comments VIII. 10, 11 and 12 above, regarding fish consumption rates used by Maine and the fact that it is not consistent with the requirements of the CWA to treat the Maine Indian Tribes as a "sensitive subpopulation" of the general population in Maine.

7. **Tribal comment: EPA has a duty to collect more accurate fish consumption rate data, and such data must account for suppression of fish consumption. Maine's WQS fail to consider and account for suppressed fish consumption.**

EPA's response

EPA does not agree that the CWA imposes a duty to collect more accurate fish consumption rate data. But states (or EPA, if EPA is developing the HHC) must use the best available fish consumption data or information to derive HHC that represent an unsuppressed fish consumption rate. EPA agrees that the fish consumption data used by Maine to establish its HHC is not representative of unsuppressed fish consumption associated with tribal sustenance fishing in waters in Indian lands. EPA's Decision Support Document explains the bases of the data derived from the Wabanaki Study and the ChemRisk Study Maine actually used. The Decision Support Document also explains EPA's basis for concluding that the Wabanaki Study provides the best available existing fish consumption data and information for deriving HHC based on an unsuppressed sustenance fish consumption rate for waters in Indian lands in Maine.

8. **Tribal comment: The situation at the Penobscot Nation is not dissimilar to that at other tribes, traditionally dependent upon a subsistence fishery. As EPA concluded in studying fish consumption rates at such tribes in the Northwest, there is "a simple relationship between tribal fish-consuming populations in the Pacific Northwest; people eat what's available to them, what's culturally preferred and at high consumption rates." EPA, TECHNICAL SUPPORT DOCUMENT FOR ACTION ON THE STATE OF OREGON'S NEW AND REVISED HUMAN HEALTH WATER QUALITY CRITERIA FOR TOXICS AND REVISIONS TO NARRATIVE TOXICS PROVISIONS SUBMITTED ON JULY 8, 2004 (June 1, 2010) at 47.**

EPA's response

See EPA's response to comment IX. 7., immediately above.

ATTACHMENT A

Analysis Supporting EPA's February 2, 2015 Decision to Approve, Disapprove, and Make No Decision on, Various Maine Water Quality Standards, Including Those Applied to Waters of Indian Lands in Maine

EXECUTIVE SUMMARY

Maine's Department of Environmental Protection (DEP) submitted numerous new or revised water quality standards (WQS) to EPA for review and approval under the Clean Water Act (CWA) between 2003 and 2014. In its decisions from 2004-2013 following review of such WQS, EPA limited its approvals of the new or revised WQS to state waters outside of Indian territories and lands in Maine ("Indian lands"), and explicitly refrained from taking any action on the WQS for waters in Indian lands. In its decision today, EPA is responding to the outstanding new and revised WQS from 2003-2014 as they relate to waters in Indian lands, and, in the case of some of the WQS, also as they relate to state waters outside of Indian lands.

As summarized below and explained in more detail in the body of this decision support document, Maine has the authority to establish WQS for waters in Indian lands, subject to EPA's authority under the CWA to review and approve or disapprove such standards. After evaluating the various new and revised WQS contained in DEP's submissions from 2003-2014, EPA is today approving all of the aquatic life criteria for toxic pollutants for waters in Indian lands except for ammonia, and all but one of the new aquatic life criteria submitted in 2013 for all waters, including in Indian lands.[1] EPA is also approving a number of other WQS provisions for waters in Indian lands, as well as Maine's classifications and designated uses for those waters. EPA is disapproving Maine's human health criteria as they apply to waters in Indian lands. Finally, EPA has identified a number of provisions on which it is taking no action because they are not WQS and therefore are not subject to EPA review.

The bases for two aspects of EPA's decision today are summarized below because of their complexity -- EPA's conclusion that Maine has the authority to establish WQS in waters in Indian lands, and EPA's conclusion that Maine's human health criteria do not protect the designated uses and therefore must be disapproved.

[1] EPA is taking no action on the ammonia criteria and certain provisions related to bacteria and pesticides, based on our understanding from discussions with DEP staff that DEP will be revising these criteria and provisions in light of recent EPA criteria recommendations and to ensure the protection of designated uses, nor is EPA taking action on the reclassification of a non-tribal water (Long Creek), pending further discussion with DEP. See section 4.8 below. EPA is also taking no action on one of the new phenol criteria for all waters pending DEP's correction of a mathematical error, which DEP has agreed to correct. See section 4.3 below. Finally, EPA is taking no action on the cancer risk level for arsenic in light of EPA's disapproval of the arsenic criteria for waters in Indian lands. See section 4.2.4 below.

The Issue: The State of Maine submitted numerous new and revised water quality standards (WQS) for EPA to approve under the Clean Water Act in the territories and lands of the federally recognized Indian Tribes in Maine – the Penobscot Nation, Passamaquoddy Tribes, Houlton Band of Maliseet Indians, and Aroostook Band of Micmacs. Under well-established principles of federal Indian law, states generally do not have authority to regulate the environment in Indian country. Maine asserts that in the Maine Indian Claims Settlement Act (MICSA) Congress granted the State jurisdiction to regulate the environment in the Tribes' lands, including the authority to set WQS. The Tribes contest that assertion, noting especially that state WQS have the potential to determine how much fish they may safely eat in waters where the Tribes fish for their sustenance. The Tribes assert the State has not adequately accounted for their sustenance fishing practices in setting the WQS submitted to EPA.

Jurisdiction to set WQS: EPA analyzed the jurisdictional provisions of MICSA extensively, including a careful review of comments from the Tribes and Maine on the jurisdictional provisions of the statute. EPA concludes that under the unique jurisdictional formula Congress established in Maine, the State has jurisdiction to set WQS in the waters on the Tribes' lands. See *Maine v. Johnson*, 498 F.3d 37 (1st Cir. 2007). But the Agency also finds that this authority is not unconstrained. EPA is required under the Clean Water Act to review state WQS, and will approve them when they comply with the Act. In these circumstances, where Maine is authorized to set WQS in tribal waters, EPA is informed by the operation of the Indian settlement acts in Maine and will require that WQS in tribal waters protect the Tribes' sustenance fishing use of those waters.

Sustenance Fishing Use in Tribal Waters: The first step in establishing and reviewing WQS is to determine the uses of the waters. In tribal waters, EPA must harmonize the CWA requirement that WQS must protect uses with the fundamental purpose for which land was set aside for the Tribes under the Indian settlement acts in Maine. Those settlement acts, which include MICSA and other state and federal statutes that resolved Indian land claims in the State, provide for land to be set aside as a permanent land base for the Indian Tribes in Maine. One clear purpose of that set aside is to provide a land base on which these Tribes could continue their unique cultures. A critical element of tribal cultural survival is the ability to exercise sustenance living practices, including sustenance fishing. There are multiple provisions in the Indian settlement acts that specifically codify the Tribes' sustenance practices. Maine general law regulating fish take accommodates sustenance fishing, and in several regards also specifically codifies the Tribes' ability to sustenance fish. The legislative record supporting the Indian settlement acts in Maine makes it clear that the statutes intend to create a land base on which the Tribes in Maine may fish for their sustenance. Therefore, EPA interprets the State's "fishing" designated use, as applied in tribal waters, to mean "sustenance" fishing; and EPA is approving a specific sustenance fishing right reserved in one of the settlement acts as a designated use for certain tribal reservation waters.

Protecting the Sustenance Fishing Use: To adequately protect that sustenance fishing use, the State must revisit two aspects of its analysis supporting the human health criteria that determine how clean the waters must be to allow the Tribes to safely consume fish for their sustenance. First, the analysis must treat the tribal population exercising the sustenance fishing use as the target general population, not as a high-consuming subpopulation of the State. EPA guidance

calls for WQS that provide a high level of protection for the general population, while recognizing that small subpopulations may face greater levels of risk. However, the Tribes are not a subpopulation using the waters on their own lands; they are the population for which that land base was established and set aside. Second, the data used to determine the fish consumption rate for tribal sustenance consumers must reasonably represent tribal consumers taking fish from tribal waters and fishing practices unsuppressed by concerns about the safety of the fish available to them to consume. The data on which the State relied to develop fish consumption rates for these WQS did not include information about the sustenance practices of tribal members fishing in their own waters, nor did they represent consumption levels that were unsuppressed by concerns about pollution. EPA concludes that the best available data that represent the unsuppressed sustenance fishing practices of tribal members fishing in tribal waters are contained in the Wabanaki Lifeways study, which looked at the historic sustenance practices of the Tribes in Maine.

EPA has received a written legal opinion dated January 30, 2015 from the Solicitor of the Department of the Interior (DOI) addressing several of the issues involved in EPA's decision. EPA sought DOI's advice because the Department is the federal government's expert agency on matters of Indian law and is charged with administering the settlement acts in Maine. *Passamaquoddy Tribe v. State of Maine*, 75 F.3d 784, 794 (1st Cir. 1996) (DOI is the department that administers MICSA). DOI has provided EPA important insight into how the Indian settlement acts in Maine address the Tribes' right to fish and the critical relationship between those rights and water quality. In making our decision on Maine's WQS, EPA has carefully considered and relied upon the DOI Solicitor's analysis, which is reflected in DOI's written opinion and is included in the administrative record for this decision.

The Remedy: EPA is disapproving Maine's human health criteria because they are not protective of human health for the target population. They are based on a fish consumption rate of 32.4 grams per day, with the exception of arsenic which is based on 138 grams per day. However, the Wabanaki study indicates that consumption values between 286 and 514 grams per day represent the sustenance fishing use in tribal waters. EPA is approving Maine's regulation requiring that human health criteria, except for arsenic, be based on a cancer risk level of no more than one in a million (10^{-6}) as applied to the Tribe's waters, because that is a reasonable level of risk for a general target population. EPA is approving nearly all the State's aquatic life criteria, because they are consistent with the Clean Water Act and unlike the human health criteria, they do not implicate the safety of fish for human consumption. The Clean Water Act gives the State 90 days to address the bases for EPA's disapproval of the human health criteria, after which time, if the State does not do so, EPA will propose and promulgate appropriate human health criteria for waters in Indian lands in Maine.

why?

1 Background

1.1 Overview

On January 14, 2013, the Maine Department of Environmental Protection (DEP) submitted a request to EPA to approve five new or revised water quality criteria (WQC) and specifically asked EPA to approve them in all waters located in the State of Maine, including waters in the territories and lands of the federally recognized Indian Tribes in Maine.

EPA's review of the State's submission determined that when the State provided public notice on its proposed WQS revisions, it was not clear on the record that the State had solicited comment on the question of the State's authority to set WQS in waters in the Tribes' territories and lands (as explained further below, hereinafter EPA will use the term Indian or tribal "lands" to refer to the entire tribal land base in Maine). Although EPA does not customarily provide public notice for state WQS submissions, the Agency exercised its discretion in the unique circumstances of this submittal to invite public comment on the issue of applying state WQS in waters in Indian lands in Maine. EPA identified two general areas for comment. First, has the State demonstrated adequate authority to set WQS in waters in Indian lands? Second, if so, are the WQC that the State submitted based on sound scientific rationale and adequate under the Clean Water Act (CWA) to protect uses in those waters?

This document contains the detailed explanation to accompany EPA's decision letter acting on the State's request that EPA approve these WQS for waters in Indian lands. In addition, from 2004 through 2010, in response to Maine's 2003 to 2009 submittals of new or revised WQS, EPA approved WQS for waters outside of Indian lands, but specifically stated that EPA was taking no action to approve or disapprove WQS within Indian lands. Today's decision addresses all of Maine's WQS submissions from 2003 through 2014 as they relate to waters in Indian lands, as well as certain submissions on which EPA has not yet acted for any waters in Maine.[2]

In summary, EPA finds that Maine has jurisdiction to set WQS for waters in Indian lands. Because EPA has not yet approved any of Maine's WQS for waters in Indian lands, EPA is first approving the State's classifications and associated designated uses for these waters. All of the relevant classifications include a designated use of "fishing," which the Agency interprets to include sustenance fishing consistent with these Tribes' sustenance practices in waters on their lands. EPA is also approving a specific sustenance fishing use for the inland waters of the reservations of the Penobscot Nation and Passamaquoddy Tribe. EPA is approving all but one of the State's aquatic life criteria. EPA has determined that Maine's human health criteria, however, do not adequately protect the designated use of sustenance fishing in the waters in tribal lands and, therefore, do not comply with the CWA's requirement that criteria protect the

[2] EPA is also approving today certain pre-2004 WQS for waters in Indian lands to the extent necessary to act on the submissions from 2003 through 2014. EPA intends to act on other pre-2004 WQS applicable to those waters as soon as possible. Before 2004, EPA's approvals or disapprovals of new or revised WQS in Maine did not address waters in Indian lands, or expressly consider the State's jurisdiction to establish WQS for such waters or the sufficiency of the State's WQS for such waters under the CWA. EPA thus takes the position that it has not previously approved any of the State's pre-2004 WQS for waters in Indian lands in Maine.

uses of the waters to which they apply. In a separate document EPA will respond to specific comments that interested parties submitted.

1.2 Indian Tribes in Maine

There are four federally recognized Indian Tribes in Maine represented by five governing bodies. The Penobscot Nation and the Passamaquoddy Tribe have reservations and trust land holdings in central and coastal Maine. The Passamaquoddy Tribe has two governing bodies, one on the Pleasant Point Reservation and another on the Indian Township Reservation. The Houlton Band of Maliseet Indians and the Aroostook Band of Micmacs have trust lands further north in the State. To simplify the discussion of the legal framework that applies to each Tribe's territory, EPA will refer to the Penobscot Nation and the Passamaquoddy Tribe together as the "Southern Tribes" and the Houlton Band of Maliseet Indians and Aroostook Band of Micmacs as the "Northern Tribes." EPA acknowledges that these are collective appellations the Tribes themselves have not adopted, and the Agency uses them solely to simplify drafting this decision.

1.3 Settlement Acts in Maine

1.3.1 MIA and MICSA

In 1980, Congress passed the Maine Indian Claims Settlement Act (MICSA), which resolved litigation in which the Southern Tribes asserted land claims to a large portion of the State of Maine. 25 U.S.C. §§ 1721, *et seq.* MICSA ratified a state statute passed in 1979, the Maine Implementing Act (MIA), which was designed to embody the agreement reached between the State and the Southern Tribes. 30 M.R.S. §§ 6201, *et seq.* In 1981, MIA was amended to include provisions for land to be taken into trust for the Houlton Band of Maliseet Indians, as provided for in MICSA. 30 M.R.S. § 6205-A, 25 U.S.C. § 1724(d)(1). Since it is Congress that has plenary authority as to federally recognized Indian Tribes, MIA's provisions concerning jurisdiction and the status of the Tribes are effective as a result of, and consistent with, the Congressional ratification in MICSA.

1.3.2 MSA and ABMSA

In 1989, the Maine legislature passed the Micmac Settlement Act (MSA) to embody an agreement as to the status of the Aroostook Band of Micmacs. 30 M.R.S. §§ 7201, *et seq.* In 1991, Congress passed the Aroostook Band of Micmacs Settlement Act (ABMSA), which ratified the MSA. 25 U.S.C. § 1721, Act Nov. 26, 1991, P.L. 102-171, 105 Stat. 1143. One principal purpose of both statutes was to give the Micmacs the same settlement that had been provided to the Maliseets in MICSA. See ABMSA § 2(a)(4) and (5). In 2007, the Federal Court of Appeals for the First Circuit confirmed that the Micmacs and Maliseets are subject to the same jurisdictional provisions in MICSA. *Aroostook Band of Micmacs v. Ryan*, 484 F.3d 41 (1st Cir. 2007).

Where appropriate, this document will refer to the combination of MICSA, MIA, ABMSA, and MSA as the "settlement acts."

1.4 Indian Territories and Lands in Maine

MICSA, MIA, MSA and ABMSA establish a unique framework for confirming and enhancing the Tribes' land base in Maine. For the Southern Tribes, MIA uses the term "Indian territory" to describe the combination of the Southern Tribes' reservations, as described in treaties with the States of Maine and Massachusetts, plus 150,000 acres of land for each Tribe to be held in trust for the Tribes by the United States. 30 M.R.S. § 6205(1) and (2). As such, the Southern Tribes' land base is made up of both the reservations continuously occupied by the Tribes, and subsequently acquired trust lands.

The land base for the Northern Tribes is made up entirely of trust lands. MIA provides for the Houlton Band of Maliseet Indians to acquire trust land, and Congress provided $900,000 in MICSA to fund that acquisition. 30 M.R.S. § 6205-A, 25 U.S.C. § 1724(d)(1). Similarly, the MSA provides for the Aroostook Band of Micmacs to acquire trust land, and Congress again provided $900,000 in ABMSA to fund that acquisition. 30 M.R.S. § 7204, ABMSA §§ 4(a) and 5(a).

In this document, where appropriate depending on the context, EPA will refer to the tribal land base relevant to this decision as follows: "territories" for the Southern Tribes' land base, which as described above includes both reservations and trust lands; "trust lands" for the Northern Tribes' land base; and "Indian" or "tribal" lands for the entirety of all the Tribes' land base in Maine.[3]

1.4.1 Identification of waters covered by this decision

The Penobscot Indian Nation and Passamaquoddy Tribe have reservation lands as defined in MIA. 30 M.R.S. § 6203(5) (defining Passamaquoddy Indian Reservation); § 6203(8) (defining Penobscot Indian Reservation). The trust lands acquired for the Maine tribes are the product of modern conveyances. Generally, based on the default Maine property rule under which owners of riparian land also own out to the thread, or middle, of most streams, *Wilson & Son v. Harrisburg*, 107 Me. 207, 212-213 (1910), Indian waters include waters adjacent to land held in trust by the Secretary of the Interior and lands in the Tribes' reservations as defined in the Settlement Acts.[4] In addition, Maine common law provides that owners of shore land above the mean high water mark presumptively hold title in fee to intertidal land. *Bell v. Town of Wells*, 557 A.2d 168 (Supreme Judicial Court of Maine, 1989). In *Bell* (often referred to as the "Moody Beach case"), the court explained that such title is subject only to the public's right to fish, fowl, and navigate, and that the rule of law governing titles to intertidal land has its origin in the

---

[3] In addition to their reservations and trust lands, the Tribes also hold certain lands in fee, which are not at issue in this matter. Any action EPA has taken to approve Maine WQS for waters outside Indian lands would apply to waters in these fee lands.

[4] See Report of the Joint Select Committee on Indian Land Claims, Maine Legislature (1980), par. 14. ("The boundaries of the Reservations are limited to those areas described in the bill, but include any riparian or littoral rights expressly reserved by the original treaties with Massachusetts or by operation of State law. Any lands acquired by purchase or trade may include riparian or littoral rights to the extent they are conveyed by the selling party or included by general principles of law. However, the Common Law of the State, including the Colonial Ordinances, shall apply to this ownership. The jurisdictional rights granted by this bill are coextensive and coterminous with land ownership.")

Colonial Ordinance of 1641-47 of the Massachusetts Bay Colony. As stated in an article written by the Marine Law Institute, University of Maine School of Law, "[t]he Moody Beach Case affirms that in Maine owners of beachfront property or property adjoining tidelands (also called littoral or riparian owners) have property rights to the low water mark or low tide area subject only to a public easement for fishing, fowling, and navigation." See Citizens' Guide to Ocean and Coastal Law, Public Shoreline Access and the Moody Beach Case, August, 1990. Therefore, the Passamaquoddy Tribe's reservation at Pleasant Point would include at least the waters present in the intertidal zone.

EPA acknowledges that there are remaining uncertainties over what waters are associated with Indian lands in Maine in a few locations. For instance, the boundaries of the Penobscot Nation's reservation are currently the subject of litigation in the United States District Court for the District of Maine. *Penobscot Nation v. Mills,* Case No. 1:12-cv-254-GZS. The United States has intervened in that case, and it is the Government's position that the reservation includes Penobscot River waters, while the State of Maine alleges it does not. Pending resolution of this dispute, EPA's decision to approve or disapprove Maine's WQS for Indian waters includes at least some portion of the Penobscot River in the main stem from Indian Island north surrounding the islands in the Nation's reservation.

In addition, this decision treats the Passamaquoddy Tribe's reservation as including the "15 islands in the St. Croix River in existence on September 19, 1794 and located between the head of the tide of that river and the falls below the forks of that river . . ." as specifically enumerated in MIA's definition of the reservation. 30 M.R.S. 6203(5).

It is not necessary or reasonable for EPA to suspend its decision on the State's WQS submissions to await an authoritative resolution of disputes over the boundaries of Indian waters. If any disputes over reservation boundaries result in an authoritative adjudication inconsistent with the assumptions made in this decision, EPA will revisit or clarify the scope of the Agency's determinations in this decision.

2 EPA's Determination that Maine has Authority to Set WQS in Indian Territories

EPA concludes that MICSA provides the State with jurisdiction to set WQS in the Northern Tribes' trust lands and that the federal statute ratifies provisions of MIA that provide the State with such authority in the Southern Tribes' territories. Although in both cases the settlement acts provide the State jurisdiction to establish WQS, EPA notes that MICSA provides a different jurisdictional framework for the Northern Tribes than that which applies to the Southern Tribes.

2.1 Northern Tribes

MICSA provides that the Northern Tribes are subject to state law:

> Except as provided in section 1727(e) and section 1724(d)(4) of this title, all Indians, Indian nations, or Tribes or bands of Indians in the State of Maine, other than the Passamaquoddy Tribe, the Penobscot Nation, and their members, and any lands or natural resources owned by any such Indian, Indian nation, Tribe or band of Indians and any

> lands or natural resources held in trust by the United States, or by any other person or entity, for any such Indian, Indian nation, Tribe, or band of Indians shall be subject to the civil and criminal jurisdiction of the State, the laws of the State, and the civil and criminal jurisdiction of the courts of the State, to the same extent as any other person or land therein.

25 U.S.C. 1725(a). In addition, MICSA ratified MIA, which also provides that all tribes in Maine, including the Northern Tribes are subject to state law:

> Except as otherwise provided in this Act, all Indians, Indian nations, and Tribes and bands of Indians in the State and any lands or other natural resources owned by them, held in trust for them by the United States or by any other person or entity shall be subject to the laws of the State and to the civil and criminal jurisdiction of the courts of the State to the same extent as any other person or lands or other natural resources therein.

30 M.R.S. § 6204. Both statutes make it clear that laws of the State include regulation and that lands and natural resources include water and water rights. 25 U.S.C. §§ 1722(b) and (d); 30 M.R.S. § 6203(3) and (4). The only exceptions to state jurisdiction provided in MIA apply to the Southern Tribes. There are no such exceptions for the Northern Tribes. Notably, the U.S. Court of Appeals for the First Circuit has expressly found that the State's jurisdictional reach in the Northern Tribes' lands is greater than in the Southern Tribes' territories. *Houlton Band of Maliseet Indians v. Ryan*, 484 F.3d 73, 74-75 (1st Cir. 2007). That same year the First Circuit ruled that, even as to the Southern Tribes, MICSA and MIA grant the State jurisdiction to regulate surface water discharge permitting. *Maine v. Johnson,* 498 F.3d 37 (1st Cir. 2007). As discussed below, EPA has concluded that the court's analysis controls our decision as to the State's authority to set WQS in the Southern Tribes' territories. Given that MICSA gives the State a broader scope of jurisdiction over the Northern Tribes than over the Southern Tribes, which are nevertheless subject to the State's authority to set WQS, it is clear that state law applies to the Northern Tribes, and the State has authority to set WQS for waters in these Tribes' trust lands.

The Aroostook Band of Micmacs has argued that the passage of ABMSA impliedly repealed the application of MICSA to the Tribe, and, therefore, that the Micmacs were not subject to the same jurisdictional framework as the Houlton Band of Maliseet Indians. The First Circuit, however, rejected that argument. *Aroostook Band of Micmacs v. Ryan*, 484 F.3d 41, 60-62 (1st Cir. 2007).

2.2 Southern Tribes

MICSA addresses the jurisdictional relationship between the Southern Tribes and the State by reference to MIA, which MICSA ratifies:

> The Passamaquoddy Tribe, the Penobscot Nation, and their members, and the land and natural resources owned by, or held in trust for the benefit of the Tribe, nation, or their members, shall be subject to the jurisdiction of the State of Maine to the extent and in the

> manner provided in the Maine Implementing Act and that Act is hereby approved, ratified, and confirmed.

25 U.S.C. § 1725(b)(1). As discussed above, MIA in turn provides generally that all Indian Tribes in the State are subject to state law:

> Except as otherwise provided in this Act, all Indians, Indian nations, and Tribes and bands of Indians in the State and any lands or other natural resources owned by them, held in trust for them by the United States or by any other person or entity shall be subject to the laws of the State and to the civil and criminal jurisdiction of the courts of the State to the same extent as any other person or lands or other natural resources therein.

30 M.R.S. § 6204. Importantly, MIA section 6204 refers to exceptions to the grant of state jurisdiction found elsewhere in the statute, and those exceptions are all applicable to the Southern Tribes. *See, e.g.*, §§ 6206 (internal tribal matters); 6207 (hunting and fishing in Indian territories); 6209-A & B (minor crimes, small claims, child custody, and domestic relations). EPA has carefully considered whether any of the exceptions provided in MIA operate to block the grant of jurisdiction to the State in the area of setting WQS in the Southern Tribes' waters. EPA concludes that they do not impede the State's jurisdiction to establish WQS under the CWA for the Southern Tribes' waters.

2.2.1 Maine v. Johnson Decision

The U.S. Court of Appeals for the First Circuit previously adjudicated the issue of Maine's authority to regulate water quality protection in the Southern Tribes' territories. In 2003, EPA approved the State to issue national pollutant discharge elimination system (NPDES) permits under the CWA generally in the Southern Tribes' territories, except for those dischargers where EPA concluded that permitting would qualify as an internal tribal matter. MIA section 6206 exempts the Southern Tribes' internal tribal matters from state regulation. EPA determined that two tribally owned and operated public treatment works, which served only tribal members on the Tribes' reservations and had minimal water quality impacts at the point of discharge, qualified as internal tribal matters, and thus excluded those two facilities from the State's approved permitting program. In *Maine v. Johnson,* 498 F.3d 37 (1st Cir. 2007), the First Circuit upheld EPA's approval of the State's program in the Southern Tribes' territories, but reversed EPA's decision to withhold approval of the State to issue the permits for the two tribal treatment works.

> In ordinary statutory construction, the [internal tribal matters] proviso thus reserves to the tribe matters pertaining to tribal membership and governance structure, expenditure of fund income and *other matters of the same kind . . .;* but it does not displace general Maine law on most substantive subjects, including environmental regulation. . . . [W]e readily uphold the position of the EPA and Maine that the nineteen non-Indian discharge sources draining into tribal waters can be regulated by the state. The only real question is the EPA's carve-out of the two source points that are on tribal lands and are owned by Tribe entities. . . .

> In our view, the Settlement Acts make ordinary Maine law apply, even if only tribal members and tribal lands are affected in the particular case, *unless* the internal affairs exemption applies; and the scope of that exemption is determined by the character of the subject matter. Discharging pollutants into navigable waters is not of the same character as tribal elections, tribal membership or other exemplars that relate to the structure of Indian government or the distribution of tribal property.

Id. at 44-46 (emphasis in original; citations omitted). EPA has concluded that the *Maine v. Johnson* decision makes it clear that the grant of jurisdiction to the State includes the area of environmental regulation, certainly as it applies to surface water discharge permitting. The Agency also finds no basis to distinguish the analysis in that case as applied to the State's authority to set WQS for surface waters in the Southern Tribes' territories.

2.2.2 Arguments Maine Tribes have Advanced for Exceptions to State Jurisdiction for Southern Tribes

EPA considered whether, given the jurisdictional provisions of the applicable statutes and the precedent set in *Maine v. Johnson*, there is any basis for concluding that the State's authority to administer the NPDES permitting program would not apply equally to the State's WQS program. EPA concludes there is no such basis.

2.2.2.1 Internal Tribal Matters

As a threshold matter, the court in *Maine v. Johnson* concluded that environmental regulation was part of the jurisdictional grant to the State in Indian lands:

> [T]he [internal tribal matters] proviso thus reserves to the tribe matters pertaining to tribal membership and governance structure, expenditure of fund income and *other matters of the same kind* . . .; but it does not displace general Maine law on most substantive subjects, including <u>environmental regulation</u>.

Id. at 45 (emphasis in original; underscore added). The WQS program is clearly a form of environmental regulation that would be covered by this characterization of the State's authority. Strictly speaking, the facts on which the court's holding rests only presented the question of the State's authority to issue waste water discharge permits. Nevertheless, the court's reasoning in that case makes it clear that this exception to State jurisdiction would not block the State from setting WQS.

When the Agency withheld approval from Maine to permit the two tribal treatment works, EPA conducted an analysis of the factors the First Circuit articulated in two prior cases examining whether a particular subject matter qualifies as an internal tribal matter not subject to state regulation. *Akins v. Penobscot Nation*, 130 F.3d 482, 486-490 (1st Cir. 1997); *Penobscot Nation v. Fellencer*, 164 F.3d 706, 710-713 (1st Cir. 1999). In its review of EPA's decision, the *Johnson* court found it unnecessary to apply the factors developed in the *Akins* and *Fellencer* cases; rather it concluded that this multi-factor assessment is relevant only when an area of regulation is

"arguably close to the (perhaps blurred) statutory borderline" of what might qualify as an internal tribal matter. 498 F.3d at 46. The court concluded that "discharging pollutants into navigable waters is not a borderline case in which balancing . . . or ambiguity canons . . . alter the result." *Id.* (citations omitted).

EPA evaluated whether the authority to set WQS is any closer to the statutory borderline the First Circuit has outlined and, therefore, might properly be analyzed using the *Akins/Fellencer* factors rather than the more categorical analysis in the *Johnson* decision. The Penobscot Nation commented to EPA that setting WQS directly affects the quality of fish the Tribe is able to consume for its sustenance, an area of concern at the core of the Nation's existence. The Penobscot Nation's view is that this effect on the Tribe's ability to safely consume fish makes setting WQS an internal tribal matter. EPA does not agree. Indeed, the Agency concludes that setting WQS is an exercise of jurisdiction even further from the "borderline" between state jurisdiction and internal tribal matters that the *Johnson* court posited.

The decision EPA is making is approval of WQS that are an integral part of a larger legal framework provided for in the CWA. Within that framework, the CWA and EPA's regulations provide that NPDES permits for upstream dischargers must include limits that assure compliance with downstream WQS. 40 C.F.R. § 122.44(d)(4) and CWA § 401(a)(2). In reviewing Maine's NPDES program, EPA found that permitting the two tribal treatment works involved only tribal members and would have minimal effect on water quality outside the Tribes' territories. See 498 F.3d at 45 n. 8. EPA cannot make a corresponding finding here that setting a WQS would not have the potential for an effect on non-members or on water quality outside the Tribes' territories. When it established the multi-factor internal tribal matters analysis, the *Akins* court noted that "*First, and foremost*, the [stumpage policy at issue] purports to regulate only members of the Tribe . . .." 130 F.3d at 486 (emphasis added). On this "foremost" factor, EPA concludes that the WQS program can have regulatory effects beyond the Tribe. Generally, downstream WQS determine what limits upstream dischargers must meet to assure protection of those WQS, which is a legal effect that could reach beyond the membership of the Tribes and the boundaries of their territories. These effects put the setting of WQS even further from the "(perhaps blurred) statutory borderline" of what qualifies as an internal tribal matter under the MIA and MICSA.

In *Maine v. Johnson* the court was prepared to accept EPA's finding that permitting the two tribal treatment works would not have a substantial effect outside the Tribes' territories, and it still refused to treat the category of waste water discharge permitting as an internal tribal matter. Here, EPA cannot find that setting WQS will have no potential for a substantial effect outside the Tribes' territories. Therefore, under the principles announced in *Maine v. Johnson*, EPA concludes that setting WQS does not qualify as an internal tribal matter.

2.2.2.2 The Southern Tribes' Sustenance Fishing Right

EPA has also considered whether the reservation in MIA of the Southern Tribes' right to take fish for their individual sustenance within their reservations provides an exception to the State's jurisdiction. That right is reserved to the Southern Tribes "[n]otwithstanding . . . any other law of the State." 30 M.R.S. § 6207(4). Arguably, if a state law interfered with the Southern Tribes' right to take fish for their individual sustenance, this provision would block that law's

application in the Southern Tribes' reservations. However, EPA concludes that the State's administration of WQS, subject to CWA requirements and EPA's oversight, does not have the potential to interfere with the Southern Tribes' sustenance fishing right.

MIA is clear that the basic grant of jurisdiction to the State includes the authority to apply laws of the State, which include regulations, to the Tribes' natural resources, which include "water and water rights and hunting and fishing rights." 30 M.R.S. §§ 6204, 6203(3) and (4). To conclude that the reserved fishing right precludes the operation of all state laws affecting environmental regulation that might indirectly affect the fishing right, one would have to conclude that the State's regulation of water quality is inherently and necessarily inimical to the Tribes' ability to take fish for their individual sustenance. EPA cannot reach that conclusion.

First, there are many state WQS that are reasonably adequate to support a fishery that could provide for an individual tribal member's sustenance. Indeed, as discussed below, EPA is approving many state WQS provisions that EPA has determined are sufficient to protect aquatic life. In *Maine v. Johnson* the court made it clear that decisions about the scope of the State's jurisdiction in the Southern Tribes' territories should be made on the basis of the category of the subject matter at issue – the court specifically rejected EPA's attempt to find or reject state jurisdiction based on the facts of any particular application of state jurisdiction within a subject matter category. "So we accept the EPA's factual premise as to the [limited] impact of the discharges but not the EPA's legal characterization. . . . [T]he scope of [the internal tribal matters] exemption is determined by the character of the subject matter." 498 F.3d at 45-46. The subject category at issue in *Maine v. Johnson* was environmental regulation of pollutants in surface waters, the same category at issue here. The impact of a specific state WQS regulation on the Tribes' sustenance fishing rights might provide the basis for a challenge to that specific regulation, but the bare potential for such a specific challenge at some point provides no basis for precluding all state regulation of that subject area. It is possible for the State to exercise jurisdiction to set WQS without necessarily or inevitably interfering with the Tribes' fishing rights.

Second, if the State does submit a new or revised WQS that would interfere with the Tribes' reserved fishing right, EPA has authority under the CWA to ensure that the Tribes' fishing right is protected. As described further below, EPA is approving the reserved sustenance fishing right as a designated use for the tribal waters to which the right applies. Where the State adopts a new or revised WQS, EPA has the authority and the obligation under the CWA to review and determine whether such new or revised WQS is consistent with the CWA. If EPA disapproves, the CWA directs EPA to propose and promulgate a new or revised WQS unless the State adopts an adequate revision to protect the use. The CWA thus provides the mechanism to protect the sustenance fishing use and prevent interference with the Southern Tribes' reserved fishing right. EPA's oversight of Maine's WQS is adequate to protect the Tribes' right while maintaining the basic statutory grant of jurisdiction to Maine, including the authority to set WQS, as provided under MICSA in the first instance.

2.3 The Relationship Among MISCA, Jurisdiction, and the Trust Responsibility

Several Tribes in Maine commented that it would be inconsistent with the federal government's trust relationship with the Tribes for EPA to approve the State to set WQS for waters in the Tribes' lands. On the other hand, the State argues that the trust relationship does not apply in the State because of MICSA.

EPA has consistently maintained that there is a trust relationship between the federal government and the Tribes in Maine in the general sense that the Tribes are federally recognized, they have sovereign governments that EPA interacts with on a government-to-government basis, and EPA has a responsibility to consult with the Tribes to understand and consider their interests when EPA is making a decision that affects the Tribes. This general trust relationship, however, does not alter the jurisdictional framework Congress ratified in MICSA. MICSA impacts the jurisdictional relationship among the Tribes and the State, within which EPA works to address the Tribes' interests as appropriate. It is consistent with the trust relationship for EPA to approve the State's authority to set WQS for waters in the Tribes' lands, because MICSA has dramatically revised the jurisdictional framework within which the trust operates in Maine as compared to the customary jurisdictional framework that applies in Indian country outside Maine. EPA intends to continue to act consistently with the trust relationship, to consult with the Tribes, and to consider their interests as we oversee the State's WQS under the CWA.

2.4 The Penobscot Nation's Application for Treatment in the Same Manner as a State

On October 8, 2014, the Penobscot Nation submitted to EPA an application "to administer water quality standards program and for federal approval of the standards" covering the Main Stem of the Penobscot River from Indian Island north to the confluence of the east and west branches of the river. EPA is not acting today on the Nation's application. EPA is only deciding today that the State of Maine has authority to set WQS for waters in Indian lands, and then acting on the State's WQS as applied to those waters. The Nation's application raises complicated issues that EPA will address in a separate decision.

3 EPA's Determination to Approve Classifications and Designated Uses for Waters in Indian Lands

In Section 2, above, EPA focused on the settlement acts and judicial interpretation of those statutes to analyze Maine's assertion of jurisdiction to set WQS in the waters in Indian lands. Having concluded that the State has jurisdiction to set those standards, EPA must now analyze whether the State's WQS as applied to waters in Indian lands are approvable under the CWA. So the balance of this document will focus primarily on the requirements of the CWA, as applied to the unique circumstances EPA must address here where a state is setting WQS for waters in lands that Congress has set aside for federally recognized Indian tribes.

The first step in developing and reviewing WQS under the CWA is to determine the uses of the waters to which the WQS apply. Here the State is not writing on a blank slate in the selection of uses for tribal waters. As described in detail in this section 3, EPA has concluded that the settlement acts operate to require Maine and the Agency to focus on the sustenance fishing use that federal and state law provide for the Tribes in Maine in waters in Indian lands. In light of

the sustenance fishing use, the CWA requires the State's water quality criteria to protect that use as explained in section 4, below.

3.1 Status of Previous State WQS as Applied to Waters in Indian Lands

3.1.1 EPA's Prior Decisions on Maine WQS

Maine has periodically submitted new or revised WQS to EPA for review and approval or disapproval. Before 2004, EPA acted on those WQS without expressly considering or approving the State's jurisdiction to establish WQS for waters in Indian lands or the sufficiency of the State's WQS for such waters under the CWA. Since 2004, EPA has expressly stated, in all decisions that it made to approve or disapprove new or revised WQS, that its decisions applied only to Maine waters outside of Indian lands.

3.1.2 EPA's Approach to State Programs in Indian Country

The State has commented to EPA that, prior to 2004, EPA approved state WQS submissions without reference to or exclusion of waters in tribal lands. From this the State infers that EPA approved the State's WQS for waters in tribal lands prior to 2004. EPA disagrees with this inference.

First, Maine did not obtain authority to regulate in tribal lands until Congress passed MICSA in 1980. While the State asserted the authority to govern the Tribes prior to MICSA, the First Circuit's decision in *Joint Tribal Council of the Passamaquoddy Tribe v. Morton*, 528 F.2d 370 (1st Cir. 1975), cast considerable doubt on that proposition, and the decision in *Bottomly v. Passamaquoddy Tribe*, 599 F.2d 1061 (1st Cir. 1979), effectively foreclosed this argument. So any WQS that Maine submitted prior to MICSA's passage could have no legal effect in tribal lands. At that point the State had no clear authority to set WQS in those waters.

But even as to WQS that Maine submitted following the passage of MICSA in 1980, EPA's position is that none of the State's WQS, whether submitted prior to or following enactment of MICSA, were approved under the CWA for waters in Indian lands. Prior to the Agency's decision today, EPA has never made a formal determination on the record expressly addressing either the State's jurisdictional authority or the sufficiency under the CWA of the State's WQS as applied to waters in Indian lands.

Today's decision demonstrates that in acting on new or revised state WQS for waters in Indian lands, EPA must consider the adequacy of such WQS to protect the uses in those specific waters. Where, as here, waters in Indian lands have a different designated use (*i.e.*, sustenance fishing) than waters outside of Indian lands, the analysis of the adequacy of criteria will necessarily be different. It would be arbitrary for EPA to assume, without analysis, that if criteria are protective for waters outside of Indian lands, they are also protective for waters in Indian lands.

In addition, under basic principles of federal Indian law, states generally lack civil regulatory jurisdiction within Indian country as defined in 18 U.S.C. § 1151. *Alaska v. Native Vill. Of Venetie Tribal Gov't*, 522 U.S. 520, 527 n.1. (1998) ("[g]enerally speaking, primary jurisdiction

over land that is Indian country rests with the Federal Government and the Indian Tribe inhabiting it, and not with the States."). See also *Okla. Tax Comm'n v. Sac and Fox Nation*, 508 U.S. 114, 128 (1993) ("[a]bsent explicit congressional direction to the contrary, we presume against a State's having the jurisdiction to tax within Indian Country . . . ."). Thus, EPA cannot presume a state has authority to establish WQS or otherwise regulate in Indian country. Instead, a state must demonstrate its jurisdiction, and EPA must determine that the state has made the requisite demonstration and expressly determine that the state has authority, before a state can implement a program in Indian country.[5] Such a demonstration and approval of Maine's authority to administer WQS in waters of Indian lands has not occurred prior to the decision EPA is making today.[6]

Maine cites to several actions by EPA employees that, in the State's view, indicate EPA's recognition that state WQS approved before 2004 apply in at least some tribal waters. EPA notes that some of those actions applied to stretches of rivers that either included both tribal and state waters or that were then and continue to be the subject of disputes over whether they included both tribal and state waters. As a result, those actions were inherently ambiguous as to their relevance to the tribal portions of the waters. But the Agency concedes that in some instances the Agency appeared to assume, without any express consideration or decision regarding the jurisdictional or CWA issues, that state WQS applied in certain tribal waters. For example, there are instances when the Region asked Maine DEP to certify under section 401 of the CWA that NPDES permits for tribal facilities discharging into tribal waters complied with state WQS. Simply put, those prior actions were mistakes that do not affect this decision. At the time, EPA had made no finding that Maine had jurisdiction to adopt WQS for tribal waters and had not approved the State's WQS for such waters. EPA notes that unexplained mistakes by mid-level Agency officials cannot unilaterally revise a considered Agency-wide policy. *Puerto Rican Cement Co. v. EPA*, 889 F.2d 292, 299 (1st Cir. 1989).

3.2 EPA Approval of Water Classifications and Associated Designated Uses

Many of the WQS revisions under review for approval or disapproval for waters in Indian lands are water quality criteria, and the CWA requires that criteria be protective of designated uses. In order to evaluate whether the submitted criteria are protective of designated uses, EPA must first approve designated uses for these waters. Accordingly, EPA also reviewed and is approving

---

[5] Consistent with EPA's responsibility to consult with Indian tribes about decisions affecting their interests, as embodied in the Agency's 1984 Indian Policy and EPA's more recent Tribal Consultation Policy, EPA would offer to consult with any Indian tribe in the context of an Agency determination that a state has authority to set standards in that tribe's territory. Notably, no such consultations occurred in the context of EPA's prior decisions on the State's WQS submissions, further evidencing that the Agency's prior approvals were not intended to extend to waters in Indian lands.

[6] Indeed, as described above in the Agency's analysis of the State's jurisdictional authority to set WQS in Indian waters, EPA's review and assessment of how Maine's WQS affect tribal uses in Indian waters is an essential step in the argument that it is possible to reconcile the State setting WQS in Indian waters with the fishing rights that MICSA reserves to Tribes in Maine. Ignoring or side-stepping EPA's role in overseeing Maine's WQS submissions as they apply to Indian waters risks creating an irreconcilable conflict between the jurisdictional grant to the State in MICSA and the provision for Tribes in Maine to sustain themselves on the land base that the Maine settlement acts established for the Tribes. Respecting EPA's oversight role effectively harmonizes those elements of the settlement acts in Maine.

Maine's surface water classifications and corresponding designated uses, adopted and submitted to EPA for review to date[7], for waters in Indian lands.[8]

The general classifications and their corresponding uses consist of the following:

- 38 M.R.S. § 465(1.A) Class AA freshwater uses: drinking water after disinfection, fishing, agriculture, recreation in and on the water, navigation, and as habitat for fish and other aquatic life. The habitat must be characterized as free-flowing and natural.
- 38 M.R.S. § 465(2.A) Class A freshwater uses: drinking water after disinfection; fishing; agriculture; recreation in and on the water; industrial process and cooling water supply; hydroelectric power generation, except as prohibited under Title 12, section 403; navigation; and as habitat for fish and other aquatic life. The habitat must be characterized as natural.
- 38 M.R.S. § 465(3.A) Class B freshwater uses: drinking water supply after treatment; fishing; agriculture; recreation in and on the water; industrial process and cooling water supply; hydroelectric power generation, except as prohibited under Title 12, section 403; navigation; and as habitat for fish and other aquatic life. The habitat must be characterized as unimpaired.
- 38 M.R.S. § 465(4.A) Class C freshwater uses: drinking water supply after treatment; fishing; agriculture; recreation in and on the water; industrial process and cooling water supply; hydroelectric power generation, except as prohibited under Title 12, section 403; navigation; and as a habitat for fish and other aquatic life.
- 38 M.R.S. § 465-A(1.A) Class GPA lake and pond uses: drinking water after disinfection, recreation in and on the water, fishing, agriculture, industrial process and cooling water supply, hydroelectric power generation, navigation, and as habitat for fish and other aquatic life. The habitat must be characterized as natural. This section applies to great ponds (as defined in 38 M.R.S. § 480-B (5)), natural lakes and ponds less than 10 acres in size, and impoundments of rivers that are defined as great ponds pursuant to 38 M.R.S. § 480-B (5).
- 38 M.R.S. § 465-B (1.A) Class SA estuarine and marine water uses: recreation in and on the water, fishing, aquaculture, propagation and harvesting of shellfish, navigation, and as habitat for fish and other estuarine and marine life. The habitat must be characterized as free-flowing and natural.
- 38 M.R.S. § 465-B (2.A) Class SB estuarine and marine water uses: recreation in and on the water, fishing, aquaculture, propagation and harvesting of shellfish, industrial process and cooling water supply, hydroelectric power generation, navigation, and as habitat for fish and other estuarine and marine life. The habitat must be characterized as unimpaired.
- 38 M.R.S. § 465-B (3.A) Class SC estuarine and marine water uses: recreation in and on the water, fishing, aquaculture, propagation and restricted harvesting of shellfish,

[7] This includes the addition of "agriculture" as a designated use for freshwaters, submitted to EPA on August 26, 2003.

[8] There are other provisions of Maine's WQS that EPA is not approving or disapproving at this time because they are not directly related to the scope of this decision, which is responding to new and revised WQS submitted to EPA from 2003 to 2014. These remaining provisions include, for example, definitions, antidegradation policies, and WQS implementation policies in regulation and statute. EPA will review those elements in the coming months and make decisions accordingly.

industrial process and cooling water supply, hydroelectric power generation, navigation and as a habitat for fish and other estuarine and marine life.

Waters throughout Maine are identified by classification in 38 M.R.S. § 467 (classifications of major river basins), § 468 (classifications of minor drainages), and § 469 (classifications of estuarine and marine waters), which results in the assignment of designated uses for each waterbody.

Each of the classification categories identified above contains designated uses that are consistent with the requirements of Section 303(c)(2)(A) of the Clean Water Act and 40 C.F.R. § 131.6(a). In addition, EPA has concluded that the classifications as applied to specific waters in Indian lands are reasonable. Therefore, EPA is approving the general classifications and associated designated uses in 38 M.R.S. § 465(1.A), (2.A), (3.A), and (4.A); § 465-A(1.A) (and the definition of "great ponds" in 38 M.R.S. § 480-B (5)); and § 465-B(1.A), (2.A), and (3.A); as well as the classification of specific waters in 38 M.R.S. § 467, § 468, and § 468, as applied to waters in Indian lands, because they are consistent with Sections 101(a)(2) and 303(c)(2)(A) of the Clean Water Act and 40 C.F.R. §131.10(a). EPA is including in its approval of specific waterbody classifications the reclassifications, submitted to EPA on December 7, 2009, of Otter Creek, a tributary of Seboeis Stream, and Alder Stream from Class B to Class A; and of Grand Falls Flowage between Route 1(Princeton and Indian Township) and Black Cat Island from Class B to Class GPA.

3.3 EPA's Identification of the "Fishing" Designated Use as "Sustenance Fishing" in Waters in Indian Lands in Maine

3.3.1 The Purpose of the Tribal Land Base and Tribal Sustenance Fishing in Maine

The settlement acts in Maine include extensive provisions to confirm and expand the Tribes' land base, and the legislative record makes it clear that a key purpose behind that land base is to preserve the Tribes' culture and support their sustenance practices. MICSA section 1724 establishes a trust fund to allow the Southern Tribes and the Maliseets to acquire land to be put into trust. In addition, the Southern Tribes' reservations are confirmed as part of their land base. 30 M.R.S. § 6205(1)(A) and (2)(A). MICSA combines with MIA sections 6205 and 6205-A to establish a framework for taking land into trust for those three Tribes, and laying out clear ground rules governing any future alienation of that land and the Southern Tribes' reservations. Sections 4(a) and 5 of the ABMSA and 7204 of the state MSA accomplish essentially the same result for the Micmacs, consistent with the purpose of those statutes to put that Tribe in the same position as the Maliseets.

EPA has concluded that one of the over-arching purposes of the establishment of this land base for the Maine Tribes was to ensure their continued opportunity to engage in their unique cultural practices to maintain their existence as a traditional culture. An important part of the Maine Tribes' traditional culture is their sustenance life ways. The legislative history for MICSA makes it clear that one critical purpose for assembling the land base for the Tribes in Maine was to preserve their culture. The Historical Background in the Senate Report for MICSA opens with the observation that "All three Tribes [Penobscot, Passamaquoddy and Maliseet] are riverine in

their land-ownership orientation." Sen. Rep. No. 96-957, at 11. The Report's "Special Issues" section specifically refutes the concern that:

> *The Settlement will lead to acculturation of the Maine Indians.* – Nothing in the settlement provides for acculturation, nor is it the intent of Congress to disturb the cultural integrity of the Indian people of Maine. To the contrary, the Settlement offers protections against this result being imposed by outside entities by providing for tribal governments which are separate and apart from the towns and cities of the State of Maine and which control all such internal matters. The Settlement also clearly establishes that the Tribes in Maine will continue to be eligible for all federal Indian cultural programs.

Id. at 17. As the Tribes have extensively documented in their comments, their culture relies heavily on sustenance practices, including sustenance fishing. So if a purpose of MICSA is to avoid acculturation and protect the Tribes' continued political and cultural existence on their land base, then a key purpose of that land base is to support those sustenance practices.

As explained in more detail below, MICSA, MIA, ABMSA, and MSA include very different provisions governing sustenance practices, including fishing, depending on the type of Indian lands involved. But each set of provisions in its own way is designed to make a homeland for these Tribes where they may safely practice their sustenance life ways.

3.3.1.1 Southern Tribes' Sustenance Fishing Right Reserved in Their Reservations in MIA/MICSA

If there were any doubt that sustenance practices are central to tribal culture, MICSA ratifies the MIA's reservation of the Southern Tribes' right to take fish for their individual sustenance:

> SUSTENANCE FISHING WITHIN THE INDIAN RESERVATIONS. Notwithstanding any rule or regulation promulgated by the commission or any other law of the State, the members of the Passamaquoddy Tribe and the Penobscot Nation may take fish, within the boundaries of their respective Indian reservations, for their individual sustenance subject to the limitations of subsection 6.

30 M.R.S. § 6207(4). Under this section, "fish" is defined as "a cold blooded completely aquatic vertebrate animal having permanent fins, gills and an elongated streamlined body usually covered with scales and includes inland fish and anadromous and catadromous fish when in inland water." 30 M.R.S. § 6207(9).

The only limitation on the Southern Tribes' right to take fish for their individual sustenance on their reservations is the State's ability to limit the take based on a finding that the Tribes' fishing practices are threatening stocks outside the Tribes' reservations in a process in which the State carries the burden of proof. 30 M.R.S. § 6207(6). To date the State has made no such determination. So a plain language reading of this provision entitles the Southern Tribes to take as much fish as they deem necessary to sustain individual members.

The legislative history for MIA makes it clear that the Maine legislature intended to continue and ratify the State's practice of not regulating the Southern Tribes' sustenance fishing practices. See transcript of the public hearing held on March 28, 1980 by the Maine Legislature's Joint Select Committee on the Maine Indian Claims Settlement at 55-56. The special issues section of the Senate Report on MICSA confirms that the intent of this provision is to shield the Southern Tribes' right to take fish from the prospect that the State might someday interfere with it. By responding to a rhetorical assertion (in italics below), the report confirms that the Southern Tribes have a right to take fish that is subject to state regulation only under very limited circumstances:

> *Subsistence hunting and fishing rights will be lost since they will be controlled by the State of Maine under the Settlement.* – Prior to the settlement, Maine law recognized the Passamaquoddy Tribe's and Penobscot Nation's right to control Indian subsistence hunting and fishing within their reservations, but the State of Maine claimed the right to alter or terminate these rights at any time. Under Title 30, Sec. 6207 as established by the Maine Implementing Act, the Passamaquoddy Tribe and the Penobscot Nation have the permanent right to control hunting and fishing not only within their reservations, but insofar as hunting and fishing in certain ponds is concerned, in the newly-acquired Indian territory as well. The power of the State of Maine to alter such rights without the consent of the affected tribe or nation is ended by Sec. 6(e)(1) of S. 2829. The State has only a residual right to prevent the two tribes from exercising their hunting and fishing rights in a manner which has a substantially adverse effect on stocks in or on adjacent lands or waters. This residual power is not unlike that which other states have been found to have in connection with federal Indian treaty hunting and fishing rights. The Committee notes that because of the burden of proof and evidence requirements in Title 30, Sec. 6207(6) as established by the Maine Implementing Act, the State will only be able to make use of this residual power where it can be demonstrated by substantial [evidence] that the tribal hunting and fishing practices will or are likely to adversely affect wildlife stock outside tribal lands.

Sen. Rep. No. 96-957, pp. 16-17. Importantly, MIA section 6207 did not create a fishing right for the Southern Tribes. Rather it confirmed an aboriginal right the Tribes have continuously exercised, and shielded that right from state regulation absent a finding of depletion. DOI's legal opinion confirms that this statutorily reserved fishing right is rooted in treaty guarantees that were upheld through the settlement acts.

The Senate Committee's discussion of the similarity between MIA section 6207 and the structure of more traditional Indian treaty hunting and fishing rights is instructive. Essentially, the State of Maine has adopted into state law and Congress has ratified a reserved fishing right like the rights reserved to other Indian tribes by treaties, executive orders, or other statutes. It is axiomatic that the settlement acts in Maine significantly revised the customary formulae of federal Indian law that apply outside the State. *Akins*, 130 F.3d at 484. But it is equally important to recognize those elements of the settlement acts where both the state and federal governments made careful provision for tribal rights that mirror those more commonly seen elsewhere in Indian country. *See Washington v. Washington State Commercial Passenger Fishing Vessel Association*, 443 U.S. 658, 674 (1979) (Stevens Treaties explicitly reserved to the Pacific Northwest tribes "'[t]he

right of taking fish, at all usual and accustomed grounds and stations . . . in common with all citizens of the Territory'"). The Southern Tribes' reserved aboriginal right to take fish for their individual sustenance within their reservations is such a right.

3.3.1.2 Federal Law Framework for Sustenance Fishing in Trust Lands

Similarly, to understand how the Maine Tribes' sustenance fishing practices are provided for in their newly acquired trust lands, it is helpful to review the federal law background against which Congress and the State of Maine were legislating when they provided for land to be taken into trust for the benefit of the Maine Tribes. Courts have found that when Congress sets aside land for a fishing tribe, it implicitly grants to the tribe the right to carry out its traditional fishing practices on that land. See *Menominee v. U.S.*, 391 U.S. 404, 405-406 (1968) (holding that lands acquired for the Menominee Tribe included the implicit right to hunt and fish on those lands); *Parravano v. Babbitt*, 70 F.3d 539, 544 (9th Cir. 1995) (recognizing the doctrine "that the grant of hunting and fishing rights is implicit in the setting aside of a reservation 'for Indian purposes.'"); see also *Katie John v. U.S.*, 720 F.3d 1214, 1230 (9th Cir. 2013) (Reserved water rights "are created when the United States reserves land from the public domain for a particular purpose, and they exist to the extent that the waters are necessary to fulfill the primary purposes of the reservation.").

Courts have found an implicit fishing right based on legislative history indicating that, in setting aside land for a tribe, Congress intended to preserve a tribe's fishing culture/practices. See *Menominee*, 391 U.S. at 405 ("The essence of the Treaty of Wolf River was that the Indians were authorized to maintain on the new lands ceded to them as a reservation their way of life which included hunting and fishing."); *Parravano*, 70 F.3d at 542 (In enacting the Hoopa-Yurok Settlement Act, "[o]ne of the concerns of Congress at the time" was "to protect the Tribes' fisheries."); see also id. at 546 ("Although the 1988 Hoopa-Yurok Settlement Act did not explicitly set aside fishing rights, it did make clear that partitioning would not dispossess the Tribes of their assets. The legislative history of the 1988 Act indicates that Congress was aware that each Tribes' interests in their salmon fisheries was one of its principal assets."). As explained in greater detail below, there is such legislative history here.

There is an important distinction between the Southern Tribes' aboriginal fishing right, which Congress explicitly reserved on those Tribes' reservations, and tribal sustenance fishing on the trust lands, which Congress provided for based on its demonstrated intent to preserve the Tribes' riverine culture. EPA is not determining that the Tribes in Maine have an aboriginal fishing right in their trust lands. The Agency acknowledges there is dispute over the scope of the Tribes' aboriginal resource rights following enactment of MICSA. See 25 U.S.C. §§ 1722(b) and 1723(b) and Assessment of the Intergovernmental Saltwater Fisheries Conflict between Passamaquoddy and the State of Maine, Maine Indian Tribal-State Commission: Special Report 2014/1 (June 17, 2014) at 7.

But regardless of the status of aboriginal fishing rights outside the Southern Tribes' reservations, it is possible for Congress to make provision for tribal sustenance fishing on trust lands, not based on the reservation of aboriginal rights, but based on Congressional intent to establish a land base for a tribe in order to sustain its unique culture. As described in detail below, EPA has

determined that Congress did just that in the Maine settlement acts, and when Congress did so, it acted against the backdrop of the principles outlined in the cases above. The legislative record regarding the trust land provisions in MIA, MICSA, MSA and ABMSA demonstrate Congress's intent to provide the Tribes with the opportunity to exercise their traditional sustenance lifeways, including traditional sustenance fishing in waters of tribal trust lands.

3.3.1.2.1 Sustenance Fishing in the Trust Lands of the Southern Tribes

Both MICSA and MIA make it clear that the land acquisition fund for the benefit of the Passamaquoddy and Penobscot Tribes was established to ensure these Tribes not only had a land base to occupy, but also access to natural resources to sustain their continued existence as a unique culture, including their ability to exercise their fishing rights. "The Secretary is authorized and directed to expend . . . the land acquisition fund for the purpose of acquiring land or natural resources for the Passamaquoddy Tribe, [and] the Penobscot Nation . . . and for no other purpose." 25 U.S.C. § 1724(b) (emphasis added). "Land or natural resources" are defined to include "water and water rights, and hunting and fishing rights." 25 U.S.C. § 1722(b).[9]

As excerpted more fully above, MICSA's legislative history also makes it clear that the Southern Tribes would be engaged in sustenance fishing in the newly-acquired trust lands:

> Under Title 30, Sec. 6207 as established by the Maine Implementing Act, the Passamaquoddy Tribe and the Penobscot Nation have the permanent right to control hunting and fishing not only within their reservations, but insofar as hunting and fishing in certain ponds is concerned, in the newly-acquired Indian territory as well.

Sen. Rep. No. 96-957, pp. 16-17 (emphasis added). The legislative history of MIA also makes it clear that the Maine Legislature understood that MIA was designed to accommodate sustenance fishing practices in the Southern Tribes' trust lands. See transcript of the public hearing held on March 28, 1980 by the Maine Legislature's Joint Select Committee on the Maine Indian Claims Settlement at 151-152.[10] So it is clear that in creating the authority to take land into trust for the Southern Tribes, Congress understood that MIA made provision for the Tribes to engage in sustenance fishing in those trust lands and intended the trust lands to provide a base for the Tribes to engage in sustenance practices.

As recognized by Congress in MICSA's legislative history, the Southern Tribes' control of fishing in certain trust waters was specifically codified in MIA. Section 6207(1) provides that

---

[9] Unlike MICSA, when MIA refers to Penobscot and Passamaquoddy trust lands, it uses the term "land acquired by the secretary [of Interior] for the benefit" of each tribe, without reference to natural resources. Compare 25 U.S.C. § 1724(d) with 30 M.R.S. § 6205(1)(B) and (2)(B). As explained in the section above, other provisions of MIA make it clear that the statute anticipated that those lands would include the attendant natural resources acquired with the land, especially fishing rights. Moreover, to the extent that this differing terminology suggests a conflict between MICSA and MIA in defining the scope of the tribes' interest in their trust lands and natural resources, the provisions of MICSA would control. 25 U.S.C.
§ 1735(a).

[10] "[The Tribes can adopt ordinances with respect to . . . fishing but only on ponds of less than ten acres in size. Those ordinances have to be equally applicable to Indians and non-Indians except that the Indians can make special provisions for sustenance hunting . . ." and fishing per MIA § 6207(1). Id. at 151.

the Southern Tribes have exclusive authority to enact ordinances regulating the taking of fish on ponds of less than ten acres in their trust lands. As with the Southern Tribes' fishing right in their reservations, this authority is subject only to the State's authority to limit the take after carrying the burden of proof that the Tribes are depleting fish stocks. MIA specifically anticipates that any tribal ordinances regulating fishing in these waters "may include special provisions for the sustenance of the individual members of the Passamaquoddy Tribe or the Penobscot Nation." *Id.*

As to greater ponds and rivers and streams in or along the Southern Tribes' trust lands, MIA also codifies the understanding that the Tribes would be engaged in sustenance fishing in those waters. MIA creates the Maine Indian Tribal-State Commission (defined as the "commission" 30 M.R.S. § 6203(1)), made up of representatives appointed by the State and the Southern Tribes. 30 M.R.S. § 6212. MIA provides that commission the exclusive authority to promulgate fishing rules in these waters. When it does so "the commission shall consider and balance" several factors, including "the needs or desires of the Tribes to establish fishery practices for the sustenance of the tribes or to contribute to the economic independence of the tribes, [and] the traditional fishing techniques employed by and ceremonial practices of Indians in Maine." 30 M.R.S. § 6207(3). Importantly, as analyzed in the record supporting this decision, none of the fishing regulations adopted by the commission would impinge on the ability of the Tribes to sustain themselves on fish taken from these waters.[11]

MICSA and MIA combine to authorize the establishment of trust lands for the Southern Tribes to provide a land base in which the Tribes can exercise their sustenance fishing practices. As compared with the sustenance fishing right reserved to the Southern Tribes within their reservations, MICSA and MIA allow for a greater, although still sharply limited, role for the State, through the commission, to participate in the development of fishing regulations on certain of the waters in the trust lands. But in exercising even that authority, the commission is charged with considering the Tribes' sustenance fishing practices. Therefore, it is clear that a critical purpose behind establishing the Southern Tribes' trust lands is to give the Tribes an opportunity to engage in sustenance fishing.

3.3.1.2.2 Sustenance Fishing in the Trust Lands of the Northern Tribes

Compared with the Southern Tribes' territories, the arrangement for the Northern Tribes' trust lands provides for more direct state regulation of fishing practices. Nevertheless, it appears Congress intended these trust lands to preserve the Northern Tribes' unique cultures as well. So the Northern Tribes' trust lands provide a land base in which the Tribes are able to exercise sustenance fishing practices to the extent consistent with the legal limits on their fishing. Again, similar to the situation for the Southern Tribes' trust lands, EPA is not concluding that there is an aboriginal fishing right reserved to the Northern Tribes on their trust lands. But the Agency does conclude that there is sufficient evidence in the legislative record to indicate that Congress intended the Northern Tribes to engage in sustenance practices on their trust lands to the extent they could.

[11] See memorandum from Ralph Abele to the file for this decision, regarding Effects of Maine Fishing Regulations on Sustenance Fishing by Maine Tribes, dated January 30, 2015.

Authority to establish the Northern Tribes' trust lands came in several rounds of legislation. The first involved the Maliseets, who came to the negotiations around MIA and MICSA late in the legislative process. In 1980, MICSA provided that "[t]he Secretary is authorized and directed to expend . . . the land acquisition fund for the purpose of acquiring land or natural resources for the . . . the Houlton Band of Maliseet Indians and for no other purpose." 25 U.S.C. § 1724(b) (emphasis added). "Land or natural resources" is defined to include "water and water rights, and hunting and fishing rights." 25 U.S.C. § 1722(b) (emphasis added).

At the time Congress authorized land to be taken into trust for the Maliseets, it specifically acknowledged that "[a]ll three tribes [Penobscot, Passamaquoddy and Maliseet] are riverine in their land-ownership orientation." Sen. Rep. No. 96-957, at 11. Congress also specifically noted that one purpose of MICSA was to avoid acculturation of the Maine Tribes:

> *The Settlement will lead to acculturation of the Maine Indians.* – Nothing in the settlement provides for acculturation, nor is it the intent of Congress to disturb the cultural integrity of the Indian people of Maine. To the contrary, the Settlement offers protections against this result being imposed by outside entities by providing for tribal governments which are separate and apart from the towns and cities of the State of Maine and which control all such internal matters. The Settlement also clearly establishes that the Tribes in Maine will continue to be eligible for all federal Indian cultural programs.

Id. at 17. Congress's purpose in providing for the establishment of the Maliseet trust lands was to provide a land base on which the Tribe could maintain its "cultural integrity." The Maliseets have submitted extensive comments documenting the sustenance fishing practices central to the Tribe's culture.

In 1981, the Maine Legislature added provisions to MIA to correspond to the action Congress took in MICSA to recognize the Maliseets and authorize trust lands to provide a resource base for the Tribe. In contrast to MIA's language describing the Southern Tribes' trust lands, the statute explicitly defines the Maliseet trust lands to include natural resources. 30 M.R.S.A §§ 6203(2-A) ("'Houlton Band Trust Land' means land or natural resources acquired by the secretary in trust for the Houlton Band of Maliseet Indians . . .."); see also § 6205-A ("Land or natural resources" may be taken into trust for the Maliseets). As in MICSA, MIA makes it clear that natural resources acquired for the Maliseets may include fishing rights. *Id.* at § 6203(3) ("'Land or other natural resources' means any real property or other natural resources . . . including, but without limitation, . . . water and water rights and hunting and fishing rights.")

It was not until 1989 that the Micmacs negotiated a settlement with Maine as codified in the MSA. Similar to the settlement with the Maliseets, MSA provides that the Micmacs' trust lands include natural resources. 30 M.R.S. § 7202(2) ("'Aroostook Band Trust Land' means land or natural resources acquired by the secretary in trust for the Aroostook Band of Micmacs . . .."). MSA further defines natural resources to include fishing rights. *Id.* at § 7202(3) ("'Land or other natural resources' means any real property or other natural resources . . . including, but without limitation . . . water and water rights and hunting and fishing rights.")

In 1991, Congress passed ABMSA, one key purpose of which was to ratify the MSA. ABMSA § 1(b)(4). Congress specifically found and declared that:

> It is now fair and just to afford the Aroostook Band of Micmacs the same settlement provided to the Houlton Band of Maliseet Indians for the settlement of that Band's claims, to the extent they would have benefited from inclusion in the Maine Indian Claims Settlement Act of 1980.

Id. at § 1(a)(5). To that end, Congress established the Aroostook Band of Micmacs Land Acquisition Fund, *id.* at § 4(a), and provided that:

> the Secretary is authorized and directed to expend, at the request of the Band, the principal of, and income accruing on, the Land Acquisition Fund for the purposes of acquiring land or natural resources for the Band and for no other purposes. Land or natural resources acquired within the State of Maine with funds expended under the authority of this subsection shall be held in trust by the United States for the benefit of the Band.

Id. at § 5(a). ABMSA defines "Band Trust Land" to mean "land or natural resources acquired by the Secretary of the Interior and held in trust by the United States for the benefit of the Band" and defines "land or natural resources" to mean "any real property or natural resources, or any interest in or right involving any real property or natural resources, including (but not limited to) . . . water and water rights, and hunting and fishing rights." *Id.* at § 3(3) and (4). As with the Maliseets, Congress clearly intended that the Micmacs' trust lands could encompass fishing rights.

The Senate conference report from the Select Committee on Indian Affairs on ABMSA indicates that Congress intended to remedy the plight of the Micmacs, who had been deprived of a land base on which to secure the Tribe's continuation as a unique culture. "As Maine's only Native American community without a tribal land base, the Aroostook Band of Micmacs faces major challenges in its quest for cultural survival." 102 S. Rpt 136 (1991). The report describes the cultural practices of the band, including its historic homeland range along the west bank of the St. John River. "The ancestors of the Aroostook Micmac made a living as migratory hunters, trappers, fishers and gatherers until the 19th century." It goes on to note that "[t]oday, without a tribal subsistence base of their own, most Micmacs in Northern Maine occupy a niche at the lowest level of the social order." The discussion of the Band's history ends by observing:

> It is remarkable that the Aroostook Band of Micmac Indians, as a long disenfranchised and landless native group, has not withered away over the centuries. To the contrary, this community in Northern Maine has demonstrated an undaunted collective will toward cultural survival.

As with the Maliseets, it is clear Congress intended to establish a land base for the Micmacs that would enable the Tribe to secure its "cultural survival" and avoid acculturation. Congress intended for the Northern Tribes' trust lands to provide a "subsistence base" on which the Tribes

could assure their continued existence as a unique culture. And Congress was aware that part of that subsistence base for the Northern Tribes was their sustenance fishing practices.

While Congress intended that the Indian lands in Maine provide a land base to support all the Tribes' sustenance practices, it ratified dramatically different regulatory frameworks within which the Southern and Northern Tribes could operate in exercising those practices. In their reservations and lesser ponds in their trust lands, the Southern Tribes are substantially free from state fishing regulations, and elsewhere in their trust lands any regulation of the Southern Tribes' fishing must consider their sustenance practices. As explained in the discussion of the State's jurisdictional authority above, the Northern Tribes and their trust lands are subject to the laws of the State, including the regulation of natural resources, which includes fishing rights. So unlike the Southern Tribes, the ability of the Northern Tribes to exercise their sustenance fishing practices is potentially subject to regulation directly under state law. As DOI's legal opinion explains, the Northern Tribes' trust lands include fishing rights appurtenant to those land acquisitions, which are subject to state regulation.

But this jurisdictional arrangement does not alter the fact that Congress established the Northern Tribes' trust lands for the purpose of providing these Tribes a land base on which to exercise their sustenance practices to the extent possible. Finding that state law applies to the Northern Tribes' fishing rights does not answer the question how those Tribes intend to use the waters on their trust lands consistent with the purpose of setting aside their land base. And the state law applicable to the Northern Tribes' fish take makes it clear that there are generous take limits that allow a catch sufficient to support sustenance fishing. As analyzed in the review of state fishing regulations supporting this decision, it appears state fishing regulations applicable to the Northern Tribes' trust lands do not impose limits that would prevent individual members of the Northern Tribes from taking fish sufficient to support a sustenance diet.[12] Further, under state law, the Department of Inland Fisheries and Wildlife has authority to set take limits on fisheries for the purposes of their preservation, protection, enhancement and use as well as the propagation of fish for the effective management of inland fisheries resources in public waters of the State. 12 M.R.S. § 10053.[13] While this regulatory process does not include the same kind of procedural and burden of proof protections MIA provides for the Southern Tribes' fishing rights, it still requires the State to have a legitimate, non-arbitrary reason for limiting the take in the Northern Tribes trust lands based on the need to preserve and protect state fisheries. So as provided under state law, there appears to be ample ability for the Northern Tribes to fish for their sustenance in tribal waters associated with their trust lands.

3.3.1.3 Passamaquoddy Marine Sustenance Fishing

The Passamaquoddy Tribe's Pleasant Point reservation is located on marine, not inland, waters. There is a dispute among the Tribe, the State, and the commission about whether the Tribe's aboriginal right to take fish in marine waters survived the passage of MICSA. See 25 U.S.C. §§ 1722(b) and 1723(b) and Assessment of the Intergovernmental Saltwater Fisheries Conflict between Passamaquoddy and the State of Maine, Maine Indian Tribal-State Commission: Special

[12] See memorandum from Ralph Abele to the file for this decision, regarding Effects of Maine Fishing Regulations on Sustenance Fishing by Maine Tribes, dated January 30, 2015.

[13] See memorandum from Greg Dain, re: Maine Fishing Regulation, December 23, 2014.

Report 2014/1 (June 17, 2014) at 7. EPA is taking no position at this time as to the Tribes' aboriginal rights to take fish in marine waters or the scope of the sustenance fishing right codified in MIA section 6207 in marine waters. Nonetheless, the marine waters that are part of the Pleasant Point reservation serve a function in supporting the sustenance of the Tribe identical to the inland waters in the Tribe's reservation and trust lands.

First, Congress understood that the Passamaquoddy Tribe exercised subsistence practices on its reservations, including the Pleasant Point Reservation. The Senate Report's discussion of Special Issues noted that "[p]rior to the settlement, Maine law recognized the Passamaquoddy Tribe's and Penobscot Nation's right to control Indian subsistence hunting and fishing within their reservations, but the State of Maine claimed the right to alter or terminate these rights at any time." As quoted more extensively above, the Senate Report then goes on to describe in detail MIA's provisions for the reserved sustenance fishing right of the Southern Tribes. Sen. Rep. No. 96-957 at 16-17. While some dispute whether the Southern Tribes' sustenance fishing extends into marine waters, at a minimum Congress understood that the Passamaquoddy Tribe fished for its sustenance on its reservation and that the State had accommodated that practice under state law.

Notably, Maine has continued its practice of recognizing and providing for the Passamaquoddy Tribe's sustenance marine fishing practices under state law. In 2013, the State codified a "tribal exemption" from otherwise applicable state fishing regulation of marine species for all four Indian Tribes in Maine to exercise a "sustenance use if the tribal member holds a valid sustenance fishing license issued by the tribe, nation or band . . .." That same subsection goes on to define "sustenance use" as:

> . . . all noncommercial consumption or noncommercial use by any person within Passamaquoddy Indian territory, as defined in Title 30, section 6205, subsection 1, Penobscot Indian territory, as defined in Title 30, section 6205, subsection 2, or Aroostook Band Trust Land, as defined in Title 30, section 7202, subsection 2, or Houlton Band Trust Land, as defined in Title 30, section 6203, subsection 2-A, or at any location within the State by a tribal member, by a tribal member's immediate family or within a tribal member's household.

12 M.S.A. § 6302-A(2)(emphasis added). This section imposes seasonal limits on the taking of sea urchins and limits on the number of lobster traps used to harvest lobsters for sustenance use. But it is a clear acknowledgement of and provision for the Passamaquoddy Tribe to take marine species for their sustenance "within Passamaquoddy Indian territory" as defined in MIA, which includes the Tribe's reservations.

Again, EPA acknowledges that there is a current dispute about the extent of the State's authority to regulate the Tribes' marine fishing practices. In citing section 6302-A, EPA does not take a position on the merits of that dispute. EPA is concluding, however, that even if EPA accepts the State's position on its ability to regulate the Passamaquoddy Tribe's marine fishing practices, state law makes ample provision for sustenance fishing on the Tribe's reservation. Therefore, as with the Northern Tribes' trust lands, even if the State has authority to regulate the Tribe's take of marine species, EPA concludes that one important purpose of the Tribe's reservation is to

serve as a land base for the Tribe's exercise of sustenance practices at least to the extent consistent with Maine law regulating the taking of fish. And consistent with that Maine law, the Tribe can consume sufficient marine species to sustain themselves under section 6302-A.

3.3.2 Purpose of MIA, MICSA, MSA, ABMSA and Water Quality

As explained above, all four settlement acts in Maine provide for the Tribes to exercise sustenance fishing practices on waters in Indian lands in Maine. The statutory mechanism supporting this conclusion is quite different depending on which element of Indian lands is involved. But the fundamental conclusion that Congress understood and intended that the Tribes be able to sustain their unique cultures and sustain themselves on Indian lands in Maine is clear.

EPA concludes that the purpose to which Congress dedicated these Indian lands has important implications for water quality regulation under the CWA. Some in Maine have argued that the fishing right reserved to the Southern Tribes in their reservations is simply an exception from otherwise applicable state creel limits, but has no bearing on whether the water supporting that fishing right must be clean enough to ensure that the fish that tribal members are consuming is safe to eat. EPA does not agree with this narrow approach to the relationship between the provisions for tribal sustenance practices on the one hand and water quality on the other. Fundamentally, the Tribes' ability to take fish for their sustenance under the Maine settlement acts would be rendered meaningless if it were not supported by water quality sufficient to ensure that tribal members can safely eat the fish for their own sustenance.

There are several examples of the courts finding that fishing rights for tribes encompass subsidiary rights that are not explicitly included in treaty or statutory language, but are nonetheless necessary to render those rights meaningful. One line of cases focuses on the tribes' ability to access fish. *See, e.g., United States v. Winans*, 198 U.S. 371, 384 (1905) (tribe must be allowed to cross private property to access traditional fishing ground); *Kittitas Reclamation District v. Sunnyside Valley Irrigation District*, 763 F.2d 1032, 1033-34 (9th Cir. 1985) (tribe's fishing right protected by enjoining water withdrawals that would destroy salmon eggs before they could hatch); *Grand Traverse Band of Ottawa and Chippewa Indians v. Director, Mich. Dept of Nat. Resources*, 141 F.3d 635 (6th Cir. 1989) (treaty right to fish commercially in the Great Lakes found to include a right to temporary mooring of treaty fishing vessels at municipal marinas because without such mooring the Indians could not fish commercially).

Another line of cases focuses on water quantity sufficient to support fish habitat. In *United States v. Adair*, the Ninth Circuit held that the tribe's fishing right implicitly reserved sufficient waters to "secure to the Tribe a continuation of its traditional . . . fishing lifestyle." 723 F .2d 1394, 1409-10 (9th Cir. 1983). *See also Colville Confederated Tribes v. Walton*, 647 F.2d 42, 47 -48 (9th Cir. 1981) (implying reservation of water to preserve tribe's replacement fishing grounds); *Winters v. United States*, 207 U.S. 564, 576 (1908) (express reservation of land for reservation impliedly reserved sufficient water from the river to fulfill the purposes of the reservation); *Arizona v. California*, 373 U.S. 546, 598-601 (1963) (creation of reservation implied intent to reserve sufficient water to satisfy present and future needs).

The preceding cases focus on fishing rights, and the attendant or implicit requirement that those fishing rights not be denied through collateral action impairing that right. Analogously, when diminished water quality has hindered tribal uses of water outside the fishing context, courts have held in favor of tribes and found that a right to put water to use for a particular purpose must include a subsidiary right to water quality sufficient to permit the protected water use to continue. This occurred in an Arizona case, *United States v. Gila Valley Irrigation District*, in which farmers whose properties were located upstream from an Indian reservation were required to take steps to decrease the salinity of the river reaching the tribe's reservation so that "the Tribe receives water sufficient for cultivating moderately salt-sensitive crops." 920 F. Supp. 1444, 1454-56 (D. Ariz. 1996), *aff'd*, 117 F. 3d 425 (9th Cir. 1997).

So there is precedent for the proposition that, when Congress identifies and provides for a particular purpose or use of specific Indian lands, an Agency should consider whether its actions have an impact on a tribe's exercise of that purpose or use and, to the extent possible, ensure that its actions protect that purpose or use. If a tribe could not survive on its land base without water, or water clean enough to farm, for example, courts have recognized that the purpose of that reservation or trust land would be entirely defeated. So too here, it would defeat the purpose of MIA, MICSA, MSA and ABMSA if the Maine Tribes cannot safely sustain themselves from the fish they can catch from their waters. DOI's legal opinion concludes that "fundamental, long-standing tenets of federal Indian law support the interpretation of tribal fishing rights to include the right to sufficient water quality to effectuate the fishing right." If EPA were to ignore the impact that water quality, and specifically water quality standards, could have on the Tribes' ability to safely engage in their sustenance fishing practices on their lands, the Agency would be contradicting the clear purpose for which Congress ratified the settlements in Maine and provided for the establishment of Indian lands in the State. Therefore, it is incumbent upon EPA when applying the requirements of the CWA to harmonize those requirements with this Congressional purpose.

3.3.3 Tribal Fishing Rights, the CWA, and the MICSA Savings Clauses

Accordingly, as explained in more detail below, EPA is identifying "sustenance fishing" to be a designated use in tribal waters, and is disapproving Maine's human health criteria because they are not stringent enough to protect the sustenance fishing use. EPA considered whether taking this action is prohibited by the so-called "savings clauses" in MICSA that are designed to block application of federal law in the State if it would both accord or relate to a special status or right for Indian tribes and affect or preempt the jurisdiction of the State. 25 U.S.C. §§ 1725(h) and 1735(b). EPA concludes that the savings clauses do not preclude EPA's actions under the CWA.

EPA is addressing the provisions of MICSA, which specifically provides for a land base for the Maine Tribes that is set aside for the purpose of preserving the Tribes' culture and sustenance practices, in the Agency's implementation of the CWA, which requires that water quality criteria protect designated uses and be based on sound scientific rationale. Unless EPA acts to ensure that the Tribes are able to safely exercise their sustenance practices, a key purpose behind the provisions in MICSA, MIA, ABMSA and MSA to assemble and preserve the Maine Tribes' land base and cultures would be largely defeated. When EPA identifies Maine's designated use of "fishing" to mean "sustenance fishing" in tribal waters, it is giving effect to MICSA within the

framework of Agency oversight of WQS provided for in the CWA. It certainly cannot be the case that the savings clauses in MICSA somehow operate to prevent the government from addressing MICSA itself.

In addition, the savings clauses cannot block operation of the CWA oversight authority EPA is exercising in this case. EPA's authority to review and approve or disapprove new or revised state WQS rests on the requirements of CWA section 303(c)(3), which provides general authority and a non-discretionary duty to review and approve or disapprove all new or revised WQS from states. Because this authority under the CWA neither "accords or relates to a special status or right of or to any Indian . . . tribe," nor "affects or preempts the ... regulatory jurisdiction of the State of Maine...," it is not blocked by the operation of the applicable MICSA savings clause. See 25 U.S.C. § 1725(h)(note that section 1735(b) would not apply to CWA section 303, because section 303 was enacted in 1972, and section 1735(b) applies only to laws enacted in and after 1980.). Nothing about EPA's oversight of Maine's WQS limits the State's jurisdiction to set WQS for waters in Indian lands. As to the adequacy of the WQS, no state has authority under the CWA to set standards that are "not consistent with the applicable requirements of this chapter [of the CWA]." 33 U.S.C. § 303(c)(3). In determining whether Maine's new or revised criteria are protective of the sustenance fishing designated use in Indian waters, EPA is simply exercising the same oversight authority it would exercise inside or outside Indian country anywhere in the nation. So this action does not accord the Indian Tribes in Maine a "special status or right."

EPA also considered whether, in looking to the federal common law of reserved tribal fishing rights when interpreting MICSA and implementing the CWA, EPA has somehow applied federal law to affect the application of state law. As a threshold matter, the MICSA savings clauses appear to be drafted entirely with Congressional statutory enactments in mind, and do not appear to address federal common law. For example, MICSA section 1725(h) provides that "no law or regulation of the United States" in existence at the time MICSA passed will apply in Maine if the conditions of that section are met. The formulation of "law or regulation" suggests Congress had in mind statutes that are routinely implemented by regulation. And the example provided in the Senate Committee Report of the operation of that section is a description of how section 164 of the Clean Air Act, a statutory law, would not apply in Maine. Sen. Rep. No. 96-957, p. 31.[14]

Finally, the operation and effect of these savings clauses is irrelevant to the use that EPA is making of federal common law in this case. The savings clauses are designed to prevent the federal government from unintentionally re-writing the jurisdictional deal embodied in MICSA. Only Congress has the authority to do that. In referencing certain principles of federal common

---

[14] Section 1735(b) is the companion "savings" provision to section 1725(h), and it blocks the application of federal law enacted after 1980 if that law would benefit the Tribes and affect or preempt the application of state law. That section refers to "enacted Federal law" and includes the idea that a federal law may apply in Maine if it is made specifically applicable in Maine. This provision also appears aimed at statutes that Congress enacts where Congress has the opportunity to decide whether to call out Maine in particular. The Senate Report on MICSA confirms this reading: "*Subsection 16(b)* [codified as section 1735(b)] provides a rule of construction to govern interpretation of Federal *statutes* enacted after the date of enactment of this Act." Sen. Rep. No. 96-957, p. 35 (underscore added). Thus it appears that both of these savings provisions were designed to operate in combination to address congressional enactments and resulting regulations that might apply in Maine, not common law.

law noted above, EPA is merely acknowledging useful precedent that can inform how to interpret the purpose to which Congress dedicated the Tribes' lands under MICSA and the other settlement acts. Doing so does not revise MICSA or change its jurisdictional formula; rather EPA is ensuring that the tribal territories can continue to serve the purpose for which they were created under MICSA. This is precisely consistent with First Circuit precedent in which the court has looked to federal principles of Indian law to help interpret the meaning of MICSA. *Akins*, 130 F.3d at 489-490 and *Fellencer*, 164 F.3d at 711-712.

3.3.4 Designated Use of Sustenance Fishing

In section 3.2 above, EPA describes its approval of the designated uses contained in the various classifications of waters in Indian lands. Each classification includes the designated use of "fishing." As explained below, EPA is interpreting the designated fishing use for all waters in Indian lands to mean "sustenance fishing"; and for certain waters in the Southern Tribes reservations, EPA is also approving a sustenance fishing designated use specified in MIA.

3.3.4.1 EPA's Decision to Approve a Sustenance Fishing Use in the Southern Tribes' Inland Reservation Waters

As discussed above, MIA provides that: "Notwithstanding any rule or regulation promulgated by the commission or any other law of the State, the members of the Passamaquoddy Tribe and the Penobscot Nation may take fish, within the boundaries of their respective Indian reservations, for their individual sustenance subject to the limitations of subsection 6." 30 M.R.S. § 6207, sub-§ 4. "Fish" is defined to mean "a cold blooded completely aquatic vertebrate animal having permanent fins, gills and an elongated streamlined body usually covered with scales and includes inland fish and anadromous and catadromous fish when in inland water." 30 M.R.S. § 6207, sub-§ 9.

These provisions clearly codify a tribal right of sustenance fishing for inland, anadromous, and catadromous fish in the inland waters of the Penobscot Nation's and Passamaquoddy's reservations.[15] This right is subject only to 30 M.R.S. § 6207, sub-§ 6, which authorizes Maine's Commissioner of Inland Fisheries and Wildlife to, among other things, adopt remedial measures, including the rescission of any tribal ordinance or regulation by the Maine Indian Tribal-State Commission, to prevent substantial diminution of fish stocks in waters outside of the boundaries of lands or waters subject to regulation by the Passamaquoddy Tribe, the Penobscot Nation or the Commission.

EPA has evaluated whether 30 M.R.S. § 6207, sub-§§ 4 and 9, constitutes a new or revised water quality standard, in light of the Agency's recent guidance regarding how it determines what is or is not a new or revised WQS, summarized in EPA's 2012 Frequently Asked Questions (FAQ) publication on the subject.[16] As explained in the FAQ, EPA considers four questions in making this determination, and in this case, all four questions are answered in the affirmative. First,

---

[15] EPA is taking no position here on whether this codified right includes or excludes fish in marine waters. See section 3.3.1.3, above. EPA is approving these provisions for inland waters where there is no ambiguity.

[16] EPA, What is a New or Revised Water Quality Standard Under CWA 303(c)(3)? Frequently Asked Questions, October 2012.

these provisions are legally binding and were established as a matter of state law. Second, they include and address one of the three core components of a water quality standard (i.e., a designated use), since they articulate a specific fishing use for the specified waters. Third, they express or establish the desired condition of the waters, or level of protection afforded the waters, by specifically providing for *sustenance* fishing. (As discussed above, to protect sustenance fishing, the water quality must be both adequate to support healthy fish populations at levels that provide a sufficient quantity of fish to be taken for sustenance purposes, and adequate to ensure that such fish may be safely consumed at sustenance rates by tribal members.[17]) Lastly, these provisions establish a new water quality standard since they have not previously been approved by EPA.

Based on this evaluation, EPA has determined that 30 M.R.S. § 6207, sub-§§ 4 and 9, constitutes a new or revised water quality standard, specifically a designated use, subject to EPA review and approval or disapproval under section 303(c) of the CWA.[18] EPA further finds that the sustenance fishing designated use established by 30 M.R.S. § 6207, sub-§§ 4 and 9, is consistent with the provisions of sections 101(a) and 303(c)(2) of the CWA, as well as EPA's implementing regulations. Accordingly, EPA is today approving the designated use of sustenance fishing for inland, anadromous, and catadromous fish, applicable to all inland waters of the Southern Tribes' reservations in which populations of fish are or may be found.[19]

3.3.4.2 EPA's Decision to Interpret the State's Designated Use of "Fishing" to Mean Sustenance Fishing for Waters in the Northern and Southern Tribes' Trust Lands

As explained above, EPA is approving the State's designated use of "fishing" as it applies to waters in Indian lands. In inland waters of the Southern Tribes' reservations EPA is also approving a specific additional designated use of sustenance fishing, as explained immediately above. In the trust lands for all the Tribes in Maine and the marine waters of the Passamaquoddy Tribe's reservation, EPA must determine how to interpret the fishing use that EPA is approving for those waters. EPA concludes that to protect the function of these waters to preserve the Tribes' unique culture and to provide for the safe exercise of their sustenance practices, EPA must interpret the fishing use to include sustenance fishing.[20]

In reviewing Maine's WQS as they apply to waters in Indian lands, EPA must reconcile two statutory frameworks. On the one hand, the CWA generally assigns to a state the responsibility of determining the designated uses in its waters (subject to certain restrictions at 40 C.F.R. § 131.10). 33 U.S.C. §§ 1251(a)(2), 1313(c)(2)(A). On the other hand, as explained above, the

---

[17] As noted above, the sustenance fishing use is subject to the limitations of 30 M.R.S. § 6207, sub-§ 6, which authorizes Maine's Commissioner of Inland Fisheries and Wildlife to take steps to prevent substantial diminution of fish stocks. EPA considers this to be a fisheries management provision, and not a restriction on the *quality* of water needed to protect the sustenance fishing use.

[18] EPA's authority and duty to review and approve or disapprove new or revised WQS does not depend on whether such WQS have been submitted by the State to EPA for review, or on where in state law they are codified. *FAQ* at 2.

[19] EPA interprets this designated use of sustenance fishing as not applying to inland waters that are inherently incapable of sustaining fish populations, such as most ephemeral streams and vernal pools.

[20] EPA interprets the designated "fishing" use for the inland waters of the Southern Tribes' reservations in the same manner. However, because EPA is also approving a specific sustenance fishing use contained in 30 M.R.S. § 6207, sub-§§ 4 and 9 for those waters, the discussion in this section is focused on the waters in the Trust lands.

settlement acts in Maine recognize and create specific areas in the State to provide for the Tribes to use their waters in a way that is distinct from waters outside Indian lands. EPA is bound to attend to and comply with both statutory frameworks to the extent EPA is able to reconcile how they apply to the Agency's review of Maine's WQS in Indian waters.

It is possible to harmonize these two statutory frameworks by recognizing that the State's designated fishing use under the CWA must include the concept of sustenance fishing as provided for in the settlement acts. To do otherwise would run the risk that state WQS could be based on assumptions about fish consumption rates that could lead to criteria that fail to protect the Tribes' ability to safely consume fish for their sustenance. The settlement acts, adopted between 1980 and 1991, are designed to establish a land base on which the Tribes can sustain themselves as unique cultures going forward. Therefore, the Agency will interpret the designated fishing use to include the ability of tribal members to safely take fish for their individual sustenance.

The extent to which existing state law either codifies or at least accommodates tribal sustenance fishing supports this approach to harmonizing the settlement acts with the structure of the WQS program under the CWA. As described above, MIA codifies an express provision for sustenance fishing in the Southern Tribes' trust lands. The state fishing code as it applies to waters in the Northern Tribes' trust lands imposes take limits that appear to be consistent with those Tribes' ability to fish for their sustenance. And finally, in 2013, Maine explicitly provided for all the Tribes in Maine to take marine species for their sustenance. The role of tribal sustenance fishing is woven into the fabric of Maine law, so requiring that use to be protected in the State's WQS program as applied to tribal waters will not conflict with state law governing how the Tribes may use these waters.

As described above, EPA acknowledges that the Tribes' sustenance fishing practices are not free from state regulation. The State has varying degrees of authority to regulate the quantity of fish that can be taken depending on the type of Indian land involved. In the Southern Tribes' reservations, the State has very narrow authority to set limits in the reservations to prevent depletion of fish stock in waters outside the Southern Tribes' reservation waters. The commission can regulate fish take on certain waters on the Southern Tribes' trust lands based on factors enumerated in MIA. On the Northern Tribes' trust lands the State regulates take consistent with state law.[21] However, the State's authority to limit the taking of fish to manage fisheries for their protection and preservation is not inconsistent with the settlements acts' provision of sustenance fishing in tribal waters and EPA's identification of "sustenance fishing" as the designated use for these waters. Neither does the State's authority to limit take mean that state water quality criteria need not protect sustenance fishing in those waters. Water quality criteria must be sufficient to protect the designated uses, whether or not the uses are currently being achieved. CWA 303(c)(2)(A) and 40 C.F.R §§131.3(f) and 131.11.

[21] As noted earlier, EPA is not taking a position one way or the other on whether the State may regulate Passamaquoddy marine sustenance fishing where such fishing occurs within their reservation.

4 EPA's Decisions on Maine's New or Revised Water Quality Standards Submissions From 2003 through 2014

4.1 General Background

Section 303 of the CWA requires each state to adopt water quality standards to protect public health and welfare, enhance the quality of water, and otherwise serve the purposes of the CWA.[22] Any new or revised standard adopted by a state under section 303(c) must be submitted to EPA for review, to determine whether it meets the CWA's requirements, and approval or disapproval. 33 U.S.C. § 1313(c)(1) and (3); 40 C.F.R. §§ 131.5, 131.6 and 131.20.

WQS describe the desired condition of a waterbody and consist of three principle elements: (1) the "designated uses" of the state's waters, such as public water supply, recreation, propagation of fish, or navigation; (2) "criteria" specifying the amounts of various pollutants, in either numeric or narrative form, that may be present in those waters without impairing the designated uses; and (3) antidegradation requirements, providing for protection of existing water uses and limitations on degradation of high quality waters. EPA's regulations at 40 C.F.R. part 131describe the minimum requirements for each of these three elements of WQS.

In accordance with CWA § 303(c) and 40 C.F.R. §§ 131.5 and 131.11, EPA must ensure that new or revised criteria are based on sound scientific rationale and contain sufficient parameters or constituents to protect designated uses.

4.2 EPA's Decision to Disapprove Maine's Human Health Criteria for Waters in Indian Lands because They Do Not Protect the Designated Use of Sustenance Fishing in Waters in Indian Lands in Maine, and to Approve Maine's Cancer Risk Level of 10^{-6}

4.2.1 Maine's Human Health Criteria Submitted to EPA on May 14, 2004, January 11, 2006 and January 14, 2013

On May 14, 2004, DEP submitted revisions to the human health criteria for mercury at 38 M.R.S. § 420(1-B.A.(2)) to EPA for review and approval or disapproval. On January 11, 2006, Maine DEP submitted numeric Human Health Criteria ("HHC") for toxic pollutants, among other revisions, to EPA for review and approval or disapproval (the "2006 HHC").[23] These criteria replaced Maine's previous regulation that incorporated EPA's CWA § 304(a) recommended criteria by reference. The revisions reflected DEP's use of a statewide fish consumption rate ("FCR") of 32.4 g/day (an increase from the 6.5 g/day FCR on which EPA's

---

[22] Section 303's requirements also apply to tribes that are authorized to implement a WQS program. Since EPA's decision today relates to a state's WQS program, the discussion of general statutory and regulatory requirements and guidance are framed in terms of state actions only.

[23] HHC are established to protect human health from exposure to pollutants that occur through the ingestion of water and/or contaminated fish and shellfish. Any human health criterion for a toxicant is based on at least three interrelated considerations: cancer potency or systemic toxicity, exposure (e.g., fish consumption rate), and risk characterization. http://water.epa.gov/scitech/swguidance/standards/handbook/chapter03.cfm#section13

then CWA § 304(a) recommended criteria were based).[24] The HHC revisions included a requirement that HHC for carcinogens be based on a cancer risk level (CRL) of $1x10^{-6}$. DEP Rule Chapter 584 § 4. Accordingly, all of the HHC for carcinogens submitted to EPA in 2006 were calculated using a 10^{-6} CRL. EPA approved the mercury criteria for waters outside of Indian lands on January 25, 2005, and approved the other criteria for waters outside of Indian lands on July 7, 2006 and September 18, 2006. EPA is today addressing these criteria for waters in Indian lands.

On January 13, 2014, DEP submitted new HHC for acrolein and phenol, and revised criteria for arsenic (discussed separately below), to EPA for review and approval. Similar to the 2006 HHC, the new HHC for acrolein and phenol were based on the statewide fish consumption rate of 32.4 g/day and a CRL of 10^{-6}. EPA is addressing these criteria in its decision today for all waters in the State, including in Indian lands.

In 2011, Maine's legislature enacted LD 515, which required DEP to revise Maine's HHC for arsenic by basing it on a CRL of 1 in 10,000 ($1x10^{-4}$) rather than the previous CRL of 1 in 1,000,000 ($1x10^{-6}$). DEP adopted the new criteria based on the 10^{-4} CRL and a revised FCR of 138 g/day, in order to protect highly exposed state subpopulations, and on January 14, 2013, submitted them to EPA for review and approval. EPA approved the revised arsenic criteria only for waters outside of Indian lands on May 16, 2013. EPA is addressing these criteria in its decision today for waters in Indian lands.

4.2.2 EPA's Analysis of the Adequacy of Maine's HHC for Waters in Indian Lands

4.2.2.1 EPA Guidance

As explained in EPA's *Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health* (the "2000 Human Health Methodology" or "2000 Guidance"), EPA recommends that states provide adequate protection from adverse health effects to the general population, as well as to highly exposed populations, such as recreational and subsistence fishers, two distinct groups whose fish consumption rates may be greater than the general population.[25] EPA provides national default fish consumption rates ("FCR") of 17.5 grams per day ("g/day") for the general population and recreational anglers, and of 142.4 g/day for subsistence fishers.[26] However, because the level of fish consumption in highly exposed populations varies by geographic location, EPA strongly recommends that states use local or regional data over the default values. EPA has also recently explained that in order to provide for safe fish consumption, it is important that HHC avoid any suppression effects that may occur

[24] Although not explicitly stated in DEP Regulation Chapter 584, the mercury criteria in 38 M.R.S. § 420(1-B.A.(2)) were based on the Maine Bureau of Health Fish Tissue Action Level of 0.2 mg/Kg, which was derived using a fish consumption rate of 32.4 g/day. See *Development of Ambient Water Quality Criteria for Mercury, A Report to the Joint Standing Committee on Natural Resources,* by DEP, dated January 15, 2001.

[25] EPA. 2000. *Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health.* U.S. Environmental Protection Agency, Office of Water, Washington, D.C. EPA-822-B-00-004, p. 2-2. Available at: http://www.epa.gov/waterscience/criteria/humanhealth/method/complete.pdf

[26] Id., pp. 1-12 and 1-13.

when a group's consumption rate is artificially diminished due to perceptions of pollutant contamination of the fish.[27]

4.2.2.2 Tribal Sustenance Fishers to be Protected as the Target Population in Tribal Waters

EPA concludes that when analyzing how the WQS program applies to the sustenance fishing use in the waters of Indian lands in Maine, the tribal population must be considered to be the "target population" for the purpose of determining whether the State's human health criteria are adequate to protect the tribes' health, including determining the appropriate fish consumption rate applicable in those waters and weighing the risk level to which tribal members should be exposed. Congress set aside Indian lands to provide a place for the Tribes to reside and to exercise their sustenance practices. Therefore, that tribal population and its sustenance fishing use must be the focus of the risk assessment supporting water quality criteria to adequately protect that use. To do otherwise risks undermining the purpose for which Congress established and confirmed the Tribes' land base.

EPA's 2000 Human Health Methodology provides that when developing in-stream water quality criteria to protect human health, states have some flexibility in determining which populations the state's criteria are designed to protect. Generally the guidance recommends that states consider how to protect both susceptible and highly exposed populations when setting criteria.

> When choosing exposure factor values [including fish consumption rates] to include in the derivation of a criterion for a given pollutant, EPA recommends considering values that are relevant to population(s) that is (are) most susceptible to that pollutant. In addition, highly exposed populations should be considered when setting criteria.[28]

EPA's approach in this guidance is to recommend protection of the general population based on fish consumption rates designed to represent "the general population of fish consumers," and then to recommend that states assess whether there might be more highly exposed subpopulations or "population groups" that require the use of a higher fish consumption rate to protect them as the "target population group(s)." *Id.* at 4-24 – 25. The guidance leaves states considerable discretion in determining which populations to target for protection using either statewide criteria or more geographically focused site-specific criteria.

The 2000 Guidance does not directly speak to the unique situation EPA confronts in this action, where 1) a state has authority to set human health criteria for waters in Indian lands, and 2) those lands have been set aside by Congress for, among other reasons, the preservation of tribal cultural practices, including sustenance fishing. Nevertheless, it is possible to apply the principles outlined in the 2000 Guidance to this situation, informed by the settlement acts. As discussed below, the settlement acts lead EPA to consider the Tribes to be the general target population in their waters, and the Guidance's recommendations on exposure and cancer risk for the general target population can be applied accordingly.

---

[28] EPA 2000 Human Health Methodology at 4-17.

In Maine, the State has authority to set WQS for the waters in tribal lands where tribal members are the exclusive or predominant population. See 30 M.R.S. § 6206(1) (Penobscot Nation and Passamaquoddy Tribe control "the right to reside within the respective Indian territories" as an internal tribal matter.) Some of those lands and the waters in them are subject to a statutorily reserved tribal fishing right; some are set aside for the purpose of giving the resident tribe a land base on which to exercise traditional sustenance practices. What all the waters in these Indian lands have in common is, as explained above, that the fishing activity on them will involve tribal members, and may be predominated by tribal members, who have the right to, and desire to, fish for their sustenance. Also as explained above, consistent with the purpose of the settlement acts to preserve the Tribes' culture, these tribal members intend to fish for their sustenance. They are not a highly exposed or high-consuming subpopulation in their own lands; they are the general population for which the federal set-aside of these lands and their waters was designed.[29]

Therefore, as described above, EPA has identified and approved a designated sustenance fishing use applicable to waters in these Indian lands. That designated use requires the Agency to focus its analysis on sustenance fishers as the target general population. In effect, the settlement acts have determined how EPA and Maine must analyze the use of these waters and the population to be targeted for protection, because those acts established Indian lands in Maine for the clearly identifiable purpose of allowing the Tribes to sustain themselves on their own lands and waters.

A similar analysis applies to another critical factor in deriving human health criteria, the cancer risk level. For carcinogenic pollutants, EPA's 2000 Guidance recommends that states protect the general population to a level of risk no greater than one in one hundred thousand to one in one million (1×10^{-5} to 10^{-6}) of an additional cancer occurring in that population. Maine DEP has selected 10^{-6} as the level of risk that must be used to establish human health criteria for carcinogenic pollutants, with the exception of arsenic. Maine Rule Chapter 584 § 4. EPA's 2000 Guidance indicates that if there are highly exposed groups or subpopulations within that target general population, such as subsistence consumers, water quality standards should protect those consumers to a level of risk no greater than one in ten thousand (1×10^{-4}).[30] EPA and Maine relied on this aspect of the guidance in approving Maine's recently submitted revision to its human health criterion for arsenic as it applies to waters outside Indian lands. The Agency analyzed whether the State's revised arsenic criterion adequately protected subsistence consumers *outside* tribal waters as a *subpopulation* to a risk level of 10^{-4}.

Again, EPA concludes that it would be inconsistent with the intent of the settlement acts to treat the Tribes as a subpopulation of the State when developing HHC for waters in their own lands, and to expose them to levels of risk above what would be reasonable for the general population of the State. Therefore, the CWA requires that when establishing WQS for these waters, the tribal members must be considered to be the target general population for the purposes of setting

---

[29] EPA recognizes that tribal members will not be the only population fishing from some of these waters. On major rivers such as the Penobscot River, for example, the general population has the right to pass through the waters in Indian lands. The presence of some nonmembers fishing on these waters, however, does not change the fact that the resident population in the Indian lands is made up of tribal members who expect to fish for their sustenance in the waters in Indian lands pursuant to the settlement acts.

[30] EPA 2000 Human Health Methodology at 2-6.

risk levels to protect the sustenance fishing use. In Maine, the State has codified a risk level of 10^{-6} for all but one carcinogen, and EPA is today approving that provision in Chapter 584 to apply to waters in Indian lands, as discussed further below.

4.2.2.3 Fish Consumption Rate

In evaluating the adequacy of Maine's HHC to protect the sustenance fishing designated use for waters in Indian lands, EPA reviewed the basis for the FCR used by Maine, and also considered whether other localized information exists that would be relevant and appropriate to consider in determining an adequate sustenance fishing consumption rate that is not artificially suppressed by pollution concerns.

4.2.2.3.1 ChemRisk Study

DEP derived the 32.4 g/day FCR, used for all of its HHC except arsenic, in part[31] from the results of a 1990 study conducted by McLaren/Hart – ChemRisk, of Portland, Maine (the "ChemRisk Study"[32]). While DEP considered several sources of information about fish consumption rates to develop the 2006 HHC, the ChemRisk Study contains the only localized data that DEP used. EPA reviewed the ChemRisk Study as well as additional information about the Study contained in comments from a primary author of the Study and responses to comments from DEP, contained in DEP's May 25, 2012 Response to Comments document submitted to EPA on January 14, 2013, to determine the Study's relevance to the target tribal populations' sustenance fish consumption rates in waters in Indian lands.

In 1990, to characterize the rates of freshwater fish consumption by Maine's resident anglers, ChemRisk conducted a statewide mail survey of Maine residents holding a valid Maine fishing license in 1989. The survey asked respondents to report the number of freshwater fish caught in Maine, their species, and the average length of each fish that was eventually consumed by them, including fish caught by other members of the respondent's household and by individuals outside the household. Along with other demographic information, respondents were asked to self-identify their ethnic background (white/non-Hispanic, Hispanic, Native American, Asian/Pacific Islander, Black, or other). Of the 2,500 surveys mailed, 1,612 were completed and returned. Of these, 1,053 anglers reported having consumed freshwater and anadromous fish obtained from Maine inland waters during the 1989-1990 ice fishing season or 1990 open water fishing season. The 95th percentile FCR (as calculated by rank without any assumption of statistical distribution) for the fish consuming anglers was 26 g/day.

[31] Maine Bureau of Health, *Fish Tissue Action Levels,* February 20, 2001, published at https://www1.maine.gov/dhhs/mecdc/environmental-health/eohp/fish/documents/action-levels-writeup.pdf

[32] ChemRisk, A Division of McLaren Hart, and HBRS, Inc., *Consumption of Freshwater Fish by Maine Anglers,* as revised, July 24, 1992. See also Ebert, E.S., N.W. Harrington, K.J. Boyle, J.W. Knight, R.E. Keenan, *Estimating Consumption of Freshwater Fish among Maine Anglers*, North American Journal of Fisheries Management, 13:4, 737-745 (1993); http://dx.doi.org/10.1577/1548-8675(1993)013<0737:ECOFFA>2.3.CO;2

According to the Study, 148 Native Americans participated in the survey (11% of total participants), and 96 of those reported consuming freshwater fish that had been sport-caught.[33] The consumption rate for the Native American participants equaled or exceeded the rate of all other population groups at the 66th, 75th, and 90th percentiles[34], and the 95th percentile for Native Americans was nearly double the 95th percentile for the next highest population group.[35] However, the maximum rate reported by the Native Americans respondents (162 g/day) was lower than the maximum rate reported by the entire surveyed population (182 g/day).[36]

Ultimately, DEP used a statewide fish consumption rate of 32.4 g/day to establish its HHC, which is the equivalent of one 8-oz. fish meal per week, and, according to DEP, represents the 97th percentile FCR for Maine recreational anglers for all waters, and the 94th percentile for Native American anglers in Maine.[37] It was "designed to protect the subpopulation of recreational anglers that frequently consume sport-caught fish….."[38]

As explained above, in evaluating whether the sustenance fishing designated use for waters in Indian lands is protected by Maine's HHC, EPA considers the tribal sustenance fishers to be the "target" general population for such waters. This means that the FCR for the applicable HHC must reflect, as accurately as possible, the Tribes' sustenance level FCR, and the CRL must be protective of the sustenance fishers as a general population rather than as a highly exposed subpopulation.

Maine's FCR is based primarily on statewide data, which EPA's 2000 HH Methodology generally prefers over the use of national data. However, it is not based on localized data for the specific waters in Indian lands or the target tribal populations. The ChemRisk Study was not intended to be, nor was it, a survey of tribal sustenance fishers in tribal waters. The survey was sent to state-licensed recreational anglers, but tribal sustenance fishers are not required to have state licenses to fish in waters in Indian lands.[39] Therefore, EPA is unable to conclude that the Study results are representative of a fish consumption rate for tribal sustenance fishers in tribal waters.

In addition, the Study does not reflect unsuppressed fish consumption levels. At the time the ChemRisk survey was conducted, Maine had issued fish consumption advisories for the main stem of the Penobscot River, where the Penobscot Nation reservation is located, the Androscoggin River (1985), and the Kennebec River, (1987), and it issued advisories for the Presumpscot River and West Branch of the Sebasticook River in 1990.[40] DEP has acknowledged that "public awareness of historical pollution in industrialized rivers can be expected to have suppressed fish consumption on a local basis," and that the ChemRisk

"estimates of fish consumption for rivers and streams as well as the inclusive 'all waters' category are likely to have been affected to some degree."[41]

Although the responses were not tallied and not analyzed in ChemRisk's report, the ChemRisk survey did include questions regarding the impact of fish consumption advisories. EPA analysis of the survey response data[42] indicates that 35% of respondents (556 individuals) were aware of the advisories during the time of the survey. Of the 160 respondents who reported that they ate fish from locations covered by fish consumption advisories, 82% (135) reported that the advisories affected whether they kept the fish caught at those locations.[43] It is not clear (because the question was not asked) whether anglers avoided certain waters in the 1989/1990 fishing season because of the fish advisories and whether that avoidance affected their total fish consumption. Nonetheless, it is clear that the existence of the advisories did result in some anglers reducing their take from those rivers.

EPA also reviewed the results of the Penobscot Nation's draft 1991 Penobscot River Users Survey.[44] While the survey was small (210 respondents) and the response rate was only 25%, and it was limited to Penobscot Nation members and their use of the Penobscot River, it does contain information that reinforces EPA's conclusion that the ChemRisk Study does not reflect unsuppressed sustenance fish consumption in tribal waters. For example, 72.9 % of the respondents stated they did not eat fish from the Penobscot River, and a majority (66.7%) stated that they had concerns about eating fish from the river.[45] The vast majority of those concerns were related to pollution.[46] In addition, of the 37.1% who reported not using the river at all, 16.3% identified the reason as concerns about pollution.[47]

4.2.2.3.2 Wabanaki Traditional Cultural Lifeways Exposure Scenario

In considering whether there are other sources of local data to inform EPA's determination of what FCR is representative of sustenance fishing in the waters in Indian lands, EPA reviewed the Wabanaki Cultural Lifeways Exposure Scenario ("Wabanaki Study"), which was completed in 2009. This peer reviewed Study was produced under a Direct Implementation Tribal Cooperative Agreement (DITCA) awarded by EPA to the Aroostook Band of Micmac Indians on behalf of all of the Maine Tribes. The purpose of the Study was to use available anthropological and ecological data to develop a description of Maine Tribes' traditional cultural uses of natural resources, and to present the information in a format that could be used by EPA to evaluate whether or not tribal uses are protected when EPA reviews or develops water quality standards in Indian lands in Maine.[48] It is relevant to contemporary water quality because another purpose of

[48] Harper, Barbara and Darren Ranco, *Wabanaki Traditional Cultural Lifeways Exposure Scenario*, prepared for EPA in collaboration with the Maine Tribes, p.7, July 9, 2009.

the Study "is to describe the lifestyle that was universal when resources were in better condition and that some tribal members practice today (and many more that are waiting to resume once restoration goals and protective standards are in place)."[49] It provides a numerical representation of the environmental contact, diet, and exposure pathways of the traditional tribal lifestyle, including the use of water resources for food, medicine, cultural and traditional practices, and recreation. The Study acknowledges that "the Wabanaki homelands extended further west and south into areas with different plants and climate and where farming was possible," but notes that "the scenario itself covers only areas most heavily used by Tribal members at present, and where farming is marginal due to climate."[50]

The report used anthropological and ecological data to identify major activities that contribute to environmental exposure and then to develop exposure factors related to traditional diet, drinking water, soil and sediment ingestion, inhalation rate and dermal exposure. Credible ethno historical, ecological, nutritional, archaeological, and biomedical literature was reviewed through the lens of natural resource use and activities necessary to survive in the Maine environment and support tribal traditions. Along with single, best-professional judgment estimates for direct exposures (inhalation, soil ingestion, water ingestion) as a reasonable representation (central tendency) of the traditional cultural lifeways, the Wabanaki Study provides an estimated range of diets that reflect three major habitat types.[51]

In developing the dietary component of the exposure scenario, the Wabanaki Study authors assembled information about general foraging, seasonal patterns, dietary breadth, abundance, and food storage. From these they evaluated the relative proportion of major food groups, including fish, as well as nutritional information, total calories and quantities of foods. This resulted in an estimate of a nutritionally complete diet for the area east of the Kennebec River, which is the area most heavily used by tribal members today and where farming is marginal due to climate.[52]

With regard to the consumption of fish, the Wabanaki Study identifies three traditional lifestyle models, each with its own diet:

1. Permanent inland residence on a river with anadromous fish runs ("inland anadromous"),
2. Permanent inland residence with resident fish only ("inland non-anadromous"), and
3. Permanent coastal residence ("coastal").

The study provides estimates of average consumption of aquatic resources, game, fowl, and plant based foods for each lifestyle model. Aquatic resources were divided into two categories: "resident fish and other resources" and "anadromous and marine fish and shellfish." Table 1 summarizes the consumption of aquatic resources for each lifestyle model.

---

[49] Id., p. 9
[50] Id.
[51] Id., p. 16.
[52] Id., pages 8-9.

Table 1 – Consumption of Aquatic Resources by Lifestyle Model[53]

Lifestyle Model	Resident Fish & Other Aquatic Resources(g/day)	Anadromous & Marine Fish, Shellfish (g/day)[54]
Inland Anadromous	114	400
Inland Non-anadromous	286	0
Coastal	57	457

The Wabanaki Study provides a range of fish consumption rates specifically for Maine Indians using natural resources for subsistence living and reduces the uncertainties associated with a lack of knowledge about tribal exposure in Maine Indian waters. On their own, these fish consumption rates could form the basis for criteria protective of sustenance fishing. Alternatively, they could be the starting point that could be modified, based on additional information, to take into account present day circumstances related to the species composition of available fish. For example, in developing its 2014 tribal water quality criteria, the Penobscot Nation used a FCR of 286 g/day. The Nation explained that it chose the inland non-anadromous total FCR of 286 g/day because, although the Penobscot lands are in areas that would have historically supported an inland anadromous diet (with total FCR of 514 g/day), the contemporary populations of anadromous species in Penobscot waters are currently too low to be harvested in significant quantities. [55]

4.2.3 Disapproval of Maine's HHC Because They Are Based on FCRs that Fail to Protect Sustenance Fishing

EPA is today disapproving, for waters in Indian lands, the mercury human health criteria in 38 M.R.S. § 420(1-B.A.(2)) submitted to EPA on May 14, 2004; the fish consumption rate of 32.4 g/day specified in DEP Rule Chapter 584 § 5.C and all human health criteria in DEP Rule Chapter 584, Surface Water Quality Criteria for Toxic Pollutants, Appendix A, submitted to EPA on January 11, 2006; and the human health criteria revisions related to arsenic, acrolein, and phenol in DEP Rule Chapter 584, Surface Water Quality Criteria for Toxic Pollutants, Appendix A, as well as the last sentence in Ch. 584, § 5.C related to the fish consumption rate, submitted to EPA on January 14, 2013. The basis for the disapproval is that the HHC do not protect the sustenance fishing use in those waters. For the reasons discussed above, Maine's 32.4 g/day FCR is not representative of an unsuppressed sustenance fish consumption rate by tribal members in waters in Indian lands.

In the absence of a local survey of current fish consumption, adjusted to account for suppression, that documents fish consumption rates for sustenance fishing in the tribal waters, EPA finds that the Wabanaki Study contains the best currently available information for the purpose of deriving an FCR for HHC adequate to protect sustenance fishing for such waters. It is local, focused on the areas most heavily used by tribal members today. It identifies historic FCRs based on

---

[53] Id., pp. 61-66.

[54] Includes marine mammals for coastal lifestyle model only.

[55] Penobscot Nation, Department of Natural Resources, *Response to Comments on Draft Water Quality Standards*, September 23, 2014, p. 9.

reasonable estimates for total calories and protein intake per day. Heritage rates provide reliable evidence of what unsuppressed rates would be for tribal populations.[56] The Study uses a sound methodology (peer reviewed, written by a range of experts in risk assessment and anthropology). It presents a range of FCRs from 286 g/day (freshwater fish only) to 514 g/day (combinations of freshwater, anadromous, and marine species), which can provide the basis for choosing an FCR that reflects traditional cultural practices in light of present day circumstances related to, for example, the species composition of available fish (as the Penobscot Nation recently did in adopting an FCR of 286 g/day).

Because the Wabanaki Study documents a substantially higher tribal sustenance fish consumption rate than the FCR on which Maine's HHC are based, EPA cannot conclude that the HHC are based on a sound scientific rationale consistent with 40 C.F.R. § 131.11(a) and protect the sustenance fishing use for the waters in Indian lands. EPA is therefore disapproving the HHC.

4.2.3.1 Remedy to Address EPA's Disapproval

Under CWA § 303(c)(3) and EPA's implementing regulations at 40 C.F.R. §§ 131.21 and 131.22, when the EPA disapproves a state's new or revised water quality standard, it must "specify the changes" necessary to meet the applicable requirements of the Act and EPA's regulations. The CWA requires that this disapproval of Maine's human health criteria for waters in Indian lands be addressed in a timely manner. In the first instance, the CWA and EPA's regulations provide the State up to 90 days to revise its WQS, and EPA prefers that Maine address this disapproval under its regulatory development process. However, if the State does not adopt necessary changes, EPA will propose and promulgate appropriate human health criteria for waters in Indian lands in Maine.

To address this disapproval action, Maine must develop new human health criteria for waters in Indian lands that protect tribal sustenance fishers as the target general population and are based on a fish consumption rate that represents unsuppressed sustenance fishing by tribal members.

Among the available existing information on fish consumption, the Wabanaki Study is most relevant for Maine to consider in revising human health criteria in Indian lands. As discussed in section 4.2.2.3, the Wabanaki study is directly applicable to the Maine Tribes fishing in waters on Indian lands. The fish consumption rates developed in the Wabanaki study are estimates of unsuppressed tribal fish consumption that could be used in the derivation of criteria protective of contemporary tribal sustenance fishing. In addressing the disapproval, Maine should use the fish consumption rates developed in the Wabanaki study either on their own or modified, based, for instance, on information that may be provided by the Maine Tribes, to take into account changes in species composition in tribal fisheries and contemporary tribal sustenance fishing goals.

---

[56] National Environmental Justice Advisory Council, *Fish Consumption and Environmental Justice,* November 2002 (revised), page 49.

4.2.4 Approval of Maine's Cancer Risk Level of 10^{-6} and No Action on Maine's Arsenic CRL of 10^{-4}

Maine's water quality regulations specify that water quality criteria for carcinogens be based on a CRL of 10^{-6} for all pollutants except arsenic. DEP Rule Chapter 584 § 4. This CRL is consistent with the range of CRLs that EPA considers to be appropriate for the general population and is the risk level that EPA uses when publishing its CWA § 304(a) recommended criteria.[57] As explained above, EPA has determined that the Tribes are the target general population for waters in Indian lands. EPA is therefore today approving Maine's requirement to use 10^{-6} CRL for all carcinogens except arsenic (discussed further below) for the waters in Indian lands. Criteria based on this low level of cancer risk, along with other appropriate factors (including an appropriate FCR), will protect the sustenance fishing use for waters in Indian lands.

EPA recognizes that the Maine Legislature enacted a law that requires DEP to use a CRL of 10^{-4} when establishing arsenic criteria,[58] and that DEP Rule Chapter 584 was revised in 2012 to reflect this requirement. Since EPA is disapproving Maine's arsenic criteria along with all of the other HHC for waters in Indian lands due to an inadequate FCR, EPA is not acting on Maine's CRL for arsenic (i.e., the last sentence in Ch. 584, § 4, related to the cancer risk level to be used to calculate human health criteria for inorganic arsenic, and the first sentence of Footnote aME in Table I of Appendix A of Chapter 584). However, we note that when Maine revises its arsenic criteria, it must ensure that the criteria protect the Tribes as the general target population in these waters, not as a subpopulation. Based on the analysis above, the use of a sustenance level FCR developed for all of the HHC, in combination with a CRL of 10^{-4} for arsenic, would not protect the designated use of sustenance fishing.

4.3 EPA's Decision to Approve Maine's Human Health Criteria for Acrolein for the Consumption of Organisms Only and for the Consumption of Water and Organisms, and Phenol for the Consumption of Organisms Only, and to Take No Action on Phenol for the Consumption of Water and Organisms, in Waters Outside Waters in Indian Lands

For all waters in Maine *except* for waters in Indian lands, EPA approves the following water quality criteria contained in DEP Rule Chapter 584, Surface Water Quality Criteria for Toxic Pollutants, Appendix A, submitted to EPA on January 14, 2013:

- Human health criteria for the consumption of water plus organisms for acrolein; and
- Human health criteria for the consumption of organisms only for acrolein and phenol.

Maine's revised human health criteria for acrolein and phenol were derived using the same methodology and equations used to calculate EPA's current 304(a) recommended criteria for non-carcinogens. EPA updated recommended human health criteria for acrolein and phenol in 2009 based on new Integrated Risk Information System Reference Doses (RfDs) for the pollutants[59]. Consistent with EPA's criteria derivation, Maine has made no changes to the

---

[57] *2000 Human Health Methodology*, p. 1-8.
[58] 38 M.R.S. § 420(1-B.J).
[59] Federal Register: June 10, 2009 (Volume 74, Number 110)

parameters incorporated into these criteria or to the equations used other than the new RfDs. The criteria calculations are summarized in attached Tables 1 and 2 below.

Table 1 – Calculation of Approved Acrolein Human Health Criteria

Parameter	2012 criteria
Reference Dose (RfD)	0.0005 mg/(kg-d)
Body Weight (BW)	70 kg
Water Consumption (DW)	2 L/day
Bioconcentration Factor (BCF)	215 L/kg
Fish Consumption Rate (FCR)	0.0324 kg/day
Criteria to protect human health for consuming fish and drinking water (water + organism) = $\frac{1{,}000\ \mu g/mg \times RfD \times BW}{DW + (BCF \times FCR)}$	3.9 µg/L
Criteria to protect human health for consuming fish only (organism only) = $\frac{1{,}000\ \mu g/mg \times RfD \times BW}{BCF \times FCR}$	5.0 µg/L

Table 2 – Calculation of Approved Phenol Human Health Criteria

Parameter	2012 criteria
RfD for Phenol	0.30 mg/(kg-d)
Body Weight (BW)	70 kg
Water Consumption (DW)	2 L/day
Bioconcentration Factor (BCF)	1.4 L/kg
Fish Consumption Rate (FCR)	0.0324 kg/day
Criteria to protect human health for consuming fish only (organism only) = $\frac{1{,}000\ \mu g/mg \times RF \times BW}{BCF \times FCR}$	462,963 µg/L

EPA's approval of Maine's revisions to its human health criteria for acrolein and to the human health criteria for phenol for the consumptions of organisms only is based on a review of whether the criteria protect the applicable designated uses, including consideration of EPA's National Recommended Water Quality Criteria published pursuant to Section 304(a) of the CWA. EPA finds that the revised criteria are scientifically defensible and are protective of designated uses for waters outside of Indian lands, for the reasons explained in the EPA criteria documents for each chemical constituent.

EPA understands that DEP will be revising the phenol criteria for the consumption of water and organisms to address a mathematical error made in the criteria derivation. Therefore, at this time EPA is not taking action on the human health criteria for phenol for the consumption of water and organisms, for waters outside of Indian lands, with the anticipation that the revised phenol criteria will be adopted and submitted to EPA for review and action within the coming months.

4.4 EPA's Decision to Approve Maine's Aquatic Life Criteria for Acrolein, Diazanon and Nonylphenol for waters throughout the State of Maine, including in Indian Lands

EPA's review of Maine's new aquatic life criteria for acrolein, diazanon and nonylphenol, submitted to EPA on January 14, 2013, is based on whether the criteria protect aquatic life uses, including consideration of EPA's National Recommended Water Quality Criteria published pursuant to Section 304(a) of the CWA. EPA finds that the revised criteria are scientifically defensible and are protective of designated uses for the reasons explained in the EPA criteria documents[60] for acrolein, diazanon and nonylphenol.

4.5 EPA's Decision to Approve Maine's Aquatic Life Criteria Tables I and II in DEP Rule Chapter 584, except for Ammonia, Approve Aquatic Life Criteria in 38 M.R.S. § 420(1-B.A.(1)), (1-B.C), (1-B.D), and (1-B.E), and Approve Biological Criteria in DEP Rule Chapter 579 for Waters in Indian lands

EPA's review of the aquatic life criteria, other than ammonia, in DEP Regulation Chapter 584 Tables I and II, submitted to EPA on January 11, 2006, and in 38 M.R.S. § 420(1-B.A.(1)), (1-B.C)[61],(1-B.D), and (1-B.E), submitted to EPA on May 14, 2004 (related to mercury and referenced in Table I of Chapter 584), for waters in Indian lands, is based on whether the criteria protect aquatic life uses, including consideration of EPA's National Recommended Water Quality Criteria published pursuant to Section 304(a) of the CWA. EPA finds that the revised criteria are scientifically defensible and are protective of designated uses for the reasons explained in the EPA criteria documents[62] for those pollutants. EPA approved these criteria for waters outside Indian lands on January 25, 2005 and July 7, 2006, and is now approving them for waters in Indian lands.

DEP Rule Chapter 579 provides numeric biological criteria that quantify aquatic life standards for Class AA, A, B and C waters. The rules use the benthic macroinvertebrate community as a surrogate to determine conformance with statutory aquatic life standards. EPA approves of these criteria because they are based on sound scientific rationale and are protective of designated aquatic life uses, as required by Section 303(c)(2)(B) of the CWA and 40 C.F.R. § 131.11. EPA approved this rule for waters outside Indian lands on January 25, 2005, and is now approving it for waters in Indian lands.

4.6 EPA's Decision to Approve Maine's Narrative Criteria for Toxic Pollutants and Implementation Policies Regarding the Development of Statewide Criteria and Site-Specific Criteria, except for Specified Fish Consumption Rates, in DEP Rule Chapter 584, for Waters in Indian Lands

EPA's review of Maine's narrative water quality criteria, as expressed in Chapter 584, §§ 1, 2, and 3.A(1), and submitted to EPA on January 11, 2006, is based on whether those provisions are protective of designated uses, as required in 40 C.F.R. § 131.11. Since the narrative criteria specifically call for waters to be free of pollutants in concentrations that cause waters to be

---

[60] See http://water.epa.gov/scitech/swguidance/standards/criteria/current/index.cfm#altable for National Recommended Water Quality Criteria and access to criteria documents for each pollutant.

[61] Not including 38 M.R.S §420(1-B.C.(1)) and (1-B.C.(2)), which are not WQS requiring EPA review and approval – see section 4.9 below.

[62] See http://water.epa.gov/scitech/swguidance/standards/criteria/current/index.cfm#altable for National Recommended Water Quality Criteria and access to criteria documents for each pollutant.

unsuitable for the designated uses of the water body, EPA finds that they are consistent with the requirements. EPA approved these provisions for waters outside Indian lands on July 7, 2006, and is now approving them for waters in Indian lands.

EPA's review of Maine's implementation policies regarding the development of statewide criteria and site specific criteria in Chapter 584 §§ 3 and 5 (other than the fish consumption rates of 32.4 g/day and 138 g/day, which EPA is disapproving as discussed above) is based on whether the criteria developed from those policies would protect the applicable designated uses including a consideration of EPA's ambient water quality criteria guidance, published pursuant to Section 304(a) of the CWA. The implementation policies include requirements for developing scientific bases for new or revised criteria as well as assumptions regarding ambient waters characteristics (such as pH, temperature, and salinity), and human health (such as water consumption rate and average body weight). EPA approved these policies for waters outside Indian lands on July 7, 2006 and now approves the implementation policies in Chapter 584 §§ 3 and 5 (other than the fish consumption rates) for waters in Indian lands because they require criteria to protect designated uses, and since the procedures and numeric assumptions are consistent with currently published EPA guidance.

EPA is not taking action on the procedures described in Chapter 584 § 3 which describe how alternative statewide and site-specific criteria are to be initiated, reviewed and adopted under state law.[63] Such procedures are not WQS requiring review and approval by EPA. Any new or revised criteria developed under the procedures for statewide, alternative statewide, or site-specific criteria must be submitted to EPA for review and approved by EPA pursuant Section 303(c)(3) of the Clean Water Act and 40 C.F.R. part 131 in order to be effective for Clean Water Act purposes.

4.7 EPA's Decision to Approve Maine's Dissolved Oxygen (DO) Criteria for Class C waters, Requirements for Compliance with DO criteria in Riverine Impoundments, Requirements for Instream Design Flows, the Requirement to Hold a WQS Review Hearing Every Three Years and Provisions that Allow for Pesticide Discharges into Class B and SB Waters for Mosquito Control, for Waters in Indian Lands

EPA's review of the revision to the DO criteria for Class C waters in 38 M.R.S. §465(4.B), submitted to EPA on January 11, 2006, is based on whether the criteria protect aquatic life uses, particularly cold waters species. For the reasons provided in our July 7, 2006 approval of these criteria for waters that are not in Indian lands, EPA finds that the criteria are protective of aquatic life uses and approves them in Indian lands as well.

EPA's review of the revision to DO measurement requirements for riverine impoundments in 38 M.R.S. §464(13), submitted to EPA on August 26, 2003, is based on whether the criteria protect existing and designated uses for waters in Indian lands. As explained in our February 9, 2004

[63] Specifically, these provisions are: the requirement in Chapter 584 § 3(A.(2)) that "statewide criteria must be initiated in accordance with the petition for rulemaking provisions of the State Administrative Procedures Act, 5 M.R.S.A., Section 8055"; the provision in the first paragraph of Chapter 584 § 3(B) that site specific criteria "must only be adopted by the Board as part of a waste discharge license proceeding pursuant to 38 M.R.S.A. Sections 413, 414 and 414-A"; and the first two sentences of the second paragraph of Chapter 584 § 3(B).

approval of this revision for waters that are not in Indian lands, EPA finds that the narrative standard that accompanies the measurement requirements ("dissolved oxygen concentration in existing riverine impoundments must be sufficient to support existing and designated uses of these waters") ensures that, notwithstanding the measurement restrictions in this provision, the revision is consistent with the requirements of the Clean Water Act.

EPA's review of the revisions to DEP Rule Chapter 530 § 4(B), which contains instream design flows for the application of water quality criteria for aquatic life and human health, submitted to EPA on January 11, 2006, is based on whether the provision protect existing and designated uses for waters in Indian lands. The instream design flows (1Q10 low flow for acute aquatic life criteria, 7Q10 for chronic aquatic life criteria, and harmonic mean flow for human health criteria), are consistent with guidance intended to ensure protection of uses provided in Section 5.2 of EPA' Water Quality Standards Handbook[64]. EPA approved this provision for waters outside Indian lands on April 17, 2006, and is now approving it for waters in Indian lands.

EPA's review of the revision to provisions in 38 M.R.S. § 464(3.B), that ensure that a hearing will be held at least every three years for the purpose of reviewing Maine's WQS, and revising them, as appropriate, submitted to EPA on May 14, 2004, is based on whether the provision is consistent with federal WQS review requirements. This revision reversed a previous change to 38 M.R.S. § 464(3.B)[65] that specified hearings only every four years. Since CWA § 303(c)(1) and 40 C.F.R. § 131.20 require states to hold public hearings every three years, the revision is consistent with federal WQS requirements. EPA approved this provision for waters outside Indian lands on January 25, 2005, and is now approving it for waters in Indian lands.

Revisions submitted on April 8, 2008 included the addition of 38 M.R.S. § 465(3.C.(2)) and § 465-B(2.C) which allow the discharge to Class B and SB waters of aquatic pesticides approved by DEP for control of mosquito-borne diseases. EPA's review is based on whether the provision will protect existing and designated uses for waters in Indian lands and is consistent with the requirements of the Clean Water Act. Given the requirements that the methods and materials used be protective of non-target species, EPA anticipates that no degradation of water quality would occur due to the discharge of aquatic pesticides authorized under these revisions. EPA approved these provisions for waters outside Indian lands on August 19, 2009 and is now approving it for waters in Indian lands.

4.8 EPA's Decision to Take No Action on Maine's Ammonia and Recreational Bacteria Criteria for Waters in Indian lands; on the Reclassification of Long Creek; and on Certain Bacteria and Pesticide Provisions for Waters throughout Maine, Including Waters in Indian Lands

EPA understands that Maine will be conducting a comprehensive triennial review in the coming months and will be reviewing the ammonia criteria for protection of aquatic life and the bacteria

---

[64] EPA-820-B-14-004, September 2014, provided on line at http://water.epa.gov/scitech/swguidance/standards/handbook/chapter05.cfm#section52.

[65] EPA did not act on the previous revision (calling for hearings every 4 years) which DEP submitted to EPA on August 26, 2003, since DEP agreed at that time to propose changing the requirement back to hearings every 3 years.

criteria for the protection of primary contact recreation, in light of EPA's recommendations[66] for these widespread pollutants, issued in 2013 and 2012, respectively. EPA expects that DEP will be revising these criteria for all waters in Maine, including waters in Indian lands, so that they are based on sound science and protective of the designated uses. For this reason, for waters in Indian lands, we are not taking action at this time on Maine's ammonia criteria for the protection of aquatic life in DEP regulation Chapter 584, Appendix A, and the numeric bacteria criteria for the protection of primary contact recreation for Class B and C waters in 38 M.R.S. §465(3.B) and (4.B), and the extension of the applicability of bacteria criteria for Class SB and SC waters to include bacteria of domestic animal origin in 38 M.R.S. § 465-B(2.B) and (3.B). For the same reason, we are not taking action for waters throughout the State, including waters in Indian lands, on the revisions to 38 M.R.S. §465(3.B) and (4.B) and 38 M.R.S. § 465-A(1.B), which extended the applicability of the bacteria criteria for Class B, C, and GPA waters to include bacteria of domestic animal origin. EPA would be happy to provide assistance to DEP as it develops the new criteria.

In addition, EPA is not taking action on the reclassification of a section of Long Creek (which is a water outside of Indian lands) from Class B to Class C. This downgrade in classification was adopted to achieve consistency in the Creek where the upstream and downstream reaches were already Class C waters. EPA agrees with DEP that it is unusual for a downstream section of a flowing water to be at a higher classification that the upstream section, However, EPA would like to discuss this reclassification further with DEP in the coming months to explore whether there are other means to remedy the inconsistency, such as reclassifying the upstream section to Class B if the restoration of Long Creek and Class B uses there are attainable.

EPA also reviewed the provisions related to certain pesticide discharges submitted to EPA in 2006, 2008 and 2014 and finds that many of these are not water quality criteria requiring review and approval by EPA (as discussed in the section that follows) and two are WQS that we have approved herein (as discussed in the preceding section). However, EPA finds that some of these revisions are WQS which EPA has not yet acted on for waters anywhere in Maine. The revisions related to pesticides that are WQS that we are continuing to take no action on are:

- The revisions made in L.D. 1304 at 38 M.R.S. § 464(4.A.(3)(a)), and § 465((3.C.(1)) and (4.C), related to certain pesticide discharges, submitted to EPA on January 11, 2006;
- The revision made in L.D. 1430 at 38 M.R.S. § 464(4.A.(3)(b)), related to certain pesticide discharges to tributaries of GPA waters, submitted to EPA on February 27, 2014.

The revisions made at 38 M.R.S. § 464(4.A.(3)(a) and (b)), would allow, in GPA waters and tributaries to GPA waters, the impairment of characteristics and designated uses and increase in trophic state due to discharges of aquatic pesticides or chemical discharges for the purpose of restoring biological communities affected by an invasive species or that are the unintended or incidental result of the spraying of pesticides. The revision made at 38 M.R.S. § 465((3.C.(1)) would allow, in Class B waters, impairment of the resident indigenous biological community due to discharges of aquatic pesticides or chemical discharges for the purpose of restoring biological

[66] See December 2, 2013 letter from EPA Region 1 Office of Ecosystem Protection Director, Ken Moraff to DEP Bureau of Land and Water Quality Director, Michael Kuhns.

communities affected by an invasive species. Similarly, the revision made at 38 M.R.S. § 465(4.C) would allow impairment of the function and structure of the indigenous biological community due to discharges of aquatic pesticides for the purpose of restoring biological communities affected by and invasive species. EPA understands from recent discussion with DEP, that Maine will be revising these provisions during the upcoming months to ensure that they are protective of designated uses. For this reason EPA is not taking action on these revisions at this time.

4.9 EPA's Determination That Various Provisions Submitted to EPA from 2004 through 2014 Are Not Water Quality Standards and Therefore EPA is Taking No Action on These Provisions

EPA has reviewed the following provisions and determined that they are not water quality standards and therefore EPA is taking no action on these provisions:

- Revisions made at 38 M.R.S. § 465(1.C.(2)) and (2.C.(2)), enacted as Chapter 574, L.D. 1833 "An Act to Amend Water Quality Laws to Aid in Wild Atlantic Salmon Restoration," submitted to EPA on May 14, 2004;
- Revisions made at 38 M.R.S. § 420(1-B.B) related to discharger compliance, submitted to EPA on May 14, 2004;
- Revisions made at in 38 M.R.S. § 420(1-B.C.(1)) and (1-B.C.(2)) that describe the state regulatory procedures for establishing site-specific bioaccumulation factors, submitted to EPA on May 14, 2004;
- Procedures in DEP Rule Chapter 584 that describe how alternative statewide and site-specific criteria are to be initiated, reviewed and adopted under state law, submitted to EPA on January 11, 2006;[67]
- Revisions made at 38 M.R.S. § 361-A(1-J) and (1-K), enacted as Chapter 330, L.D. 1588, Sections 7 and 8, which updated the definitions of "Code Of Federal Regulations" and "Federal Water Pollution Control Act" to include their amendments through January 1, 2005, submitted to EPA on January 11, 2006;
- Revisions made at 38 M.R.S. § 464(4.A.(1)(c) and (d)); § 465(1.C.(3)) and (2.C.(3)); and § 465-A(1.C), enacted as Chapter 182, L.D. 1304 "An Act Concerning Invasive Species and Water Quality Standards," submitted to EPA on January 11, 2006;
- Revisions made at 38 M.R.S. § 464(4.A.(1)(e)); § 465(1.C.(4)) and (2.C.(4)); § 465-A(1.C.(4)); and § 465-B(1.C.(2)), enacted as Chapter 291, L.D. 1274, "An Act to Allow the Discharge of Aquatic Pesticides Approved by the Department of Environmental Protection for the Control of Mosquito-borne Diseases in the Interest of Public Health and Safety," submitted to EPA on April 8, 2008;
- Revisions made at 38 M.R.S. § 420(1-B.F) and § 464(4.J) and (4.K), related to testing and licensing requirements for waste discharges that were included in LD 515, submitted to EPA on January 14, 2013; and

[67] Specifically, these provisions are: the requirement in Chapter 584 § 3(A.(2)) that "statewide criteria must be initiated in accordance with the petition for rulemaking provisions of the State Administrative Procedures Act, 5 M.R.S.A., Section 8055"; the provision in the first paragraph of Chapter 584 § 3(B) that site specific criteria "must only be adopted by the Board as part of a waste discharge license proceeding pursuant to 38 M.R.S.A. Sections 413, 414 and 414-A"; and the first two sentences of the second paragraph of Chapter 584 § 3(B).

- Revisions made at 38 M.R.S. § 464(4.A.(1)(f)); § 465(1.C.(5)) and (2.C.(5)); § 465-A (1.C.(5)); and § 465-B(1.C.(4)), enacted as Chapter 193, L.D. 1430, "An Act to Clarify the Permitted Use of Aquatic Pesticides," submitted to EPA on February 27, 2014.

Since many state and tribal laws that establish WQS include related provisions that are not themselves WQS, as defined by the Clean Water Act and EPA's regulations, EPA routinely reviews state submissions and identifies revisions that, while an important element of state law, are not WQS requiring EPA review and approval or disapproval pursuant to Section 303(c)(2) of the Clean Water Act and 40 C.F.R. part 131. EPA has in the past considered certain discharge prohibition exceptions, discharge licensing requirements, and alternative criteria adoption procedures in Maine to be WQS revisions and acted on them accordingly.[68] However, since the Region last considered such a revision in Maine, EPA has clarified how it determines what is or is not a new or revised WQS, as summarized in EPA's 2012 Frequently Asked Questions (FAQ) publication on the subject.[69] After careful review of Maine's submissions in light of this clarification, EPA finds that the provisions listed above are not WQS requiring EPA review and approval or disapproval.

As noted in the FAQ, one salient feature of a water quality standard is that it includes or addresses one of the three core components of WQS: designated uses, water quality criteria (narrative or numeric) to protect designated uses, and/or antidegradation requirements for waters of the United States. The provisions listed above, in contrast, do not establish, alter, or in any other way include or address designated uses, criteria or antidegradation requirements. Rather, most of the provisions allow the DEP to issue discharge licenses for certain previously prohibited discharges to occur in certain waters, and address compliance and testing requirements for certain discharges. In all cases, such discharges would still need to satisfy all applicable water quality standards. Therefore, the provisions are more accurately characterized as permit implementation provisions rather than water quality standards. The remaining provisions are purely procedural in nature, updating federal statutory and regulatory references, and establishing processes for adopting alternative criteria and establishing bioaccumulation factors, but they do not themselves alter uses, criteria, or antidegradation requirements, or mandate how they must be expressed or established in the future.

EPA has previously written approval letters for some of the above-listed provisions as applied in state waters, assuming that they were WQS (such as the discharge prohibition exceptions), or without calling out embedded non-WQS language in a longer narrative (such as the state adoption procedures in DEP rule Chapter 584). However, under CWA §303(c), EPA only has authority to approve or disapprove new or revised state WQS. Therefore, EPA's prior "approval" letters related to these provisions have no legal effect. EPA is hereby clarifying that

---

[68] The latest example of EPA action on discharge prohibition exemptions in Maine as WQS was EPA's August 19, 2008 approval of discharge prohibition exemptions related to the discharge of aquatic pesticides for the control of mosquito-borne diseases in the interest of public health and safety using methods and materials that provide for the protection of non-target species.

[69] EPA, *What is a New or Revised Water Quality Standard Under CWA 303(c)(3)? Frequently Asked Questions*, October 2012.

in spite of letters that might indicate otherwise, the Agency has not taken action pursuant to CWA §303(c) on any of these provisions.

With respect to the new provisions enacted in L.D. 1304, submitted to EPA on January 11, 2006, and L.D. 1430, submitted to EPA on February 27, 2014 (both listed above), it is important to note that federal antidegradation regulations and Maine's WQS require that water quality in Outstanding National Resource Waters (ONRWs) be "maintained and protected" (*See* 40 C.F.R. § 131.12(a)(3) and Title 38 M.R.S. § 464(4)(F)(2)). EPA has interpreted that language to mean that states may only allow "some limited activity which may result in temporary and short-term changes in water quality" (*See* 48 FR 51402, November 8, 1983 preamble to changes in 40 C.F.R. part 131). The new provisions enacted in L.D. 1430 do not alter antidegradation requirements. Therefore, in any review of a request to apply pesticides to Class AA or other ONRWs, DEP must ensure that such application will result in no more than temporary and short term changes in water quality, as well as comply with all other CWA applicable WQS requirements.

4.10 List of Submissions from 2003 through 2014

DEP submissions from 2003-2014 to which EPA is responding in today's decision are:

- August 26, 2003 submission which included enacted legislative chapters from the 2002-2003 legislative session;
- May 14, 2004 submission which included statutory amendments and rulemakings from 2000 to 2004 that had not been previously submitted to EPA ;
- January 11, 2006 submission which included statutory amendments and rulemakings from 2004 and 2005;
- April 8, 2008 submission which included statutory amendments from the 2007 legislative session;
- December 7, 2009 submission which included statutory amendments from the 2009 legislative session;
- May 16, 2013 submission which included statutory amendments from the 2011-2012 legislative session and 2012 rulemaking; and
- February 27, 2014 submission which included statutory amendments from the 2013 legislative session.

Fish Consumption Rates Used in Human Health Criteria Calculations

*A Compilation of Fish Consumption Rates used by Assorted States and Tribes to Calculate Surface Water Quality Human Health Criteria**

** Data compiled from information provided to Ecology by the Environmental Protection Agency, Region 10, in January 2013.*

Entity	Entity Type	EPA Region	Fish Consumption Rate *	Additional Information
Alabama	State	4	30 grams/day	
Alaska	State	10	6.5 grams/day	Criteria in National Toxics Rule are also applicable.
Arizona	State	9	17.5 grams/day	
Arkansas	State	6	7.5 grams/day	
Bad River Band of Lake Superior Tribe of Chippewa Indians of the Bad River Reservation (WI)	Indian Tribe	5	142.4 grams/day	
California	State	9	6.5 grams/day	Mercury criterion uses 18.7 grams/day (fresh water, enclosed bays and estuaries) and 19.5 grams/day (ocean waters). More recent site-specific mercury criteria in CA apply the methymercury tissue criterion and a rate of 32 grams/day. Criteria in the National Toxics Rule and California Toxics Rule are also applicable.
Colorado	State	8	17.5 grams/day	
Confederated Salish and Kootenai Tribes of the Flathead Indian Reservation	Indian Tribe	8	17.5 grams/day	
Confederated Tribes of the Chehalis Reservation	Indian Tribe	10	6.5 grams/day	
Confederated Tribes of the Colville Reservation	Indian Tribe	10	narrative criteria	

02118

Entity	Entity Type	EPA Region	Fish Consumption Rate *	Additional Information
Confederated Tribes of the Umatilla Indian Reservation of Oregon	Indian Tribe	10	389 grams/day	
Confederated Tribes of the Warm Springs Indian Reservation of Oregon	Indian Tribe	10	170 grams/day	
Connecticut	State	1	17.5 grams/day or 6.5 grams/day	17.5 grams/day used for most parameters.
Coeur d'Alene Tribe	Indian Tribe	10	17.5 grams/day	Initial WQS submission - EPA has not acted on the submission.
Delaware	State	3	17.5 grams/day	
District of Columbia	State	3	17.5 grams/day	
Florida	State	4	6.5 grams/day	Florida is proposing to update criteria with an approach that calculates the criterion level necessary to achieve the minimum risk to Florida's population. This approach is currently being reviewed as part of the public comment process.
Georgia	State	4	17.5 grams/day	
Grand Portage Band of the Minnesota Chippewa Tribe	Indian Tribe	5	142.4 grams/day	
Hawaii	State	9	19.9 grams/day	
Idaho	State	10	6.5 grams/day	Idaho proposed a rate of 17.5 grams/day in 2006, which was disapproved by EPA in 2012.
Illinois	State	5	15 grams/day (Great Lakes Basin); 20 grams/day (outside Great Lakes Basin)	
Indiana	State	5	15 grams/day (Great Lakes Basin); 6.5 grams/day (outside Great Lakes Basin)	
Iowa	State	7	17.5 grams/day	
Kalispel Indian Community of the Kalispel Reservation	Indian Tribe	10	17.5 grams/day	Nickel, arsenic, and chloroform, use a FCR of 6.5g/day.

Entity	Entity Type	EPA Region	Fish Consumption Rate *	Additional Information
Kansas	State	7	6.5 grams/day or 17.5 grams/day	Criteria in National Toxics Rule are also applicable. Kansas is proposing to adopt updated criteria based on EPA's recommended §304(a) criteria in its current revision.
Kentucky	State	4	17.5 grams/day	
Lac du Flambeau Band of Lake Superior Chippewa Indians of the Lac du Flambeau Reservation	Indian Tribe	5	32 grams/day	
Louisiana	State	6	20 grams/day	6.5 grams/day for Monte Sano Bayou.
Lummi Nation	Indian Tribe	10	142.4 grams/day	
Maine	State	1	32.2 grams/day	
Makah Tribe	Indian Tribe	10	142.4 grams/day	
Maryland	State	3	17.5 grams/day	
Massachusetts	State	1	17.5 grams/day or 6.5 grams/day	
Miccosukee Tribe Indians of Florida	Indian Tribe	4	17.5 grams/day	
Michigan	State	5	15 grams/day (Great Lakes Basin); 15 grams/day (outside Great Lakes Basin)	
Minnesota	State	5	30 grams/day (Great Lakes Basin); 30 grams/day (outside Great Lakes Basin)	
Mississippi	State	4	6.5 grams/day	Mississippi completed a WQS revision in June 2012, with criteria based on a consumption rate of 17.5 grams/day (will be submitted to EPA).
Missouri	State	7	6.5 grams/day	

Entity	Entity Type	EPA Region	Fish Consumption Rate *	Additional Information
Mole Lake Band of the Lake Superior Tribe of the Chippewa Indians, Sokaogon Chippewa Community	Indian Tribe	5	Superior Tribe of the Chippewa Indians, Sokaogon Chippewa Community 15 grams/day	
Montana	State	8	17.5 grams/day	
Nebraska	State	7	6.5 grams/day	Mercury criterion uses 32.4 grams/day
Nevada	State	9	6.5 grams/day	Mercury criterion uses 18.7 grams/day. Criteria in National Toxics Rule are also applicable.
New Hampshire	State	1	6.5 grams/day	
New Jersey	State	2	17.5 grams/day	
New Mexico	State	6	17.5 grams/day	
New York	State	2	33 grams/day	
North Carolina	State	4	17.5 grams/day	
North Dakota	State	8	17.5 grams/day	
Ohio	State	5	15 grams/day (Great Lakes Basin); 6.5 grams/day (outside Great Lakes Basin)	
Oklahoma	State	6	6.5 grams/day	Oklahoma intends to update criteria using 17.5 grams/day in next triennial revision.
Oregon	State	10	175 grams/day	
Pennsylvania	State	3	17.5 grams/day	
Port Gamble S'Klallam Tribe	Indian Tribe	10	142.4 grams/day	
Puyallup Tribe of Indians	Indian Tribe	10	6.5 grams/day	Puyallup Tribe has proposed rate of 142.4 grams/day, but has not submitted to EPA.
Rhode Island	State	1	17.5 grams/day	
Saint Regis Mohawk Tribe		2	33 grams/day	
South Carolina	State	4	17.5 grams/day	
South Dakota	State	8	17.5 grams/day	
Spokane Tribe of Indians	Indian Tribe	10	86.3 grams/day	Spokane Tribe submitted revised standards to EPA in 2010 using rate of 865 grams/day, but EPA has not acted on this submittal.
Tennessee	State	4	17.5 grams/day	

Entity	Entity Type	EPA Region	Fish Consumption Rate *	Additional Information
Texas	State	6	17.5 grams/day (carcinogens); 5.6 grams/day (noncarcinogens, childhood exposure factors)	Mercury criteria use 10 grams/day (fresh water) and 15 grams/day (salt water).
The Fond du Lac Band of the Minnesota Chippewa Tribe	Indian Tribe	5	60 grams/day	
Utah	State	8	17.5 grams/day	
Vermont	State	1	6.5 grams/day	
Virginia	State	3	17.5 grams/day	
Washington	State	10	6.5 grams/day	Applicable human health criteria are in the National Toxics Rule.
West Virginia	State	3	17.5 grams/day	
Wisconsin	State	5	20 grams/day (Great Lakes Basin); 20 grams/day (outside Great Lakes Basin)	
Wyoming	State	8	17.5 grams/day

Response to Comments on the Draft NPDES Permits for the City of Coeur d'Alene, City of Post Falls and the Hayden Area Regional Sewer Board

September 2014

Contents

02125

Overview

On February 16, 2007, the EPA issued three draft reissued National Pollutant Discharge Elimination System (NPDES) permits for publicly owned treatment works (POTWs) operated by the City of Coeur d'Alene (Coeur d'Alene), City of Post Falls (Post Falls) and the Hayden Area Regional Sewer Board (HARSB) for public review and comment. The NPDES permit numbers for these permits are ID0022853, ID0025852, and ID0026590, respectively. These POTWs all discharge treated wastewater to the Spokane River, in Kootenai County, Idaho. The public comment period was scheduled to close on April 17, 2007, but was extended to May 17, 2007.

During the 2007 public comment period, the EPA received comments applicable to all three of the subject permits from the following parties:

- Bonnie Beavers
- Blue Water Technologies, Inc.
- Edward K. Bower
- The Center for Environmental Law and Policy (CELP)
- City of Coeur d'Alene (Coeur d'Alene)
- Center for Justice (CFJ)
- Scott Chaney
- Julie Dalgago
- Bart Haggin
- Hayden Area Regional Sewer Board (HARSB)
- Dennis Hinrichsen
- Jim Hollingsworth
- Gerry House
- JUB Engineers
- Kevin L. Lewis
- Jim Kimball
- Richard Moon
- John Osborn
- Public Employees for Environmental Responsibility (PEER)
- City of Post Falls (Post Falls)
- Zandra Saez
- Steve Shamion
- Clyde Sheppard
- W. Thomas Soeldner
- City of Spokane

On July 18, 2013, the EPA reopened the public comment period pursuant to 40 CFR 124.14. The EPA issued revised draft permits and revised fact sheets for all three dischargers for public review and

comment at that time. The public comment period was scheduled to close on September 3, 2013, but was extended until October 3, 2013.

During the 2013 public comment period, the EPA received comments applicable to all three of the subject permits from the following parties:

- Bob Bingham
- Coeur d'Alene
- HARSB
- Idaho Conservation League (ICL)
- Lisa Fitzner
- Post Falls
- City of Spokane
- Spokane Riverkeeper
- Spokane Tribe of Indians (Spokane Tribe)
- Washington State Department of Ecology (Ecology)

This document provides the EPA's response to the comments provided during both the 2007 and 2013 public comment periods which are germane to all three of the subject permits. The EPA has also prepared individual response to comments documents for comments that were specific to one of the subject permits. The comments are organized by the comment period during which they were received. Within each comment period, the comments are further organized by topic.

As a result of the comments received during the 2013 public comment period, the final permits include some changes relative to the 2013 draft permits. Changes made to the 2013 draft permits that were based upon comments received during the 2013 public comment period are identified in this document or in the individual response to comments documents, as appropriate.

Section 1: Comments Received during the 2013 Comment Period

Effluent Limits and Best Management Practices for Polychlorinated Biphenyls (PCBs)

Comment #1-1

The EPA received comments from several parties regarding whether or not the discharges from the POTWs operated by Coeur d'Alene, Post Falls and HARSB have the reasonable potential to cause or contribute to excursions above water quality standards for PCBs. Effluent limits are required for pollutants or pollutant parameters which "are or may be discharged at a level which will cause, have the reasonable potential to cause, or contribute to an excursion above any State water quality standard…." (40 CFR 122.44(d)(1)(i)).

The Spokane Tribe stated that the EPA has sufficient data to perform a reasonable potential analysis for PCBs. Specifically, the Spokane Tribe referenced a decision by the Pollution Control Hearings Board

(PCHB) in Washington State, in the matter of the State of Washington's permit for the Spokane County Regional Water Reclamation Facility (WRF), in which the PCHB found that information such as the type of plant the applicant is operating, the available dilution, existing data, Washington State's 303d list and fish advisories were adequate to perform the reasonable potential analysis.

The Spokane Tribe stated that the PCHB also found that that there was a reasonable potential for the discharges of the Spokane County Regional WRF to cause or contribute to water quality violations. The Spokane Tribe also stated that the information available to Ecology for use in developing the Spokane County Regional WRF permit are also available to the EPA. Specifically, the Tribe referenced the Ecology's PCB Source Assessment and fish advisories issued by the Washington State Department of Health in the Spokane and Columbia rivers, and a statement by Ecology that "the Spokane River is one of the most studied rivers" in the State of Washington. The Spokane Tribe stated that "once EPA performs the reasonable potential analysis it will likely conclude that the potential for violations exists."

Coeur d'Alene, Post Falls and HARSB stated in their comments that there are insufficient data for PCBs in the publicly owned treatment works' (POTW) effluents and in the receiving water to perform a reasonable potential analysis and calculate effluent limits for PCBs.

Post Falls and HARSB stated that the PCHB's rationale for finding reasonable potential for the Spokane County WRF permit is not persuasive as applied to Post Falls and HARSB. Specifically, Post Falls and HARSB stated that the PCHB decision cited Section 3.2 of the EPA's *Technical Support Document for Water Quality-based Toxics Control* (TSD), which discusses factors other than effluent data that permitting authorities may consider as part of a reasonable potential analysis. Post Falls and HARSB stated that they have "few if any" industrial discharges that would be likely to contribute PCBs, and that they also have more dilution than the Spokane County WRF.

Post Falls and HARSB stated that the U.S. EPA NPDES Permit Writers' Manual (Permit Writers' Manual) expresses a strong preference for calculating water quality-based effluent limits (WQBELs) based on site specific monitoring data. Post Falls and HARSB note that the Permit Writers' Manual states that "EPA recommends that monitoring data be generated before effluent limitation development whenever possible," (Page 6-23), and that, when there are no site-specific data, "the permit writer must either postpone a quantitative analysis of the need for WQBELs and generate, or require the discharger to generate, effluent monitoring data, or base a determination for the need for WQBELs on other information, such as effluent characteristics of a similar discharge" (Page 6-15). Post Falls and HARSB stated that the EPA's proposal to require the POTWs to gather the missing data, which will be used to conduct a reasonable potential analysis in future permits, is fully consistent with the Permit Writers' Manual and the TSD.

Post Falls and HARSB also stated that the existing data does not support a finding of reasonable potential for PCBs. Specifically, Post Falls and HARSB stated that the EPA has no numeric PCB data for those utilities, that the PCB Source Assessment states that PCB sources to the Spokane River in Idaho are "negligible," that the Spokane River is not listed as water quality limited for PCBs in Idaho, and that there are no fish advisories in effect for PCBs in the Spokane River in Idaho. Post Falls and HARSB stated

that the concentration of PCBs in POTW effluents varies widely, and that Post Falls and HARSB are likely to be on the low end of the range. Post Falls and HARSB stated that the City of Medical Lake POTW, located southwest of Spokane, is similar to Post Falls and HARSB in that it is a primarily residential community without a large number of industrial users and that the Medical Lake POTW's effluent PCB concentration, as reported in the Fact Sheets for the Coeur d'Alene, Post Falls and HARSB permits, is 46.6 pg/L. Post Falls and HARSB also stated that none of the factors listed in on Page 6-30 of the Permit Writers' Manual, which may be used to determine reasonable potential without facility specific data, support numeric limits in their cases.

Post Falls and HARSB stated that the unique nature of PCB pollution supports the EPA's decision not to impose numeric effluent limits because PCBs have been banned since 1979 yet remain ubiquitous in the environment, and they are persistent and cannot be practically removed to low levels from municipal effluent. Post Falls and HARSB stated that "the dispersed nature of PCB pollution makes a point source treatment strategy singularly ineffective and impractical."

Post Falls and HARSB stated that, "in the Draft Fact Sheets, EPA notes that samples taken by the U.S. Geological Service ("USGS") in 1999 revealed fish-tissue concentrations of 270 µg/L, which arguably is above the fish-tissue concentrations that would be expected at the water-column criteria of 170 pg/L." Post Falls and HARSB stated that this information does not support numeric effluent limits for the following reasons: First, the relevant criterion is 170 pg/L in the water column; there is no criterion for fish-tissue concentration. Second, USGS study stated that "the brevity of sampling for this study did not allow adequate determination of the extent or permanence of contamination or impairment." Third, the study does not indicate the types of fish sampled, their probable origins or primary habitat, or other relevant information necessary to evaluate the study's accuracy. Finally, no data indicate the relationship between the subject discharges and fish-tissue concentrations.

Coeur d'Alene stated that the monitoring data for the Spokane River at the Idaho-Washington state line do not establish that Coeur d'Alene is a source of PCBs. Coeur d'Alene stated that the Fact Sheet describes a wide range of effluent data from other treatment plants in the Northwest and throughout the country. Coeur d'Alene stated that, while this information may support the imposition of best management practices under the authority of 40 CFR 122.44(k) to "carry out the purposes and intent of the Clean Water Act," EPA should acknowledge that it does not have sufficient information to conduct a qualitative reasonable potential analysis within the meaning of EPA's Permit Writer's Manual Section 6.3.3.

Response #1-1

Overview

The fact sheets (see, e.g., the Coeur d'Alene fact sheet at Page 16) state that:

> "currently, there are insufficient data to determine if the discharges from point sources to the Spokane River in Idaho have the reasonable potential to cause or contribute to excursions above water quality standards for PCBs or dioxin in waters of the State of

> Washington or the Spokane Tribe of Indians. Therefore, no numeric water quality-based effluent limits are proposed for PCBs or dioxin in the draft permit."

Specifically, the EPA has no effluent PCB data for any of the three POTWs receiving reissued permits and no receiving water data for PCBs in the water column for the Spokane River in Idaho. Although the fact sheets (see, e.g., the Coeur d'Alene fact sheet at Pages 16 and 17) state that the USGS measured high concentrations of PCBs in fish tissue in the Spokane River in Idaho,, as noted by HARSB and Post Falls in their comments, the USGS stated that "the brevity of sampling for this study did not allow adequate determination of the extent or permanence of contamination or impairment" (USGS 2003). Without effluent data for the POTWs being permitted or data for PCBs in the water column in Lake Coeur d'Alene or in the Spokane River upstream of the subject discharges, the EPA cannot reasonably determine whether and to what extent any of the subject POTWs contribute to the measured PCB concentrations in the Spokane River at the Washington-Idaho state line, or to the measured PCB concentrations in fish tissue in Idaho.

As stated in the Permit Writers' Manual at Page 6-23, the "EPA recommends that monitoring data be generated before effluent limitation development whenever possible." Therefore, the EPA has required influent, effluent, and receiving water monitoring for PCBs. These data will be used to determine if the discharges have the reasonable potential to cause or contribute to excursions above water quality standards for PCBs when the permits are reissued.

The EPA may also modify permits for cause during their terms. One of the allowable causes for modification is the EPA's receipt of new information that was not available at the time of permit issuance and would have justified the application of different permit conditions at the time of issuance (40 CFR 122.62(a)(2)). If the effluent and receiving water monitoring data for PCBs demonstrates that one or more of the subject discharges has the reasonable potential to cause or contribute to excursions above water quality standards, the EPA may modify the appropriate permits to include effluent limits for PCBs, after preparing a draft permit and following other procedures for decisionmaking in 40 CFR Part 124 (see also 40 CFR 122.62). This is a discretionary action; the EPA may choose not to modify a permit during its term even if cause exists.

Reasonable Potential Analysis Without Effluent Data

Some commenters have correctly noted that the EPA may perform a reasonable potential analysis without facility-specific effluent data (see the TSD at Section 3.2 and the Permit Writers' Manual at Section 6.3.3). The TSD states that permit writers should consider the following factors when performing a reasonable potential analysis for a POTW without facility-specific effluent data:

- Dilution
- Type of industry or POTW
- Existing data on toxic pollutants
- History of compliance problems and toxic impact
- Type of receiving water and designated use

As explained below, the factors listed above do not support a finding of reasonable potential for the subject discharges to cause or contribute to PCB excursions in the absence of facility-specific effluent data.

Dilution

The Spokane River provides substantial dilution of the subject discharges, which suggests that the discharges may not have the reasonable potential to cause or contribute to excursions above water quality standards for PCBs.

The combined design flow of the three subject POTWs is 13.4 million gallons per day (mgd), which is 20.7 cubic feet per second (CFS). Actual effluent flow rates are less than the design flows. For pollutants such as PCBs, for which the water quality criteria are based on cancer risk from lifetime exposure, the TSD recommends the long term harmonic mean stream flow for use in determining reasonable potential and calculating effluent limits (Page 88). The harmonic mean flow of the Spokane River is 2,050 CFS near Post Falls, Idaho (USGS station # 12419000), and 3,610 CFS at the Long Lake Dam in Washington (USGS station #12433000), which is near the upstream boundary of the Spokane Indian Reservation. Thus, the combined design flow of the three discharges is 1.01% of the harmonic mean flow of the Spokane River at Post Falls (99:1 dilution) and 0.57% of the harmonic mean flow of the Spokane River at the Long Lake Dam (174:1 dilution).

Type of POTW

The TSD states that POTWs with loadings from indirect dischargers (particularly primary industries) may be candidates for toxicity limits, but also states that household disposal of toxic pollutants may cause toxicity as well. The TSD states that permit writers should evaluate the types of industrial users, their product lines, and their control equipment.

HARSB has no significant industrial users. Post Falls has three significant industrial users, all of which are categorical industrial users: Two metal finishers and one pharmaceutical manufacturer. Coeur d'Alene has three significant industrial users, two of which are categorical industrial users. One of Coeur d'Alene's categorical industrial users is in the anodizing subcategory of the electroplating point source category, and the other is in the precious metals forming subcategory of the nonferrous metals forming and metal powders subcategory.

Among these, the only industrial category for which PCBs were sampled or otherwise mentioned as part of the development of categorical pretreatment standards is metal finishers. PCB Aroclors were known to be present in 1 – 6 cases (depending on the Aroclor) out of 1,048 data collection portfolios sent by the EPA to manufacturing facilities in the Metal Finishing Category (EPA 1983). Thus, PCBs were not known to be present in the wastewaters from the vast majority of metal finishers. PCBs were not specifically selected for regulation under effluent limit guidelines or categorical pretreatment standards for metal finishers. However, the categorical pretreatment standards for metal finishers include limits for total toxic organics (TTO), which includes PCBs (40 CFR 433.11(o), 433.15, 433.17). Buck Knives, which is one of the two metal finishers discharging wastewater to the Post Falls POTW, has tested its effluent for PCB aroclors using EPA method 608, with a practical quantification limit of 0.2 µg/L (200,000

pg/L) per aroclor. In semi-annual testing conducted between 2010 and 2013 (8 samples), no PCB aroclors were detected.

Thus, the EPA is not aware of any industrial users of any of the subject POTWs that would be likely to discharge measurable amounts of PCBs to the POTWs. However, the subject permits all require the permittees to address source control and elimination of PCBs from industrial and commercial sources in their toxics management plans.

Existing Data on Toxic Pollutants

There are a large number of pollutants that are toxic to humans, wildlife, livestock, and aquatic life, many of which are unrelated to PCBs in their chemical structures, chemical and physical properties, and sources. Data on toxic pollutants that are unrelated to PCBs are irrelevant to the question of whether or not the discharges cause or contribute to excursions above water quality standards for PCBs.

PCBs are classified as persistent organic pollutants (POPs). Other persistent organic pollutants include aldrin, chlordane, dichlorodiphenyl trichloroethane (DDT), dieldrin, endrin, heptachlor, hexachlorobenzene, mirex, toxaphene, dioxins, and furans (EPA 2009). If other POPs had been measured in the effluents of any of these POTWs, this might suggest that the discharge has the reasonable potential to cause or contribute to excursions above water quality standards for PCBs. Of these compounds, only hexachlorobenzene has been tested for in any of the three POTWs' effluents. Hexachlorobenzene was not detected in the Post Falls or HARSB effluents, using EPA Method 8270, at a detection limit of 1.0 µg/L. None of these compounds have been analyzed for the Coeur d'Alene effluent. Therefore, although the existing data on POPs are limited, they do not suggest that the discharges have the reasonable potential to cause or contribute to excursions above water quality standards for PCBs.

History of Compliance Problems and Toxic Impact

The TSD states that "regulatory authorities may consider particular dischargers that have had difficulty complying with limits on toxicants or that have a history of known toxicity impacts as probable priority candidates for effluent toxicity limits."

In general, the POTWs' compliance history for non-toxic pollutants unrelated to PCBs is irrelevant to a reasonable potential analysis for PCBs, except for the total suspended solids (TSS) removal performance discussed below. As discussed above, there are no quantitative data for any persistent organic pollutants, including PCBs, for these three POTWs.

Removal of PCBs from POTW influents is strongly correlated with TSS removal, with overall removal efficiencies for PCBs being slightly lower than the overall TSS removal efficiency of the POTW (EPA 1977). The average TSS removal rates for Coeur d'Alene, Post Falls, and HARSB during 2012 were 97.5%, 98.3%, and 98.0%, respectively, and the minimum TSS removal rates during 2012 were 96%, 97.2%, and 97%. These TSS removal efficiencies are consistently higher than the minimum permit requirement (85%) and are also higher than those for the POTWs evaluated in the EPA's *PCBs Removal in Publicly Owned Treatment Works*, for which TSS removal efficiencies ranged from 84 to 95%, and PCB removal efficiencies ranged from 82 to 89 % (id at 50). Thus, it is likely that the three POTWs remove most of any

PCBs that may be present in their influents. The permits include a condition requiring that a split of all influent and effluent samples analyzed for PCBs must be analyzed for TSS. This will facilitate a better understanding of the relationship between TSS and PCBs for the subject POTWs.

Furthermore, in order to comply with the new WQBEL for total phosphorus (TP), the subject POTWs will need to install filtration systems, which will further reduce effluent TSS concentrations. Because PCB removal is correlated with TSS removal, the filtration systems are likely to further improve PCB removal rates at the subject POTWs. For the purpose of a reasonable potential analysis without effluent data, these facilities do not have a history of compliance problems or toxic impact.

Type of Receiving Water and Designated Use

The TSD states that permitting authorities should compile water quality data for the discharges' receiving waters and "use this information as a means of identifying point sources that discharge to impaired waterbodies and that thus may be contributing to this impairment."

As stated in the fact sheets for these permits (see, e.g., the Coeur d'Alene fact sheet at Page 16) and by commenters, the Spokane River is listed in Washington's 2010 303(d)/305(b) integrated report as not attaining or not being expected to attain water quality standards for total polychlorinated biphenyls (PCBs), due to elevated concentrations in fish tissue. As also stated in the fact sheets, the Spokane Tribe has EPA-approved water quality standards for its waters, which are downstream of the Long Lake Dam, and data from lower Lake Spokane indicate that the Tribe's water quality criterion for PCBs (in the water column) is not being attained (Serdar et al. 2011). The EPA disagrees with Post Falls' and HARSB's characterization of the PCB load to the Spokane River at the Idaho-Washington border as "negligible." Although the State of Washington's *Spokane River PCB Source Assessment 2003 – 2007* (PCB Source Assessment) states that PCB sampling performed in 1994 "showed that sources upstream of the Idaho border were negligible," (id at 31), more recent sampling has shown that "PCB loading from Idaho at the state line represented 30% of the overall loading" (id at 9).

However, the fact that the Spokane River is currently impaired in Washington due to high concentrations of PCBs does not by itself justify a finding that the subject discharges have the reasonable potential to cause or contribute to excursions above water quality standards for PCBs. The Spokane River is also impaired by temperature in Washington and cadmium in both Idaho and Washington, yet the EPA found that none of the subject discharges have the reasonable potential to cause or contribute to excursions above water quality standards for cadmium or temperature. The mere fact that the waterbody is currently impaired does not necessarily require the conclusion that all dischargers to the waterbody are contributing to the impairment.

Although it has been suggested that loading at the Idaho-Washington border may account for 30 percent of the overall PCB loading to the Spokane River (Serdar et al. 2011 at 9), it is not known what fraction of the loading measured at the border, if any, is discharged by the subject POTWs. Available information suggests that PCB sources to the Spokane River watershed in Idaho other than the subject POTWs may be significant. Fish tissue sampling in Lake Coeur d'Alene near Blackwell Island (upstream from the three subject POTWs) showed PCB concentrations of 158 – 443 µg/kg in the tissue of largescale

and long-nose suckers (id at 86). Air deposition "holds the potential to deposit measurable quantities of PCBs in the mountains in the eastern portion of the Spokane River basin, eventually delivering PCBs to Lake Coeur D'Alene through the St. Joe, St. Maries, and Coeur D'Alene Rivers" (id at 91). City of Spokane stormwater contributes 44 percent of the overall PCB loading to the Spokane River (id at 9). Municipal stormwater PCB loads from Idaho are unquantified, but the large loading from City of Spokane stormwater suggests that Idaho municipal stormwater loads could be significant. Furthermore, the PCB concentration measured at the Washington-Idaho border is lower than that measured in the Little Spokane River (199 pg/L), a 35-mile-long tributary of the Spokane River that receives no permitted point source discharges.[1] Thus, the PCB loading to the Little Spokane River is entirely from non-point and legacy sources. Therefore, non-point, legacy, and stormwater sources to Lake Coeur d'Alene and its tributaries and to the main stem Spokane River in Idaho may account for the PCB loading measured in the Spokane River at the Idaho-Washington border.

Conclusion of Reasonable Potential Analysis Without Effluent Data

Although the EPA has no effluent PCB data for any of the three POTWs receiving reissued permits and no receiving water data for PCBs in the water column for the Spokane River in Idaho, the EPA has performed a reasonable potential analysis for PCBs in the subject discharges. As explained above, based on the available information, the EPA does not conclude at this time that the subject discharges have the reasonable potential to cause or contribute to excursions above water quality standards for PCBs. The EPA reached this conclusion because the Spokane River affords the discharges substantial dilution, and because none of the existing data for other pollutants, nor the facilities' compliance history with existing permit requirements, nor information about the industrial users discharging to the POTWs suggest that the discharges have the reasonable potential to cause or contribute to PCBs, and, although it is known that the Spokane River transports a significant PCB load from Idaho into Washington, the origin of the Idaho PCB loading is currently unknown.

PCHB Decision

The fact that the PCHB held that the Spokane County WRF has the reasonable potential to cause or contribute to excursions above water quality standards for PCBs does not mean that the subject permits have the reasonable potential to cause or contribute to excursions above water quality standards for PCBs. As explained above, the EPA has performed a reasonable potential analysis for the subject POTWs using available information and considering the specific factors identified in the TSD. The EPA does not conclude at this time that the subject discharges have the reasonable potential to cause or contribute to excursions above water quality standards for PCBs.

Summary

In summary, the EPA does not have the necessary data to perform a reasonable potential analysis using facility-specific effluent data, as described in Section 3.3 of the TSD. Therefore, EPA performed a reasonable potential analysis conducted without facility-specific effluent data, as described in Section

[1] The Little Spokane River had one source that was covered under Washington's construction stormwater general permit (permit #WAR011881) but that coverage is now inactive. Information about permitted point sources to the Little Spokane River was obtained from the State of Washington's Water Quality Permitting and Reporting Information System (PARIS) on December 20, 2013.

3.2 of the TSD. The EPA's conclusion is that there is insufficient information to justify a finding of reasonable potential for PCBs. Therefore, the EPA has not established effluent limits for PCBs in the subject permits.

As the EPA stated in the fact sheets for these permits:

> "(T)he EPA believes that, similar to POTWs in the State of Washington and elsewhere, the Idaho POTWs may be discharging PCBs and dioxin, and that best management practices (BMP) requirements to control or abate the discharge of PCBs and dioxin are reasonably necessary to carry out the purposes and intent of the Clean Water Act. Due to the lack of data, it is infeasible to calculate numeric water quality-based effluent limits for PCBs and dioxin at this time. Therefore, the draft permit includes BMP requirements for PCBs and dioxin, consistent with 40 CFR 122.44(k)(3) and (4)."

It is not necessary for the EPA to find that the discharges have the reasonable potential to cause or contribute to excursions above water quality standards for PCBs in order to require BMPs.

Comment #1-2

The Spokane Tribe stated that the PCHB found that the conditions in the Spokane County WRF permit do not constitute a narrative limit. Specifically, the Tribe stated that a requirement in the Spokane County WRF permit to develop a toxics management plan with a goal of reducing PCB discharges to the "maximum extent practicable" does not meet the requirements of the Clean Water Act (CWA).

The Spokane Tribe requested that the EPA revise the permits "to include numeric or narrative standards that will ensure that the discharges from these three facilities do not cause or contribute to the violation of water quality standards, including the Tribe's."

Post Falls and HARSB stated that the NPDES permitting rules do not refer to narrative effluent limitations in the context of point source discharge permits. Rather, the regulations and guidance uniformly refer to BMPs as the proper type of condition to impose when data is sparse or when it is infeasible to impose numeric limits, e.g., 40 CFR 122.44(k).

Post Falls and HARSB stated that the Spokane County PCHB Ruling insists that the conditions "must require defined steps toward compliance with standards" (Spokane County PCHB Ruling at 24), and that the conditions must specify "the expected reductions in toxicant loadings, the schedule for initiating such reductions, and at a minimum, offer greater definition and timelines for/of this expected outcome." Id. at 25. Post Falls and HARSB stated that, while we all hope the PCB BMPs will improve water quality, nothing in the CWA requires the performance-based approach to the BMPs mandated by the PCHB. Rather, BMPs "are inherently pollution prevention practices." Guidance Manual for Developing Best Management Practices, EPA 833-B-93-004) (October 1993) at 1-4. As the name implies, BMPs are practices the permittee undertakes to minimize the pollutants discharged from a facility. If the permittee implements the practices, it complies with the conditions.

Post Falls and HARSB stated that "numeric reduction targets should be left for when there is sufficient data and a need to impose a numeric effluent limitation."

Response #1-2

The BMP requirements for PCBs in the draft permit need not be revised.

As explained in the response to comment #1-1, currently available information does not support a finding that the subject POTWs have the reasonable potential to cause or contribute to excursions above water quality standards for PCBs, so the permits do not include effluent limits.

Having determined that it is neither necessary nor feasible to include effluent limits for PCBs in the permits at this time, the EPA instead has chosen to require BMPs to reduce or eliminate the three subject POTWs' discharge of PCBs (if any). BMPs are defined as "schedules of activities, prohibitions of practices, maintenance procedures, and other management practices to prevent or reduce the pollution of 'waters of the United States.' BMPs also include treatment requirements, operating procedures, and practices to control plant site runoff, spillage or leaks, sludge or waste disposal, or drainage from raw material storage" (40 CFR 122.2). The EPA Permit Writers' Manual elaborates on this definition, stating that "BMPs are, by their nature, pollution prevention practices." One way of requiring BMPs in an NPDES permit is to require the permittee to develop a BMP plan, and this approach is preferable when the specific practices that the permittee should use to prevent pollution are not known at the time of permit issuance (see the EPA Permit Writers' Manual at Section 9.1.2.2). In general, the BMP requirements in the subject permits are required by way of a toxics management plan, although the permits do require the toxics management plan to address source control and elimination of PCBs in certain specific ways.

Effluent limitations, on the other hand, are defined as "any restriction imposed by the Director on quantities, discharge rates, and concentrations of 'pollutants' which are 'discharged' from 'point sources' into 'waters of the United States,' the waters of the 'contiguous zone,' or the ocean (40 CFR 122.2). Because they restrict "quantities, discharge rates and concentrations," effluent limitations are inherently quantitative.

Thus, there is an important distinction between effluent limitations and BMPs. Effluent limitations restrict the "quantities, discharge rates and concentrations" of pollutants, and generally leave the decision of how to achieve compliance with these restrictions up to the permittee. BMP requirements, in a sense, do the reverse; i.e., they specify the practices that the permittee must use in order to reduce their discharges of pollution, with the expectation that, when properly implemented, these practices will reduce the discharge of pollutants, although they do not explicitly restrict the quantity of pollutants discharged.

Since the EPA has appropriately required BMPs in the subject permits instead of effluent limitations for PCBs, it is not necessary for the permits to specify the expected reductions in toxicant loadings.

Comment #1-3

Post Falls and HARSB stated that the Spokane County PCHB Ruling exceeds the reopener requirements of the CWA by requiring "the use of ongoing monitoring data to set a numeric effluent limitation at the earliest possible time, including during the term of the current permit, in order to be in compliance with water quality standards." Spokane County PCHB Ruling at 26. Post Falls and HARSB stated that the EPA should not adopt this approach. Rather, the agency should retain its discretion as to the timing of permit modification and /or reissuance, and include only a standard reopener clause in the permit.

Response #1-3

As provided for in 40 CFR 122.62, the EPA may modify a permit during its term for cause. This is a discretionary action; the EPA may choose not to modify a permit during its term even if cause exists.

One of the allowable causes for modification is the EPA's receipt of new information that was not available at the time of permit issuance and would have justified the application of different permit conditions at the time of issuance (40 CFR 122.62(a)(2)). If the effluent and receiving water monitoring data for PCBs demonstrates that one or more of the subject discharges has the reasonable potential to cause or contribute to excursions above water quality standards, the EPA may modify the appropriate permits to include effluent limits for PCBs, after preparing a draft permit and following other procedures for decisionmaking in 40 CFR Part 124 (see also 40 CFR 122.62). Since this authority is provided by the NPDES regulations, it is not necessary to include a reopener clause in the permit for this purpose.

Comment #1-4

The City of Spokane stated that the EPA should consider how the PCHB's decision in the matter of the NPDES permit issued to the Spokane County WRF might affect permits issued to Idaho dischargers.

Spokane Riverkeeper stated that the PCHB found that the NPDES permit needs to specify that measures to achieve PCB reductions must be clarified regardless of the work of the Spokane River Regional Toxics Task Force.

Response #1-4

As described in the responses to comments 1-1, 1-2, and 1-3, the EPA has reviewed the PCHB decision in the matter of the Spokane County WRF. The EPA has determined that no changes are necessary to the subject draft permits' requirements as a result of the PCHB decision in the matter of the Spokane County WRF.

Comment #1-5

Coeur d'Alene requests that the EPA remove the requirement for a new local pre-treatment standard for PCBs at 3 µg/L. The City has reviewed its industrial and commercial customers and cannot identify any customer with effluent that might be a particular source of PCB loading. Coeur d'Alene should be allowed to identify any potential PCB problems in its effluent before engaging in source control through its pre-treatment program. The City ordinance and EPA regulations regulating pre-treatment do not require monitoring for PCBs, so setting any pretreatment limit now would be meaningless and unnecessary.

Response #1-5

Coeur d'Alene is referring to Part II.I.1.b.ii of their draft permit; this requirement is identical in the other two subject permits. This requirement is included in the permits because federal regulations already prohibit discharges of water containing PCBs in concentrations greater than or equal to 3 µg/L by any person to any treatment works, including POTWs (40 CFR 761.50(a)(3), see also 40 CFR 503.9(aa)).

This requirement is not a "local pre-treatment standard" since it applies to all treatment works in the United States and it also applies to any person, not just to industrial users of the POTW. This requirement therefore requires the permittee to enforce an existing requirement of federal law, which restricts discharges of PCBs to treatment works. Consistent with 40 CFR 761.50(a)(3), the permits do not prevent the permittees from establishing local pretreatment limits more stringent than 3 µg/L.

Since this requirement applies to any person, the EPA has moved this requirement so that it is not subordinate to the requirement to address source control and elimination of PCBs from industrial and commercial sources.

Spokane River Regional Toxics Task Force (SRRTTF or Task Force)

Comment #1-6

The Spokane Tribe expressed concern about the EPA's reliance on the Task Force as a means to achieve applicable water quality standards on numerous occasions. The Spokane River PCB TMDL Stormwater Loading Analysis Final Technical Report identifies a total PCB load reduction of 95% from Idaho as necessary to meet the Tribe's water quality standards for PCBs. First, the EPA has clearly stated that it does not believe that it has the authority to force Idaho dischargers to participate in the Task Force and can only require participation in the permits by the voluntary agreement of the dischargers. (Attachment E). Second, the PCHB identified the Task Force as a good idea but far too vague to have much effect, and the Tribe agrees with this assessment. (Order at 26). Third and finally, the EPA has presented the Task Force as a way to eventually meet the Tribe's water quality standards. The Tribe fundamentally believes that the decision to attempt to use the Task Force as a means to meet water quality standards is not supportable in law or fact because the Task Force and all of its goals are unenforceable, there is no required funding mechanism, and there are no deadlines to meet any of the amorphous goals. Simply put, the EPA cannot reasonably expect 95- to 99-percent reductions in PCBs through voluntary means alone.

The EPA has the authority to develop a multi-jurisdiction PCB TMDL and this approach could utilize the efforts of the Task Force, but in the end have an enforceable plan to meet water quality standards. Given the complexity of the watershed, it will only delay the goals of the CWA by imposing the Task Force on the Idaho Dischargers without the EPA simultaneously leading a multi-jurisdictional PCB TMDL. EPA is the only entity that can prepare such a PCB TMDL given that the State of Idaho, the Coeur d'Alene Tribe, the State of Washington, the Spokane Tribe, and the Colville Confederated Tribe all assert some jurisdiction over the waters impacted by these discharges of PCBs.

In the end, these permits contemplate 10-year compliance schedules, a multi-jurisdictional PCB TMDL would give the Idaho dischargers regulatory certainty in understanding what the various technologies they are implementing will need to accomplish for PCB removal.

The Tribe requests that the EPA reassess its decision to utilize the Task Force and instead begin the process of preparing a multi-jurisdictional PCB TMDL.

Response #1-6

The issue of a PCB TMDL for the Spokane River is beyond the scope of these permitting actions. Nothing in the CWA or NPDES regulations requires that a TMDL be developed to address water quality impairments in the permittee's receiving water prior to the issuance of an NPDES permit. Indeed, the Spokane River is on the 303(d) list for pollutants other than PCBs and for which there are no valid TMDLs, including cadmium, lead, zinc, and total phosphorus in Idaho and temperature in Washington. The EPA addressed PCBs in the same way as it addressed these other pollutants; i.e., it performed a reasonable potential analysis to determine if the discharges cause or contribute to excursions above water quality standards for those pollutants. If the EPA found that the discharges had the reasonable potential to cause or contribute to such excursions, the EPA included effluent limits for those pollutants in the permits. As explained in the response to comment #1-1, based on the available information, the EPA did not find that the subject discharges have the reasonable potential to cause or contribute to excursions above water quality standards for PCBs.

If, in the future, a TMDL for PCBs which includes wasteload allocations for the subject discharges is approved or prepared by the EPA, then the EPA will reissue or modify the subject permits to include effluent limits for PCBs that are consistent with the wasteload allocations, as required by 40 CFR 122.44(d)(1)(vii)(B).

It is correct that the EPA has stated that it does not have the authority to require the subject permittees to participate in the SRRTTF. The draft permits contain a requirement to participate in the task force because the permittees mutually agreed with Spokane Riverkeeper, the Lands Council, and Kootenai Environmental Alliance that the permits should include language requiring such participation.

The EPA supports the goal of the SRRTTF to make measurable progress toward bringing the Spokane River into compliance with applicable water quality standards for PCBs. The EPA believes the SRRTTF should be given an adequate opportunity to achieve its goal, and participation in the SRRTTF is the preferred option at this time for achieving toxics loading reductions in the Spokane River. Numeric toxics control remains an option once more effluent and receiving water data and an appropriate approved test method approved for use in NPDES permits are available, and in the event that the SRRTTF fails to achieve measurable reductions in PCB loads.

Comment #1-7

Coeur d'Alene stated that the EPA should affirm that it will become a signatory to the Task Force agreement and that it will seek funding to support the Task Force.

Spokane Riverkeeper stated that success of the SRRTTF depends upon consistent participation of the EPA (and Idaho Department of Environmental Quality (IDEQ)) in the process, in order to track the effectiveness of Idaho permittees in the process and assess measureable progress. Spokane Riverkeeper requests that the EPA dedicate staff to participate in a meaningful way in the SRRTTF, and that the EPA's and IDEQ's participation in the SRRTTF is built into work plans and budgets to ensure that there is consistent participation as the process proceeds.

Response #1-7

The EPA intends to sign the SRRTTF memorandum of agreement (MOA) once the subject NPDES permits are finalized.

The SRRTTF is eligible to compete for EPA grants, and the EPA can work to ensure that the SRRTTF is aware of related grant competitions. If the SRRTTF is amenable to this option, the EPA could pursue contract funding in an existing EPA contract to support SRRTTF work efforts. In that case, the EPA would have to manage that work in partnership with the SRRTTF.

As stated in a letter to Spokane Riverkeeper on September 20, 2013, Tom Eaton, the Director of the EPA's Washington Operations Office, is the EPA's primary representative on the SRRTTF.

Comment #1-8

Spokane Riverkeeper requests that the requirements for "measurable progress" contained in the Washington NPDES permits be included in the EPA-issued permits. The Washington permits state:

> If Ecology determines the Regional Toxics Task Force is failing to make measurable progress toward meeting applicable water quality criteria for PCBs, Ecology would be obligated to proceed with development of a TMDL in the Spokane River for PCBs or determine an alternative to ensure water quality standards are met.

Spokane Riverkeeper views "measurable progress" as concrete, on-the-ground efforts toward reduction of PCBs, including, but not limited to, source control, implementation of best management practices, institutional practices (e.g., eliminating the purchase of products with PCBs), local ordinances, and site cleanup. If measurable progress is not achieved, the EPA must take appropriate action to require end-of-the-pipe cleanup to ensure compliance with water quality standards.

Response #1-8

The EPA does not agree with Spokane Riverkeeper that the permits must include a clause requiring "measurable progress" toward meeting water quality standards for PCBs. The permits do include requirements for some of the actions that Spokane Riverkeeper views as "measurable progress," including preferentially using PCB-free products, source control, and including industrial and commercial users of the POTWs' collection systems and sources within the direct control of the permittee. As explained in the responses to comments 1-1 and 1-2, the BMP requirements in the draft permit are appropriate and authorized by NPDES regulations (40 CFR 122.44(k)).

Effluent Limits for Nutrients and Oxygen-Demanding Pollutants

Comment #1-9

Post Falls and HARSB stated that the infrastructure improvements required in the Idaho NPDES permits completely address the water quality impacts to the Spokane River coming from the State of Idaho point sources and provide substantial assimilative capacity to their downstream neighbors. Any further efforts to meet Washington regulations should therefore be led and implemented solely by and within the State of Washington.

Response #1-9

The issue raised by this comment is whether the subject permittees will be required to implement "further" (presumably meaning more stringent) efforts to meet Washington's water quality standards for dissolved oxygen (DO), beyond those required in the subject permits. The issue raised by this comment is therefore beyond the scope of the subject permit actions. The EPA will not speculate as to what specific requirements may be necessary in reissued or modified permits for the subject POTWs in the future.

If, at the time that the permits are reissued, new information demonstrates that more stringent effluent limits for nutrients and/or oxygen demand are necessary for any or all of the subject permits in order to meet Washington's water quality standards for DO, the EPA will include such limits in the permits.

Any reissued or substantively modified permits will be made available for public review and comment prior to issuance and subject to appeal, as required by 40 CFR 122.62 and Part 124.

Comment #1-10

The Idaho Conservation League (ICL) stated that the draft permits call for Phosphorus Management Plans in lieu of phosphorus limits in the winter months, and that while the plans contain laudable practices, a management plan is not an effluent limit and should not take the place of one. Instead, the new seasonal limits for phosphorus should be applied throughout the year. When phosphorus enters the watershed, whether in the winter or the summer, some of it will remain in the watershed. As the draft permit acknowledges, the effects of nutrient loading are not immediate. Some of the phosphorus discharged in the winter months will settle in the sediments downstream in Long Lake and could be released due to negative retention in the sediments during the summer months.[2] This release could contribute to plant growth in the summer, and cause a decrease in DO. Therefore, these limits should be applied throughout the year, not just during the warmer months.

Response #1-10

The subject permits include seasonal average effluent limits for total phosphorus (TP), which apply from February 1st to October 31st, or nine months of the year. During November, December, and January, there are no effluent limits for TP in any of the permits.

[2] Martin Sondergaard, Jens Peder Jensen, Erik Jeppesen, "Role of sediment and internal loading of phosphorus in shallow lakes," Hydrobiologia 506-509, (2003), 235-145.

The EPA does not dispute the commenter's statement that the effects of nutrient loading are not immediate. Indeed, modeling has shown that discharges of phosphorus as early as January can affect DO concentrations in Lake Spokane during the following summer. Therefore, the modeling that supports the limits in the draft permits assumes that, because there are no effluent limits in effect, the discharge concentrations of phosphorus in January will be unchanged from typical current discharges. The modeling shows that water quality standards for DO will be attained in Lake Spokane on a cumulative basis despite the impact of these relatively high TP discharges in January.

Currently, the CE-QUAL-W2 model used to develop the State of Washington's DO TMDL and the subject permits cannot simulate the effects of pollutants discharged late in one calendar year (e.g., November and December) upon DO concentrations in Lake Spokane during the following year. Therefore, it is infeasible for the EPA to calculate effluent limits for TP for November and December at this time. Federal regulations allow the EPA to establish BMP requirements in lieu of effluent limits when numeric effluent limits are infeasible (40 CFR 122.44(k)(4)), and, as the commenter notes, the permits require BMPs for phosphorus through the phosphorus management plans. The EPA has used the best available information and tools to establish protective WQBELs for nutrients in the subject permits. The EPA has addressed the model's inability to simulate the effects of pollutants discharged late in one calendar year upon DO concentrations in Lake Spokane during the following year by requiring year-round BMPs.

Comment #1-11

ICL stated that, although phosphorus is greatly reduced, they are concerned that the combined reductions of phosphorus, carbonaceous biochemical oxygen demand (CBOD), and ammonia are not sufficient to achieve the Washington State DO criteria. Of the three pollutants, ammonia discharges remain relatively high in the draft permits, and it appears that the seasonal amount that would be allowed under Post Falls' permit would actually increase from the existing permit's average monthly limit. According to the Spokane DO TMDL, Ecology developed assumptions about "the anticipated permit-driven reductions of anthropogenic loading of phosphorous, CBOD and ammonia from wastewater treatment plants and stormwater in Idaho. These assumptions are based on point sources discharging equivalent pollutant concentrations at wastewater treatment plants in both states and have been incorporated into the model scenarios supporting this TMDL." (p. 35, Spokane DO TMDL). The sum total of the seasonal averages for TP, CBOD, and ammonia in the draft permits for the three Idaho dischargers is significantly more than the total assumed anthropogenic loading of the three pollutants as listed in the Washington TMDL. For example, the presumed load from ammonia was 94.4 lb/day, while the actual loading under the draft permits is 604.4 lb/day. Therefore, the overall reduction in the oxygen-consuming pollutants does not appear to be sufficient to meet the downstream State's needs. Given the state of DO downstream, it would make all the more sense to attempt to decrease ammonia from Post Falls, rather than allow an increase in discharge. It's difficult to see how the state of Washington is going to achieve its goals downstream in the Spokane River TMDL if the Idaho dischargers are allowed to exceed the suggested wasteload allocation assigned to Idaho in the TMDL. We recommend the EPA revisit the CBOD and ammonia levels in an effort to be consistent with the downstream TMDL.

Response #1-11

As explained in Appendix B to all three fact sheets, the seasonal average ammonia limits in the draft permits, in combination with the TP and CBOD limits, the load and wasteload allocations for Washington pollution sources in the Spokane DO TMDL, and Avista Corporation's DO responsibility, will ensure compliance with Washington's water quality standards for DO on a cumulative basis.

As explained in Appendix B to all three fact sheets, the modeling assumptions that Ecology made when developing the TMDL are not binding on the EPA when it drafts the Idaho permits. The EPA is free to establish any limits in the Idaho permits for CBOD5, ammonia, and TP so long as those limits ensure compliance with both Idaho and Washington WQS, when considered cumulatively with other sources of pollution (40 CFR 122.4(d), 122.44(d)(4)).

The subject dischargers may have higher ammonia limits than assumed in the TMDL modeling because, in other respects, their limits for nutrients and oxygen-demanding pollutants are lower than assumed in the TMDL modeling. For example, the TMDL modeling assumed that stringent limits for TP, ammonia, and CBOD would begin on March 1st, but the subject permits generally have seasonal average limits for those pollutants that become effective on February 1st, with the sole exception being that Coeur d'Alene's ammonia limits do not take effect until March 1st.

Comment #1-12

Mr. Bob Bingham of the North West Property Owners Association (NWPOA) asked the EPA to please describe the current percent permit removal or achievement for nitrogen and phosphorus and the proposed change.

Response #1-12

None of the subject permits include effluent limits for any form of nitrogen other than ammonia. All of the subject permits include effluent limits for TP; the phosphorus limits are stated in terms of mass as opposed to percent removal.

Tables 1-3, below, provide a comparison of the ammonia and phosphorus effluent limits in the 1999 permits and the corresponding limits in the reissued permits.

Table 1: Comparison of Ammonia and Phosphorus Effluent Limits in the 1999 and 2013 Permits for Coeur d'Alene

Comment #1-13

Mr. Bob Bingham of the NWPOA asked, if these permits are instituted, please provide the projected net gains (whatever they may be) to river quality and the methods used to predict/forecast such gains.

Response #1-13

The goal of the WQBELs for TP, ammonia, and CBOD in the subject permits is to meet water quality standards for DO in Lake Spokane. Because Lake Spokane is more sensitive to loading of nutrients and oxygen-demanding pollution than the relatively free-flowing upstream reaches of the Spokane River, the limits will ensure compliance with water quality standards for DO in the Spokane River, as well.

Improving DO levels in Lake Spokane will provide better habitat for fish and other aquatic life. The reductions in TP discharges will also reduce the occurrence of algae blooms in Lake Spokane, including blooms of blue-green algae or cyanobacteria, which can be toxic to humans, livestock, and wildlife. The

reductions in TP discharges will also prevent periphyton (i.e. attached algae) densities in the Spokane River from reaching nuisance levels.

As explained in the 2013 Fact Sheets to the subject permits at Appendix B, the EPA used the CE-QUAL-W2 model to predict the impact of the subject discharges as well as other point and non-point sources of nutrients and oxygen-demanding pollution in both Idaho and Washington upon water quality in Lake Spokane. The same model was used by the State of Washington to develop the Spokane DO TMDL.

Effluent Limits for Metals

Comment #1-14

Coeur d'Alene previously submitted comments on the cadmium and lead effluent limits proposed in the Idaho's Revised Draft 401 Water Quality Certification for its draft permit. Those comments are attached and incorporated herein. We request that the cadmium and lead limits be adjusted in the permit to the extent IDEQ modifies the proposed limits in its final 401 Certification. We also request that the permits allow for modification of the limits following any review of the state 401 Certification.

Response #1-14

Although this comment was submitted by Coeur d'Alene, all three of the subject draft permits contained cadmium and/or lead limits that are specified in the Idaho's draft CWA Section 401 certifications, thus, the comment could be applicable to any of the subject permits.

As stated in the fact sheets (e.g., the Coeur d'Alene Fact Sheet at Page 13), the State of Idaho specified effluent limits for cadmium (and, for Coeur d'Alene, lead) in its draft CWA Section 401 certifications. The draft certifications stated that these limits were necessary to ensure compliance with IDAPA 58.01.02.055.04. The draft permits included these effluent limits in order to incorporate the requirements specified in the draft CWA Section 401 certifications (40 CFR 124.53(e), 124.55(a)(2)).

The final CWA Section 401 certifications do not specify any cadmium or lead limits. On June 4, 2014, a rule became effective under Idaho state law (Docket No. 58-0102-1301), which repealed the language in IDAPA 58.01.02.055.04 that had stated that the loading of pollutants causing water quality impairments in high-priority water-quality-limited waters must remain constant or decrease within the watershed. As stated in Appendix D to each of the subject fact sheets, none of the subject POTWs have the reasonable potential to cause or contribute to excursions above water quality criteria for cadmium. In addition, Coeur d'Alene does not have the reasonable potential to cause or contribute to excursions above water quality criteria for lead (see the Coeur d'Alene fact sheet at Table 2 in Appendix D).

Thus, there is no basis to include effluent limits for cadmium in any of the subject final permits, and there is no basis to include effluent limits for lead in the Coeur d'Alene final permit. The final permits do not include such limits.

Comment #1-15

Several parties submitted comments comparing the effluent limits for cadmium, lead, and/or zinc to those in the State of Washington's permits for POTWs discharging to the Spokane River in Washington.

Ecology stated in its comments on the subject draft permits that the Spokane River Dissolved Metals TMDL for cadmium, lead, and zinc requires waste load allocations for Washington dischargers as the more stringent of either end-of-pipe limits based on discharge hardness or performance-based limits for each facility. In its comments on the subject draft permits, Ecology recommended that the EPA use the same method of calculation for the Idaho dischargers.

The City of Spokane stated that they reviewed the effluent limits for metals such as zinc. In order to protect water quality, Spokane (53.8 µg/L monthly average) is required to achieve effluent limits for zinc that are twice as stringent as the EPA's proposed effluent limits for Idaho dischargers (135 µg/L monthly average). The City of Spokane stated that it is not clear from the Fact Sheets why municipal discharges in Idaho are not being held to the same standard as Spokane.

Riverkeeper stated that the proposed effluent limits for the Idaho dischargers for metals do not appear to be protective of water quality in Washington. For example, the effluent limit for zinc is twice the limit of the dischargers in Washington (53.8 v. 135 µg/L monthly average), the average monthly limit for lead is 2.5 v. 0.772 µg/L, and the average monthly limit for cadmium is 0.149 v. 0.076 µg/L. It is unclear why these limits are significantly higher than the limits set for Washington dischargers.

Response #1-15

The bases for the cadmium, lead, and zinc effluent limits in the draft permits are explained in Appendix C to the subject fact sheets.

As explained in the response to comment #1-14, above, the effluent limits for cadmium (and, for Coeur d'Alene, lead) in the draft permits were removed from the final permits because they were removed from the final CWA Section 401 certifications, following changes to Idaho's water quality rules at IDAPA 58.01.055.04.

The effluent limits for lead and zinc in the subject final permits have two possible bases, as summarized in Table 4, below. Some of the limits are based on meeting Idaho water quality criteria at the end-of-pipe (i.e., with no mixing zone), using discharge hardness. Other limits are based on ensuring compliance with the anti-backsliding requirements of the CWA. The limits that appear in the permits are the more stringent limits resulting from these possible bases.

Table 4: Bases for Cadmium, Lead, and Zinc Effluent Limits

Metal	Average Monthly Limit	Maximum Daily Limit
City of Coeur d'Alene		
Zinc	Idaho water quality criteria	Idaho water quality criteria
City of Post Falls		
Lead	Anti-backsliding[1]	Anti-backsliding[1]
Zinc	Anti-backsliding[1]	Anti-backsliding[1]
Hayden Area Regional Sewer Board		
Lead	Concentration: Idaho water quality criteria[2] Mass: Anti-backsliding[1]	Anti-backsliding[1]
Zinc	Anti-backsliding[1]	Anti-backsliding[1]

Notes:
1. Concentration limits were identical to the limits in the 1999 permits, but mass limits were increased because of the increased design flows of the Post Falls and HARSB POTWs.
2. Because the shape of the lead criteria curves, when plotted against hardness, are "concave up," (i.e., the second derivative is always positive), calculating criteria end-of-pipe water quality-based effluent limits for lead, using the hardness of the effluent, can contribute to excursions above water quality criteria as the discharge mixes with a receiving water that is softer than the effluent. This was addressed in this case by calculating a tangent line to the water quality criteria at the State of Idaho's hardness "floor" of 25 mg/L as CaCO3 and calculating water quality-based effluent limits based on the tangent line.

As stated by Ecology in its comments, some of the wasteload allocations (WLAs) for cadmium, lead, and zinc in the State of Washington's Spokane River Dissolved Metals TMDL are based on the dischargers' performance. States have the discretion to set any WLA for a discharger in a TMDL, including WLAs based on performance, as long as the TMDL complies with the EPA's regulations in 40 CFR 130.7. However, there is no provision in the CWA or the NPDES regulations that allows the EPA to independently set effluent limits based on performance.

Effluent limits in an NPDES permit are either technology-based (TBEL) or water quality-based (WQBEL). Effluent limits based on WLAs in a TMDL are a type of WQBEL. When a state specifies additional or more stringent requirements in a CWA Section 401 certification, these requirements are also based on the state's water quality standards or other provisions of state law.

The applicable technology-based limits for POTWs are the secondary treatment standards in 40 CFR Part 133. The secondary treatment standards do not address cadmium, lead, or zinc. Therefore, unless more stringent effluent limits are necessary to ensure compliance with the anti-backsliding provisions of the CWA or to ensure consistency with a state certification, the effluent limits for cadmium, lead, and zinc in the permits are WQBELs. WQBELs apply Idaho water quality criteria at the end-of-pipe, using discharge hardness. Some of WLAs in the Spokane River Dissolved Metals TMDL are calculated similarly, using Washington's water quality criteria.

As stated in the fact sheets (e.g., the Coeur d'Alene fact sheet at Page 15), the EPA has determined that the subject discharges do not have the reasonable potential to cause or contribute to excursions above Washington's water quality standards for cadmium, lead, or zinc. Idaho and Washington have identical water quality criteria for lead. Because the effluent limits for lead ensure compliance with Idaho's water quality criteria, they will also ensure compliance with Washington's water quality criteria. Idaho's water quality criteria for cadmium are more stringent than Washington's. Because none of the subject POTWs have the reasonable potential to cause or contribute to excursions above Idaho's water quality criteria for cadmium, none of the subject POTWs have the reasonable potential to cause or contribute to excursions above Washington's water quality criteria for cadmium.

Regarding zinc, the increase in zinc concentration attributable to the Idaho dischargers at the state line is less than the increase in water quality criteria (and, in turn, loading capacity) caused by the hardness of the effluents. Therefore, although Idaho's water quality criteria for zinc are marginally less stringent than Washington's criteria, the EPA has determined that the subject discharges do not have the reasonable potential to cause or contribute to excursions above Washington's water quality criteria for zinc.

Therefore, the effluent limits for lead and zinc in the subject permits are as stringent as necessary to ensure compliance with the water quality standards of both Idaho and Washington, as well as the anti-backsliding provisions of the CWA. Washington dischargers may have more stringent effluent limits where the Spokane River Dissolved TMDL specified more stringent WLAs for Washington dischargers. For example, the Washington WLAs and limits may be more stringent if they were performance-based. Or, since the water quality criteria are based on discharge hardness, and water quality criteria for cadmium, lead, and zinc increase with increasing hardness, the effluent limits for a particular Washington discharger may be more stringent than the Idaho dischargers' effluents if the effluent of a particular Washington discharger was softer than the Idaho dischargers' effluents.

Influent and Effluent Monitoring and Reporting Requirements

Comment #1-16

Coeur d'Alene requests clarification as to how the EPA will use data collected using the unapproved test method 1668. The fact sheet states that the EPA will be using the data to perform a reasonable potential analysis and derive numeric limits but acknowledges that compliance with such limits cannot be enforced using an unapproved test method. Is it correct to assume that this statement in the Fact Sheet regarding the use of method 1668 is a statement of current intentions and not a permit decision? That is, is it correct to assume that the reasonableness and legality of the potential future use of 1668 data to set permit limits will be fully considered in future permits and is not being determined in this permit cycle? This is an important issue given the expense, variability, and uncertainty regarding the reliability of the data that will be collected using an unapproved test method.

Response #1-16

The EPA believes, barring unforeseen data quality issues, that the data collected using EPA Method 1668 (or Method 8082) will be useful in performing a reasonable potential analysis for PCBs in the future.

Nothing in the CWA or regulations prevents the EPA from using data produced using an analytical method that is not approved under 40 CFR Part 136 in a reasonable potential analysis. Indeed, as discussed in the response to comment #1-1, reasonable potential analyses may be conducted without *any* facility-specific effluent data (see also the TSD at Section 3.2). Although the EPA chose to defer approval of Method 1668C while it considers the large number of comments received on the proposed approval, the EPA has stated that "this decision does not negate the merits of this method for the determination of PCB congeners in regulatory programs or for other purposes when analyses are performed by an experienced laboratory" (77 FR 29763). The EPA also requires permittees to submit data for any parameter upon request, regardless of the test methods used (see the permits at Part III.D.).

As stated in the fact sheets, (e.g. the Coeur d'Alene Fact Sheet at Page 27), the EPA may require the use of methods 1668 or 8082 in this case because the permit requires analysis of PCB congeners, and the methods approved under 40 CFR 136 are not capable of analysis for individual PCB congeners. For pollutants for which there are no approved methods under 40 CFR Part 136 (such as PCB congeners),

monitoring must be conducted according to a test procedure specified in the permit (40 CFR 122.44(i)(1)(iv); see also the EPA Permit Writers' Manual at Section 8.3).

In addition to their inability to differentiate PCB congeners, the PCB analytical methods that are approved under 40 CFR Part 136 have high detection limits that render them useless for effluent characterization for the purpose of a reasonable potential analysis. The lowest published method detection limit for the approved PCB methods is 0.065 µg/L, which is 65 ng/L or 65,000 pg/L, for PCB-1242, in Method 608. This is 383 times the Washington water quality criterion for PCBs (170 pg/L), 1,016 times the Idaho water quality criterion for PCBs (64 pg/L) and 50,000 times the Spokane Tribe's water quality criterion for PCBs (1.3 pg/L).

EPA Method 1668 is the only analytical method for PCBs with detection limits comparable to the water quality criteria for the States of Washington and Idaho (i.e. 64 – 170 pg/L). The EPA is not aware of any analytical methods that can detect PCBs in whole water samples at the Spokane Tribe's water quality criterion.

Comment #1-17

Post Falls and HARSB stated that the draft permits require PCB monitoring of the influent at the frequency of once every two months but quarterly for the final effluent. Since HARSB's and Post Falls' collection and treatment system was constructed after 1978 when PCB production and use was banned and it has no Significant Industrial Users that predate the ban, it is not reasonable to expect significant fluctuations in influent concentrations of PCB. In addition, it would be beneficial to conduct influent PCB sampling contemporaneously with effluent PCB sampling in order to calculate removal rates. The influent and effluent PCB sampling will be further coordinated with the required Toxics Management Plan, with the Regional Toxics Task Force, and with surface water quality monitoring. Therefore, we request the Draft Permit be revised with the influent PCB monitoring to match the quarterly effluent monitoring for this permit cycle.

Coeur d'Alene stated that the monitoring frequency in Table 1 for influent and effluent samples for PCBs should be equivalent.

Response #1-17

The EPA does not agree that the influent PCB sampling frequency should be reduced. As explained below, the EPA believes the proposed influent sampling frequency of once every two months is reasonable.

As stated in the fact sheets (e.g. the Coeur d'Alene Fact Sheet at Page 26), the proposed influent and effluent monitoring frequencies for PCBs are the same as those in the State of Washington's permit for the Liberty Lake Sewer and Water District, which operates the smallest of the three POTWs that discharge to the Spokane River in Washington and, like the subject dischargers, serves a primarily residential community.

As explained in the response to comment #1-1, POTWs that comply with removal requirements for TSS are likely to remove a large percentage of the PCBs in their influents. Thus, some PCB congeners that

are present at detectable concentrations in the influent may not be detectable in the effluent. Since the specific PCB congeners detected can aid in source identification, influent sampling will be more useful for source identification than effluent sampling. Since source identification aids in source control, it is reasonable to require PCB sampling of the influents to the POTWs somewhat more frequently than the effluents.

Furthermore, the fact that the required influent sampling frequency is different from the required effluent sampling frequency does not preclude contemporaneous influent and effluent sampling, because sampling once every two months will result in at least one influent sample every quarter. For example, influent sampling during the odd-numbered months would result in two samples during the first quarter (January – March) and the third quarter (July – September) and one sample during the second quarter (April – June) and the fourth quarter (October – December). Conversely, influent sampling during the even-numbered months would result in one sample during the first and third quarters and two samples during the second and fourth quarters. The quarterly effluent sample could be taken at the same time as one of the influent samples for a given quarter, thus allowing the calculation of a PCB removal rate.

Comment #1-18

Ecology stated that, currently, DO monitoring is required only once per month. Ecology would like the EPA to consider increasing the DO monitoring to five times per week for a more representative monitoring event. The facilities will be required to monitor pH five times per week and we feel that including the additional parameter will not be burdensome on the facilities. Also, since the permits were written with the intention of protecting DO levels in Lake Spokane, the increased DO monitoring will help in the validation that our state water quality standards will be met.

Response #1-18

The EPA agrees that, since pH must already be monitored at least 5 times per week with a grab sample, it would not be a significant burden for the permittees to test for DO 5 times per week as well. The EPA agrees that, since many of the subject permits' conditions are intended to ensure compliance with water quality standards for DO, it is reasonable to better characterize the discharges' effluent DO concentrations. Therefore, the EPA has changed the required effluent monitoring frequency for DO from once per month in the draft permits to five times per week in the final permits.

Comment #1-19

Ecology stated that they would like to be allowed access to review monthly DMRs from each of the three dischargers.

Response #1-19

Effluent data, as reported on DMRs, for all NPDES discharges in Idaho, including the subject POTWs, will be entered into the EPA's Integrated Compliance Information System (ICIS) database. The EPA will assist in granting access to the ICIS database to appropriate Ecology staff so that Ecology staff may review the DMR data. Also, to address this comment, the subject POTWs will be required to submit their DMR data electronically using NetDMR within 6 – 12 months and, thereafter, will not submit paper DMRs to the EPA. This is consistent with EPA Region 10's current reporting policy for major dischargers.

The public can access the information in ICIS on the internet by using Enforcement and Compliance History Online[3] (ECHO), Envirofacts[4], or the DMR Pollutant Loading Tool[5].

Comment #1-20

ICL stated that the PCB monitoring should be more frequent to ensure a robust database for determining the sources of contamination and the ability of the treatment plants to capture the PCBs. A monitoring regimen that compares influent to effluent should be added.

Response #1-20

The EPA believes the influent and effluent PCB monitoring requirements in the draft permits are adequate to characterize the utilities' discharges of PCBs (if any). The influent and effluent monitoring frequencies for PCBs are identical to those in the NPDES permit for the Liberty Lake Sewer and Water District, which discharges to the Spokane River in Washington and is of comparable size to the subject POTWs.

The following relative errors were calculated using the procedures described in Appendix N to the EPA's Local Limits Development Guidance (EPA 2004).

Assuming a coefficient of variation of 0.6, which is recommended by EPA permitting guidance in cases where the actual effluent variability is unknown (see TSD at Pages 53 and E-3), the 20 effluent samples that will be collected over the permit term (i.e., quarterly sampling for five years) will quantify the average effluent concentration with a 22.5% relative error, at a confidence level of 90%. For the influent (30 samples) the relative error will be 18.3%, at a confidence level of 90%.

Analysis of PCBs using EPA Method 1668 is expensive, costing about $1,000 per sample. The EPA has attempted to balance the cost of the monitoring with the need to adequately characterize the utilities' discharges of PCBs (if any).

Comment #1-21

Coeur d'Alene requests that the permit clarify that any test results below the detection limit of the test method be treated as zero for calculating monthly mass discharge levels.

Response #1-21

The draft permits state, in relevant part, "For purposes of calculating seasonal, monthly and weekly averages, except for E. coli, zero may be assigned for values less than the method detection limit (MDL)…." This language is applicable to the reporting of averages for both concentration and mass. In the final permits, this sentence has been edited to read, "For purposes of calculating seasonal, monthly and weekly average mass loadings and concentrations, except for E. coli, zero may be assigned for values less than the MDL…."

[3] echo.epa.gov
[4] www.epa.gov/enviro/index.html
[5] cfpub.epa.gov/dmr

Comment #1-22

Coeur d'Alene requests that the text in Part I.B.3 be revised to state, "Effluent loading of zinc and silver (October-June) and concentrations of cadmium, copper, lead, silver and zinc must be reported as total recoverable metal." The language in the draft permit suggests that loading must be reported for all parameters where zinc and silver (October-June) are the only metal parameters with mass loading limits.

Response #1-22

The EPA agrees that the language suggested by Coeur d'Alene is clearer than the language of the draft permit. The EPA has made the suggested change to the Coeur d'Alene permit and has made similar changes to the Post Falls and HARSB permits.

Comment #1-23

Coeur d'Alene requests that the reporting deadline for seasonal average TP, $CBOD_5$ and ammonia loads be revised from the October DMR to the November DMR to allow sufficient time for analysis and reporting.

Response #1-23

The EPA has addressed this comment by changing the DMR due date from the 10th day of the month following the monitoring month to the 20th day of the month following the monitoring month, for all three of the subject permits. The seasonal average TP, ammonia, and $CBOD_5$ loads are still required to be reported on the October DMR, but the October DMR is now due on November 20th instead of November 10th.

The EPA does not agree that more time is necessary for analysis and reporting of a seasonal average limit than for an average monthly limit. A seasonal average discharge is calculated in much the same way as a monthly average discharge (i.e., it is the arithmetic average of daily discharges measured during a defined time frame).

Comment #1-24

Mr. Bob Bingham of the NWPOA asked the EPA to please provide a summary of the methods used for collection, handling and analyzing of samples including standardization of equipment.

Response #1-24

In general, the required methods used for collection, handling, and analysis of samples are specified in 40 CFR Part 136. The one exception is the influent, effluent, and receiving water sampling and analysis of PCB congeners. The EPA specified the methods to be used for analysis of PCB congeners, because there is no approved method for PCB congeners in 40 CFR part 136.

Specific information about analytical methods can be found online at the National Environmental Methods Index at www.nemi.gov and at the EPA's website at water.epa.gov/scitech/methods/cwa/methods_index.cfm.

Comment #1-25

Coeur d'Alene stated that, Table 2, in Part I.B.6; some of the maximum Minimum Levels (MLs) for reporting are not consistent with approved EPA Methods. Coeur d'Alene stated that the permit writer seems to have picked the lowest value for any EPA approved or non-approved method regardless of its applicability.

For example, most laboratories utilize EPA Method 351.2 for total Kjeldahl nitrogen (TKN). This method has a working range according to the method of 100 ug/L to 20 mg/L. The approved EPA Method 351.1 has a working range of 50 ug/L to 2 mg/L, but it is only applicable to surface or saline waters, and not to domestic or industrial wastewaters. Thus, the ML for TKN in Table 2 should be set at 100 ug/L in this case to match EPA Method 351.2.

Response #1-25

The EPA agrees that the ML for total Kjeldahl nitrogen (TKN) for effluent monitoring (Table 2) should be changed to 100 µg/L, consistent with the minimum of the working range of EPA Method 351.2 (O'Dell 1993).

Surface Water Monitoring and Reporting Requirements

Comment #1-26

The Spokane Tribe stated that the monitoring should require that the dischargers utilize high volume sampling such as the CLAM methodology when collecting surface water samples for PCBs to increase sensitivity.

Response #1-26

The permits require the use of EPA Method 1668 for receiving water sampling of PCBs. Method 1668 is the most sensitive method available for analysis of whole-water samples for PCBs. According to the May 1, 2014, draft Quality Assurance Project Plan prepared for the Spokane River Regional Toxics Task Force, the Task Force's analyses for PCBs will use EPA Method 1668C (LimnoTech 2014). Method 1668 is not necessarily a high-volume method. Method 1668C does not specify a sample volume for aqueous samples, but rather states "collect one liter (or a larger or smaller volume) of sample sufficient to meet project needs."

Comment #1-27

Coeur d'Alene stated that Part I.F.1 requires monitoring stations upstream and downstream from the Coeur d'Alene outfall. The locations have to be approved by IDEQ. Coeur d'Alene requests guidance as to where the monitoring stations should be located.

Response #1-27

The permittees should work with IDEQ to establish monitoring locations that fit the descriptions in Part I.F of the final permits. The EPA has chosen to leave the required monitoring locations somewhat general, so that representative, safe, and accessible monitoring locations may be chosen based on site-specific conditions.

Comment#1-28

Ecology stated that the permits specify that analysis for PCB congeners must use EPA Method 1668, with target MDLs no greater than 10 picograms per liter per congener. You should note that EPA Method 1668C includes MDLs for individual congeners, many of which exceed the 10 pg/L target value. Ecology wants to ensure that the permit language will not exclude EPA Method 1668C as a preferred monitoring method. In addition, Ecology would like to ensure that the discharger's involvement in the Spokane River Toxics Task Force (SRRTTF) requires each facility to follow their recommended Quality Assurance Plan for toxics monitoring in the receiving water.

Response #1-28

In the final permits, the EPA has changed the language in Part I.B.11.e to require the permittees to target the MDLs listed in Table 2 of EPA Method 1668 Revision C for analyses of PCBs using Method 1668. The EPA referenced the MDLs from Method 1668C because the earlier revisions of Method 1668 listed *estimated* MDLs (EMDLs). This will provide clarity as to the acceptable MDLs for each congener. The reference to the MDLs published in Method 1668 Revision C does not require the use of Revision C.

Comment #1-29

Coeur d'Alene stated that Parts I.B.11 (PCB Congeners) and I.B.12 (2,3,7,8 TCDD) of the draft permit incorporate the word "target" for MDLs and MLs. Coeur d'Alene asked how "targeting" is accomplished and explained to EPA inspectors during audits. Coeur d'Alene stated that none of the three permittees have or will have the capability to analyze for PCBs or TCDD onsite, and contract laboratories do not provide target MDLs or MLs, only sample results and the associated reporting/quantitation limits (i.e. minimum level of detection (ML). Coeur d'Alene asked if an MDL above the target MDL is a permit violation.

Response #1-29

The word "target" is intended to recognize the fact that, even if a sensitive method is used and appropriate quality assurance and quality control (QA/QC) procedures are followed, the actual MDL or ML achieved in a particular analysis is dependent upon the sample matrix and may be higher than the MDLs or MLs published in the method. If the permittee can demonstrate that it has strived to meet the "target" MDLs and MLs in the draft permit, then, an actual MDL or ML higher than the targets would not be considered a permit violation.

Comment #1-30

Coeur d'Alene stated that total phosphorus has an ML of 10 µg/L in Table 2, which is consistent with the working ranges of approved EPA Methods 365.1, 365.3, 365.4, but Section I.F. Table 4 for "Surface Water Monitoring Requirements" indicates an ML of 5 µg/L for Total Phosphorus and Orthophosphate which is not consistent with any approved EPA method. Total Phosphorus and Orthophosphate target MLs should be consistent with ML requirements listed in Table 2 at 10 µg/L. Coeur d'Alene stated that all current approved EPA TP methods list a working range minimum of 10 µg/L.

Coeur d'Alene stated that all other MLs should be reviewed for consistency with approved EPA Methods and applicability to domestic wastewater and or surface/receiving water.

Response #1-30

The EPA does not agree that the required MLs for total phosphorus and orthophosphate in Table 4 should be changed to 10 µg/L. There are EPA-approved methods for surface water that can achieve a ML no greater than 5 µg/L, for example, Standard Method 4500-P F, which has an applicable concentration range of 1 µg/L to 10 mg/L.

The EPA has reviewed all of the other MLs and MDLs in the permits. The EPA has changed the ML for total Kjeldahl nitrogen, for effluent monitoring, from 50 µg/L to 100 µg/L consistent with the minimum of the working range of EPA Method 351.2 (O'Dell 1993). Otherwise, the EPA has not found any other MLs or MDLs that cannot be achieved.

Phosphorus Management Plan

Comment #1-31

Coeur d'Alene, HARSB and Post Falls requested that the EPA delete the phosphorus management plan requirements from the permits.

Coeur d'Alene stated that a ban on the retail or wholesale sale of phosphorus-containing laundry cleaning products in Coeur d'Alene has been in place since 1990 (Coeur d'Alene Municipal Code Chapter 13.28) and that the state of Washington's ban on dishwashing detergent containing phosphorus applies to Northern Idaho as well since distributors carry only Washington compliant products in the Coeur d'Alene market.

Coeur d'Alene requests that the EPA remove the requirement in Part II.B.2 to evaluate the WWTP TP reduction potential because the City has already engaged in an extensive evaluation of multiple treatment trains for TP removal. Based on this information, the City has updated its facility plan and secured financing and increased utility rates to construct facilities that are tailored to unique needs of Coeur d'Alene. No further evaluation of TP removal should be required until the current facility plan needs to be updated.

Coeur d'Alene requests that the EPA remove the requirement in Part II.B.3 to identify "total phosphorus reduction goals" and any reference to "goals" in Parts II.B.4, 5 and 7 to the extent such goals are anything other than the final effluent limits in the permit. Coeur d'Alene also objects to the potentially vague and burdensome obligation to meet some "typical value" outside its permit limits. The treatment system to be developed by the City was the result of a multi-year evaluation of several different treatment systems. The resulting design is unique to Coeur d'Alene and should not at any time be compared to other facilities. Simply stated, the TP reduction goal for Coeur d'Alene is to achieve compliance with its final effluent limits through optimal operation of its existing, and to be improved, treatment plant.

Coeur d'Alene requests that the EPA remove Part II.B.7 regarding revision of a phosphorus management plan. The performance of the WWTP and applicable TP limits, which should be the only "goals" that are legally required, should be addressed in the ordinary course of the permit cycle. TP removal planning should be addressed in the Facility Plan. It is improper and unlawful for the EPA to impose a de facto

permit limit through the proposed phosphorus removal planning and deadlines of 180 days as proposed in this permit condition. The City cannot manage its utility, its utility rate base, or public financing obligations when subject to an unpredictable extra-permit process. EPA should explain in response to these comments how the 180-day deadline in this section can be consistent with the ten-year compliance schedule to meet the final TP limits.

Coeur d'Alene requests that the EPA remove the annual reporting requirements for a phosphorus management plan in Part II.B.8. An annual report in the next permit cycle is redundant and unnecessary. The City will be filing monthly DMRs. Under Section I.D Coeur d'Alene must file annual progress reports on meeting the final phosphorus limits and reports on interim milestones of the compliance schedule. It is unlikely during the compliance schedule that the City will have anything else to report in terms of phosphorus management. Even if the City engaged in the "planning" required under Part II.B, it is more likely than not that the City would ultimately rely on Part II.B.6.g "total phosphorus removal at the WWTP" and Part II.B.6.h "ongoing monitoring" as its specific actions under the plan throughout the compliance period. EPA does not need a separate report under Part II.B.8 to determine the status of the implementation and optimization of the WWTP upgrades.

Post Falls and HARSB stated that the Draft Permit requires preparation of a Phosphorus Management Plan, ostensibly to reduce influent TP to the treatment plant so as to reduce resulting loading to the Spokane River. This requirement serves no purpose for HARSB and Post Falls for two reasons. First, HARSB has no significant industrial or commercial entities that would discharge inordinate quantities of TP to the treatment plant (i.e. dairies, food processors, metal finishers, etc.).

Post Falls stated that they have utilized a year-round biological TP removal process since the late 1990's which requires the influent TP in order to maintain adequate populations of phosphorus accumulating organisms. Reducing influent TP will reduce the population of those organisms but will have virtually no impact, or perhaps a slightly negative impact, on effluent TP concentrations. Therefore, we request that the requirements for a Phosphorus Management Plan be removed from this permit.

Coeur d'Alene, Post Falls and HARSB stated that the current influent concentrations and loadings of TP are typical for domestic wastewater. Thus, it would be elusive to reduce the influent loading.

Response #1-31

The phosphorus management plan requirements in the draft permits are not unduly burdensome. The requirements are modeled after the Phosphorus Management Plan Guide developed by the Minnesota Pollution Control Agency (MPCA) and the Minnesota Technical Assistance Program at the University of Minnesota. The Phosphorus Management Plan Guide is a 14-page template, available as a Microsoft Word document from the MPCA website[6], which allows utilities to complete a phosphorus management plan by printing the document and filling it in by hand, or by entering information electronically into the document using Microsoft Word and/or Excel. The goal of the phosphorus management plan is to help

[6] www.pca.state.mn.us/index.php?option=com_k2&view=item&id=722

the utilities achieve the lowest possible effluent TP concentrations, in part through strategies to reduce influent TP concentrations.

The EPA recognizes that, in this case, the final water quality-based effluent limits for TP can only be achieved through upgrades to the treatment facilities. Because the final water quality-based effluent limits will require roughly 99% removal of TP from the influent wastewater, the EPA agrees that, once the TP removal upgrades are completed, strategies to reduce influent TP concentrations, even if successful, are unlikely to result in substantial further reductions in effluent TP loads from February to October, when the TP effluent limits apply. Such strategies would be more likely to reduce effluent TP loads at treatment plants that are not designed for TP removal, or that use chemical addition as their only means of TP removal. Therefore, the EPA has deleted those portions of the phosphorus management plan requirements that are intended to reduce influent TP concentrations.

However, the EPA believes those portions of the phosphorus management plan requirements that are concerned with improving the TP removal performance of the treatment plants themselves are useful and are authorized by federal regulations, which allow permitting authorities to include BMP requirements in permits when "(t)he practices are reasonably necessary to achieve effluent limitations and standards or to carry out the purposes and intent of the CWA" (40 CFR 122.44(k)(3)).

Even after the necessary upgrades are completed, the achievement of the subject permits' stringent TP effluent limits will require a high level of skill and attention by the POTW operators. The EPA believes it will be beneficial for the utilities to develop a plan for achieving the high level of performance necessary to achieve the effluent limitations. Careful attention to maintenance, operational parameters such as chemical dosing and in-plant DO concentrations, and up-to-date knowledge of performance achieved by other POTWs using similar treatment technology has the potential to save the utilities money on energy and chemicals.

Couer d'Alene asked the EPA to explain how the 180-day deadline in Part II.B.7 of the draft permit (which appears as Part II.B.5 in the final permits) for revising the phosphorus management plan under certain circumstances is consistent with the ten year compliance schedule to meet the final water quality-based TP limits. The 180-day deadline for revision of the phosphorus management plan is independent of the compliance deadline for the final TP limits, because the phosphorus management plan requirements apply during the term of the compliance schedule. Part II.B.3.a of the final permits states that "effluent total phosphorus reduction goals must be consistent with interim or final total phosphorus effluent limits, as appropriate, or with typical values for the type of treatment process employed by the wastewater treatment plant…." Thus, it is not necessary for the final effluent TP limits to have become effective in order for the utilities to develop phosphorus reduction goals. The EPA believes that implementation of the phosphorus management plans prior to completion of phosphorus removal upgrades and imposition of the final TP limits may result in reductions in TP loadings during the terms of the compliance schedules, which is also consistent with the purposes and intent of the CWA.

The EPA understands that the phosphorus management plan will have some overlap or redundancy with other efforts, such as the utilities' facility plans and operation and maintenance plans. However, since

the TP limits present unique challenges, and because it will take several years to complete the upgrades necessary to comply with those limits, the EPA believes it is nonetheless useful and authorized by 40 CFR 122.44(k)(4) to have a plan specifically for TP removal.

Furthermore, as explained in the response to comment #1-10, modeling predicts that discharges of TP during the month of January can influence DO concentrations in Lake Spokane during the following summer. Therefore, even though there are no numeric effluent limits in effect from November to January, it is reasonably necessary to carry out the purposes and intent of the CWA (e.g., to achieve water quality standards) for the EPA to require the phosphorus management plan to include a phosphorus reduction goal for November to January. This requirement is not intended to significantly increase operating costs above those necessary to meet the February to October TP limits. That is to say, the phosphorus reduction goal for November to January should reflect the level of TP control that the permittee can achieve without incurring significant additional operating costs (e.g., for chemicals and energy) beyond those necessary to comply with permit requirements other than TP limits.

The permits require the utilities to "compare … effluent total phosphorus concentrations against typical values for wastewater treatment plants utilizing similar treatment technology," and further requires that "if the effluent total phosphorus concentrations are higher than typical levels, the permittee must investigate the cause of the high total phosphorus concentrations and take steps to reduce total phosphorus concentrations." The EPA disagrees with Coeur d'Alene that there are no "typical" values for its facility. This requirement does not require a comparison with treatment plants using identical technology, merely "similar" technology. For example, Coeur d'Alene could compare its performance against other treatment plants that use trickling filters for biological treatment and chemical addition for TP removal, Post Falls could compare its performance against other treatment plants using oxidation ditches with biological phosphorus removal, and HARSB could compare its performance against oxidation ditches without biological phosphorus removal. Once upgrades are completed, there are likely to be other treatment plants using similar tertiary processes for TP removal against which the treatment plants' performance could be compared.

Therefore, those portions of the phosphorus management plan requirements that are concerned with improving the TP removal performance of the treatment plants themselves, as well as the associated reporting requirements, have been retained in the final permits.

Tribal Trust Responsibility

Comment #1-32

The Spokane Tribe stated that it has specific water rights and fishing rights in the Spokane and Columbia River that are negatively impacted by upstream pollution and that the federal government is the trustee of the Spokane Tribe's rights, including its fishing rights

The Tribe further stated that if the EPA proceeds to issue these permits substantially unchanged and also fails to initiate a multi-jurisdictional PCB TMDL, it will be in violation of its fiduciary duties.

The Tribe requests that the EPA review these draft permits for compliance with its statutory duties under the Clean Water Act in light of its trust responsibility to the Spokane Tribe of Indians. Further, the EPA should articulate how it is meeting its separate federal common law trust responsibility that is owed to the Spokane Tribe.

Response #1-32

The EPA has reviewed the draft permits for compliance with the CWA and applicable federal regulations. As explained in the response to comment #1-1, the EPA did not conclude, based on the available information, that the subject discharges have the reasonable potential to cause or contribute to excursions above water quality standards for PCBs, and therefore has not included effluent limits for PCBs, consistent with 40 CFR 122.44(d). As explained in the response to comment #1-2, the EPA has also reviewed the BMP requirements for PCBs in the draft permits and has determined that these requirements are consistent with 40 CFR 122.44(k) and thus do not need to be changed, even though the PCHB held that similar requirements in the Spokane County WRF permit needed to be changed. As explained in the response to comment #1-5, the issue of a PCB TMDL for the Spokane River is beyond the scope of these permitting actions. The EPA need not delay issuance of these permits until a PCB TMDL is in place.

Because the permits comply with the CWA and applicable federal regulations, the EPA has met its trust responsibility to the Spokane Tribe.

Schedules of Compliance

Comment #1-33

The City of Spokane stated that each Idaho discharger will receive a compliance schedule to meet final effluent limits in 2023. Spokane noted that each discharger has interim milestones for engineering (1 yr), pilot testing (3 yrs), system design (5 yrs), and construction completion (8 yrs). Spokane is encouraged by these milestones, and by the fact that each Idaho discharger will have a period of time (2 to 3 years) to work with their new system and then comply with final limits in 2023. It is concerned that Ecology is scheduled to complete its initial ten-year review of the success of the DO TMDL in 2020. The concept was for Ecology to look at water quality in the Spokane River after all municipal entities had installed the next level of treatment and operated these new systems for a period of 2 to 3 years. EPA and Ecology should consider how a useful ten-year review can be conducted in 2020 if the Idaho dischargers do not upgrade their wastewater facilities until 2023.

Response #1-33

The regulatory requirement for the length of a compliance schedule in a permit is that the schedule "shall require compliance as soon as possible" (40 CFR 122.47(a)(1)). As explained in Appendix G to each of the fact sheets, the EPA has determined that the schedules of compliance proposed in the draft permits require compliance with the final water quality-based effluent limits as soon as possible. Therefore, the EPA has no basis to require compliance sooner than proposed in the draft permits.

The EPA believes that, even if some Spokane River dischargers have not achieved compliance with their final water quality-based effluent limits at the time of the ten-year assessment for the State of

Washington's DO TMDL, there nonetheless will be substantial reductions made in discharges of nutrients and oxygen-demanding pollution to the Spokane River, relative to pre-TMDL conditions, as well as additional water quality data, that can be used to update the CE-QUAL-W2 model used to develop the TMDL and the permits.

Comment #1-34

Mr. Bob Bingham NWPOA stated that the EPA should amend the permits to extend the compliance date (of 10 years) to a point when at least 50% to 70% of all the Washington State municipal NPDES point discharge entities also meet these same stringent standards along the river system to the west coast and/or extend the compliance deadline to 15 to 18 years to allow each of the permittees to gradually begin to raise sewer rates and to gradually accumulate the required funds instead of having to force citizens to experience doubling and perhaps tripling of their sewer rates.

Response #1-34

Federal regulations state that schedules of compliance in NPDES permits must require compliance with effluent limits as soon as possible (40 CFR 122.47(a)(1)). As explained in Appendix G to the fact sheets for all three permits, the ten-year schedules of compliance in the permits require compliance as soon as possible. If the schedules of compliance were extended beyond ten years, they would not comply with 40 CFR 122.47.

Furthermore, it would not be consistent with federal regulations nor would it be practical or reasonable to link the schedules of compliance for new water quality-based effluent limits in the subject permits to schedules for permits in Washington. Federal regulations state that compliance schedules must require compliance as soon as possible. Some permittees will be able to achieve compliance with new water quality-based effluent limits sooner than others, so the meaning of "as soon as possible" will be different for each permit. Furthermore, different permits are reissued on different schedules. Therefore, it would be unreasonable and would violate federal regulations if schedules of compliance were somehow linked to the achievement of similar effluent limits by municipalities in Washington.

Finally, it should be noted that the schedules of compliance for TP and CBOD effluent limits in the NPDES permits for existing POTWs in the State of Washington that discharge to the Spokane River above Lake Spokane (i.e. the City of Spokane and the Liberty Lake Sewer and Water District) do, in fact, require compliance with their new water quality-based effluent limits no later than March 1, 2021, which is sooner than the subject POTWs must achieve compliance with such limits. The Spokane County WRF permit does not include any schedules of compliance because it is a new discharger, and schedules of compliance are generally prohibited for new dischargers (40 CFR 122.47(a)(2)).

Timing of Permit Issuance

Comment #1-35

The City of Spokane stated that the EPA's decision approving the Spokane River DO TMDL was appealed to the U.S. District Court in Idaho by dischargers in Idaho. The City of Spokane filed a motion to intervene in the litigation in order to preserve the progress achieved through the TMDL process, and to protect Spokane's investment in new wastewater treatment systems. The appeal is pending but we

understand it will be dismissed with prejudice after the Idaho dischargers receive final NPDES Permits. We urge EPA to move quickly so that the uncertainty created by the litigation is alleviated and the Idaho dischargers can join Spokane and others in implementing new technologies and programs that will continue to improve water quality in the Spokane River.

Response #1-35

The EPA has issued the subject permits as expeditiously as possible.

Effluent Limit Structure

Comment #1-36

ICL stated that the permits do not list any average weekly limits for E. coli, total residual chlorine, total ammonia, or metals (except for cadmium). Weekly average limits should be established for these pollutants. Those pollutants with only monthly average limits and daily maximum limits risk exceeding the monthly limit if the daily maximum is reached multiple times over a period of several days. Therefore, average weekly limits for E. coli, total residual chlorine, total ammonia, and metals should be included.

Response #1-36

There is no basis to include average weekly limits for any of the pollutants mentioned, to the extent that such limits were not already included in the draft permits.

Federal regulations state that effluent limits for POTWs that discharge continuously shall be stated as average monthly and average weekly discharge limitations "unless impracticable" (40 CFR 122.45(d)(2). The HARSB permit does, in fact, include average weekly limits for total residual chlorine, from October to May. Otherwise, the effluent limits in the permits for the pollutants mentioned by ICL in its comments are stated as average monthly and maximum daily limits, because it is impracticable for the EPA to state the limits as average weekly limits.

Specifically, for E. coli, as explained in Appendix C to the 2013 fact sheets, it is impracticable to properly implement a 30-day geometric mean criterion in a permit using monthly and weekly arithmetic average limits. Therefore, the permit limits for E. coli are stated as a monthly geometric mean concentration, which is identical to the water quality standard in both its magnitude and its averaging. Because a single sample value exceeding 406 organisms per 100 ml indicates a likely exceedance of the geometric mean criterion, the EPA has imposed an instantaneous (single grab sample) maximum effluent limit for E. coli of 406 organisms per 100 ml, in addition to a monthly geometric mean limit.

For ammonia, chlorine, and metals, structuring the limits as average monthly and maximum daily limits is consistent with the recommendations of the TSD. The TSD recommends using maximum daily limits in lieu of the generally required average weekly limits for POTWs, because an average weekly limit has an averaging period that is too long to prevent acute toxicity to aquatic life (Section 5.2.3). The October to May limits for chlorine for HARSB are an exception because they are technology-based effluent limits, which are based upon standard operating practices rather than toxicity.

Availability of Information

Comment #1-37

Ecology respectfully requests a courtesy review of the required toxics monitoring quality assurance plans to confirm the monitoring protocols meet the same requirements as Washington dischargers.

Response #1-37

To address this comment, the EPA has required Post Falls and Coeur d'Alene to submit their quality assurance plans (QAPs) to the EPA as an electronic attachment to their DMRs. Thus, the QAPs will thus be available in the ICIS database. As explained in the response to comment #1-19, the EPA will assist in providing ICIS access to the appropriate Ecology staff. This will allow Ecology staff to obtain and review the QAPs.

In its final permit, HARSB is not required to begin submitting monitoring data using NetDMR by the time they must submit their QAP to the EPA. Thus, HARSB's QAP may not be submitted as an electronic attachment to a DMR. The EPA will work with Ecology staff to obtain a copy of the HARSB QAP for review by Ecology.

Other Comments

Comment #1-38

Mr. Bob Bingham of the NWPOA asked how many municipal wastewater NPDES permits are there in the EPA database that the EPA oversees, and how many municipal wastewater NPDES permits are there in State run programs database that the EPA requires, but allows the respective state to assume oversight and jurisdiction? Mr. Bingham also asked what percentage of those permits are as strict as the proposals being put forth upon Post Falls, Coeur d'Alene, and HARSB. Mr. Bingham also asked the EPA to please quantify the number of total other municipal permits being required to attain these same reduction goals.

Response #1-38

The database that is used to track NPDES permits is the Integrated Compliance Information System (ICIS). The public can access the information in ICIS on the internet by using Enforcement and Compliance History Online[7] (ECHO), Envirofacts[8], or the DMR Pollutant Loading Tool[9]. The EPA performed queries of the ICIS database in order to answer the questions posed in this comment.

According to the ICIS database, there are 22,369 NPDES permits for facilities with a standard industrial classification (SIC) code of 4952, which is the code for sewerage systems. This includes individual NPDES permits and coverages under general NPDES permits. Of these, 20,779 (93%) were issued by State and Territorial agencies, and 1,590 (7%) were issued by the EPA.

[7] echo.epa.gov
[8] www.epa.gov/enviro/index.html
[9] cfpub.epa.gov/dmr

It is not clear what the commenter meant by permits that are "as strict as" the subject permits. The subject permits have water quality-based effluent limits for a number of pollutants. However, the phosphorus limits in the subject permits are the limits that present the greatest technical challenge and that require the most extensive upgrades to meet. Thus, for the purpose of this comment, the EPA has searched for permits with phosphorus effluent limits that are comparable to or more stringent than the phosphorus limits in the subject permits.

The phosphorus limits in the subject permits are expressed as seasonal average limits for mass. Effluent limits for phosphorus may be expressed in terms of mass, concentration, removal rate, or a combination of these. The effective stringency of a mass limit depends on the facility's flow rate and, in turn, the effluent concentration that a POTW must achieve in order to achieve the mass limit. As explained in the fact sheets (see Table 4 in Appendix B), the phosphorus mass effluent limits in the draft permits are equivalent to a discharge of 0.05 mg/L (50 µg/L) TP at projected future flow rates. The ICIS database does not include flow projections, but it does include facilities' current design flow rates as reported on their most recent permit applications. At the POTWs' current design flow rates, the phosphorus mass limits in the subject draft permits are equivalent to 63 µg/L, 66 µg/L, and 76.5 µg/L for Coeur d'Alene, HARSB and Post Falls, respectively.

Effluent limits may also be expressed using a variety of different averaging periods. Because effluent discharges are variable, meeting an effluent limit of a given magnitude requires the POTW to achieve lower long-term average concentration or loading if the averaging period for the limit is relatively short. Thus, it is important to consider the differences in averaging periods when comparing the stringency of effluent limits. Regarding effluent variability, for the purpose of reasonable potential and effluent limit calculations, the TSD recommends making the assumption that the coefficient of variation (CV) is equal to 0.6, if there are not enough effluent data available to calculate a CV (Pages 53 and E-3). Assuming a sampling frequency of four samples per month, a CV of 0.6, and using the 99th percentile probability basis for both the average monthly and maximum daily limits, the ratio between an average monthly and an average weekly limit is 1.64:1 (see TSD at Table 5-3). Thus, a maximum daily limit of 126 µg/L is roughly equally as stringent as an average monthly limit of 76.5 µg/L (76.5 µg/L × 1.64 = 126 µg/L).

Thus, to address this question, the EPA searched for facilities with phosphorus limits that met at least one of the following criteria:

- For concentration limits:
    - Limits with an averaging period of monthly or longer with a magnitude of 76.5 µg/L or lower. As explained above, Post Falls' proposed seasonal average TP limit is equivalent to a concentration of 76.5 µg/L at the facility's current design flow rate. Or,
    - Limits with an averaging period shorter than monthly (e.g., average weekly limits or maximum daily limits) with a magnitude of 126 µg/L or lower.
- For mass limits:
    - Effluent limits that meet the above criteria for concentration limits, when the mass limits are converted to equivalent concentrations using the design flow of the facility. Facilities without a design flow value in ICIS were not considered.

- For percent removal:
    - A minimum percent removal requirement of at least 98%.

The database queries located 52 NPDES permits for POTWs in 11 States and in the Virgin Islands that have limits that meet the above criteria. The TP limits in the permits for the three POTWs discharging to the Spokane River in Washington were not in the ICIS database; these three POTWs also have TP limits that meet the above criteria. The final water quality-based TP effluent limits for the City of Boise, Idaho's two POTW treatment plants were not in the ICIS database, and would have also met these criteria. The phosphorus limits in the Boise, City of Spokane, Spokane County and Liberty Lake permits are shown in Table 5, below.

Thus, there are at least five permits (the two City of Boise permits and the three Washington permits for discharge to the Spokane River) that have limits at least as strict as those in the subject permits that were not found by the ICIS search, resulting in a total of 57 permits in 12 States and in the Virgin Islands. There may be other permits with similar limits which are not in the database. Of these 57 permits, 8 (14%) were issued by the EPA and the remaining 49 (86%) were issued by State or territorial permitting authorities.

Comment #1-39

Please list all municipal permits that have equal to or stricter limits and their permit limits along the entire river path to the Pacific Ocean.

Response #1-39

It is not clear what the commenter meant by "the entire river path to the Pacific Ocean." The subject POTWs discharge to the Spokane River, which is a tributary to the Columbia River, which flows to the Pacific Ocean. For the purposes of responding to this comment, the EPA will list permits with phosphorus limits at least as stringent as those in the subject permits, which are in the Columbia River watershed. Those permits are listed in Table 5, below. The permits listed may have other phosphorus limits in addition to those listed in the table. If the permit had phosphorus limits with multiple averaging periods (e.g. average monthly and average weekly limits), then the limits listed in the table are those with the longest averaging period. If the permit had phosphorus limits for both mass and concentration, only the concentration limits are listed.

Table 5: Permits with Low Phosphorus Limits in the Columbia River Watershed

NPDES ID	Permit Effective Date	Permit Name	City	State	Issuing Agency Type	TP Limit	Limit Unit	Statistical Base	Design Flow (mgd)	Equiv. Conc. Limit (mg/L)

Comment #1-40

Mr. Bob Bingham of the NWPOA asked how many municipal wastewater NPDES permits are there in Region 10 along the waterway system that these three utilities discharge into. Mr. Bingham asked the EPA to provide a map showing the locations of each and their respective permit limits (nitrogen and phosphorus/phosphate) and respective permit renewal dates.

Response #1-40

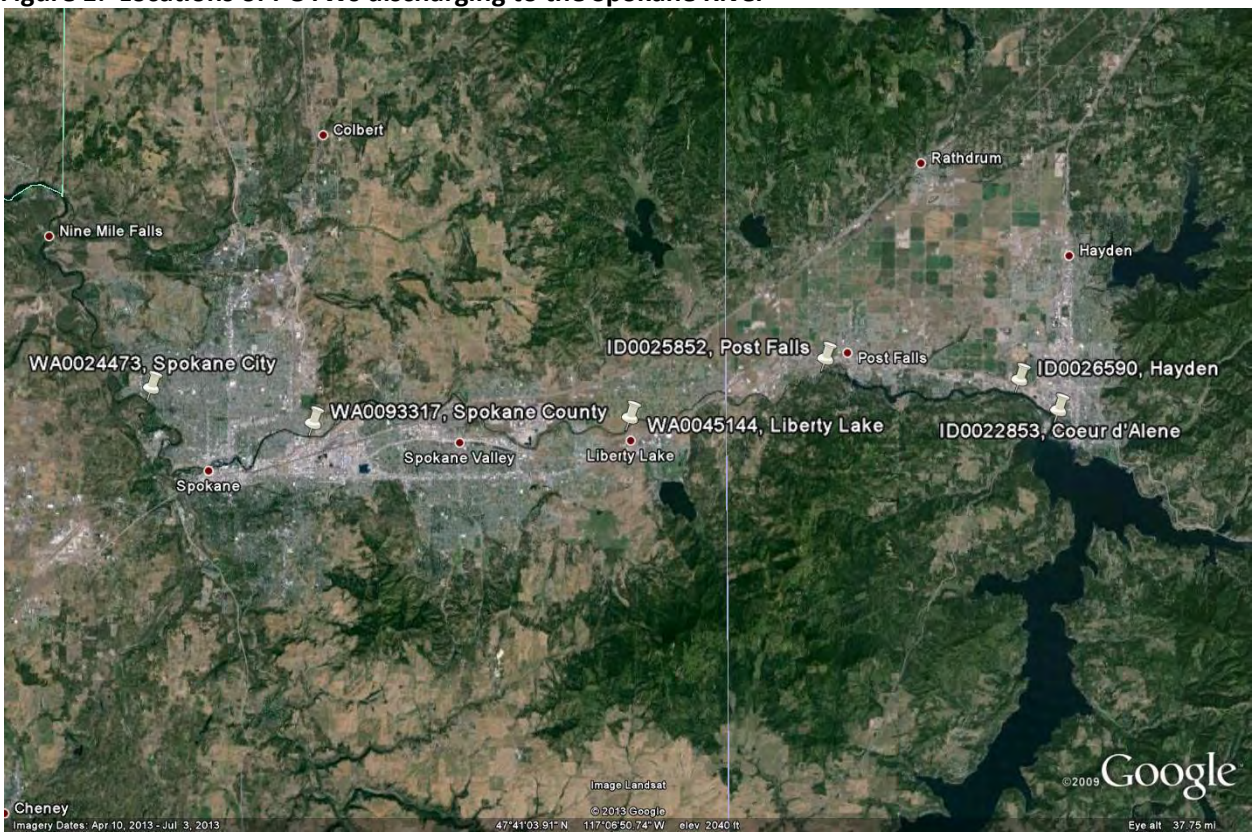
It is not clear what the commenter meant by "the waterway system that these three utilities discharge into." For the purposes of responding to this comment, the EPA will assume that the commenter was referring to the Spokane River, which flows about 111 miles from Lake Coeur d'Alene in Idaho to the Columbia River (Lake Roosevelt) in Washington.

The three subject permits (Coeur d'Alene, HARSB and Post Falls) are the only three NPDES permits for discharges of municipal wastewater to the Spokane River in Idaho. In the State of Washington, there are three additional NPDES permits for discharges of municipal wastewater to the Spokane River. These permits are issued to the Liberty Lake Sewer and Water District, the Spokane Advanced Wastewater Treatment Plant, which is operated by the City of Spokane, and the Spokane County Regional Water Reclamation Facility. Table 6, below, shows the effective dates and the TP and ammonia limits for all six of these permits (none of the permits include effluent limits for any form of nitrogen other than ammonia). As shown in the table, all six of these permits have stringent water quality-based effluent limits for phosphorus and ammonia, which are necessary to meet water quality standards for DO in Lake Spokane.

A map showing the outfall locations of these six POTWs is shown in Figure 1, below.

Table 6: NPDES Permits for Discharge of Municipal Wastewater to the Spokane River					
Name	**Permit #**	**Design Flow**	**Effective Date**	**TP Limit**	**NH3 Limit**
Liberty Lake Sewer and Water District	WA0045144	2 mgd	7/1/2011	0.45 lb/day	2.27 – 8.94 lb/day
Spokane County Regional Water Reclamation Facility	WA0093317	8 mgd	12/1/2011	2.8 lb/day	14.0 – 55.4 lb/day
Spokane Advanced Wastewater Treatment Plant	WA0024473	55.9 mgd	7/1/2011	17.8 lb/day	89 – 351 lb/day
City of Coeur d'Alene	ID0022853	6 mgd	12/1/2014	3.17 lb/day	272 lb/day
City of Post Falls	ID0025852	5 mgd	12/1/2014	3.19 lb/day	255 lb/day
Hayden Area Regional Sewer Board	ID0026590	2.4 mgd	12/1/2014	1.33 lb/day	77.4 lb/day

Figure 1: Locations of POTWs discharging to the Spokane River



Comment #1-41

Mr. Bob Bingham of the NWPOA asked the EPA to please discuss the known effects of farming and ranching along the path 50 miles upstream and 250 miles downstream of these 3 cities.

Response #1-41

The water quality-based effluent limits in the subject permits are based on the effects of the discharges upon water quality in the Spokane River and Lake Spokane. In developing the draft permits, the EPA did not evaluate the effects of the subject discharges at points downstream from the Long Lake Dam, which forms Lake Spokane and is located at river mile 33.9 on the Spokane River. The farthest upstream of the subject discharges is the City of Coeur d'Alene, which is located at river mile 110.2. Thus, the EPA evaluated the effects of the subject discharges only as far as 76.3 miles downstream from any of the subject POTWs. Because the effluent limits in the permits ensure compliance with water quality standards either at the point of discharge, at the edges of small mixing zones near the outfalls, or, for nutrients and oxygen demand, in Lake Spokane, and the discharges will experience additional dilution and attenuation of discharged phosphorus, the discharges will have a negligible effect upon water quality at points downstream from the Long Lake Dam. Therefore, the effects of farming and ranching upon the Spokane and Columbia Rivers at points downstream from Long Lake Dam (i.e., more than 76.3 miles downstream of the subject POTWs) are irrelevant to the subject permits.

The Spokane DO TMDL addresses non-point source loading to the Spokane River, including loading from farming and ranching, in Figure 4, on Page 32, and on Pages 36 – 40. The Spokane DO TMDL was based on 2001 river flow conditions (see the Spokane DO TMDL at Page 20) and the CE-QUAL-W2 model was calibrated to the conditions observed in 2001. As shown in Figure 4, in 2001, from March to October, most of the anthropogenic phosphorus loading to Lake Spokane was discharged by point sources. Non-point source loadings from Hangman Creek, the Little Spokane River, groundwater inflow, and the Lake Spokane watershed can be significant at times. Loading from Coulee Creek, stormwater discharges, and combined sewer overflows are less significant. The Spokane DO TMDL calls for reductions from current levels of non-point source loading as shown in Table 6.

Comment #1-42

Mr. Bob Bingham of the NWPOA asked the EPA to please provide the last 10 yrs of annual historical records for nitrogen and phosphorus/phosphate sampling along the path 50 miles upstream and 250 miles downstream of these 3 discharge source points.

Response #1-42

The subject POTWs discharge to the Spokane River, which is 111 miles long and flows from Lake Coeur d'Alene in Idaho to Lake Roosevelt in Washington, and the length of the Spokane River within Idaho is only about 15 miles. Therefore, to provide data for nitrogen and phosphorus "50 miles upstream" and "250 miles downstream" requires including data from the Columbia River downstream from the Spokane River and from the Lake Coeur d'Alene watershed, upstream from the Spokane River.

To respond to this comment, the EPA used the EPA's Nitrogen and Phosphorus Data Access Tool[10] to download nitrogen and phosphorus data for the watershed that receives the discharges (Upper Spokane, HUC 17010305), as well as the Coeur d'Alene Lake watershed, which is upstream from the discharges (HUC 17010303) and the Lower Spokane (HUC 17010307), Franklin D. Roosevelt Lake (HUC

[10] gispub2.epa.gov/npdat

17020001), and Chief Joseph (HUC 17020005) watersheds, downstream from the discharges. The EPA also downloaded data from the Washington Department of Ecology's river and stream water quality monitoring website[11], for water resource inventory areas (WRIAs) 57 (Middle Spokane), 54 (Lower Spokane), 53 (Lower Lake Roosevelt), 50 (Foster), 47 (Chelan) and 44 (Moses Coulee).

The Nitrogen and Phosphorus Data Access Tool includes data from 1995 to the present, which is sourced from the USGS National Water Information System (NWIS) and from the EPA's Storage and Retrieval (STORET) database. No data from the Nitrogen and Phosphorus Data Access Tool was excluded from the summary provided below because it was older than the ten-year time frame requested by the commenter. To ensure consistency with the NWIS and STORET retrievals, data from prior to 1995 was excluded from the summary statistics provided below, for the Washington Department of Ecology data. There were no post-1995 water quality data from Ecology for the Columbia River in WRIAs 50 or 47.

For the Upper Spokane watershed and all watersheds and WRIAs downstream of the subject POTWs, only data from the main stem Spokane and Columbia rivers are summarized below. Data were available for multiple species of phosphorus and nitrogen. Data are summarized below for TP, and, if available, total nitrogen. If total nitrogen data were not available, data are summarized below for nitrate+nitrite and for ammonia. The downstream watersheds and WRIAs encompass the Columbia River as far downstream as Wenatchee, Washington. The data are summarized in the tables below. All concentrations are reported in mg/L unless otherwise noted.

Table 7: Lake Coeur d'Alene Watershed (HUC 17010303) Total Phosphorus Data from USGS NWIS

Comment #1-43

Mr. Bob Bingham of the NWPOA asked why not all permits are being forced to the same standards for phosphorus removal.

Response #1-43

As explained in Appendix C to the subject fact sheets, there are two kinds of effluent limits that may appear in an NPDES permit: technology-based effluent limits and water quality-based effluent limits.

For POTWs, the EPA has promulgated technology-based effluent limits (40 CFR Part 133, see also CWA §301(b)(1)(B)). The technology-based effluent limits for POTWs define the minimum level of effluent quality that can be achieved through application of secondary treatment in terms of BOD_5 or $CBOD_5$, TSS, and pH. The secondary treatment rule, which requires all POTWs to meet certain minimum standards, does not include technology-based effluent limits for any other parameters, including phosphorus.

The phosphorus effluent limits in the subject permits are water quality-based effluent limits. Water quality-based effluent limits are based on the water quality standards for a specific facility's receiving water and the receiving water's capacity to assimilate pollutant loading while still meeting the water quality standards. NPDES permits include conditions that meet the water quality requirements of all States that are affected by the discharge, not just the State in which the discharge originates.

Permits would only need to include stringent effluent limits for phosphorus if facility's discharge of phosphorus had the reasonable potential to cause or contribute to excursions above water quality standards (e.g., for DO, pH, or nuisance algae growth), and the loading capacity of the receiving water for phosphorus was small.

In this case, the State of Washington's DO water quality criterion for lakes and reservoirs is stringent, allowing only a small (0.2 mg/L) decrease in DO concentrations from natural conditions (WAC 173-201A-200(1)(d)(ii)). In the summer, Lake Spokane has a long residence time (greater than 50 days overall and as much as 150 days for the hypolimnion) due to reduced flows in the Spokane River, and it thermally stratifies, both of which make it sensitive to nutrient loading (Moore and Ross 2010). Furthermore, the Spokane River flows through a densely populated area, which includes Spokane, which is the second most-populous city in the State of Washington (pop. 208,916), Spokane Valley (89,755), Coeur d'Alene (44,125), Post Falls (27,574), and Liberty Lake (7,591). Thus, there are numerous other point and non-point sources of nutrients and oxygen-demanding pollution to the Spokane River in addition to the subject permits. The combined effects of all of these factors result in a need to establish stringent phosphorus limits in the subject permits.

Other POTWs that discharge to waters with less stringent water quality standards, fewer sources of nutrients, and/or with characteristics that allow them to assimilate greater loadings of nutrients (e.g. higher flow rates, lower temperatures, shorter residence times) than the Spokane River and Lake Spokane may not need effluent limits for phosphorus as stringent as those that are necessary here.

Comment #1-44

Mr. Bob Bingham of the NWPOA asked the EPA to please comment on the BPA government program that is adding both phosphate and nitrogen to improve fisheries in a NW river.

Response #1-44

It is not clear which nutrient supplementation project the commenter was referring to, so the EPA cannot comment on any specific nutrient supplementation project.

In general, in some waterbodies, human actions such as dam construction and operation can cause a phenomenon called cultural oligotrophication, resulting in waters with nutrient (i.e., phosphorus and/or nitrogen) concentrations that are too low to support a healthy fishery (Anders and Ashley 2007). Nutrient supplementation can increase fish populations in such waters. This is not the case in the Spokane River and in Lake Spokane, which suffer from cultural eutrophication, in which anthropogenic nutrients from numerous municipal and industrial wastewater, stormwater, and non-point sources have over-enriched the waters to such an extent that they do not meet applicable water quality standards for DO and aesthetics.

Comment #1-45

Ms. Lisa Fitzner commented "Great job getting Coeur d'Alene, etc. to clean up the Spokane River. Just wish it could happen sooner."

Response #1-45

Comment noted. The EPA has issued the subject permits as expeditiously as possible. As explained in Appendix G to the three subject fact sheets, the compliance schedules in the permits require compliance with new water quality-based effluent limits as soon as possible.

Section 2: Comments Received during the 2007 Public Comment Period

Effluent Limits for Nutrients and Oxygen-Demanding Pollutants

Comment #2-1

A number of commenters, including the Center for Justice (submitting comments on behalf of the Sierra Club, Upper Columbia River Group) (CFJ), the Lands Council, the Center for Environmental Law and Policy (CELP), Public Employees for Environmental Responsibility (PEER), and several individuals, stated that the proposed effluent limits for TP, ammonia, and CBOD in the 2007 draft permits were not stringent enough and will contribute to violations of Washington's water quality standards for DO in Lake Spokane. The central issue raised by these commenters is that the effluent limits must be based on a cumulative analysis of all sources of human-caused pollution to the watershed, including those in the State of Washington. The commenters assert that it is not enough for the EPA to ensure that the Idaho permits will ensure the Idaho sources do not *cause* an exceedance of Washington's DO criterion for Lake Spokane. Rather, the commenters' position is that the EPA must ensure that the effluent limits for the three Idaho municipalities will ensure that the resulting discharges will not *contribute* to an exceedance of the DO standard by taking into account the contributions from all other sources in the watershed when deriving the effluent limits for the three Idaho municipalities.

Response #2-1

These comments have been addressed by changes made in the revised draft permits issued for public comment in 2013. As explained in the fact sheets to all three permits, the EPA has recalculated the water quality-based effluent limitations for TP, ammonia, and $CBOD_5$ in the 2013 draft permits. These effluent limits ensure that the level of water quality to be achieved by limits on point sources is derived from and complies with all applicable water quality standards (40 CFR 122.44(d)(1)(vii)(A)) and are based on the cumulative impact of all human actions that affect DO concentrations in Lake Spokane, including the load and wasteload allocations and Avista Corporation's DO responsibility in the State of Washington's Spokane DO TMDL. See the 2013 fact sheets at Appendix B.

Comment #2-2

CFJ stated that the EPA assumed there was more dilution than is truly available when setting water quality-based effluent limits for oxygen-demanding pollutants, when developing the 2007 draft permits.

Response #2-2

In the context of water quality, "dilution" means a reduction in pollutant concentration caused by mixing with water with a lower concentration of the pollutant. Wastewater effluents discharged to flowing waters are diluted by mixing with the flow of the receiving water. When the receiving water flow is lower, there is less dilution available.

The modeling performed in support of the effluent limits in the 2007 and 2013 draft Idaho permits (and the draft TMDLs prepared by the State of Washington) used river flow rates that were very conservative. The flows used were the actual flows observed in calendar year 2001. The calendar year mean flow rate of the Spokane River at Long Lake (USGS station #12433000) during calendar year 2001 was 4,000 CFS, which was the third lowest annual mean flow rate measured between 1940 and 2011, which is the period of record for which full calendar years of data are available. The calendar year mean flow rate of the Spokane River at Long Lake was lower than it was in 2001 only in 1944 (3,576 CFS) and 1994 (3,939 CFS). By using the 2001 actual flows in the modeling, the EPA was assuming less dilution than will normally be the case.

Comment #2-3

CFJ stated that the proposed permits "leave Washington sources no allowable loading" for nutrients and oxygen-demanding pollution. CFJ stated that, if the State of Washington were to "(consider) the Idaho discharges as boundary or background conditions at the State line" for the purposes of completing a DO TMDL, it would violate its own standards and the Clean Water Act. CFJ stated that "the combined effect of the EPA proposed permit limitations…as incorporated into the Washington TMDL is to…(support) an additional 0.2 mg/L degradation." The commenters conclude that the total DO decrease will be 0.4 mg/L below natural conditions. As such, the commenters request that the EPA recalculate the effluent limits considering the presence of Washington loading and request that the EPA require Washington's TMDL to do the same.

CFJ further stated that the State of Washington has a duty to object to the issuance of these permits under Section 401(a) of the Act. Moreover, CFJ stated that the absence of an objection from the State of Washington does not relieve the EPA of its independent duty to "condition these permits such that they do not cause or contribute to nonattainment" of Washington water quality standards pursuant to Clean Water Act Section 301(b)(1)(C).

CFJ cited to a 2005 e-mail from Mark Hicks of Ecology. In this email, Mr. Hicks appears to question EPA's approach for permitting the Idaho dischargers. Specifically, Mr. Hicks stated that "EPA appears poised to grant a 0.2 mg/L depression from naturally low DO levels to the point sources in Idaho, and then grant another 0.2 mg/l depression for the Washington dischargers."

Response #2-3

This comment was addressed by the revised draft permits issued for public review and comment in 2013. Both the Spokane DO TMDL and the subject NPDES permits for discharge to the Spokane River in Idaho have been revised such that compliance with the State of Washington's water quality standards for DO are achieved on a cumulative basis in Lake Spokane. See also the response to comment #2-1 and the 2013 fact sheets at Appendix B.

Comment #2-4

CFJ recommends that the EPA allocate 0.1 mg/L DO decrease for the Idaho permits (one half of the 0.2 mg/L decrease allowed under the Washington standards), or apportion loading according to flow. CFJ

states that by accepting their recommendation, Ecology's TMDL would be more defensible and the EPA could then state that the Idaho permits conformed with the Washington TMDL.

Response #2-4

This comment was addressed by the revised draft permits issued for public review and comment in 2013. The Spokane DO TMDL and the NPDES permits for discharge to the Spokane River in Idaho have been revised such that compliance with the State of Washington's water quality standards for dissolved are achieved on a cumulative basis in Lake Spokane. See also the response to comment #2-1 and the 2013 fact sheets at Appendix B.

Comment #2-5

CFJ stated that effluent limits for TP, ammonia, and CBOD should be expressed in concentration and mass.

Response #2-5

The federal regulation at 40 CFR 122.45(f) requires NPDES permits to contain mass limitations except (1) for pH, temperature, radiation, or other pollutants that cannot be expressed as mass, (2) when applicable standards are expressed in terms of other measurements, or (3) if in establishing permit limits pursuant to 40 CFR 125.3, (i.e. technology-based effluent limits), mass limitations are infeasible. In all cases, effluent limits for TP, ammonia, and CBOD have been, at a minimum, expressed in terms of mass. See the 2013 fact sheets at Page B-13.

Effluent limits expressed in terms of mass may also be expressed in terms of other units of measurement (40 CFR 122.45(f)(2)). Whenever there was a basis to include concentration limits for TP, ammonia, and CBOD in addition to mass limits, the concentration limits were included in the permits. See the 2013 fact sheets at Page B-14.

In general, effluent limits for CBOD are expressed in terms of mass, concentration, and removal rate. The concentration and removal rate limits are the applicable technology-based limits (40 CFR 133.102(a)(4)), and the mass limits are water quality-based effluent limits.

In general, the water quality-based effluent limits for ammonia are expressed in terms of mass. However, concentration limits have also been established where necessary to ensure compliance with the anti-backsliding provisions of the Clean Water Act or to prevent direct toxicity to aquatic life.

With respect to TP, as stated on Page B-13 of the 2013 fact sheets:

> "Effluent limits for TP are expressed exclusively in terms of mass because there are no applicable technology-based standards or numeric in-stream water quality standards for TP, the effluent limitations for TP are intended to meet Washington water quality standards, which apply several miles downstream from the discharges after complete mixing has occurred, and phosphate phosphorus is neither directly toxic to aquatic life nor directly hazardous to human health. Therefore, there is no basis to express the water quality-based TP limits in units other than mass."

Comment #2-6

CFJ stated that effluent limits for CBOD, TSS, and phosphorus should include maximum daily limits. They cite the fact that DO criteria are expressed as daily minima, and the *Friends of the Earth* v. *EPA* decision regarding "daily loads" in TMDLs.

Response #2-6

The averaging periods for effluent limits in NPDES permits for POTWs are governed by 40 CFR 122.45(d)(2), which states that, "(f)or continuous discharges all permit effluent limitations, standards, and prohibitions, including those necessary to achieve water quality standards, shall unless impracticable be stated as…(a)verage weekly and average monthly discharge limitations for POTWs."

The effluent limits for TSS and the November to January effluent limits for $CBOD_5$ in the subject permits are technology-based effluent limits, which are stated as maximum allowable 30-day and 7-day averages (40 CFR 133.102). The EPA has determined that the technology-based effluent limits for TSS and for $CBOD_5$ from November to January are adequately stringent to ensure compliance with water quality standards. There is no basis to express the effluent limits for TSS or November to January $CBOD_5$ as maximum daily limits.

As explained on Pages B-9 – B-12 of the 2013 fact sheets, the EPA has determined that it is impracticable to state the water quality-based effluent limits for phosphorus and $CBOD_5$, which apply from February 1st through October 31st, as average monthly and average weekly limits, and that those limits should be expressed as seasonal average limits. As explained on Page B-10, modeling shows that controlling the average loading of oxygen-demanding pollution to the Spokane River will ensure compliance with water quality standards for DO in Lake Spokane. It is not necessary to control short-term (e.g. daily or weekly) maximum concentrations or loadings of phosphorus or CBOD in order to ensure such compliance.

Friends of the Earth v. EPA, 446 F.3d 140 (DC Cir. 2006), is inapplicable to these discharges because *Friends of the Earth* is a decision that is relevant only to TMDLs, not effluent limits in NPDES permits. None of the effluent limits in the subject permits are based on a wasteload allocation in an approved TMDL.

Comment #2-7

CFJ is concerned about the ammonia limits in the 2007 draft permits, which CFJ stated are much higher than the waste load allocations (WLAs) in Washington's draft Spokane DO TMDL. CFJ believes that 0.1 mg/L ammonia is achievable.

Response #2-7

Although CFJ was comparing the ammonia limits in the subject permits to the ammonia WLAs in a draft of the State of Washington's TMDL for DO in the Spokane River and Lake Spokane, for the purposes of this response, the EPA will compare the ammonia limits in the subject permits to the final, EPA-approved TMDL.

This comment was addressed to some extent by changes made in the revised draft permits issued for public comment in 2013. As shown in Figures 2 and 5, the seasonal average ammonia effluent limits in

the permits for Coeur d'Alene and HARSB require lower effluent ammonia loads than the monthly average ammonia limits in the 2007 draft permits at all times from February to October. The seasonal average ammonia limits for Post Falls are 7% higher than the monthly average ammonia limits in the 2007 draft permit from March to October (255 lb/day instead of 238 lb/day), but are 65% lower during February (255 lb/day instead of 726 lb/day). The seasonal average ammonia effluent limits for the subject discharges are expressed in terms of mass, but are equivalent to concentrations of 3.9 – 6.1 mg/L at the facilities' design flow rates.

The WLAs for ammonia for point sources discharging to the Spokane River in the State of Washington's TMDL for DO in Lake Spokane and the Spokane River, are, in fact, more stringent than the ammonia limits in the subject permits. The ammonia WLAs for Washington POTWs range from 0.18 – 0.83 mg/L (see Moore and Ross 2010 at Table 5).

However, there is no basis to include more stringent ammonia limits than proposed in the drafts in any of the subject permits. The EPA has determined that the proposed seasonal average ammonia limits ensure compliance in Lake Spokane with the State of Washington's water quality criteria for DO as well as Washington's water quality criteria for ammonia (see the 2013 fact sheets at Appendix B). Post Falls and HARSB do not have the reasonable potential to cause or contribute to excursions above Idaho's water quality standards for ammonia near their respective outfalls; therefore, it is not necessary to include ammonia limits in addition to the seasonal average limits, which are based on Washington's water quality standards for DO, in the Post Falls or HARSB permits in order to ensure compliance with Idaho's water quality criteria for ammonia[12].

Coeur d'Alene does have the reasonable potential to cause or contribute to excursions above Idaho's water quality criteria for ammonia near its outfall from March to September. Therefore, in addition to the seasonal average effluent limit for ammonia, the Coeur d'Alene permit includes average monthly and maximum daily effluent limits which are derived from and ensure compliance with Idaho's water quality criteria for ammonia.

The EPA's permits are designed to ensure compliance with Washington's and Idaho's water quality standards. The practicability of achieving 0.1 mg/L ammonia is consequently not relevant.

Comment #2-8

Blue Water Technologies, Inc. states that sediments in the river and particularly behind dams will use up DO in the water. These sediment beds are loading year round. According to the commenter, phosphorus laden sediments deposited in the winter when there is no phosphorus control required on the Spokane River will become stirred up and/or released during turbulent activity in the spring.

Response #2-8

As stated in the response to comment #1-10, modeling predicts that Idaho discharges of TP during the month of January can influence DO concentrations in Lake Spokane during the following summer. Due

[12] The July – September average monthly and maximum daily ammonia limits in the City of Post Falls permit are included to ensure compliance with the anti-backsliding provisions of the Clean Water Act.

to limitations of the model, the EPA cannot determine at this time if Idaho discharges of TP during November or December influence DO concentrations in Lake Spokane during the following year.

The modeling scenario that supports the TP, CBOD, and ammonia limits in the permits assumes that discharges of high concentrations of TP will continue from January 1st until the TP effluent limits become effective on February 1st. Therefore, the modeling demonstrates that the proposed effluent limits will ensure compliance with water quality standards, even though no TP effluent limits are proposed for the winter. Furthermore, the phosphorus management plan requirements apply throughout the year.

Comment #2-9

Post Falls and HARSB commented that the State of Washington adopted water quality standards for Lake Spokane (formerly Long Lake) classifying it as a "lake" with no allowable measurable decrease in DO from "natural conditions". Post Falls and HARSB feel that this is a factual contradiction because the reservoir is a man-made impoundment, not a lake that ever existed in an actual natural condition. Moreover, Post Falls and HARSB state that the free-flowing reaches of the Spokane River continue to demonstrate very few water quality impairments, as demonstrated by the EPA and Washington in the recent modeling efforts for this permit. Therefore, although the EPA has attempted to balance this inherent unfairness through the permit process, Idaho dischargers are still being required to help pay for solving a problem that was only created by a for-profit corporation's construction of an impoundment.

Response #2-9

As recognized by the commenters, the Washington water quality standards do not distinguish between natural and man-made lakes (WAC 173-201A-200(1)(d)(ii)). Washington's water quality standards have been approved by the EPA. Federal regulations state that the EPA must establish conditions in the subject permits that ensure compliance with the applicable water quality requirements of the State of Washington, including its water quality standards, even though Washington's water quality standards do not apply to waters of the State of Idaho.

Water quality standards are set at a level which protects the designated and existing uses of surface waters, without regard to the cost of attaining those standards. Likewise, water quality-based effluent limits are set without regard to the cost of attaining such limits. Regardless of the origins of Lake Spokane, it has designated and existing uses which must be protected through the application of the Washington water quality standards. Although the EPA recognizes that the commenters find this unfair, the permits must still be written to ensure compliance with downstream water quality standards.

Comment #2-10

Post Falls and HARSB commented that, based on the EPA and Washington computer model of the river, even if all the point dischargers were removed along with a substantial loading from the non-point dischargers, the Long Lake reservoir would still not meet the Washington 8.0 mg/L DO water quality standard. The commenters point out that a Use Attainability Analysis (UAA) was completed by the Spokane River dischargers to address this issue, but this UAA was apparently rejected by Ecology. Post Falls believes it is necessary to maintain its right to enter into a UAA process should that be necessary in the future.

Response #2-10

The Washington DO water quality criterion for Lake Spokane (Long Lake) is not 8.0 mg/L. The commenters may have confused Washington's water quality criterion for DO in lakes with that for flowing fresh waters supporting the uses of salmonid spawning, rearing, and migration (WAC 173-201A, Table 200(1)(d)). The DO criterion for lakes (WAC 173-201A-200(1)(d)(ii)) is "human actions considered cumulatively may not decrease the dissolved oxygen concentration more than 0.2 mg/L below natural conditions" The natural condition of Lake Spokane varies with space and time, so the numeric value of the DO criterion may be greater than, less than, or equal to 8.0 mg/L depending on the place and time of interest.

The fact that an applicable water quality standard may be difficult to attain does not relieve the EPA of its duty to establish water quality-based effluent limits necessary to meet that standard (CWA Section 301(b)(1)(C), 40 CFR 122.4(d), 40 CFR 122.44(d)).

Ecology did not act on the Use Attainability Analysis (UAA) petition referenced by the commenters. The petition was withdrawn by the dischargers in favor of a collaborative approach to TMDL implementation.[13] The commenters (Post Falls and HARSB) were both members of the Spokane River TMDL Collaboration which took place following withdrawal of the UAA petition.[14] The EPA's issuance of NPDES permits to the Idaho dischargers to the Spokane River in no way prevents a future UAA for Lake Spokane.

Comment #2-11

CFJ stated that the EPA's permitting approach for the 2007 draft permits is being used to support a pollution trading strategy in Washington that is not scientifically defensible. CFJ noted the large percent reductions in non-point source pollution that the 2004 draft DO TMDL stated were necessary to meet the DO criterion in Lake Spokane, and noted that under the revised draft TMDL, the tributaries are now able to contain much more loading of phosphorus, ammonia, and CBOD, according to a technical memorandum from Portland State University regarding pending revisions to the TMDL. The commenters stated that the non-point source load allocations in the pending revised DO TMDL were manipulated. The commenters state that, because it is difficult to reduce non-point source pollutant loading, it is unlikely that there could be a viable trading program.

Response #2-11

Washington's TMDL and the issuance of the Idaho permits are independent actions. Comments on the Washington TMDL for DO and its implementation are beyond the scope of the NPDES permitting actions proposed.

[14] http://www.ecy.wa.gov/programs/wq/tmdl/spokaneriver/dissolved_oxygen/historicalinfo-ross/historical_info-fullgroup.html. Accessed September 29, 2014.

In general, the EPA supports water quality trading as a means to achieve water quality standards, where appropriate.

Comment #2-12

CFJ stated that the EPA's permitting approach is inconsistent with the EPA's policy for watershed-based approaches, which includes permitting actions. The EPA's policy acknowledges that watersheds transcend political boundaries; therefore, CFJ stated that the EPA must examine the long-term consequences of the current permitting actions and, pursuant to the EPA's policy, reintegrate the Washington and Idaho permitting actions.

Response #2-12

The Policy Statement and the Watershed Permitting Guidance clearly state that the statements in the documents are not binding and that the permitting authority can consider other approaches consistent with the Clean Water Act and its implementing regulations. See Policy Statement at p. 3; Watershed Permitting Guidance introduction. Thus, even if the permits were inconsistent with the EPA's watershed-based permitting guidance, that would not necessarily mean that they are not in compliance with the Clean Water Act and its implementing regulations.

However, the EPA has made changes in the revised draft permits issued for public comment in 2013. The revised permits are consistent with the *Watershed-Based National Pollutant Discharge Elimination System (NPDES) Permitting Implementation Guidance* (Watershed Permitting Guidance) and *Watershed-Based NPDES Permitting Policy Statement*, from G. Tracy Mehan III, dated January 7, 2003 (Policy Statement).

The watershed-based permitting documents encourage the permitting authority to focus on watershed goals and to consider multiple pollutant sources and stressors, including where watersheds transcend political boundaries. As explained Appendix B in the 2013 fact sheets to all three permits, the EPA has recalculated the water quality-based effluent limitations for TP, ammonia, and $CBOD_5$. The effluent limits in the final permits ensure that the level of water quality to be achieved by limits on point sources is derived from and complies with all applicable water quality standards (40 CFR 122.44(d)(1)(vii)(A)). The current limits are based on the cumulative impact of all human actions that affect DO concentrations in Lake Spokane, including the load and wasteload allocations and Avista Corporation's DO responsibility in the State of Washington's Spokane River DO TMDL. The Watershed Permitting Guidance also discusses the benefits of synchronizing the issuance of permits in a given basin. Here, the EPA has chosen to issue the three permits for discharge to the Spokane River in Idaho on the same schedule.

Comment #2-13

The Spokane River Property Owners Association stated that, based on the current Coeur d' Alene Lake Management Plan (1996) (LMP) it is clearly evident by subtracting the acceptable phosphate content in Lake Coeur d'Alene (i.e., 9 parts per billion) from the median phosphate level of the lake (i.e., 6 parts per billion), Coeur d'Alene's wastewater treatment facility is adding a maximum of approximately 3 parts per billion phosphate to the Spokane River. Therefore, the commenter states that Coeur d'Alene should

not have to expend a large amount of money to upgrade its facility and believes that the money is more well spent on addressing non-point source pollution.

Response #2-13

The Clean Water Act (section 301(b)(1)(C)) requires the establishment of effluent limitations in NPDES permits necessary to meet water quality standards. The EPA has determined that the discharges of phosphorus from the subject point sources have the reasonable potential to cause or contribute to nonattainment of water quality standards in the State of Washington. Therefore, the permits contain water quality-based effluent limits for phosphorus, consistent with federal regulations (40 CFR 122.4(d), 40 CFR 122.44(d)(1)). See the 2013 fact sheets at Appendix B.

Comment #2-14

Ms. Julie Dalgago noted that, in the 2007 draft permits, the strictest phosphorus effluent limits are applied for Idaho during a four-month period, meaning June, July, August, and September, and requested that the EPA evaluate the need to expand the period of time during in which these phosphorus limits apply.

Response #2-14

This comment was addressed by changes made in the revised draft permits issued for public comment in 2013. The phosphorus limits in the revised permits are seasonal average limits that apply for nine months out of the year, from February 1st through October 31st.

Comment #2-15

Mr. Jim Hollingsworth stated that EPA should not rely only on computer models. Instead, EPA should rely on actual observations. If EPA is unable to document any actual health impacts, then EPA should wait until it is certain that the discharges impact human health.

Response #2-15

The only effluent limits in the subject permits that are based on computer modeling are the seasonal average effluent limits for phosphorus, ammonia, and CBOD that are based on Washington's water quality standards for DO.

As explained in the 2013 fact sheets at Appendix B, the effluent limits for phosphorus, ammonia, and CBOD are intended to meet Washington's water quality standards for DO. DO criteria are necessary to provide suitable habitat for fish and other aquatic life, as opposed to protecting human health. The Clean Water Act protects aquatic life, as well as human health. The absence of a human health hazard is not a basis to fail to implement water quality criteria. Furthermore, as discussed in the response to comment #1-13, human health could be at risk from blue-green algae blooms in Lake Spokane, which are caused by excess nutrients.

The water quality problems caused by excess nutrients have been extensively documented by the Department of Ecology in its *Spokane River and Lake Spokane (Long Lake) Pollutant Loading Assessment for Protecting Dissolved Oxygen* (Cusimano 2004). This document references earlier studies of nutrient-related water quality problems in Lake Spokane by Cunningham and Pine (1969), Patmont, et. al. (1985,

1987), Soltero, et. al., (1973-1976, 1978-1985, and 1992), and URS Corporation (1981). The fact that excess nutrient loading to the Spokane River from human sources causes eutrophication, toxic algae blooms, and low DO in Lake Spokane is well-documented and has been studied for decades.

Washington's water quality standard for DO in lakes and reservoirs is expressed in terms of natural conditions. "Natural conditions" are defined in Washington's water quality standards as "surface water quality that was present before any human-caused pollution" (WAC 173-201A-020).

In this case, actual measurements cannot provide EPA with the required information to establish water quality-based effluent limits for nutrients and oxygen-demanding pollutants, because measurements can only quantify the current condition of the watershed, at the current levels of discharge. As shown by numerous studies dating back as far as 1969, the current condition of the watershed in terms of nutrient enrichment and DO is poor, does not meet applicable water quality, and is far removed from the natural condition. Computer modeling is necessary to ascertain the natural condition of the watershed and to derive effluent limitations that comply with water quality standards, which are linked to natural conditions.

Comment #2-16

Mr. Jim Hollingsworth stated that EPA has accepted the standards set by the State of Washington without question and that this does not seem fair.

Response #2-16

The only effluent limits in the subject permits that are based on Washington's water quality standards are the seasonal average effluent limits for phosphorus, ammonia, and CBOD.

The Washington water quality standards have been reviewed and approved by EPA pursuant to Section 303(c) of the Clean Water Act. See the letter dated February 11, 2008, from Michael F. Gearheard, EPA Region 10, to Dave Peeler, Washington State Department of Ecology. The process by which standards are approved is the same for Washington and Idaho. Once state water quality standards are approved, the permitting authority (in Idaho's case, EPA is the permitting authority) is required to include effluent limits in NPDES permits that are necessary to meet those standards pursuant to Section 301(b)(1)(C) of the Act. Pursuant to 40 CFR 122.4(d), the permitting authority must impose conditions in NPDES permits that ensure compliance with the water quality standards of all affected States, including, in this case, the State of Washington.

Comment #2-17

Mr. Jim Hollingsworth comments that, although the public has been told that the problem is phosphorus, phosphorus is not really a pollutant unless it reaches toxic levels. The commenter further states that phosphorus in the water is actually a benefit to the plants that live in the water. Moreover, the commenter believes that there are cheaper ways to deal with the phosphorus problem, such as introducing fish into Lake Spokane which eat the excess algae, or introducing zinc or copper into the lake to inhibit algae growth.

Response #2-17

Pollutants, as defined by the Clean Water Act and its regulations, include sewage and municipal waste that is discharged into waters of the United States. See Section 502 of the CWA and 40 CFR 122.2. As explained in the fact sheets, EPA has established conditions and limits, including the limits on phosphorus, in accordance with the Clean Water Act and its implementing regulations.

It is true that dissolved zinc and copper are toxic to, and therefore inhibit the growth of, algae. Metal salts (e.g., copper sulfate) can be added to constructed impoundments, which are not waters of the United States (e.g., wastewater stabilization ponds or lagoons) in order to control the growth of algae. It is also true that nutrients such as phosphorus and nitrogen are beneficial to water quality in small amounts. However, excess nutrients can cause violations of water quality standards for DO, pH, and can cause nuisance algae growth including toxic blue-green algae blooms.

One reason it is necessary to reduce excess algae growth is to increase DO concentrations in order to ensure that the Spokane River and Lake Spokane provide suitable habitat for fish and other aquatic life. Zinc and copper are both toxic to fish and other aquatic life at very low concentrations, and in fact the Spokane River already contains concentrations of zinc that are above the levels necessary to protect aquatic life from its toxic effects. The State of Washington has developed a TMDL to reduce discharges of zinc (as well as cadmium and lead) to the Spokane River, with the goal of meeting water quality standards. Because zinc and copper are both toxic to fish at very low concentrations, it would be counterproductive and may cause or exacerbate violations of water quality standards and/or the CWA to add zinc or copper to Lake Spokane for the purpose of inhibiting algae growth or improving DO concentrations.

The EPA is not aware of any fish species that could be introduced into Lake Spokane that would consume the excess algae. In any event, the introduction of nonnative species could potentially displace native fish species, which would be counter to the Clean Water Act goal of protecting native fish through improved water quality.

Comment #2-18

Mr. Jim Hollingsworth asked in his comments why DO is only a problem in the lower end of Lake Spokane.

Response #2-18

Low DO is not a problem exclusively in the lower end of Lake Spokane. However, the CE-QUAL-W2 model predicts that the nutrients and biochemical oxygen demand discharged by the sources upstream from Lake Spokane exert their greatest impact upon DO in the lower end of Lake Spokane. This is because the lower end of Lake Spokane is the deepest part of the lake, and since the lake thermally stratifies in the summer, the deeper water is isolated from, and therefore cannot be oxygenated by, the atmosphere.

Comment #2-19

Mr. Jim Hollingsworth asked in his comments about the quality of the water that leaves the State of Washington.

Response #2-19

The quality of waters outside the watersheds affected by the subject permits is irrelevant to the subject permit actions. The EPA has provided a summary of water quality data for phosphorus and nitrogen in the Spokane and Columbia rivers as far downstream as Wenatchee, Washington in the response to comment #1-39.

Additional water quality data for waters of the State of Washington can be found at the State of Washington Department of Ecology's environmental assessment program website at www.ecy.wa.gov/programs/eap/index.html, on the EPA's STOrage and RETreival (STORET) website at www.epa.gov/storet, or at the USGS National Water Information System (NWIS) website at waterdata.usgs.gov/wa/nwis/qw.

Comment#2-20

Mr. Jim Hollingsworth states that the State of Washington can make demands, but it would be far better if (Idaho and Washington) could work together as neighbors to implement a plan that would be mutually acceptable.

Response #2-20

Because waters of the State of Washington are affected by the subject discharges, the EPA is required to establish water quality-based effluent limits that meet Washington's water quality standards. This is not a "demand" made by the State of Washington; it is a requirement of federal law (40 CFR 122.4(d)).

The State of Idaho has had extensive involvement in the development of the subject permits as well as the Spokane DO TMDL developed by the State of Washington.

Comment #2-21

Coeur d'Alene made several comments about how EPA evaluated the impact of the Idaho dischargers upon waters of the State of Washington, including the following:

- EPA should explain in more detail how the assumptions made for determining the appropriate loads for DO parameters and associated permit limits for ammonia, $CBOD_5$ and phosphorous will not cause or contribute to downstream water quality standards non-attainment in Washington State portions of the Spokane River and Lake Spokane.
- EPA should explain if its model assumptions are the same as the assumptions in the Washington DO TMDL model for upstream waste load allocations.
- EPA should more fully explain how the limits in the draft permit ensure compliance with the applicable water quality requirements of all affected states as required in 40 CFR 122.4(d).
- EPA should provide a better explanation of its rationale for ensuring that the draft permit limits will not cause nonattainment of Washington DO standards and any other State of Washington standards applicable to the permit limits.
- EPA should also explain whether a revision to TMDL model assumptions used by Ecology would impact EPA's derivation of the limits in the draft permit.
- EPA should disclose whether Ecology concurs with EPA's determination and whether there is any documentation of such concurrence.

Response #2-21

In general, this comment has been addressed by changes made in the revised draft permits issued for public comment in 2013.

Appendix B to the 2013 fact sheets explains in detail how the effluent limits for TP, ammonia, and $CBOD_5$ ensure compliance with water quality standards in the Spokane River and Lake Spokane in the State of Washington, and, in turn, with 40 CFR 122.4(d). As stated in Appendix B, the effluent limits for the subject dischargers are somewhat different than those assumed in the modeling supporting the State of Washington's Spokane DO TMDL, but they have an impact to DO in Lake Spokane that is no greater than the discharges assumed in the modeling supporting the TMDL.

Regarding whether revisions to the TMDL model assumptions used by Ecology would impact the EPA's derivation of limits, as stated in the permits at Part I.G:

> "In the future, the State of Washington may modify the Spokane River TMDL and/or the effluent limits in NPDES permits for point sources discharging to the Spokane River within the State of Washington. Such modifications may allow for less-stringent effluent limits for total phosphorus, ammonia and/or $CBOD_5$ in this permit, while nonetheless ensuring that the cumulative effect of all such revised effluent limitations will ensure the attainment of water quality standards for DO in the State of Washington. In that case, EPA could revise the water quality-based effluent limits for total phosphorus, ammonia and/or $CBOD_5$…."

Regarding Ecology's concurrence with the EPA's determination, the EPA shared preliminary drafts of the subject permits with Ecology prior to the public comment period, and the EPA made changes to the draft permits in order to address concerns raised by Ecology. Although Ecology submitted comments on the draft permits during the public comment period, none of those comments concerned the effluent limits for TP, ammonia, or CBOD. Ecology stated in its comment letter that, "We feel that the draft permits are protective of downstream water quality and meet the intent of Washington State water quality rules for the Spokane River and Lake Spokane. Comments for the draft permits are relatively minor…."

After receiving final CWA section 401 certifications from the State of Idaho and before issuing the final permits, the EPA notified the State of Washington that it had received the certifications and that the discharges may affect the quality of waters of the State of Washington, consistent with Section 401(a)(2) of the CWA. Also, pursuant to Section 401(a)(2) of the CWA, the State of Washington was allowed 60 days to notify the EPA of any objection to the issuance of the permits, and the State of Washington did not object within the 60-day period.

Comment #2-22

BlueWater Technologies, Inc. (BlueWater) stated that it believes that the "waste load computation" that EPA conducted is faulty. According to BlueWater, if a discharger with a 10 µg/L phosphorus limit increases their flow, then their phosphorus limit will become more stringent. This would mean that a growing city such as Post Falls would have a very stringent limit that would rob the ecosystem of an

important and essential nutrient. BlueWater concludes that "[t]o require a standard less than 10 µg/L when that is considered natural background is mathematically incongruent."

Response #2-22

This comment was addressed by changes made in the 2013 draft permits. None of the 2013 draft permits nor the final permits have an effluent limit for TP equal to 10 µg/L, nor do they have a mass limit equivalent to 10 µg/L at the POTWs' design flow rates or at the POTWs' projected future flow rates. Rather, the effluent limits for TP are equivalent to a discharge of TP at a concentration of 50 µg/L at projected future flow rates. The background concentrations of nutrients in the Spokane River are less than 50 µg/L, therefore, the permits will not result in a shortage of phosphorus in the river ecosystem.

The mass effluent limits in the final permits require the permittees to achieve lower concentrations of phosphorus (and other pollutants) if and when their effluent flows increase above the projected future flow rates used in modeling and effluent calculations, in order to maintain compliance with effluent limits expressed in terms of mass. These limits will ensure that the permits remain protective of water quality even if flow rates increase above the current design flows of the treatment plants.

The commenter expressed its comments as if the effluent limitations were expressed as concentrations. Federal regulations require that effluent limitations in NPDES permits be expressed in terms of mass, with certain exceptions, none of which are applicable to effluent limits for phosphorus (40 CFR 122.45(f)).

Comment #2-23

Mr. Jim Kimball, representing Post Falls and the Hayden Area Regional Sewer Board, stated that the 2004 draft TMDL prepared by Ecology would have allocated 0.1 lb/day of phosphorus to the City of Post Falls. Mr. Kimball states that, at the design flow of the Post Falls treatment plant, this would be equivalent to a concentration of 4 µg/L in the effluent, which "would cause a severe economic impact on Idaho." Mr. Kimball notes that this contrasted with a loading of 2.9 lb/day for the City of Spokane and Spokane County.

Response #2-23

Mr. Kimball was referring to Figure 10 of Ecology's October 2004 draft TMDL for DO in Lake Spokane (Merrill and Cusimano 2004). Although Mr. Kimball's statement was specific to the City of Post Falls, EPA notes that this figure also included loading figures for the City of Coeur d'Alene and HARSB. EPA will therefore consider this comment to be applicable to all three dischargers.

This comment was addressed by the revised draft permits issued for public review and comment in 2013. The water quality-based effluent limit for TP in the City of Post Falls' final permit is 3.19 lb/day, which is equivalent to 76.5 µg/L at the City's current design flow of 5.0 mgd. The final water quality-based TP effluent limits for Coeur d'Alene and HARSB are equivalent to 63 µg/L and 66 µg/L, respectively, at the facilities' current design flows.

The State of Washington can neither regulate discharges of pollution nor set water quality standards for waters of the State of Idaho or any other jurisdiction outside of Washington. The figures referenced by

Mr. Kimball came from a draft TMDL that was neither finalized by the State of Washington nor approved by EPA.

Comment #2-24

Ms. Julie Dalgago states that if the EPA were to "apply the (strictest) standards to the people that are upriver…that will affect the outcome at the end of the river and Lake Roosevelt."

Response #2-24

It is not clear what Ms. Dalgago meant by the phrase "the people that are upriver." The EPA believes it is reasonable to assume she was referring to the subject POTWs, since Ms. Dalgago was commenting on the subject permits, and the Spokane River originates in Idaho, at Lake Coeur d'Alene. Thus, it appears that Ms. Dalgago is stating that the effluent limits in permits for discharge to the Spokane River in Idaho should be "the strictest," meaning they should be more stringent than those in permits issued by Ecology, to dischargers in the State of Washington.

As explained in detail in Appendix B to the 2013 fact sheets, the permits contain effluent limits for phosphorus, ammonia, and CBOD that ensure compliance with Washington's water quality standards for DO in Lake Spokane and the Spokane River on a cumulative basis. In developing these permits, the EPA did not evaluate the effects of the discharges at points downstream of the Long Lake Dam, including Lake Roosevelt. Due to additional dilution, continued decay of the effluent CBOD, and continued attenuation of the effluent phosphorus (e.g., accumulation in sediment behind dams), the discharges' effect on water quality in Lake Roosevelt is likely to be too small to measure.

Comment #2-25

Ms. Julie Dalgago states that "discharge limits must be (the) more stringent of both the technology and water quality-based limits." Ms. Dalgago stated that she was concerned that the "stringent standards" in the permits were based on "economic feasibility."

Response #2-25

The Clean Water Act requires that all NPDES permits contain technology-based effluent limits (CWA Sections 301(b)(1)(B), 304(d)(1), 40 CFR Parts 125.3, 133), and more stringent effluent limitations if necessary to ensure that water quality standards are met(CWA Section 301(b)(1)(C), 40 CFR 122.4(d), 40 CFR 122.44(d)). As stated in the fact sheets and in this response to comments, EPA has established water quality-based effluent limits that are more stringent than technology-based effluent limits, whenever those limits were necessary for pollutants discharged by the subject permittees. Whenever a technology-based effluent limit was imposed in lieu of a water quality-based effluent limit, EPA made a finding in the fact sheet that the technology-based effluent limit was adequately stringent to protect water quality. Water quality-based effluent limits are based solely on the water quality standards; they are not based on economic feasibility.

Comment #2-26

The City of Spokane stated that the interim and final effluent limits for phosphorus and other nutrients in the proposed permits are too generous. By imposing these effluent limits, the City of Spokane is

concerned that other downstream discharges, such as the City of Spokane, will be unable to meet the phosphorus goals and targets set forth in the Foundational Concepts.

Response #2-26

In this comment, the City of Spokane was referring to the *Foundational Concepts for the Spokane River TMDL Managed Implementation Plan*, dated June 30 2006.[15] This comment was addressed by the revised draft permits issued for public review and comment in 2013. The final water quality-based effluent limits for TP, ammonia, and CBOD in the subject permits ensure compliance with water quality standards for DO in Lake Spokane on a cumulative basis.

Like all point sources discharging to the Spokane River in Washington, the City of Spokane's obligations with respect to phosphorus are stated in its NPDES permit, which is based on the City's phosphorus wasteload allocation in the Spokane DO TMDL. Even if the allocations in the Spokane DO TMDL and the limits in the NPDES permits for discharges to the Spokane River should fail to ensure compliance with water quality standards, the limits in the City of Spokane's permit could not be changed without following the requirements in 40 CFR Part 124, including preparation of a draft permit, a public comment period of no less than 30 days, and the opportunity for a public hearing. Nothing in the subject permits will affect the City of Spokane's ability to meet its phosphorus effluent limit or wasteload allocation.

Comment #2-27

The City of Spokane stated that "it is critical that both the EPA and the State interpret and apply the State of Washington standards for dissolved oxygen consistently." The City of Spokane cited numerous examples where it believed that EPA has not consistently interpreted Washington's DO water quality standards. For example, the City of Spokane believed that EPA had concluded that the Washington standards allow each Idaho discharger to reduce DO by up to 0.2 mg/L in Long Lake, while the State of Washington appeared to look at all human-caused sources combined when determining compliance with this standard. The City of Spokane compared the 2007 Coeur d' Alene Fact Sheet, p. C-10, with the 2004 Draft TMDL (Merrill and Cusimano 2004), pp. 5 and 21. In addition, the City of Spokane stated that Washington used 0.005 to 0.006 mg/L for the "natural background" phosphorous concentration whereas the EPA appeared to have used 0.14 mg/L.

Response #2-27

This comment was addressed by the revised draft permits issued for public review and comment in 2013. The final water quality-based effluent limits for TP, ammonia, and CBOD in the subject permits ensure compliance with water quality standards for DO in Lake Spokane on a cumulative basis, considering all human actions that affect DO in Lake Spokane, which is consistent with the plain language of the standard (WAC 173-201A-200(1)(d)(ii)).

The EPA did not state in the 2007 HARSB fact sheet that the natural background phosphorus concentration in the Spokane River was 0.14 mg/L. It appears that the commenter is referring to the proposed average monthly phosphorus loading limit of 0.14 *lb/day*. This loading of phosphorus is

[15] http://www.ecy.wa.gov/programs/wq/tmdl/spokaneriver/dissolved_oxygen/foundational_concepts-v21.pdf

equivalent to a concentration of 10 µg/L (0.010 mg/L) at the HARSB facility's design flow rate (at the time the 2007 draft permit was issued for public review and comment) of 1.65 mgd. When EPA stated on Page C-7 of the 2007 HARSB fact sheet that this level of phosphorus was "comparable to natural background," EPA was referring to an effluent concentration of 10 µg/L (0.010 mg/L), which is equivalent to the proposed phosphorus loading limit of 0.14 lb/day in the 2007 draft HARSB permit.

Comment #2-28

The City of Spokane stated in comments on the 2007 draft permits that, in establishing the effluent limits in the permits, it appeared that EPA had assumed that the Washington dischargers would control nonpoint sources. The City of Spokane believed that EPA should require the Idaho dischargers to work on nonpoint source control so that the burden is not just placed on the downstream Washington dischargers.

Response #2-28

The effluent limits for TP, ammonia, and CBOD in the 2013 draft permits and the final permits are based on the assumption that the load allocations for non-point sources, the wasteload allocations for point sources, and Avista Corporation's DO responsibility in the Spokane DO TMDL will be attained. The EPA did not assume that the Washington dischargers would be involved in controlling non-point sources so that the non-point source load allocations in the TMDL would be attained.

The modeling supporting the Spokane DO TMDL and the subject permits also considered the estimated loading from municipal stormwater in Idaho. Non-point source loading to the Spokane River in Idaho from tributaries is unquantified, but is believed to be negligible (Annear, Wells and Berger 2005).

Comment #2-29

HARSB and Post Falls stated that EPA appeared to have resolved an issue by providing a "dynamic" permit. These commenters provided an Exhibit 4 that was obtained from Ecology's files. The exhibit shows that a substantially higher loading in April, May, June, and October (the shoulder season) can be discharged to the river. HARSB and Post Falls both included diversion from the river to reuse (e.g., for irrigation) during the July, August, and September critical period. HARSB and Post Falls commended EPA for providing a defendable dynamic permit that would possibly reduce some of the required technology for phosphorus removal in the shoulder season so that entities like the City can invest in land application reuse during the critical months.

Response #2-29

The phosphorus limits in the 2013 draft permits and the final permits are not "dynamic" in the same way as those in the 2007 draft permit. The 2007 draft permits had phosphorus limits from March to October, but there were different limits within that time frame. For example, the average monthly loading limits in the 2007 draft permit for the City of Post Falls were 29 lb/day in March, 7.26 lb/day in April and May, 1.45 lb/day from June to September, and 29 lb/day in October. The final Post Falls permit has a seasonal average limit of 3.19 lb/day, which applies from February to October. See Figures 1 – 9 in Appendix B to the 2013 fact sheets for comparisons of the TP, ammonia, and CBOD limits in the 2007 draft permits to those in the 2013 draft permits (which are identical to those in the final permits).

However, because the phosphorus limits in the final permits are stated in terms of mass and as seasonal averages, the limits afford the dischargers flexibility similar to the "dynamic" limits in the 2007 draft permits. For example, if a utility employs partial re-use to reduce its effluent flow rate, it could discharge a somewhat higher concentration of TP in its effluent and still comply with its seasonal average loading limit. Also, if a utility ceases its discharge to the river through 100% re-use, the permittee may report a loading of zero pounds per day for the period of time when there is no discharge. This will reduce the seasonal average loading that the utility must report, thus allowing the utility to discharge somewhat more loading during the time when it is discharging to the river and still comply with the seasonal average loading limit.

The effluent limits nonetheless restrict the total amount of TP, ammonia, and CBOD that the utilities may discharge to the Spokane River from February through October to amounts which have been shown through modeling to ensure compliance with Washington's water quality standards for DO. The flexibility described above will therefore not result in violations of water quality standards.

Comment #2-30

Post Falls and HARSB stated that, at the 2007 public hearing on the three Idaho NPDES permits, there were numerous pleas for a basin approach and that EPA should not have interceded in providing separate analyses for the Idaho dischargers. Post Falls and HARSB provided a loading reduction table obtained from Ecology's files, which shows that the ultimate loading from the point source dischargers in both Idaho and Washington should be reduced to 4.6 pounds of phosphorus per day. In the table referenced by the commenters, only 0.2 pounds (4 percent) was allocated to the Idaho dischargers. According to Post Falls and HARSB, this restriction would cause severe limitations on the Idaho dischargers because the loading set forth in the permits are less than one half the 0.44 pounds that should have been allocated. The Idaho dischargers were not given a realistic and equitable portion of the loading in the Spokane River. Post Falls and HARSB stated that they believe the 2007 draft permits equitably allocate loading to the Spokane River.

Response #2-30

As explained in Appendix B to the 2013 fact sheets, the EPA determined to use a "basin approach," in which the effluent limits for nutrients and oxygen-demanding pollution are calculated such that they ensure compliance with Washington's water quality criteria for DO in Lake Spokane on a cumulative basis.

The sum of the final water quality-based TP effluent limits for the subject Idaho POTWs is 7.69 lb/day. The sum of the TP wasteload allocations for Washington's point sources (except for stormwater and combined sewer overflows) in the Spokane DO TMDL is 25.5 lb/day. Thus, the Idaho dischargers have been allocated 23% of the total non-stormwater point source load.

Effluent Limits for Metals

Comment #2-31

CFJ stated that the EPA incorrectly calculated the reasonable potential for lead, cadmium, and zinc. CFJ notes that the EPA used effluent hardness for cadmium, lead, and zinc, and stated that this approach "is

appropriate if no dilution factor (mixing zone) is included in the reasonable potential calculations." The commenters believed that, since the EPA calculated and presented dilution factors in Appendix E of the fact sheets, the EPA used these dilution factors in reasonable potential calculations for cadmium, lead, and zinc. The commenters concluded that the EPA should have used the hardness at the edge of the mixing zone.

Response #2-31

The toxicity of metals to aquatic life, and, in turn, the water quality criteria, varies depending on the hardness of the water. As stated in the fact sheets, the EPA did not use dilution factors in reasonable potential and effluent limit calculations for cadmium, lead, or zinc. See the 2007 fact sheets at Appendices E and F, the 2013 fact sheets at appendices D and E, and the discussion under the heading of "Water Quality Limited Segment" in the bodies of the 2013 and 2007 fact sheets. Reasonable potential and effluent limit calculations for cadmium, lead, and zinc applied water quality criteria at the end-of-pipe, using effluent hardness.

For metals other than cadmium, lead, and zinc, dilution was considered (because the ambient water meets criteria). For those metals, the EPA used the hardness at the edge of the mixing zone to calculate the values of the metals criteria.

EPA has used the 5th percentile hardness for both the effluent and the receiving water in calculating effluent limits for metals. This is a reasonable "worst case" effluent hardness, thus, it is not necessary to place an additional limit on effluent hardness.

Comment #2-32

CFJ stated that the EPA cannot assume that the effluent limits for cadmium, lead, and zinc will not contribute to WQS violations in Washington simply because Idaho's criteria are as stringent as or more stringent than Washington's. CFJ concluded that the EPA must "condition these permits such that they do not cause or contribute to water quality violations downstream." CFJ stated that the EPA did not calculate the cumulative impact of all existing and identified sources downstream and did not include a "margin of safety."

Response #2-32

NPDES regulations require the EPA to identify pollutants that are or may be discharged at a level which has the reasonable potential to cause or contribute to excursions above WQS and then establish limits on those pollutants that are derived from and comply with the applicable water quality criteria (40 CFR 122.44(d)(1). There is no requirement for a margin of safety when establishing NPDES permit conditions. It is, however, appropriate to use conservative assumptions when deriving water quality-based effluent limits, and the EPA has done so here.

The EPA established criteria end-of-pipe effluent limits for cadmium, lead, and zinc, expressed in terms of concentration, where reasonable potential existed, and where it was necessary to continue forward effluent limits from the 1999 permit in order to ensure compliance with the anti-backsliding provisions of the Clean Water Act. These limits are derived from and comply with Idaho WQS. Idaho's cadmium and lead criteria are at least as stringent as those in Washington. The Idaho dischargers either do not

have the reasonable potential to cause or contribute to excursions above the Idaho criteria (at the end-of-pipe) or are required to meet water quality-based effluent limits that apply the Idaho criteria concentrations at the end-of-pipe. Discharges of pollutants at concentrations at or below the applicable water quality criteria do not contribute to excursions above those criteria. Therefore, the water quality-based effluent limits for lead comply with the water quality standards of both States, and the reasonable potential analyses for lead and cadmium, including the finding that the dischargers do not have the reasonable potential to cause or contribute to excursions above water quality standards for cadmium, are valid for both States, in compliance with 40 CFR 122.4(d).

The Idaho zinc criteria are marginally less stringent than those in Washington, but the EPA has demonstrated that the Idaho dischargers do not have the reasonable potential to cause or contribute to excursions above Washington's zinc criterion. See, e.g. the 2007 Coeur d'Alene fact sheet at Page 14. Therefore, the effluent limits for zinc in the subject permits comply with 40 CFR 122.4(d).

Comment #2-33

CELP stated that the EPA has abandoned adopting a TMDL for metals in Idaho and is therefore obligated to condition wastewater discharge permits with water quality-based toxics control for metal discharges causing or contributing to water quality violations in Idaho and Washington. Washington's ambient monitoring show repeated violations for metals lead, zinc, and cadmium when river hardness is low. The EPA protocols for these limits should be followed using the appropriate in-stream criterion and actual river critical conditions.

Response #2-33

A TMDL for metals encompassing the Spokane River in Idaho was completed jointly by the Idaho Department of Environmental Quality and the EPA and was approved by the EPA in August of 2000. The TMDL was vacated by the Idaho Supreme Court in 2003. In the absence of a TMDL, the EPA is required by Section 301(b)(1)(C) of the Act and 40 CFR 122.44(d)(1) to include water quality-based effluent limits for metals where the discharge has the reasonable potential to cause or contribute to excursions above water quality standards. In any case where the subject dischargers had the reasonable potential to cause or contribute to excursions above water quality standards for any metal or any other pollutant, a water quality-based effluent limit has been imposed, with water quality criteria applied at the end-of-pipe. Because these limits apply at the end-of-pipe, the discharge will comply with water quality criteria under all likely hardness scenarios. The imposition of such effluent limits wherever reasonable potential exists satisfies the EPA's obligations under Section 301(b)(1)(C) of the CWA and its implementing regulations, for the pollutants in question.

Comment #2-34

CELP stated that there is inadequate information presented in the Fact Sheets to determine if appropriate water quality criteria were applied during critical conditions. A general reference to the old NPDES permits as justification for lead and zinc limits in the new permits is not adequate, particularly given that the old permit limits were likely inappropriately derived. Since the Spokane River already exceeds metals criteria for lead, zinc, and cadmium, the discharges must meet end-of-pipe limits.

CELP stated that end-of-pipe toxicity-based limits must be derived from criteria for critical conditions in the river where aquatic organisms live.

Response #2-34

In neither the 2007 nor the 2013 draft permits did the EPA did "reference" or continue any previously-established effluent limits under the anti-backsliding provisions of the CWA in the reissued permits without verifying that these effluent limits remain protective of water quality.

Water quality criteria for metals were applied under critical conditions. However, the appropriate critical condition for hardness depends on whether the metals criteria are applied at the end-of-pipe or at the edge of a mixing zone. For cadmium, lead, and zinc, water quality criteria qre applied at the end-of-pipe (no mixing zone). Thus, the receiving water flow rate and receiving water hardness are irrelevant because mixing with the receiving water is not a factor in determining whether the discharge has the reasonable potential to cause or contribute to excursions above water quality standards. The appropriate hardness to use in determining reasonable potential or calculating effluent limits is the hardness expected at the point where criteria are applied (either at the end-of-pipe or the edge of the mixing zone). Therefore, in these permits, the appropriate hardness to use in determining reasonable potential and in calculating effluent limits for cadmium, lead, and zinc is the effluent hardness.

The Spokane River does not consistently meet criteria for these metals. However, any point source discharge of these metals when the criteria are met at the end-of-pipe, with effluent hardness, will not contribute to excursions above criteria in-stream, even though the effluent concentration of the metals may be relatively high. This is because the hardness of the effluents reduces the toxicity of the discharged metals and raises the numeric value of the water quality criteria accordingly, wherever the hardness and the metal concentration is influenced by the discharge. This phenomenon is explained in detail in the Washington State Department of Ecology's total maximum daily load for metals in the Spokane River (Butkus and Merrill 1999).

Due to the "concave up" curvature (positive second derivative) of the water quality criterion for lead, this is not always the case for lead. However, in establishing water quality-based effluent limits for lead, the EPA has corrected for this, by establishing effluent limits for lead based on the tangent line to the lead water quality criteria curve at a hardness of 25 mg/L.

For other metals (e.g. copper), the hardness used in reasonable potential and effluent limits calculations is the hardness at the edge of the mixing zone (a mixture of ambient and effluent hardness in the proper proportions). Where a mixing zone is allowed, the critical river flow rates used in calculating dilution factors are the 7-day, 10-year low flow (7Q10) for chronic water quality criteria and the 1-day, 10-year low flow for acute water quality criteria (1Q10) for acute criteria. These are the flows recommended for use in steady-state modeling in the TSD (see Appendix D). The critical river flow rates used in calculating dilution factors are the design flow rates of the treatment works. The dilution factors are provided in Appendix D to each of the 2013 fact sheets.

The specific hardness values used to calculate the values of the water quality criteria for metals are shown in Table 30, below.

Table 30: Hardness Values Used to Calculate Metal Criteria (mg/L as $CaCO_3$)			
Parameter	Coeur d'Alene	HARSB	Post Falls
Cadmium, lead and zinc	132	95.3	97.6
Others	25	25	25

Comment #2-35

Mr. Jim Hollingsworth recommends that the EPA reevaluate the level at which dissolved metals are beneficial and/or harmful to human health.

Response #2-35

Water quality standards and the effluent limits based upon those standards must protect all existing and designated uses of the subject waters, including, in this case, cold water aquatic life (CWA §301(b)(1)(C), 40 CFR 131.11, 131.12, IDAPA 58.01.02.051.01, 58.01.02.110.12). Human health is only one of several concerns that must be considered when establishing water quality criteria and effluent limits based upon those criteria. The effluent limits in the subject permits are set to ensure that both human health and aquatic life are protected.

In general, human beings can tolerate much higher concentrations of metals in drinking water than fish can tolerate in their habitat. For example, the State of Idaho's water quality criteria for zinc, for human health protection, are 7,400 µg/L for consumption of water and organisms and 26,000 µg/L for the consumption of organisms only. In contrast, the acute and chronic water quality criteria for protection of aquatic life are both 120 µg/L, at a hardness of 100 mg/L as $CaCO_3$.

Temperature

Comment #2-36

CFJ stated that the EPA failed to consider the cumulative temperature impact of these discharges on waters of the State of Washington. Specifically, CFJ recommended that the EPA consider whether the total cumulative impact is greater than 0.3 °C downstream of the border (assuming non-point sources are not an issue during the critical period) as specified in 40 CFR 122.44(d).

Response #2-36

As explained on pages B-22 to B-23 of the 2013 fact sheets, the EPA has considered the cumulative temperature impact of the subject discharges on waters of the State of Washington and has determined that the dischargers do not have the reasonable potential to cause or contribute to excursions above Washington's water quality standards for temperature. Specifically, the maximum temperature increase attributable to the Idaho dischargers, at any time, is 0.27 °C, which is much less than the allowable increase (0.96 °C).[16] At times when the predicted temperature, with no discharge from Idaho point

[16] Washington's site-specific temperature criterion for the Spokane River from Nine Mile Bridge to the Idaho border reads as follows: "Temperature shall not exceed a 1-DMax of 20.0 ºC due to human activities. When natural conditions exceed a 1-DMax of 20.0 ºC, no temperature increase will be allowed which will raise the receiving water temperature by greater than 0.3 ºC; nor shall such temperature increases, at any time, exceed t = 34/(T + 9)." (WAC 173-201A-602). The capital "T" represents the background temperature as measured at a point or points unaffected by the discharge and representative of the highest ambient water temperature in the vicinity

sources, is greater than or equal to 20 °C, the maximum temperature increase attributable to the Idaho point sources is 0.13 °C, which is less than half the increase allowed by the criterion (0.3 °C) (WAC 173-201A-602).

Monitoring Requirements

Comment #2-37

Mr. Jim Hollingsworth objected to requiring the dischargers to incur significant costs in conducting their own monitoring, and expressed concern that there is no incentive for the permittees to actually perform the monitoring, and to accurately and truthfully report the results of the monitoring. The commenter recommends that the EPA conduct the monitoring.

Response #2-37

The NPDES permitting program is a self-monitoring program. 40 CFR 122.44(i) requires all NPDES permits to impose monitoring requirements on permittees that will "assure compliance with permit limitations." In addition, 40 CFR 122.41(j) requires that records of monitoring information include the results of the sampling analysis.

Monitoring, recording, and reporting requirements are enforceable provisions of NPDES permits. If the permittees choose not to perform the required monitoring, or not to report the results of such monitoring, or to make false statements in such reporting, they will be subject to civil or criminal enforcement action at the EPA's discretion. Possible penalties for violations of permit conditions are listed in Part IV.B of the permits.

Comment #2-38

Post Falls stated that paragraph F.1 on Page 12 of the 2007 Post Falls draft permit unreasonably requires surface water sampling at multiple locations that are outside the influence or control of the City and its wastewater discharge. Post Falls stated that only the water quality immediately above and below the City's outfall is pertinent to this permit and the sampling points should be changed to reflect such an approach. Post Falls stated that it will cooperate with the IDEQ to select appropriate sampling locations at or near the Post Falls Dam and at or near the old Pleasant View Bridge in the River.

Post Falls also stated that Paragraph F.1 on Page 12 and Fact Sheet Page C-2 list Skalan Creek as a sampling point but maintained that Skalan Creek is unaffected by the City's discharge and rarely flows with water. Sampling requirements for Skalan Creek also require access to private property that cannot reasonably be assured by the City. Skalan Creek should be removed from this permit as a sampling point.

Response #2-38

The surface water monitoring requirements in all three of the 2007 draft permits were very similar. Therefore, EPA will consider this comment to be applicable to all three of the 2007 draft permits.

---

of the discharge (WAC 173-201A-200(1)(c)(ii)(A)). The maximum "no source" temperature is 26.4 ºC; the value of 34/(T + 9) therefore equals 0.96 ºC.

This comment has been addressed by changes proposed in the 2013 draft permits and retained in the final permits. Specifically, the permits no longer require receiving water monitoring in Skalan Creek, and the sampling locations within the Spokane River have been changed such that sampling is required in the Spokane River upstream and downstream from each facility's outfall.

Comment #2-39

CFJ stated that there is no evidence that the required monitoring is adequate to populate the Spokane CE-QUAL-W2 model to verify and/or determine water quality trends as restoration activities are implemented, or to provide statistically significant information on PCBs. CFJ recommended that EPA consult with EPA staff working on the PCB TMDL to ensure that the sampling is adequate and further suggested a minimum sampling frequency of once per month for total PCBs with a quarterly congener specific analysis, as well as quarterly measuring of dissolved and particulate PCBs attached to sediment.

Response #2-39

The monitoring for PCBs required by the final permits will result in statistically robust data sets. The TSD states that the uncertainty is too large to calculate a standard deviation or mean with sufficient confidence for data sets with less than 10 results (Page 53). Over the five-year term of the permits, the required monitoring for PCBs will result in 30 influent samples, 20 effluent samples, 10 upstream receiving waters samples, and 10 downstream receiving water samples. Therefore, the PCB monitoring requirements will produce a data set that meets the TSD's recommendation of at least 10 samples at each of the required monitoring locations.

The following relative errors were calculated using the procedures described in Appendix N to the EPA's Local Limits Development Guidance (EPA 2004).

Assuming a coefficient of variation of 0.6, which is recommended by EPA permitting guidance in cases where the actual effluent variability is unknown (see TSD at Pages 53 and E-3), the 20 effluent samples that will be collected over the permit term (i.e., quarterly sampling for five years) will quantify the average effluent concentration with a 22.5% relative error, at a confidence level of 90%. For the influent (30 samples) the relative error will be 18.3%, at a confidence level of 90%.

The receiving water monitoring requirements for parameters that would be useful for CE-QUAL-W2 modeling to refine permit requirements for nutrients and oxygen demand (i.e., CBOD5, ammonia, pH, nitrate + nitrite, TP, orthophosphate, DO, and chlorophyll a), require 8 samples per year both upstream and downstream of the outfalls, resulting in 40 upstream samples and 40 downstream samples for each permit. Assuming a coefficient of variation of 0.6, 40 samples will quantify the average concentrations of these constituents with a relative error of 15.7%, at a confidence level of 90%.

Phosphorus Management Plan

Comment #2-40

CFJ stated that the phosphorus management plans required in the permits provide no regulatory mechanism to track performance. CFJ recommended that the EPA include requirements for regular

reporting requirements on phosphorus reductions achieved through the phosphorus management plans. Moreover, CFJ stated that there should be an opportunity for public "review and comment."

Response #2-40

This comment has been addressed by changes made to the revised draft permits issued for public review and comment in 2013. The revised draft permits were changed to require annual reporting of reductions achieved through the phosphorus management plans, and to require that the plans themselves be submitted to the EPA. These requirements have been retained in the final permits.

The annual reports and the phosphorus management plans themselves are a matter of public record. As such, the general public will be able to request them from the EPA pursuant to the Freedom of Information Act.

Polychlorinated Biphenyls

Comment #2-41

CELP stated that PCBs are present in municipal effluent. The commenter cited to Ecology's latest PCB studies to explain that extremely low levels of PCBs will need to be achieved to protect water quality. Therefore, the commenter recommended that EPA include permit limits for PCBs that are derived from existing data obtained in these Spokane River studies performed by Ecology. Monthly samples of effluent PCB in the first year are needed to fully and adequately characterize each discharge.

Response #2-41

As explained in the response to comment #1-1, based on the available information, the EPA has not concluded at this time that the subject discharges have the reasonable potential to cause or contribute to excursions above water quality standards for PCBs. Therefore, the permits do not contain effluent limits for PCBs. The permits include monitoring requirements for PCBs in the influent, effluent, and receiving water. The data obtained from this monitoring will be used to determine if the discharges have the reasonable potential to cause or contribute to excursions above water quality standards for PCBs in the future. The permits also include BMP requirements to control or abate the discharge of PCBs (if any) from the subject POTWs.

Pretreatment

Comment #2-42

CELP stated that the pretreatment program requirements need to specifically require industrial dischargers of phosphorus to be classified as SIUs and to require phosphorus removal down to 5 mg/L before discharge to the treatment plants. This requirement should include sludge discharges, for example from water treatment system maintenance.

Response #2-42

The term "significant industrial user" (SIU) is defined in 40 CFR 404.3(v) as an industrial user that is subject to categorical pretreatment standards, and any other industrial user that discharges an average of 25,000 gallons per day or more of process wastewater to the POTW (excluding sanitary, non-contact

cooling and boiler blowdown wastewater); contributes a process wastestream which makes up five percent or more of the average dry weather hydraulic or organic capacity of the POTW treatment plant, or is designated as such by the "control authority" on the basis that the industrial user has a reasonable potential to adversely affect the POTW's operation or to violate any pretreatment standard or requirement. The control authority is the POTW in cases where the POTW has an approved pretreatment program. Otherwise, it is the approval authority (which, for the State of Idaho, is the EPA). The City of Coeur d'Alene has an approved pretreatment program. The City of Post Falls and the Hayden Area Regional Sewer Board do not. However, the City of Post Falls is required to develop a pretreatment program for EPA approval as a condition of its reissued permit.

In general, the determination of whether an industrial user is an SIU is independent of whether that discharger discharges phosphorus. The only time in which a discharge of phosphorus would be relevant to this determination would be when the discharge of phosphorus "has a reasonable potential for adversely affecting the POTW's operation or for violating any Pretreatment Standard or requirement."

The decision to label an industrial user (which does not otherwise fit the definition of an SIU) as an SIU on the basis that the user has the reasonable potential for adversely affecting the POTW's operation or for violating any pretreatment standard or requirement would be made by the control authority. Therefore, the EPA, as the control authority for HARSB and (for the time being) Post Falls, would be required to demonstrate that a particular industrial user's discharge of phosphorus to the POTW has the reasonable potential to adversely affect the POTW's operation or to violate any pretreatment standard or requirement, in order to label this user as an SIU (if the user did not otherwise fit the definition of an SIU). At this time, the EPA has no information demonstrating this reasonable potential and the commenter submitted none with this comment. Typical untreated domestic sewage contains 4 to 15 mg/L of total phosphorus. Therefore, most of the phosphorus loading to a POTW treatment plant is from domestic sources, and pretreatment program requirements are inapplicable to such sources (40 CFR 403.1). Additional phosphorus from non-domestic sources would be unlikely to adversely affect the POTW's operation, because POTWs are designed to operate properly in spite of the relatively high concentrations of total phosphorus in untreated domestic wastewater. Therefore, the EPA cannot label an industrial user as an SIU simply because it discharges phosphorus.

Capacity Expansions

Comment #2-43

CFJ stated that the EPA did not discuss the planned POTW capacity expansions in the 2007 Fact Sheets.

Response #2-43

In compliance with 40 CFR 122.45(b)(1), all of the effluent limits in the 2007 fact sheets were calculated based on the existing design flows of the treatment plants as reported on the most recent applications available at the time the draft permits were issued for public review and comment.

The City of Post Falls and the Hayden Area Regional Sewer Board submitted updated applications in 2010, reflecting the facility expansions that had taken place at that time. In compliance with 40 CFR

122.45(b)(1), the effluent limits in revised permits are calculated based on the expanded design flows of the treatment plants.

Whole Effluent Toxicity

Comment #2-44

CELP stated that reasonable potential determinations and permit limits to prevent effluent toxicity need to consider additive or synergistic toxicity affects when multiple heavy metal pollutants consistently occur together in relatively high concentrations.

Response #2-44

Effluent limits for individual chemical constituents intended to prevent direct toxicity to aquatic life are derived from and comply with numeric water quality criteria that have been shown to be protective of aquatic life. However, the EPA recognizes that mixtures of chemicals in a point source discharge can be more toxic than the individual chemical constituents within that discharge. Since the toxicity of mixtures of chemicals cannot be generalized or predicted with any certainty, the permits require quarterly chronic whole effluent toxicity (WET) testing. This is consistent with the *Regions 9 and 10 Guidance for Implementing Whole Effluent Toxicity Programs* (EPA 1996).

The EPA has determined, based on existing WET data, that none of the three discharges have the reasonable potential to cause or contribute to excursions above water quality standards for toxicity (see the 2013 fact sheets at Appendix D).

The 2007 draft permits did omit some WET permit conditions that are recommended in EPA guidance. The EPA has incorporated these permit conditions in the 2013 draft permits, and these requirements have been retained in the final permits. These conditions include accelerated testing when toxicity is detected above the toxicity triggers for each facility, and a requirement that the facility re-test its effluent if a test does not meet test acceptability criteria. In the final permits, the EPA added language to Part I.E.2.b to clarify how the most sensitive species is to be determined. The WET results will be used to determine if the discharges have the reasonable potential to cause or contribute to excursions above Idaho's narrative criterion for toxicity in the next permit reissuance.

Compliance Schedules and Interim Limits

Comment #2-45

CFJ states that Section 301(b)(1)(C) of the Clean Water Act establishes a firm deadline of July 1st, 1977, for complying with water quality-based effluent limits, beyond which no extensions can be granted by a state. CFJ points out that, under Section 301(i) of the Act, compliance schedules could be granted for POTWs in certain circumstances if construction could not be completed by the July 1st, 1977, deadline, but that such schedules are not allowed to extend past July 1st, 1988. CFJ references 40 CFR 122.47, which states that compliance schedules cannot extend past "the applicable statutory deadline under the CWA." Therefore, CFJ concludes that the statutory deadline for compliance has expired and any attempt to extend compliance with such limitations after those dates violates the statutory compliance deadline in the Clean Water Act.

Response #2-45

The issue raised by this comment is whether Sections 301(b)(1)(C) and 301(i) of the Act and 40 CFR 122.47 prohibit schedules of compliance in permits after July 1, 1977, or July 1, 1988, respectively.

Section 301(i) of the Act is irrelevant to the subject permits. In order to invoke Section 301(i), the owner or operator of a POTW would have needed to request the EPA to issue an NPDES permit within 180 days after February 4, 1987 (August 4, 1987). This could not have happened for the permit reissuances in question.

In *In The Matter of Star-Kist Caribe, Inc.*, 3 E.A.D. 172 (1990), EPA's Administrator interpreted Section 301(b)(1)(C) of the Act to mean that NPDES permits must require immediate compliance with effluent limitations based on water quality standards adopted before July 1, 1977. Thus, the subject permits may not contain compliance schedules for effluent limits that are based on pre-1977 water quality standards. However, for new or revised water quality standards adopted after July 1, 1977, NPDES permits may contain compliance schedules as long as the state has clearly indicated in its water quality standards or implementing regulations that it intends to allow them. See StarKist at 176-177; see also the Permit Writers' Manual at Section 9.1.3. Therefore, if a state adopts a new or revised water quality standard after July 1, 1977, the state may authorize the permitting authority to include a compliance schedule in the NPDES permit to allow time for the permittee to meet the new water quality-based effluent limit in the permit.

Compliance schedules are authorized under the water quality regulations in both Idaho and Washington. See IDAPA 58.01.02.400.03 and WAC 173-201A-510. Since the discharges authorized in the subject permits occur in Idaho, it is Idaho's regulation that is applicable to these permits.

Since the water quality standards of both affected states allow schedules of compliance, the next issue is whether the relevant water quality standard was in effect prior to July 1, 1977. The Washington water quality standard upon which the effluent limits for phosphorus, CBOD, and ammonia are based is the DO criterion for lakes and reservoirs, applied in Lake Spokane (WAC 173-201A-200(1)(d)(ii)). The currently effective version of that standard appears in the 2003 revision of Chapter 173-201A WAC and became effective for Clean Water Act purposes when it was approved by EPA on February 11, 2008. This standard reads, "For lakes, human actions considered cumulatively may not decrease the dissolved oxygen concentration more than 0.2 mg/L below natural conditions." Prior to 2003, the State of Washington's DO standard for lakes and reservoirs read "no measurable decrease from natural conditions." The Washington water quality criterion for DO in lakes and reservoirs has therefore been revised after 1977. Since the relevant water quality standard has been revised after 1977, and because the applicable state law allows for compliance schedules, a compliance schedule may be authorized.

Comment #2-46

CFJ stated that, by extending beyond the term of the permit, the compliance schedules violate the CWA's mandate that NPDES permits be established for a fixed term not to exceed five years. CFJ stated that the compliance schedules "are not for a fixed term." CFJ referenced a 9th Circuit Court of Appeals decision in *Citizens for a Better Environment* v. *Union Oil Company of California* (*CBE* v. *UNOCAL*) and

quotes the following language from the opinion: "there is a five year duration on the life of an NPDES permit that the 'effective modification' here would violate." CFJ argued that the proposed compliance schedules extend the substantive requirements of a permit beyond the five-year limit established by the Act. CFJ referenced the City of Moscow NPDES permit appeal before the Environmental Appeals Board (EAB) and stated that the EPA argued in that case that to extend the compliance schedule beyond the term of that permit would be illogical as there was no guarantee that the permit would be administratively extended or renewed.

Response #2-46

The EPA does not agree with the commenters that a compliance schedule longer than five years violates the Clean Water Act's mandate that NPDES permits be established for a fixed term not to exceed five years. The five-year maximum permit term required by Section 402(b)(1)(B) of the Act does not establish a deadline for meeting a water quality-based effluent limitation; it simply requires the permitting authority to re-evaluate NPDES permits every five years (see letter dated 11/29/06 from Alexis Strauss, EPA Region 9 to Tom Howard, California State Water Resources Control Board at Page 6, and the enclosure to that letter at Page 6).

The *CBE* v. *UNOCAL* case referenced by the Center for Justice (CFJ) is irrelevant to the issue of how long a compliance schedule in a permit may be. In *CBE* v. *UNOCAL,* the Ninth Circuit addressed two issues: 1) whether the cease and desist order (CDO) barred a citizen suit under Clean Water Act Section 309(g)(6)(A), and 2) whether the CDO effectively deferred the compliance date for a selenium effluent limit such that UNOCAL was not in violation of that effluent limit. The Court concluded that the CDO neither barred a citizen suit nor effectively deferred the compliance date for the selenium effluent limit.

The Court determined that the CDO did not defer the compliance date for the selenium effluent limit for the following reasons: 1) the CDO was an exercise of prosecutorial discretion and did not purport to modify the permit, 2) the federal and state regulations (e.g. 40 CFR 122.62) that govern the modification of permits were not followed, and, 3) even if the CDO were considered a modification of the permit, that modification may have violated the Clean Water Act's anti-backsliding provisions.

The language from the opinion that CFJ quoted in its comments on these permits was an observation made by the *CBE* Court that one of the requirements of the NPDES permitting program that was not followed by the CDO was the requirement that permits be limited to a fixed term not to exceed five years. However, the question of whether a compliance schedule could extend beyond the term of an NPDES permit was not before the Ninth Circuit in *CBE* v. *UNOCAL* and was not addressed by the Court.

CFJ also references the City of Moscow, Idaho NPDES permit appeal, 10 EAD 135 (EAB 2001). That case does not stand for the proposition that compliance schedules as a general matter are limited to five years under the CWA. Furthermore, that case is not applicable to the current situation. In City of Moscow, the EAB upheld EPA's authority to impose compliance schedules shorter than those set forth in the state's 401 certification where the State of Idaho's compliance schedule authorizing provision at the time the City of Moscow permit was issued allowed compliance schedules only for "five years or the life of the permit."

Following that decision, the State of Idaho revised its compliance schedule regulations to allow schedules with no specific time limitation. The State of Idaho's current compliance schedule regulation states, in full: "Discharge permits for point sources may incorporate compliance schedules which allow a discharger to phase in, over time, compliance with water quality-based effluent limitations when new limitations are in the permit for the first time." See IDAPA 58.01.02.400.03. The State of Idaho can now determine, on a case-by case basis, what an appropriate schedule of compliance is for a particular effluent limitation and discharger. The schedules of compliance in these permits were determined by the State of Idaho in its 401 certification for these permits.

The commenters also point out that there is no guarantee that the subject permits will be administratively extended or reissued, so that each point source will hold an effective NPDES permit at the time that compliance with the final water quality-based effluent limits is ultimately required by the compliance schedule certified by the State of Idaho. This is largely irrelevant to the subject permits. It is unlikely that any of the subject permittees will implement an alternative method of disposing of their wastewater and cease their discharges within the five-year terms of these permits. Therefore, the permits are likely to be administratively continued or reissued. In the unlikely scenario that a permit for any of the subject POTWs is neither administratively continued nor reissued, the discharger would have no authorization to discharge at all upon expiration of the permit, so the compliance schedule would be irrelevant.

If the permits were administratively extended, the final compliance deadline, as well as any interim deadlines, would be in effect and enforceable.

If the permits were reissued before the compliance deadline, then, as with all of the permit conditions, the permitting authority would be required to re-evaluate the compliance schedule at the time of reissuance. Depending on the particular facts, the permitting authority may conclude that the compliance schedule in the initial permit need not be altered, or the permitting authority may find that the schedule should be shortened, extended, or deleted.

The status of the permit is not a concern as long as the initial permit contains the entire compliance schedule and final effluent limits that must be met. See further discussion below in 2-48 as to the enforceability of these terms in an NPDES permit.

Comment #2-47

CFJ stated that a compliance schedule beyond the term of a permit is unenforceable and is inconsistent with EPA's definition of a compliance schedule (CWA Section 502(17) and 40 CFR 122.2). CFJ stated that the permits' attempts to issue schedules that extend the deadline for compliance for nine years are unenforceable schedules.

Response #2-47

The term "schedule of compliance" is defined in federal statute (Clean Water Act Section 502(17)), federal regulations (40 CFR 122.2), and in State of Idaho regulations (IDAPA 58.01.02.010.15). None of the definitions of "schedule of compliance," nor the provision allowing schedules of compliance in the Idaho Water Quality Standards, limit the term of a schedule of compliance to the term of an NPDES

permit or any other specific length of time. This gives the State of Idaho and the EPA the discretion to make case-by-case determinations as to the appropriate length of the compliance schedules.

The schedules of compliance for the Idaho permits are established under Idaho state law. The permits therefore comply with the Clean Water Act's requirement that permits be conditioned to comply with "schedules of compliance established pursuant to any State law or regulations" (Section 301(b)(1)(C), see also the enclosure to letter dated 11/29/06 from Alexis Strauss, EPA Region 9, to Tom Howard, California State Water Resources Control Board at pages 8-9). The fact that compliance schedules established under state law are to be included in a permit issued for a term not to exceed five years does not mean that the length of the compliance schedule must be limited to five years.

In Idaho, the length of a compliance schedule is limited only by the federal regulatory requirement of 40 CFR 122.47(a)(1) that compliance be achieved "as soon as possible." The State of Idaho determined that the appropriate length of the schedules of compliance for new water quality-based effluent limits for TP, $CBOD_5$, and for Coeur d'Alene, ammonia, is ten years. To ensure compliance with Section 301(b)(1)(C) of the Act, the schedules, including the final effluent limits and any interim requirements with compliance deadlines beyond the term of the permit, have been included in the permit.

EPA agrees with the commenter that schedules of compliance in NPDES permits must be enforceable. Every condition in an NPDES permit, including those that are part of a compliance schedule, are enforceable conditions (see Locust Lane v. Swarta Township Authority, 636 F. Supp. 534, 539 (M.D. Pa. 1986)). Therefore, a compliance schedule that includes interim milestones leading to compliance with a final effluent limitation at a date later than the expiration date of the initial permit is enforceable, as long as all the requirements of the compliance schedule, including those that extend beyond five years or begin after the fifth year, are included as permit terms (See enclosure to letter dated 11/29/06 from Alexis Strauss, EPA Region 9, to Tom Howard, California State Water Resources Control Board at Page 9). The requirements of the compliance schedules have been included as permit terms in the subject permits and are therefore enforceable.

The schedules in the final permits were included as conditions in Idaho's Clean Water Act Section 401 certifications, which defer the deadline for compliance with water quality-based effluent limits for a fixed amount of time, unless the schedules are modified at some future date. The compliance schedules in the final permits represent IDEQ's judgment as to the amount of time that the subject dischargers require to achieve compliance with new WQBELs in the final permits, based on the record before IDEQ at the time. The EPA concurs with IDEQ's findings regarding the compliance schedules, based on the record before the EPA at this time, as discussed in the 2013 fact sheets at Appendix G, and has included the schedules in the permits.

The reissuance of the permits will provide EPA and IDEQ an opportunity to re-evaluate the compliance schedules (along with the other permit conditions) to determine if the schedules remain appropriate (40 CFR 122.47(a)(1)) in light of any new information obtained during the term of the permit. In addition, the State of Idaho reserves the right to modify its Clean Water Act Section 401 certifications, and EPA may modify the compliance schedules (or other permit conditions) in compliance with 40 CFR 122.62

and 122.63. The fact that the compliance schedules (like any other permit conditions) may be modified in the future does not mean that they are not enforceable.

Comment #2-48

CFJ stated that a compliance schedule longer than five years undermines the public's right to comment on future NPDES permits.

Response #2-48

The public has had an opportunity to comment on the compliance schedule. Indeed, the EPA has received comments on the compliance schedules and has responded to them in this response to comments. When the subject permits are reissued, the EPA and IDEQ will re-evaluate the compliance schedules. The public will be able to submit comments on any condition in the reissued permits, including any compliance schedules. If the compliance schedules are modified during the terms of the permits, the public will have an opportunity to comment on the modifications at that time, since permit modifications must follow the public review and comment procedures of 40 CFR Part 124 (see also 40 CFR 122.62).

The only change that may be made to a compliance schedule without public review and comment is to change an *interim* compliance date in a schedule of compliance, provided the new date is not more than 120 days after the date specified in the existing permit and does not interfere with attainment of the final compliance date requirement (40 CFR 122.63(c)).

The fact that the compliance schedules extend beyond the terms of the permits in no way denies the public the right to comment on the compliance schedules nor does it deny the public the right to comment on any other aspect of a future permit.

Comment #2-49

CFJ stated that the interim phosphorus limits for Post Falls and HARSB are inconsistent with the 1989 Phosphorus Management Plan, which required 85% phosphorus removal, seasonally. CFJ believed that the interim limits should be at least this stringent.

Response #2-49

The interim phosphorus limits in the subject permits are discussed in the 2013 fact sheets (see the 2013 Post Falls fact sheet at Pages 20-21, the 2013 HARSB fact sheet at Pages 20-22, and both fact sheets at Appendix G). The interim limits ensure compliance with 40 CFR 122.44(l)(1), which generally requires that interim effluent limits be at least as stringent as the final limits in the previous permit. The interim phosphorus limits also comply with 40 CFR 122.45(f), which generally requires effluent limits to be expressed in terms of mass. The interim mass limits for phosphorus were calculated based on the design flows of the POTWs at the time the prior permits were issued (in 1999), which ensures that they are "as stringent" as any phosphorus limits in the 1999 permits.

The Spokane River Phosphorus Management Plan would not independently require 85% phosphorus removal for Post Falls or HARSB. This plan is not a legally binding or enforceable document.

Furthermore, the plan has been superseded by the Spokane River DO TMDL. Nonetheless, we discuss below the substantive content of the plan as well.

The management plan was signed in 1989 and was intended to implement the 25 µg/L euphotic zone site-specific phosphorus criterion for Lake Spokane. The management plan stated that the City of Spokane had been removing phosphorus at its wastewater treatment plant "for many years, and will continue to operate with a discharge permit that requires at least 85% (phosphorus) removal." See Spokane River Phosphorus Management Plan at Page 2. The City of Spokane had begun phosphorus removal in late 1977 (Cusimano 2004).

As for the other municipal dischargers, including Post Falls and HARSB, the management plan stated that "as the need for further phosphorus reduction is identified, the other municipalities will sequentially implement phosphorus removal, at rates of at least 85%, and that "the discharger with the greatest daily total phosphorus load is required to treat first." The management plan anticipated that the sequence for additional phosphorus removal to be Coeur d'Alene, followed by Post Falls, followed by Liberty Lake, followed by HARSB. The City of Coeur d'Alene is already required to remove 85% of influent phosphorus and has done so since the early 1990s.

The management plan stated that the next phosphorus removal action would be triggered when existing phosphorus controls no longer achieved a loading of 259 kg/day or less to Lake Spokane (Long Lake). This trigger loading has not yet been reached. Although more recent studies show that phosphorus loading to Lake Spokane must be reduced below 259 kg/day in order to meet Washington's water quality criterion for DO, the 1989 phosphorus management plan has not been updated. Because the trigger loading of 259 kg/day has not yet been reached, the phosphorus management plan does not independently require interim phosphorus limits of 85% phosphorus removal.

Comment #2-50

CELP and CFJ stated that interim limits that apply during the terms of compliance schedules in the permits should be based on performance.

The Center for Environmental Law and Policy stated that, because in-stream water quality violations for DO currently exist, the permits must be conditioned so that the ultimate BOD loading does not increase during the interim compliance schedule. This will require controls on both CBOD and NBOD (nitrogenous biochemical oxygen demand). CELP stated that it is not appropriate to use technology-based CBOD limits without also controlling ammonia to appropriate levels.

The Center for Environmental Law and Policy recommended that the EPA include an evaluation of performance as part of determining interim ammonia limits so that ammonia loadings are not allowed to increase where they contribute to water quality standards violations.

CFJ also stated that "no increases in pollutant loading through growth should be allowed during the interim period while treatment facilities are being upgraded." CFJ stated that EPA must "ensure no increases in pollutant loading while these facilities are being upgraded" in order to "avoid backsliding."

Response #2-50

In the final permits, schedules of compliance have been established for new water quality-based effluent limits for TP, CBOD, and, for Coeur d'Alene, ammonia. The limits that apply during the compliance schedules in the permit are the interim limits.

Interim limits are discussed in the fact sheets at Appendix G and also in the bodies of the fact sheets (see the Coeur d'Alene fact sheet at pages 20-21, the Post Falls fact sheet at pages 20-21, and the HARSB fact sheet at pages 20-22). Nothing in the CWA or NPDES regulations requires the EPA to establish interim effluent limits based on performance so that the actual pollutant loading does not increase during the compliance schedules. Federal regulations require only that, in general, the interim limits are at least as stringent as the limits in the previous permit (40 CFR 122.44(l)(1)). That is to say, the regulations generally prohibit increases to *authorized* loading (i.e., the loading authorized by the effluent limits) during the term of a compliance schedule, but do not necessarily prohibit increases to actual loading as long as the actual loading is in compliance with effluent limits.

In all cases, the interim effluent limits are at least as stringent as the final limits in the previous permit. The interim phosphorus limits in the subject permits are discussed in the 2013 fact sheets (see the 2013 Post Falls fact sheet at Pages 20-21, the 2013 HARSB fact sheet at Pages 20-22, and both fact sheets at Appendix G). The interim limits ensure compliance with 40 CFR 122.44(l)(1), which generally requires that interim effluent limits be at least as stringent as the final limits in the previous permit. The interim phosphorus limits also comply with 40 CFR 122.45(f), which generally requires effluent limits to be expressed in terms of mass. Interim mass limits for phosphorus were calculated based on the design flows of the POTWs at the time the prior permits were issued (in 1999).

The interim $CBOD_5$ limits in the Coeur d'Alene permit are identical to the limits in the previous permit. As explained in the HARSB and Post Falls fact sheets at Appendix G, the interim limits for $CBOD_5$ for those facilities are as stringent as the previous permits' limits for BOD_5. The technology-based average monthly concentration limit for $CBOD_5$ is numerically 17% less than that for BOD_5 (i.e., 25 mg/L instead of 30 mg/L), in recognition that some fraction of the total BOD discharged by a facility is nitrogenous. The interim loading limits for $CBOD_5$ are calculated from the technology-based concentration limits using the design flows of the POTWs as of 1999, when the prior permits were issued. The BOD_5 limits in the previous (1999) permits were calculated from the technology-based BOD_5 limits using those same flows.

With respect to ammonia, for HARSB and Post Falls, this comment was addressed by changes made in the revised draft permits issued for public comment in 2013. Neither the revised draft permits nor the final permits for HARSB or Post Falls include schedules of compliance for ammonia limits; the final water quality-based ammonia limits in those permits must be met immediately upon the effective dates of the final permits. The final ammonia limits, in combination with the effluent limits on phosphorus and CBOD, ensure compliance with Washington's water quality standards for DO, on a cumulative basis.

Coeur d'Alene has a compliance schedule for ammonia, which includes interim effluent limits. Coeur d'Alene's interim ammonia limits are identical to the ammonia limits in the previous permit, in compliance with 40 CFR 122.44(l)(1).

Comment #2-51

The City of Spokane stated that the compliance schedules in the proposed permits are too generous. The City of Spokane was concerned that the although the Idaho dischargers do not need to improve their effluent until at least mid-2016, the downstream Washington dischargers will be required to upgrade their facilities sooner (i.e., by 2011 and 2012). The City of Spokane concluded that any data collected after 2011 and 2012 would be of little use unless the Idaho dischargers are required to upgrade by 2011 and 2012.

Response #2-51

The Idaho regulation allowing the State of Idaho to authorize compliance schedules (IDAPA 58.01.02.400.03) does not contain a specific limitation on the duration of a compliance schedule. Federal regulations, however, require that compliance is achieved as soon as possible (40 CFR 122.47(a)(1)). As explained in Appendix G to each of the three fact sheets, the compliance schedules in the subject permits do, in fact, require compliance with water quality-based effluent limits as soon as possible.

Comment #2-52

CFJ stated that the proposed compliance schedules do not comply with 40 CFR 122.47, which requires that compliance with final effluent limits be achieved "as soon as possible."

Moreover, CFJ did not believe that the 401 certifications or the fact sheets explained the need for a nine-year schedule of compliance and did not make an adequate showing that the nine-year compliance schedule satisfied the "as soon as possible" test. CFJ attached and referenceds a report from a third-party engineering firm that concludeds that 56 to 58 months is a reasonable time frame to achieve the proposed limits. CFJ further referenced cost estimates by BlueWater Technologies showing the cost of upgrading a plant to meet 50 ppb TP in the effluent would be roughly $1 million per MGD of capacity. CFJ referred to an e-mail from Dave Ragsdale of EPA Region 10 in which he noted that compliance schedules to complete new secondary treatment plants are generally 5 years or less. The commenters stated that EPA and DEQ should require permittees to better justify the need for a compliance schedule of a certain duration.

Response #2-52

As explained in Appendix G to each of the 2013 fact sheets, the schedules of compliance in each of the permits require compliance with new water quality-based effluent limits as soon as possible, in compliance with 40 CFR 122.47(a)(1).

Comment #2-53

CFJ stated that EPA has an independent duty to incorporate more stringent permit conditions than those in Idaho's certifications if necessary to achieve WQS pursuant to CWA Section 301(b)(1)(C). CFJ did not believe that the compliance schedules set forth in Idaho's 401 certifications were protective of

downstream water quality standards and illegally deferred compliance with the final effluent limits in violation of 40 CFR 122.47(a)(1).

Response #2-53

As explained in the 2013 fact sheets at Appendix G, the schedules of compliance in each of the permits require compliance with new water quality-based effluent limits as soon as possible, in compliance with 40 CFR 122.47(a)(1).

State Certification

Comment #2-54

Mr. Jim Hollingsworth asked the EPA to explain the purpose of the Section 401 certification that is issued by IDEQ.

Response #2-54

Section 401(a)(1) of the Clean Water Act requires IDEQ to either grant or waive Section 401 certification before EPA issues a NPDES permit. In issuing the 401 certification, IDEQ is essentially stating that they have reviewed the subject NPDES permit and certifying that the permit meets state water quality requirements.

States may respond to requests for certification of EPA-issued NPDES permits in one of three ways. First, the state may certify the permit, with or without specifying additional or more stringent conditions in the certification that the State deems necessary to comply with the CWA and state law. Second, the state may waive certification, which allows the permit to be issued. Third, the state may deny certification, which prevents a final permit from being issued.

The State may not condition or deny a certification on the grounds that state law allows a less stringent permit condition (40 CFR 124.55(c)). Therefore, EPA's effluent limits, which are based on Washington's water quality standards in compliance with 40 CFR 122.4(d), may be more stringent than necessary to meet Idaho's water quality standards, but that is not a basis for the State of Idaho to deny or condition their certifications.

Comment #2-55

CFJ stated that Section 401(a)(1) of the Act requires that the State of Idaho certify that the conditions in all three permits comply with Sections 301, 302, 303, 306, and 307 of the Act and that Section 301 requires compliance with Sections 302, 306, 307, 308, 402, and 404.

CFJ stated that neither the interim nor the final limits are protective of Washington's water quality standards, in violation of Section 301 of the Clean Water Act, and that the permits were not in compliance with Section 301's effluent limitations and timelines. The Center for Justice also stated that the permits were not in compliance with Section 302's requirement that effluent limitations be established that will ensure attainment or maintenance of water quality, Section 308's requirement to monitor at such intervals and in such manner as to track river restoration and PCB pollution, and Section

402's requirement that permits be conditioned to protect the water quality of all affected States, that permits be limited to five years, and that the permits not allow backsliding.

CFJ stated that, for these reasons, the State of Idaho should not issue 401 certifications, and final permits should therefore not be issued, unless EPA includes more stringent conditions in the permits.

Response #2-55

The issuance or denial of a 401 certification for any of the three subject permits is an action to be taken by the State of Idaho. Moreover, the legality of a state's CWA 401 certification, or its conditions, is not to be determined by EPA, the permit issuing agency. The 401 certification and its conditions must be challenged in State court. *American Rivers v. FERC*, 129 F. 3d. 99, 102 (2d Cir. 1999). However, having reviewed the commenter's concerns with the certification in light of the 2013 draft permits, EPA believes the final permits comply with sections 301, 302, 308, and 402 of the Clean Water Act, as explained below. EPA believes that the State of Idaho can appropriately issue 401 certifications for the subject permits.

Section 301

There are two main requirements in Section 301 of the. First, the permits must comply with Section 301(b)(1)(B), which requires that NPDES permits for POTWs require compliance with effluent limitations based on secondary treatment. As explained in the fact sheets, the effluent limits in the permits are at all times at least as stringent as the secondary treatment requirements of 40 CFR Part 133, which implements Section 301(b)(1)(B) of the Act. Second, Section 301(b)(1)(C) requires that NPDES permits contain effluent limits that are more stringent than technology-based effluent limits (such as secondary treatment) when those limits are necessary to meet water quality standards or other requirements of state or federal laws and regulations. The final permits contain water quality-based effluent limits whenever necessary, i.e., whenever the discharges had the reasonable potential to cause or contribute to excursions above water quality standards (40 CFR 122.44(d)(1)(i)), as explained in the fact sheets. The permits are also in compliance with Section 301(b)(1)(C)'s "timelines" (i.e., compliance schedules) as explained in Appendix G to each of the three 2013 fact sheets.

Section 302

Section 302 authorizes the EPA to promulgate water quality-based effluent limits when discharges from a point source will interfere with the attainment of WQS after the application of technology-based limits based on the "best available technology economically achievable" (BAT). Section 302 is not applicable to the subject permits for a number of reasons.

BAT limits are applicable to point sources other than POTWs. The subject permits are for POTWs, so Section 302 is not applicable to these permits. Furthermore, any effluent limits that would apply under Section 302 would be arguably less stringent than the effluent limits included in the final permits (which are based on Section 301(b)(1)(C) of the Act) because Section 302 requires a cost-benefit analysis and Section 301(b)(1)(C) does not. Finally, even though Section 302 is not applicable, the Section 301(b)(1)(C) water quality-based limits can nonetheless "reasonably be expected to contribute to the attainment or maintenance of…water quality," which is what would be required under Section 302.

Section 308

Section 308 of the Act concerns monitoring and reporting requirements, inspections, and entry. The subject permits contain monitoring, reporting, and recordkeeping requirements, including receiving water monitoring requirements, which ensure that the permits comply with Section 308 of the Act. The permits also contain conditions requiring that EPA, Idaho DEQ, and authorized representatives may enter and inspect the facilities, perform sampling, and access and copy records, in compliance with Section 308 of the Act.

Section 402

Section 402 of the Clean Water Act creates the National Pollutant Discharge Elimination System (NPDES). NPDES permits represent one of the exceptions to the general prohibition on discharges of pollutants in Section 301(a) of the act. The subject permits comply with all applicable requirements of Section 402 of the Act.

As stated in the 2013 fact sheets, the subject permits are conditioned to ensure compliance with the water quality standards of all affected states, as required by Section 402 of the Act and 40 CFR 122.4(d). Section 402(b)(1)(B) states that permits shall be issued for a fixed term not to exceed five years. The subject permits comply with this requirement, which is not violated by the fact that the permits implement compliance schedules that extend beyond the durations of the permits. See the response to comment 2-51 and the letter dated 11/29/06 from Alexis Strauss, EPA Region 9, to Tom Howard, California State Water Resources Control Board, and its enclosure.

Section 402(o) of the Act concerns backsliding, or the establishment of less-stringent effluent limitations in a reissued permit than the corresponding limits in the previous permit. There are exceptions provided in Sections 402(o)(2) and 303(d)(4) of the Act. Whenever an effluent limit in the subject draft permits was less stringent than that in the expired permits, this was explained in the fact sheets, and was done in compliance with Section 402(o) of the Act. This was the case for Post Falls' and HARSB's mass limits for TSS and November to January $CBOD_5$ and ammonia, Post Falls' limits for copper mass and chlorine, and HARSB's discharge authorization for June to September when river flows are less than or equal to 2,000 CFS.

Ammonia Toxicity

Comment #2-56

The Center for Environmental Law and Policy stated that since the upper pH limit is 9.0, EPA should use this value to model pH at the edge of the mixing zone and subsequent ammonia criteria instead of actual performance. Moreover, the commenter recommended that if performance limits for pH are used to calculate effluent limits for ammonia, they should also be placed in the permit to regulate pH.

Response #2-56

The EPA has used appropriately conservative pH assumptions to evaluate water quality criteria for ammonia, and to determine reasonable potential, and to calculate effluent limits based on Idaho's water quality standards for ammonia toxicity. Therefore, it is not necessary for the EPA to establish

more stringent "performance-based" effluent limits for pH in the permits in order to ensure compliance with water quality criteria.

Specifically, the EPA has used the 95th percentile pH observed at all the available USGS stations in the Spokane River in Idaho. There were a total of 349 pH results, and the 95th percentile pH was 7.9 standard units. Chronic water quality criteria for ammonia are influenced by both pH and temperature, and the EPA has also used the 95th percentile temperature of the Spokane River for each season to calculate the values of the ammonia criteria. By using an upper percentile for both pH and temperature, the EPA has ensured that there is a low probability that the ammonia criteria will be more stringent than the values used to determine reasonable potential and calculate effluent limits.

In addition to using conservative assumptions for pH and temperature when calculating the values of the ammonia criteria, the EPA has also used critical conditions for the receiving water flow rate when calculating the available dilution, specifically the 30Q10 for use with chronic ammonia criterion and the 1Q10 for use with the acute criterion, or, if it was greater than the critical low flows calculated from historic data, the minimum flow rate of 500 CFS mandated by the Federal Energy Regulatory Commission (FERC) License for the Spokane River Hydroelectric Project (FERC 2009 at page 17).

The cumulative effects of the conservative assumptions used to calculate the value of the ammonia criteria, to determine reasonable potential to cause or contribute to excursions above those criteria, and, if necessary, to calculate effluent limits ensures that the discharges are very unlikely to cause or contribute to excursions above water quality criteria for ammonia because of pH.

Elimination of Surface Water Discharges

Comment #2-57

Mr. Gerry House, chairman of the Hayden Lake Recreational Water and Sewer District, stated that utilities and regulatory agencies should be "looking at ways to not discharge into the [Spokane] river at all."

Mr. Bart Haggin of the Lands Council stated that "the small amounts of discharges from these three discharge(s)…can easily be taken care of without putting any water in the [Spokane] river."

Response #2-57

Coeur d'Alene, Post Falls, and the Hayden Area Regional Sewer Board currently have administratively extended NPDES permits and have applied for new NPDES permits, which authorize the cities to discharge treated wastewater to the Spokane River subject to the conditions set forth in those permits, for five years. The permits contain conditions that, among other things, ensure compliance with all affected states' water quality standards.

Pursuant to 40 CFR 122.64, EPA has the authority to deny NPDES permit applications, which would effectively force the applicants to cease discharging pollutants, but only when at least one of the listed causes are met. In this situation, EPA has concluded that it does not have an allowable cause to deny the subject applications under 40 CFR 122.64.

Wastewater re-use is a method by which the dischargers can reduce the amounts of pollutants they discharge to the Spokane River, in an effort to achieve the stringent water quality-based effluent limits set forth in the final permits. For example, HARSB currently re-uses (or land applies) 100% of its wastewater during the summer months. All three permits require the dischargers to consider wastewater re-use as a means to reduce phosphorus discharges as part of their phosphorus management plans. The phosphorus management plan requirements in the permits are authorized by federal regulations (40 CFR 122.44(k)).

Anti-backsliding and Antidegradation

Comment #2-58

CFJ stated that the permits violate federal and state antidegradation and anti-backsliding requirements because EPA did not limit phosphorus, CBOD5, and ammonia to prior performance.

The commenter noted that, in general, effluent limitations for POTWs are based on design flow, and that Washington's permit writers' manual requires no additional loading of the pollutants of concern. The commenter pointed out that EPA did not calculate current mass loadings of pollutants from the Idaho dischargers. The commenter back-calculated the flow rates used to calculate effluent limits in the permits, and noted that the City of Coeur d'Alene's average flow rate over the previous five years was 3.2 mgd and the maximum daily flow rate was 4.62 mgd, both of which are well below the design flow rate of 6.0 mgd. The commenter therefore argued that "the proposed mass limits will exceed the loadings discharge during the last five years…(causing) further degradation for another nine years."

The commenter argued that Section 303(d)(4)(a) "governs backsliding into impaired waterways for which there is a TMDL or other wasteload allocation." Although the commenter disagreed with how EPA calculated wasteload allocations and effluent limits for the Idaho permits, the commenter argued that these are nonetheless wasteload allocations and that therefore EPA "may not allow increased loading into Lake Spokane."

The commenter argued that EPA "must conduct an antidegradation analysis to calculate permissible loading limits in compliance with federal and state antidegradation policies to restrict loading to prior performance and to ensure that any expansion does not further degrade the waters."

Response #2-58

Anti-backsliding

The anti-backsliding restrictions in Sections 402(o) and 303(d)(4) of the Clean Water Act and 40 CFR 122.44(l) limit the circumstances under which effluent limits and other permit conditions may be made less stringent than those in previous permits. The anti-backsliding restrictions would only be violated if the conditions in the reissued permits were made less stringent than the effluent limits in the previous NPDES permit without meeting one of the exceptions in the CWA or the regulations.

The EPA Permit Writers Manual discusses anti-backsliding requirements in Section 7.2. In general, the Permit Writers' Manual recommends that the permit writer follow the statutory provisions for effluent

limits based on state standards (including water quality-based effluent limits), and that the permit writer apply the statutory anti-backsliding provisions. For other limitations, standards, or conditions, the permit writer should apply the regulatory provisions in 40 CFR 122.44(l)(1). The anti-backliding requirements do not apply to actual historic discharge levels, but rather they apply to current permit effluent limits as compared to previous NPDES permit limits. Current permitted limits may only be less stringent than previous limits if there is an applicable exception to the general prohibitions on backsliding in the CWA or federal regulations.

From February to October, all of the interim and final effluent limits for TP, ammonia, and CBOD in all of the subject permits are at least as stringent as the final effluent limits in the previous permits. This is true for the $CBOD_5$ limits in the reissued permits for Post Falls and HARSB even though the prior permits had BOD_5 limits in lieu of $CBOD_5$ (see the 2013 Post Falls and HARSB fact sheets at Appendix G). Therefore, none of those limits violate the anti-backsliding provisions of the CWA or federal regulations.

From November to January, for Post Falls and HARSB, the loading limits for CBOD have been increased due to the increased design flows of the treatment plants. As explained in the 2013 fact sheets for these facilities, the increased loading limits comply with the anti-backsliding provisions of 40 CFR 122.44(l) because the physical expansions of the subject POTWs are material and substantial alterations to the permitted facilities that justify different permit conditions. See the 2013 Post Falls fact sheet at Page 22 and the 2013 HARSB fact sheet at Pages 22 – 23).

Antidegradation

Neither Idaho's nor Washington's antidegradation policies require the EPA to limit phosphorus, ammonia, or $CBOD_5$ to prior performance.

Idaho

As stated in the 2013 fact sheets, the antidegradation reviews were conducted as part of the State of Idaho's CWA section 401 certifications. The draft certifications, including the antidegradation reviews, were appended to the 2013 fact sheets as Appendix H. The State of Idaho determined that the permits are consistent with Idaho's antidegradation policy and implementation methods.

IDEQ properly provided Tier 1 antidegradation protection to the Spokane River for aquatic life uses and both Tier 1 and Tier 2 protection for recreation uses. Ammonia and CBOD discharges would not affect the recreation use, so only a Tier 1 analysis was performed for ammonia and CBOD. IDEQ determined that, because the ammonia and CBOD limits in the permits are set at levels that ensure compliance with the narrative and numeric criteria in the Idaho WQS the permits will protect and maintain existing and designated beneficial uses in the Spokane River, thus ensuring compliance with Tier I antidegradation requirements. IDEQ found that the phosphorus limits in the permits meet the Tier 2 requirements under the antidegradation policy because there will be no degradation in water quality, but rather an improvement in TP levels.

The EPA has reviewed Idaho's antidegradation reviews for the subject permit and finds that they are consistent with the state's 401 certification requirements and the state's antidegradation implementation procedures.

Washington

The subject permits can affect water quality in the State of Washington, therefore Washington's antidegradation policy is potentially applicable to the subject permits pursuant to 40 CFR 122.4(d). As explained in Appendix B to each of the 2013 fact sheets, the subject permits are consistent with the Washington's antidegradation policy. With respect to the phosphorus, CBOD, and ammonia limits, the Spokane River and Lake Spokane are 303(d)-listed for DO in the State of Washington. Washington's antidegradation policy states that "for waters that do not meet assigned criteria, or protect existing or designated uses, the department will take appropriate and definitive steps to bring the water quality back into compliance with the water quality standards." As explained in Appendix B to the fact sheets, the subject permits' final effluent limits for TP, $CBOD_5$, and ammonia ensure compliance with Washington's water quality criteria for DO on a cumulative basis.

Other Comments

Comment #2-59

Mr. Dennis Hinrichsen stated that he is troubled that "only cities are being required to meet these standards," and asked why there is "no mandate for near lake developments like Arrow Point who allegedly spilled 20,000 gallons of untreated sewage."

Response #2-59

Alleged previous noncompliance with the Clean Water Act or similar state laws by entities other than those receiving permits cannot affect the permits in question.

Arrow Point Resort (on the east side of Lake Coeur d'Alene) is now connected to the Gozzer Ranch Development/Golf Course's wastewater treatment and disposal system. Arrow Point was formerly on a community drain field. The new system utilizes a membrane bioreactor (MBR) to produce high-quality (Class A) effluent that is seasonally stored in golf course ponds and then used to irrigate the golf course during the growing season.

Comment #2-60

Mr. Gerry House stated that "the water quality in Hayden Lake continues to deteriorate because elected officials and agencies are unable to enforce storm water, site disturbance ordinances….Yet, we seem to focus most of our interest on sewer and sewage treatment plants."

Response #2-60

The subject permits authorize POTWs to discharge treated wastewater to the Spokane River. The Spokane River does not drain to Hayden Lake, and the subject discharges do not affect water quality in Hayden Lake. Water quality problems in Hayden Lake are not relevant to the subject permits.

Comment #2-61

Mr. Clyde Sheppard of the Spokane River Property Owners' Association stated that "we believe the current monitoring by DEQ of all the waste water treatment facilities of one visit per year is not satisfactory."

Response #2-61

The commenter was referring to inspections conducted by Idaho DEQ. The NPDES program is a self-monitoring program. The permits require the dischargers to conduct routine self-monitoring of the discharges and to report the results of this monitoring on a monthly basis to allow EPA and citizens to determine whether the effluent limits and other conditions in the permits are being met. The permits also require the permittees to report all instances of noncompliance with the permits. Inspections may reveal some violations that would not be detected in monitoring reports, but discharges causing water quality violations will show up in the monitoring. The frequency with which a facility is inspected by DEQ or EPA is a separate issue from the reissuance of the permits.

Comment #2-62

Mr. Jim Hollingsworth stated that, although the fact sheets state that the permits protect human health, there is nothing in the draft permits that indicate that human health is at risk and that the only thing that may be affected by the discharge are fish at the lower end of Lake Spokane.

Response #2-62

NPDES permits must contain effluent limits necessary to meet water quality standards. Water quality standards are established in part to protect human health, but also to protect other beneficial uses of the waters such as the growth and propagation of fish, aquatic life and wildlife, aesthetics, and water supply for industry or agriculture. Waters are generally protected for multiple beneficial uses, each of which has water quality criteria that are necessary to support those uses.

For some pollutants, the criteria necessary to support aquatic life uses are more stringent than those necessary to protect human health, e.g., DO, temperature, and certain metals. For other pollutants, the human health criteria are more stringent. For example, the effluent limits for *E. coli* bacteria are based on water quality criteria that protect swimmers from illness, and the monitoring and best management practices for PCBs are intended to reduce the concentration of PCBs in fish tissue, which will minimize the risk of cancer for people who eat fish caught from the Spokane River.

The CWA and NPDES regulations require the TP limits in the subject permits in order to achieve water quality criteria to protect fish and other aquatic life. But human health may also be at risk because of the excess nutrient loading to Lake Spokane. The excess nutrient loading to Lake Spokane has resulted in blue-green algae blooms in the lake (Cusimano 2004). Blue-green algae can be highly toxic to humans, wildlife, and livestock. The toxins in certain kinds of blue-green algae can attack the liver or the nervous system and can cause death in as little as 30 minutes. Blue-green algae are unsightly, so adults are unlikely to drink water contaminated with blue-green algae, but wildlife, livestock, and children may drink not reject contaminated water and could therefore suffer illness or death as a result of the contamination. The toxins in blue-green algae are not removed by boiling the water. Swimming in water contaminated with blue-green algae (even without ingesting any of the water) can cause skin and eye irritation (British Columbia Ministry of Health 2012). Reducing levels of nutrients to the level necessary to meet DO criteria (for aquatic life) will also address the risks to humans, livestock, and wildlife from the algae problem.

Comment #2-63

CFJ stated that the Spokane Tribe of Indians is an "affected State," thus, EPA is required to evaluate the impacts of the Idaho dischargers upon waters of the Spokane Tribe of Indians.

Response #2-63

In developing the draft permits, the EPA did not specifically evaluate the effects of the subject permits upon waters of the Spokane Tribe of Indians. The EPA evaluated the effects of the subject permits as far downstream as the Long Lake Dam, which is at river mile 33.9 on the Spokane River. The permits include conditions that ensure compliance with the water quality standards of the states of Idaho and Washington in Lake Spokane and in the Spokane River upstream from Lake Spokane. Due to additional dilution and continued decay of non-conservative pollutants at points downstream of the Long Lake Dam, the subject discharges will have a lesser impact upon water quality in waters of the Spokane Tribe of Indians than in Lake Spokane and in the Spokane River upstream from Lake Spokane.

The following toxic pollutants have been detected in the effluents of at least one of the subject POTWs:

- Ammonia
- Butylbenzyl Phthalate
- Cadmium
- Chlorine
- Chloroform
- Copper
- Diethyl Phthalate
- Di-N-Butyl Phthalate
- Lead
- Nitrate + Nitrite
- Phenol
- Silver
- Zinc

Idaho's water quality criteria for ammonia, cadmium, chlorine, lead, nitrate + nitrite[17], and silver are at least as stringent as the Spokane Tribe's water quality criteria for these pollutants. Since the permits are conditioned to ensure compliance with Idaho's water quality criteria for these pollutants, they will also ensure compliance with the Spokane Tribe's water quality criteria for these pollutants.

The Spokane Tribe's aquatic life criteria for zinc are more stringent than Idaho's water quality criteria, but are identical to Washington's aquatic life criteria for zinc. As explained in the 2007 fact sheets, the subject POTWs do not have the reasonable potential to cause or contribute to excursions above Washington's water quality criteria for zinc. Thus, the subject POTWs do not have the reasonable

[17] Idaho does not have numeric criteria for nitrate + nitrite, but for the purpose of developing the subject draft permits, the EPA interpreted Idaho's narrative criterion for toxic pollutants using the EPA's recommended criterion of 10 mg/L, which is identical to the Tribe's criterion for primary contact ceremonial and spiritual uses.

potential to cause or contribute to excursions above the Spokane Tribe's aquatic life water quality criteria for zinc. The Spokane Tribe also has human health water quality criteria for zinc that are more stringent than those of Idaho or Washington. However, in all cases, the effluent limits for zinc in the subject permits require lower effluent concentrations of zinc than the Tribe's human health zinc criterion for consumption of water and organisms (470 µg/L).

Butylbenzyl phthalate, diethyl phthalate, di-n-butyl phthalate (or dibutyl phthalate), and phenol were detected in the effluent from Post Falls but not Coeur d'Alene or HARSB. Table 31, below, shows the maximum projected receiving water concentrations of these pollutants from Table 2 on Page D-6 of the 2013 Post Falls fact sheet, as well as the most stringent criterion for these pollutants in the Spokane Tribe's water quality standards. The maximum projected receiving water concentrations are calculated based on the mixing zones authorized by Idaho under critical conditions for river flow, effluent flow, and effluent concentration. These pollutants will be further diluted by the time the Spokane River reaches waters of the Spokane Tribe. In all cases, the maximum projected receiving water concentrations are less than the Spokane Tribe's water quality criteria. Therefore, the Post Falls discharge does not have the reasonable potential to cause or contribute to excursions above the Spokane Tribe's water quality criterion for butylbenzyl phthalate, diethyl phthalate, di-n-butyl phthalate (or dibutyl phthalate), or phenol, even though the Spokane Tribe's criteria for these pollutants are more stringent than Idaho's criteria.

Table 31: Comparison of Maximum Projected Receiving Water Concentrations in Post Falls Reasonable Potential Analysis to Spokane Tribe WQS for Phthalates and Phenol

Pollutant	Maximum Projected Receiving Water Concentration in RPA (µg/L)	Most Stringent Spokane Tribe Criterion (µg/L)
Butylbenzyl phthalate	1.08	38.7
Diethyl phalate	1.08	834
Di-n-butyl phthalate	1.23	86.4
Phenol	6.92	8,060

Chloroform was detected in the effluent from HARSB, but not Coeur d'Alene or Post Falls. In the reasonable potential analysis for HARSB, the maximum projected receiving water concentration of chloroform was 0.22 µg/L (see the 2013 HARSB fact sheet at Page D-5). This is less than the Spokane Tribe's criterion of 1.58 µg/L. Therefore, the HARSB discharge does not have the reasonable potential to cause or contribute to excursions above the Spokane Tribe's water quality criterion for chloroform, even though the Spokane Tribe's criterion is more stringent than Idaho's criterion.

The Spokane Tribe's water quality criteria for copper are more stringent than Idaho's criteria. However, in all cases, the maximum projected receiving water concentrations of copper in the reasonable potential analyses are less than the Tribe's chronic water quality criterion for copper for protection of aquatic life, which is the most stringent copper criterion in the Spokane Tribe's water quality standards. The maximum projected receiving water concentrations are calculated based on the mixing zones authorized by Idaho, under critical conditions for river flow, effluent flow, and effluent concentration. The copper in the subject effluents will be further diluted by the time the Spokane River reaches waters of the Spokane Tribe.

Table 32: Comparison of Maximum Projected Receiving Water Concentrations in Reasonable Potential Analyses to Spokane Tribe WQS for Copper		
POTW	Maximum Projected Receiving Water Concentration in RPA (µg/L)	Spokane Tribe Chronic aquatic life criterion (µg/L)[1]
Coeur d'Alene	0.96	3.05
Post Falls	1.55	
HARSB	0.86	

Notes:
1. The Spokane Tribe's aquatic life water quality criteria for copper are based on the hardness of the receiving water. The chronic criterion listed was calculated at a hardness of 28.4 µg/L, which is the 5th percentile hardness measured at USGS station number 12433000 (Spokane River at Long Lake, WA) from 1998 to 2003. These were the most recent hardness data available at this station.

With respect to nutrients and oxygen-demanding pollution, the effects of upstream nutrients and oxygen-demanding pollution upon the Spokane Arm of Lake Roosevelt are discussed in the *Lake Roosevelt/Spokane River Arm Modeling Project* (Cadmus Group and Scott Wells and Associates 2009). Two of the modeling scenarios described in this report are relevant to the question of whether the subject dischargers significantly impact DO in waters of the Spokane Tribe: scenario 1, which used the draft Spokane River TMDL's modeling predictions as upstream boundary conditions, and set DO concentrations in the Long Lake Dam outflow to 8 mg/L, which is the Spokane Tribe's water quality criterion for the Spokane River, if they were below 8 mg/L, and scenario 3, which used "no source" (i.e. natural conditions) modeling predictions as upstream boundary conditions, and set DO concentrations in the Long Lake Dam outflow to 8 mg/L if they were below 8 mg/L. Thus, the difference between scenarios 1 and 3 represents the effect of anthropogenic sources of nutrients and oxygen-demanding pollution as allocated in the draft TMDL. As explained in Appendix B, the TP, ammonia, and CBOD limits in the subject permits are somewhat different from those assumed in the TMDL modeling, but they have an equivalent impact upon DO in Lake Spokane. As shown in Tables 30 and 31, of the *Lake Roosevelt/Spokane River Arm Modeling Project*, the difference between the average DO concentrations from Scenarios 1 and 3 is 0.13 mg/L for January 1st through October 29th and 0.2 mg/L for July 1st through September 30th. The difference between the average TP concentration between Scenarios 1 and 3 is 3 µg/L for both January 1st through October 29th and July 1st through September 30th. A change of 0.2 mg/L is within the monitoring measurement error for recording instruments typically used to monitor DO (see the enclosure to the letter dated February 11, 2008 approving Washington's water quality standards, from Michael F. Gearheard, EPA Region 10, to Dave Peeler, Washington State Department of Ecology). The subject dischargers represent a small fraction of the total anthropogenic loading of nutrients and oxygen-demanding pollution to Lake Spokane. The DO and TP impacts of the subject POTWs upon waters of the Spokane Tribe, which are just downstream from Lake Spokane and thus subject to additional dilution and continued decay of non-conservative pollutants, will be negligible.

With respect to PCBs, as explained in the response to comment #1-1, the EPA does not have the necessary data to perform a reasonable potential analysis using facility-specific effluent data, as described in Section 3.3 of the TSD. Therefore, a reasonable potential analysis was conducted without facility specific effluent data, as described in Section 3.2 of the TSD. That analysis did not result in a

finding of reasonable potential for PCBs. Therefore, the EPA has not established effluent limits for PCBs in the subject permits.

Comment #2-64

CFJ states that EPA needs to better explain which water quality based effluent limits are based on mixing zones, and the EPA should describe the size of the mixing zones.

Response #2-64

A mixing zone is "an area where an effluent discharge undergoes initial dilution and is extended to cover the secondary mixing in the ambient waterbody. A mixing zone is an allocated impact zone where water quality criteria can be exceeded as long as acutely toxic conditions are prevented" (EPA 2010 at page A-10).

This comment was addressed by the revised fact sheets that were issued with the revised draft permits in 2013. Idaho's draft CWA Section 401 certifications, dated June 25, 2013, which were included in the 2013 fact sheets as Appendix H, identified the pollutants for which mixing zones are authorized and the sizes of the mixing zones in terms of the percentages of the critical low flow volumes allowed for mixing. In Table D-1, in Appendix D to the 2013 fact sheets, the EPA listed the dilution factors afforded by the authorized mixing zones. The mixing zone sizes and dilution factors are also listed in the reasonable potential and effluent limit calculation tables in Appendices D and E of the fact sheets.

In some cases, effluent limits based on the anti-backsliding provisions of the Clean Water Act or upon Washington water quality standards were more stringent than the limits that would have resulted from the application of Idaho water quality criteria at the edge of the authorized mixing zones. In those cases, in Appendix C to the 2013 fact sheet, the EPA identified anti-backsliding or the requirement to meet the water quality requirements of all affected States (40 CFR 122.4(d)) as the bases for the limits. In those cases, as a practical matter, less dilution than authorized by Idaho in its draft CWA Section 401 certification is necessary to meet Idaho's water quality criteria.

Subject: RE: Environmental Justice

Hi Ken,

Sorry for the delay in responding, its been a busy week. Here are my responses to your questions. Let me know if you'd like to discuss further. Thanks.

1) does EPA read into 40 CFR 131.11 and .21 that there must be a stand-alone EJ review, or does it implicitly occur in the judgment on whether criteria will allow designated uses to be protected?

EPA must ensure that the human health water quality criteria that Washington adopts are protective of applicable designated uses and based on a sound scientific rationale, consistent with 40 CFR § 131.11(a) and .21. EPA does not read these requirements to necessitate the development of a stand-alone EJ analysis in the context of reviewing water quality standards and taking approval or disapproval actions under the Clean Water Act. Consistent with Executive Order 12898, EPA incorporates environmental justice considerations into its decision-making, and has the discretion to complete a stand-alone EJ review for an Agency action.

2) which of the documents listed below offer the current/relevant EPA thinking on how to make whatever EJ assessment is needed?

I recommend that you review the Executive Order 12898 (http://www.epa.gov/environmentaljustice/resources/policy/exec_order_12898.pdf); and EPA's December 2011 EJ Legal Tools document (http://www.epa.gov/compliance/ej/plan-ej/law.html). Section 4-4 of Executive Order 12898 addresses fish consumption and states that the federal agency shall: 1) collect, maintain, and analyze information on subsistence consumption and communicate information to the public; and 2) publish guidance on human health risks related to consumption of pollutant bearing fish and consider the guidance in developing policies and rules. The December 2011 EJ Legal Tools document has a discussion on water quality criteria guidance and water quality standards on pages 24-29.

UNITED STATES DISTRICT COURT
FOR THE WESTERN DISTRICT OF WASHINGTON
AT SEATTLE

SIERRA CLUB; and CENTER FOR ENVIRONMENTAL LAW AND POLICY, Plaintiffs, and THE SPOKANE TRIBE OF INDIANS, Plaintiff-Intervenor v. DENNIS McLERRAN; GINA MCCARTHY and U.S. ENVIRONMENTAL PROTECTION AGENCY, Defendants. and SPOKANE COUNTY; KAISER ALUMINUM OF WASHINGTON LLC; and STATE OF WASHINGTON DEPARTMENT OF ECOLOGY, Defendant-Intervenors.	No. 2:11-cv-01759-RSL EPA'S CONSOLIDATED BRIEF (A) IN SUPPORT OF ITS CROSS-MOTION FOR SUMMARY JUDGMENT AND (B) IN OPPOSITION TO PLAINTIFFS' AND INTERVENOR-PLAINTIFF TRIBE OF SPOKANE INDIANS' RESPECTIVE MOTIONS FOR SUMMARY JUDGMENT Filed pursuant to order on briefing schedule Oral Argument Requested

TABLE OF CONTENTS

INTRODUCTION AND SUMMARY

Defendants United States Environmental Protection Agency, et al., (collectively "EPA"), oppose Plaintiffs' and Intervenor Spokane Tribe of Indians' motions for summary judgment and cross-move for summary judgment in EPA's favor.

The Washington State Department of Ecology ("Ecology") has a robust program establishing total maximum daily loads ("TMDLs") throughout Washington State. Over the past fifteen years, Ecology has established hundreds of TMDLs, and it is continuing to develop others for waterbody segments that do not meet water quality standards, including many within the Spokane River Basin. Notwithstanding such ongoing TMDL work, because many TMDLs remain to be completed, Ecology has had to make necessarily difficult choices regarding the priority and timing of which TMDLs will be developed before others, how to allocate limited resources among competing environmental demands, and the establishment of interim, supplemental steps to reduce pollution until required TMDLs are completed. Among its many prioritization decisions, Ecology determined that a TMDL for polychlorinated biphenyls ("PCBs") for the Spokane River should be a lower priority, primarily due to the lack of critical information and analysis, and that Ecology will devote its efforts and resources in the interim to reduce PCBs in the River through a Task Force created for this purpose comprised of State and local agencies, dischargers of pollutants, and environmental groups created for this purpose. If these or other supplemental measures are not enough for the Spokane River to attain applicable PCB standards, Ecology has committed to develop a Spokane River PCB TMDL. Based upon EPA's review of Ecology's plans and the rest of the record in this case, EPA reasonably concluded that Ecology has not renounced its obligation to develop and establish a Spokane River PCB TMDL and that the absence of such a State-submitted TMDL at this time does not constitute Ecology having constructively submitted "no" PCB TMDL (i.e., a State determination that none will be needed). Accordingly, the Clean Water Act ("CWA") does not require that EPA approve or disapprove such a constructive submission.

Plaintiffs and the Spokane Tribe invoke the constructive submission theory in an effort to

circumvent and undermine this and other ongoing State decisions as to how best to protect the environment. By demanding a PCB TMDL for the Spokane River, which Plaintiffs and the Tribe believe should be prioritized before all other TMDLs and other State efforts to reduce pollution, and by seeking a court order that EPA establish that particular TMDL, Plaintiffs and the Tribe ask the Court to usurp Ecology's role and substitute their own priorities for the State's reasonable pollution prevention and remediation plans. Plaintiffs and Intervenor are understandably focused on concerns posed by PCBs in the Spokane River. There are, however, other, ongoing efforts to reduce PCBs and other pollutants in the Spokane River and in numerous other impaired water-bodies throughout the State that also require the attention of limited State and federal resources.

Section I.A below demonstrates that as a matter of law the constructive submission theory is not applicable where, as here, parties seek to compel the establishment of one particular TMDL above all others, and that such claims must therefore be dismissed and summary judgment entered for EPA. Section I.B explains that Plaintiffs have waived their right to challenge EPA's administrative finding that there has been no constructive submission, because they elected not to brief that Administrative Procedure Act challenge in their summary judgment motion. Section I.C demonstrates that EPA reasonably concluded that Ecology has not disavowed establishing a PCB TMDL for the Spokane River, that Ecology has a reasonable plan for reducing PCBs in the Spokane River and obtaining needed information, and that Ecology remains committed to developing a TMDL if necessary. Ecology, therefore, has not made a constructive submission, and thus EPA has no duty to approve or disapprove such a submission. Section II responds to the arguments proffered by Intervenor Spokane Tribe. Finally, Section III demonstrates that even if there is a constructive submission, Plaintiffs and the Tribe are not entitled to the relief they seek.

BACKGROUND

I. STATUTORY AND REGULATORY BACKGROUND

The Clean Water Act establishes a comprehensive program "to restore and maintain the chemical, physical, and biological integrity of the Nation's waters" through the reduction and eventual elimination of the discharge of pollutants into those waters. 33 U.S.C. § 1251(a). States

are primarily responsible for achieving these goals. *Id.* § 1251(b); *Chevron U.S.A. v. Hammond*, 726 F.2d 483, 489 (9th Cir. 1984) ("[T]he states maintain primary responsibility for abating pollution in their jurisdictions."); *District of Columbia v. Schramm*, 631 F.2d 854, 860 (D.C. Cir. 1980) (the CWA "scheme . . . impose[s] major responsibility for control of pollution on the states"). State lists of water quality limited segments ("WQLS") within their boundaries ("Section 303(d) lists") and Total Maximum Daily Loads ("TMDLs") are but one part of the complex water pollution control regime created by the CWA.

A. The NPDES Permit Program

The CWA's central regulatory features are established by the National Pollutant Discharge Elimination System ("NPDES") permit program. 33 U.S.C. § 1342(a)(1); 40 C.F.R. §122.44(a), (d)(1). Pollutant discharges from point sources[1]/ into waters of the United States are prohibited unless in compliance with specified sections of the CWA. 33 U.S.C. § 1311(a). If the conditions of a permit are violated, they may be enforced by the United States, or any interested person, including a State. *Id.* § 1319. Forty-six States, including Washington, are authorized to administer NPDES permit programs under their State laws and regulations, though EPA retains an oversight role. *Id.* § 1342(b). In the remaining States, EPA issues the permits. *Id.* § 1342(a). EPA first approved Washington's NPDES permitting program in 1973. 54 Fed. Reg. 40517 (Oct. 2, 1989).

NPDES permits control water pollution from point sources by means of two different overarching strategies. The first approach, the "technology-based" approach, reduces pollution by requiring dischargers to achieve specified restrictions on the quantities, rates, and concentrations (known as "effluent limitations") based on specific process-based controls. 33 U.S.C. §§ 1311, 1314, 1316-17, 1363(11). The CWA requires EPA to develop and promulgate national technology-based regulations establishing minimum levels of wastewater treatment for categories of industrial sources. *Rybachek v. EPA*, 904 F.2d 1276, 1283 (9th Cir. 1990). During the 1970s

---

[1]/ A "point source" is defined as "any discernible, confined and discrete conveyance ... from which pollutants are or may be discharged." *Id.* § 1362(14) (*e.g.*, industrial, commercial and municipal discharges). This statutory definition excludes "agricultural stormwater discharges and return flows from irrigated agriculture." *Id.* § 1362(14). The term "nonpoint source" commonly refers to any source of water pollution that is not a point source and is typically associated with diffuse sources and rural areas.

and 1980s, EPA gave priority to developing the new technology-based regulations, which EPA and the states implemented through the new NPDES permit program. Because of the magnitude and scope of the national water pollution control task, and consistent with stated Congressional intent, EPA and the States dedicated implementation resources to developing these technology-based controls and basic programs, deferring action on the next level of controls based on water quality standards. *See* 1A *Leg. History of the Water Pollution Control Act Amendments of 1972* (Comm. Print 1973), at 171. Accordingly, EPA has issued technology-based regulations for more than 50 major categories of industrial dischargers. 40 C.F.R. Pts. 405-471. After establishment of NPDES permitting programs, including technology-based controls, regulatory efforts focused on the difficult task of determining the desired water quality for each waterbody and establishing effluent limits based upon such standards.

B. Water-Quality-Based Controls

The CWA is designed to ensure that water quality standards would be attained even if technology-based controls were insufficient to do so. CWA § 303 directs the States, with federal approval and oversight, to adopt water quality standards for each particular waterbody or waterbody segment within their boundaries. 33 U.S.C. § 1313(a), (b) & (c)(1). Water quality standards identify (1) the "designated uses" for each waterbody (e.g., public water supply, propagation of fish, and/or recreational uses) and (2) the "water quality criteria" expressed as levels (e.g., concentrations and/or conditions) that must not be exceeded in order for the waterbody to support those uses (e.g., oxygen concentrations necessary for healthy fish). *Id.* § 1313(c)(2). EPA either approves a State's proposed water quality standards or, if it disapproves, proposes and promulgates standards for the State. *Id.* § 1313(c)(3).

After adoption and approval of water quality standards, CWA section 303(d) directs the States to identify and prioritize the impaired or threatened waters within their borders, known as water-quality-limited segments ("WQLSs"). *Id.* § 1313(d)(1)(A) & (B); 40 C.F.R. § 130.7(b)(1). States are then to develop plans, known as total maximum daily loads ("TMDLs") for pollutants in those WQLSs. 33 U.S.C. § 1313(d).

CWA § 303(d)(2) requires that each State submit "from time to time" its list of WQLSs. *Id.* § 1313(d)(2). EPA's regulations specify that the States submit their lists of WQLSs (the "Section 303(d) list") to EPA on a biennial basis. 40 C.F.R. § 130.7(d). EPA must approve or disapprove Section 303(d) lists within 30 days after submission. 33 U.S.C. § 1313(d)(2). If EPA disapproves, it must identify the WQLSs to be added within 30 days from the date of disapproval. *Id*. Although States submit their priority rankings of WQLSs for TMDL development with their Section 303(d) lists, EPA does not approve or disapprove the substance of these rankings. *Id.* Moreover, if a WQLS on a 303(d) list subsequently achieves the water quality standard for which it is impaired, it may be removed from the next Section 303(d) list and thus a TMDL is no longer required. 40 C.F.R. §§ 131.7(b)(1) & 130.2(j).

States are required to establish a priority ranking for TMDL development for WQLSs included on the Section 303(d) list. 33 U.S.C. § 1313(d)(1)(A). In establishing priority ranking, States must consider the severity of the pollution and the uses of the listed waterbody. *Id.* § 1313(d)(1)(A). Beyond these two statutory factors, States retain considerable discretion and may consider other factors, including: vulnerability of particular waters; recreational, economic, and aesthetic importance of particular waters; restoration potential; degree of public interest and support; State or national policies and priorities; technical considerations, such as the complexity of the impairment; availability of adequate data and models; and implementation of watershed-based permitting programs or basin planning cycles. *See* V.1, T.47 at 971-72; V.1, T.19 at 242.[2]/

States identify those WQLSs targeted for TMDL development in the next two years. 40 C.F.R § 130.7(b)(4) & (d)(1). States have discretion in selecting higher and lower ranked waters for TMDL development based on the numerous factors described above.

TMDL development requires States to identify the maximum amount of pollutant

---

[2]/ The administrative record for judicial review in this case was filed on April 22, 2013, in paper form, in five binders (or volumes), as well on a compact disc. Dkt. No. 60. References in this brief to that record are to the volume and document number (or tab), cited as "V._, T._, at __." Page numbers are to the bate-stamped number, except as indicated. Documents supplementing the Court's review were filed September 17, 2013, Dkt. 79, and are bate-stamped beginning with "Supp." Some exhibits to Plaintiffs' brief attach only selected pages from the record, with Plaintiffs' underlining that is not in the record.

"loading", *i.e.*, quantity of a particular pollutant that the WQLS can receive from all combined sources and still meet the relevant water quality standard for a pollutant. 33 U.S.C. § 1313(d)(1)(C); 40 C.F.R. § 130.2(e). Each TMDL must, among other things: (1) be designed to meet water quality standards; (2) include, as appropriate, both wasteload allocations from point sources and load allocations from non-point sources; (3) consider the impacts of background pollutant contributions; (4) consider seasonal variations; (5) include a margin of safety; and (6) be subject to public participation. *Id.* §§ 130.7, 130.7(c)(1), 130.2(g)-(i). Developing a TMDL often requires a significant amount of work, and may take years once initiated depending, among other things, upon the information and studies required. Once a State submits a TMDL to EPA, the CWA requires that EPA approve or disapprove that TMDL within 30 days of its submittal by the State, and if EPA disapproves a particular TMDL, EPA must establish a federal TMDL for the WQLS within 30 days of the Agency's disapproval. 33 U.S.C. § 1313(d)(2).

The CWA does not requires States to develop and submit TMDLs to EPA on any particular schedule, requiring instead that States submit TMDLs to EPA "from time to time." *Id.* § 1313(d)(2). In 1997 Guidance, EPA recommended that States normally plan to establish TMDLs for all WQLSs on their 1998 Section 303(d) lists and subsequent lists within eight to thirteen years of initial listing, but recognized that shorter or longer times may be needed depending on State-specific factors.[3]/ These factors may include: number of impaired segments; length of river miles, lakes or other bodies for which TMDLs are needed; proximity of list waters to each other within a watershed; number and relative complexity of TMDLs; number and similarities or differences among the source categories to be allocated; availability of monitoring data or models; and relative significance of the environmental harm or threat. *Id*.

Importantly, TMDLs function primarily as planning devices and are not self-executing. *Pronsolino v. Nastri*, 291 F.3d 1123, 1129 (9th Cir. 2002). A TMDL does not, by itself, prohibit any conduct or require any actions. Instead, each TMDL represents a goal that may be

---

[3]/ *See* http://water.epa.gov/lawsregs/lawsguidance/cwa/tmdl/upload/2003_10_21_tmdl_ratepace 1997guid.pdf (at p.3). Though not part of the administrative record in this case, the Court may take judicial notice of this document for the purpose for which it is introduced.

implemented by adjusting pollutant discharge requirements in individual NPDES permits and/or by establishing nonpoint source controls. *Sierra Club v. Meiburg*, 296 F.3d 1021, 1025 (11th Cir. 2002). Thus, TMDLs form the basis for further State actions that may require or prohibit conduct with respect to particularized pollutant discharges. Regardless of whether a TMDL has been established, States must include effluent limits as stringent as necessary to meet water quality standards in NPDES permits. 33 U.S.C. § 1311(b)(1)(C); 40 C.F.R. § 122.44(d)(1)(vii)(A).

Where a TMDL has been established for a WQLS, the TMDL may provide allocation information for individual NPDES permits for point sources and/or establish goals for non-point source controls. The absence of TMDLs does not prevent NPDES permitting authorities from otherwise assuring that point source discharges do not cause or contribute to exceedances of water quality standards. *See* 43 Fed. Reg. 60,662, 60,665 (Dec. 28, 1978). EPA guidance to permitting agencies explains how to derive water-quality-based permit limits, both prior to establishment of a TMDL and consistent with any applicable TMDL once established.[4/] Where a TMDL has not been established, EPA's guidance recommends that the permit writer establish as part of the process to develop a specific NPDES permit, a facility-specific allocation, sometimes referred to in this context as a discharge-specific concentration allowance. Manual at 6-31--6-35. In this process, the more current and reliable the underlying information, the more effective and defensible the allocation. *See id.* at 6-30--6-31. Where numeric effluent limitations are infeasible to calculate, NPDES permits may include best management practices. 40 C.F.R. § 122.44(k)(3).

C. The Constructive Submission Theory

The CWA requires that EPA approve or disapprove a TMDL within 30 days of its submittal by the State, and if EPA disapproves, EPA must establish a federal TMDL for the WQLS at issue within 30 days of disapproval. 33 U.S.C. § 1313(d)(2). On its face, however, the CWA imposes no duty for EPA to establish TMDLs if a State fails to establish and submit them to

---

[4/] [NPDES] Permit Writers' Manual, EPA-833-K-10-001 (2010) ("Manual"), Ch. 6, 6-30–6-35 (available at: http://cfpub.epa.gov/npdes/writermanual.cfm?program_id=45). Though not part of the administrative record in this case, the Court may take judicial notice of this document for the purpose for which it is introduced.

EPA. In the past, many States were not able to develop any TMDLs while implementing technology-based approaches to address water pollution. Because a State's refusal to submit any TMDLs over a prolonged period of time could frustrate the TMDL program, some courts adopted what came to be known as the "constructive submission" theory. The theory holds that the prolonged failure by a State to submit *any* TMDLs may constitute the "constructive" submission of no TMDLs (*i.e.*, that none are necessary), which submission EPA must approve or disapprove. *San Francisco Baykeeper v. Whitman*, 297 F.3d 877, 881 (9th Cir. 2002). If EPA disapproves such a constructive submission, this triggers the requirement that EPA establish TMDLs for the State.

D. Judicial Review Under the Clean Water Act

The CWA jurisdictional scheme restricts the types of claims that can be brought against EPA. The citizen suit provision allows suits to be brought in district court against the "the Administrator [of EPA] where there is alleged a failure of the Administrator to perform any act or duty under this chapter which is not discretionary with the Administrator." 33 U.S.C. § 1365(a)(2). Such citizen suit claims are available only where Congress has imposed a clear-cut, mandatory duty for EPA to act in the statute. *Infra* at 26, n.12. The reasonableness of the content of EPA's action or prospective action, however, cannot be dictated or reviewed by the Court under the citizen suit provision. *Scott v. City of Hammond, Ind.*, 741 F.2d 992, 995 (7th Cir. 1984).

In contrast, content-based review of certain EPA final actions, not at issue here, is available under the CWA exclusively in the U.S. Courts of Appeal. 33 U.S.C. § 1259(b)(1). Review of other "final agency actions" not covered by that Section is based upon the Administrative Procedure Act, in federal district court, under the APA's arbitrary, capricious or not in accordance with law standard of review. 5 U.S.C. § 706(2)(A).

NPDES permit decisions by Ecology are reviewed in the appropriate State tribunals.

II. FACTUAL BACKGROUND

A. The Development of Washington's Section 303(d) Program

Ecology's first Section 303(d) list was prepared in 1992. The 1996 Section 303(d) list had

666 WQLS listed. Ecology subsequently submitted, and EPA approved, 303(d) lists in 1998, 2004, 2008, and 2010. See V.1, T.16 & 21; V.2, D.40. As Ecology has continued to monitor the numerous waterbody segments throughout Washington, it has added additional WQLS to its 303(d) lists. Ecology's 2010 303(d) list, which EPA approved on December 21 2012, contains 4009 WQLSs for TMDL development. V.2, D.40 at 672..

In 1998, after two environmental groups filed a lawsuit in this Court, EPA entered into an out-of-court settlement agreement by which Ecology would complete a large number of TMDLs by December 31, 2013. The agreement provides that EPA would complete the TMDLs, if Ecology failed to do so. V.1, D.32 at 446-447. Ecology has since devoted significant resources to TMDL development. Since 1999, Ecology has completed 1372 TMDLs. V.1, T.A, at 1 n.1; V.1, D.16 at 220. Ecology is currently working on the development of TMDLs in 23 sub-watersheds throughout the State for numerous pollutants, including temperature, dissolved oxygen, bacteria, and pH. The Administrative Record in this case amply documents Ecology's TMDL output and its continued commitment to develop TMDLs. *E.g.*, V.1, T.A, 3, 5, 6, 8-14, 16-17 & 19-29.

Four segments of the Spokane River and one tributary (called the Little Spokane River) were first listed for PCBs on its 1996 Section 303(d) list. Dkt. 79, at Supp. 2710 & 2732. Over the years, as Ecology continued to gather information, the numbers of segments and parameters for the Spokane watershed continued to increase. There are currently 15 waterbody segments of the Spokane exceeding standards for PCBs. V.1, D.15 at 80. Ecology spent over 12 years completing work on dissolved oxygen TMDLs that addressed elevated levels of phosphorus, ammonia and CBOD (carbonaceous biochemical oxygen demand) in the Spokane River. V.1, D.4 at 503. EPA approved these nine Spokane River and Lake Spokane Dissolved Oxygen TMDLs in May 2010. V.1, D.17 at 000224. Ecology also developed 23 TMDLs for waters impaired by temperature, bacteria and turbidity in a major tributary to the Spokane River, Hangman (Latah) Creek. EPA approved these TMDLs in September 2009. *Id.* at 222-23. Ecology also developed 36 TMDLs for waters impaired by temperature, bacteria and turbidity in the Little Spokane River. EPA approved

these TMDLs in April, 2012.[5]/ In 1999, Ecology developed, and EPA approved, five TMDLs for cadmium, lead, and zinc in the Spokane watershed. *See* V.1, T.15 at 82. Ecology is currently working on an additional TMDL to address the dissolved oxygen and pH impairments on the Little Spokane River. Even with these TMDLs, the Spokane watershed remains impaired for temperature, fecal coliform, and dioxin, as well as PCBs.

B. Ecology's Preliminary Work on a PCB TMDL for the Spokane River

1. The Nature of PCB Pollution

PCBs were first produced for commercial use in 1929 and have been used for hundreds of purposes. Production continued until a 1979 ban on all PCB manufacturing, processing, and distribution due to evidence that PCBs build up in the environment and concerns about possible human carcinogenicity. V.1, T.15 at 91. PCBs are released into the environment through improper disposal or leakage. *Id.* Even after their release, PCBs do not break down readily in the environment and can bioaccumulate. *Id.* at 92. Many of the same properties that made PCBs commercially desirable - their stability and resistance to degradation - make them extremely persistent in the environment. *Id.* at 92. Thus, in important respects, PCBs are a legacy pollutant.

Washington State's water quality standards include a human health criterion for PCBs at 170 picograms per liter ("pg/l"). V.1, T.15 at 83-84. When this lawsuit was filed, the Spokane Tribe water quality standard included a PCB human health criterion set at 3.37 pg/l. *Id.* at 83.[6]/ Based on elevated levels of PCBs and other pollutants in Spokane River fish, the Washington Department of Health and the Spokane Regional Health District issued an advisory in 2003, updated in 2008, to avoid or limit consumption of fish in parts of the Spokane River. *Id.* at 97.

Though PCBs can pose significant environmental concerns, they are one of many pollutants that demand attention within Washington's waterways. As discussed above, numerous

---

[5]/ *See* http://www.ecy.wa.gov/programs/wq/tmdl/littlespokane/ (EPA's April 2012 approval is available by clicking the link in next to last paragraph of this page). Though not part of the record in this case, the Court may take judicial notice of this document for the purpose for which it is introduced.

[6]/ EPA recently approved, on December 19, 2013, a revised Tribal criterion set at 1.3 pg/l.

WQLSs continue to require attention, and Ecology continues to prioritize this task consistent with its assessment of the environmental benefits that would be realized and the resources available.

2. Ecology's Efforts to Obtain Information Necessary for a Spokane River PCB TMDL

While devoting significant resources to investigations supporting TMDL development for numerous WQLSs on its 303(d) lists, Ecology also conducted preliminary investigations into PCBs and the Spokane River. For example, Ecology's environmental assessment program identified numerous ongoing projects to which it intended to commit resources in Fiscal Year 2003, including TMDL development. V.5, T.105. Among many TMDL projects, Ecology explained that it was initiating certain preliminary work for potential use in developing a PCB TMDL in the Spokane River, pertaining to the "numerous variables [that] present sampling and analytical difficulties in developing predictive models of PCB behavior in the environment." *Id.* at 002426. This would "develop a sampling and monitoring strategy for gathering information to understand PCB dynamics in wastewaters, sediment, surface waters, and fish tissue from the Spokane River." *Id.*

By June of 2006, Ecology had prepared a document titled "Spokane River PCBs Total Maximum Daily Load[:] Water Quality Improvement Plan." V.3, T.90, at 1319-1645. This document includes the header "Draft – 6-19-06 – Do not cite or quote," *id.* at 1319, and was submitted for inclusion in the administrative record in this case by Plaintiffs. *See* V.1, T.B & C. Although this draft document focused on portions of the Spokane River administered by Washington, Ecology used the more stringent PCB water quality standard adopted by the Spokane Tribe as the basis for any such potential TMDL. V.3, D.90 at 1331. Although this document included, in preliminary draft form, some elements of a proposed TMDL, it failed to include critical information in numerous areas, primarily because more investigation remained necessary. For example, in a section titled "What Needs to be Done?," *id.* at 1419, the draft document explains that "PCB Source Identification" must occur in numerous significant areas. *Id.* The draft document states that stormwater discharges contribute significantly to PCBs in the Spokane River

David Kaplan; US Department of Justice PO Box 766; Washington DC 20044

(55 percent of known source categories). The draft explained, however, that particular sources of PCBs in stormwater are not generally known and thus could not be targeted for reduction, *id.* at 1419-21, and that the stormwater data available was not reliable.[7]/ The draft document stated that "more thorough sampling needs to be conducted in this first step in this process," *id.* at 1419, explaining that "PCB source identification begins with determining how the PCBs have entered the storm drains and if ongoing sources exist." *Id.* at 1420. The draft explained the similar need to identify PCB sources within the sanitary sewer system. *Id.* at 1421.

Another example of critical, missing information involves the fact that "[t]he Spokane River at Stateline [the Idaho/Washington border] contributes about 25 percent of the PCB load to the system." *Id.* The draft document explains that "data needs to be gathered on the potential sources of PCBs (e.g, point sources, stormwater, contaminated and/or potential contaminated sites) in the Idaho portion of the Spokane River." *Id.* A similar need exists to identify PCB sources from watersheds draining to the Little Spokane River, which enters the Spokane River. *Id.*

Finally, the 2006 draft document identified the total daily loading of PCBs into the relevant reach of the Spokane River (3,664 mg/d), V.3, D.90 at 1401, but failed to identify PCB sources or otherwise account for nearly half (46.3%) of that daily loading. *Id.*[8]/ Thus the 2006 draft document does not account for 46.3% of the PCB loading, in addition to the lack of information described above regarding PCB loading from the Spokane stormwater, the Spokane sanitary sewer, the Stateline border, and the Little Spokane River source categories. Because of the limited information available and inability to assign reductions to unknown sources, the draft document suggested that for the known categories of PCB sources very aggressive reductions could be necessary for the known catagories of PCB sources, in some cases exceeding 99%. *Id.* at 1402-03.

---

[7]/ *See id.; also id.* at 1413 (*"*Stormwater from Spokane has the potential to deliver large PCB loads to the river (1,100 mg/d) and may account for a significant portion of loading from exogenous sources. However, stormwater sampling was limited and since data had not been previously collected from this source in the Spokane River basin, the representativeness of those data is uncertain.")

[8]/ The chart at 1401 (V.3, T.90) shows a total daily PCB load of 3,664 mg/d, but identifies sources totaling only 1968.9 mg/d, which includes the loading of 477 mg/d at the Idaho border. Thus the 2006 draft document fails to identify sources or categories of sources or otherwise account for 46.3% of the PCB loading.

The draft document contemplated that some of the missing information and analysis may be included in a separate, future document to be developed by Ecology that would be called a "Water Quality Implementation Plan." *Id.* at 1417-21. The draft did not suggest a strategy to identify the sources or otherwise account for the very high percentage of unidentified PCB loading to the River.

Ultimately, given the significant information gaps about PCB occurrences and sources in the Spokane River, Ecology recognized that considerable new studies and analyses would be necessary before a PCB TMDL for the Spokane River could be completed. *See, e.g.*, V.1, T.14A at 503; *infra* at 16-17 (Ecology's decision not to prioritize the completion of the PCB TMDL). Thus the State did not issue the 2006 draft document for the public notice and comment that would be required for any proposed TMDL prior to deeming it complete for submission to EPA.[9]/ Rather, Ecology initiated additional investigations regarding PCBs in the Spokane River. For example, to better understand the role of stormwater and obtain more reliable data, the State conducted a study "to refine PCB loading estimates to the Spokane River from the City of Spokane's stormwater drainage system" and, as "[a] secondary goal . . . to begin PCB source identification for future mitigation efforts," and issued a report in 2007 based on its findings.[10]/

Thereafter, the State further sought to identify other information gaps and the means to close those gaps. One 2009 draft document, entitled "Draft Spokane River PCBs TMDL: Volume 1. Water Quality Study Findings," which also includes the header "DRAFT – 7-09 – Do not cite or quote," V.3, T.69 at 1102, was submitted to EPA by Plaintiffs for inclusion in the administrative record in this case. V.1, T.B &C. This draft document is not a draft TMDL – it does not, for

---

[9]/ Although some Ecology reports suggest that Ecology submitted a proposed Spokane River PCB TMDL for the public notice and comment required before it could be finalized, V.2, T.42 at 705; V.1, T.14 at 503, EPA believes that this statement is in error. The administrative record in this case does not contain any such proposal, public notice, public comments nor Ecology responses to comments from such a process, and EPA has no record that it ever occurred.

[10]/ *See* Spokane River PCB TMDL Stormwater Loading Analysis Final Technical Report, at v. (abstract) (December 2007). Although not included in the administrative record in this case, this report is available on the State's web site, https://fortress.wa.gov/ecy/publications/publications/0703055.pdf, and the Court may take judicial notice of it for the purpose for which it is introduced.

example, contain proposed load allocations for sources. Rather, as its subtitle indicates, it is a draft technical study that could be used in developing a future draft TMDL V.2, T.68 at 1217 ("This project constitutes a technical water quality study to support TMDL development for PCB contaminants in the Spokane River."); *also id.* at 1121-21.

In part to better reflect this draft document's contents, and the fact that it was not itself a draft TMDL, in 2011 Ecology issued this report, in modified and final form, titled "Spokane River PCB Source Assessment 2003-2007." V.1, T.15 at 63-216. Although this 2011 report indicates progress in addressing some information gaps and data reliability issues in some areas, *see* V.5, T132 at 2675, it did not, among other things, identify or otherwise account for the large unknown sources of PCB loadings into the relevant reach of the Spokane River. For example, of the total daily PCB loading of 3,664 mg into the River, only a total loading of 1571 mg/day from seven categories of sources were identified, including 477 mg/day at the Stateline. V.1, T.15 at 163. Based upon its updated data, this 2011 report could not account for 57% of the PCB loading in the relevant reach of the River. The 2009 precursor draft also lacks this information. V.3, T.69 at 1205.

C. Ongoing State Efforts to Reduce PCBs and Other Toxics in the Spokane River

Ecology has worked to reduce PCBs in the Spokane River while investigating PCBs and their sources for a potential PCB TMDL. Ecology has utilized available information and taken significant steps to reduce and cleanup toxics in or that may enter the River, including PCBs. For example, as detailed in Ecology's 2012 Spokane River Toxics Reduction Strategy, V.2, T.42, Ecology in 2007 provided oversight as contractors removed PCB-contaminated soil from Donkey Island in the Spokane River. *Id.* at 701. Prior to that, Ecology directed contractors in 2006 to cap over PCB-contaminated sediments on the river bottom near the Upriver Dam. *Id.* PCBs at several other sites have either been cleaned up or are undergoing required investigation of appropriate remedial options pursuant to the State's cleanup laws to address past pollution. *Id.* at 701-2; V.2, T.68, at 1091-93. In addition to these cleanup efforts focused on PCBs, the 2012 Spokane River Toxics Reduction Strategy details the State's ongoing efforts to reduce other toxics in the Spokane

River, such as dioxins and furans, metals such as arsenic, cadmium, lead and zinc, and pharmaceuticals and personal care products. *Id.* at 692-95 & 697-712.

Ecology has also worked closely with the City of Spokane, which in 2011 entered into a settlement agreement with the Spokane Riverkeeper to develop an adaptive management plan for reducing PCB discharges from Spokane's stormwater as much as possible, by:

> 1. Analyzing, organizing, and interpreting existing PCB sampling data as it relates to the City's stormwater NPDES permit.
> 2. Identifying likely sources of PCBs and prioritizing appropriate remedial actions to be accomplished and best management practices to be followed.
> 3. Developing and designing an adaptive approach for additional data collection and additional remedial actions that further reduce PCBs within the City and in the Spokane River for the long term.

Id. at 707-708.

In addition, in 2011, the Department of Ecology, together with PCB dischargers in the Spokane River Basin, conservation and environmental groups, local and regional government agencies, EPA, and other interested parties created the Spokane River Regional Toxics Task Force ("Task Force"). V.1, T.4, at 14. The final January 23, 2012, Memorandum of Agreement establishing the Task Force explains that its "goal . . . will be to develop a comprehensive plan to bring the Spokane River into compliance with applicable quality standards for PCBs." *Id.* This includes the more stringent PCB water quality standard adopted by the Spokane Tribe. *Id.* at 15. To accomplish that goal, the Task Force's functions include:

> – Identify data gaps and collect necessary data on PCBs and other toxics . . . for the Spokane River
>
> – Further analyze the existing and future data to better characterize the amounts, sources and locations of PCBs and other toxics as defined above entering the Spokane River.
>
> – Prepare recommendations for controlling and reducing the sources of listed toxics in the Spokane River.
>
> – Review Toxic Management Plans, Source Management Plans, and BMPs [Best Management Practices].
>
> – Monitor and assess the effectiveness of toxic reduction measures. . . .

Id. at 14.

Members of the Task Force include the Washington Departments of Ecology and Health, the City of Spokane, Spokane County, and the Spokane Regional Health District, the Lake Spokane Association, the Spokane Riverkeeper, the Lands Council, Kaiser Aluminum Washington, LLC, and the Inland Empire Paper Co. *Id.* at 30-40. EPA has also committed its support for and participation in the Task Force. V.1, T.7. All holders of Washington NPDES permits that may discharge PCBs into the Spokane River are required, as a condition of their permit, to participate in the Task Force. *See, e.g.*, V.2, T.45, at 845. The Spokane Tribe was invited to join the Task Force. Although it initially supported the Task Force and its efforts, V.3, T.89 at 1317, it ultimately elected not to participate in it. Plaintiffs in this case also elected not to participate in the Task Force.

The first draft work plan of the Task Force, adopted October 24, 2012, explains in detail specific work plan elements for the years 2012 through 2016, which include "Work Plan Element 1 – Data review, data gap evaluation, analysis, and implementation plan," V.2, T.41 at 679-81 (emphasis in orig.), and "Work Plan Element 5 – Develop strategy for reduction of point sources and non-point sources of PCBs," *id.* at 683-84 (emphasis in org.). The Task Force's documents its monthly activities and other information regarding its operation on its web site (www.srrttf.org). Thus, the Task Force works to identify PCB sources and to develop strategies for reducing PCBs.

Current PCB concentrations in fish tissue are lower than they have been historically. Between 1996 and 2005 there has been a significant decrease in the PCB levels in Mountain Whitefish and Rainbow Trout in the Spokane River. V.1, D.15 at 152-53.

D. Ecology's Decision to Defer Continued Development of a Spokane River PCB TMDL for Submission to EPA at This Time

Ecology has determined not to continue to devote its limited resources for the development and completion of a PCB TMDL for the Spokane River at this time. Ecology's reasons for deferring completion of the TMDL are documented in the administrative record in this case. As an initial matter, Ecology has a robust TMDL program, and Ecology is continuing to devote its limited resources to the development of other TMDLs, both within the Spokane Basin Watershed

and in other water-quality-limited segments throughout the State. *See supra* at 9-10. Against this backdrop, Ecology explained several specific reasons for deferring a PCB TMDL at this time. First, there are significant data gaps that precluded it from completing a TMDL at this time, with much work remaining. *See, e.g.*, V.1, T.A at pp 3-4; V.2, T.42 at 705; V.1, T.15 at 173 & V.1, T.35 at 481-83 (data to be obtained). In this regard, Ecology employee Jim Bellatty, testifying on behalf of Ecology in 2013 before the Washington State Pollution Control Hearings Board, explained that Ecology's draft PCB TMDL could not be finalized because sources for 57% of the PCB loading in the relevant reach of the Spokane River have not been identified. V.5, T.132, at 2671-72 & 2683. In light of key gaps in information, Ecology is concerned that any TMDL at this time would be highly uncertain, inequitable, and impracticable. *Id.* at 7671 & 2683. In addition, Ecology had recently devoted a great deal of its resources, spanning 12-years, in a difficult process to complete in 2010 a dissolved oxygen TMDL for the Spokane River. V.1, D.4 at 503; V.5, T132 at 2671-72. In light of that experience, Ecology was concerned that, given the significant information gaps for PCBs, and absent a cooperative approach, the continued development to finalization of a PCB TMDL at this time would suffer lengthy delays and expend considerable resources, without resulting in timely environmental benefits. *Id.; also* V.1, T.A at p.4. At the same time, Ecology was aware that community support exists for it to make as much direct progress as possible to reduce PCBs through its Task Force (described *supra*), rather than to delay such potential progress until after a TMDL is completed. V.2, T.42 at 706; V.1, T.1.

Ecology has also made clear that the Task Force's work is not in lieu of development of a Spokane River PCB TMDL. V.1, T.1, at 2. The Task Force serves as a measure designed to obtain critical information about PCBs and their sources in the Spokane River and to implement strategies that can obtain near-term PCB reductions where possible. *Supra* at 15-16; V.1, T.35. Ecology expressly recognized that it would still be obliged to complete a PCB TMDL for the Spokane River if the Task Force or other measures fail to achieve applicable water quality standards. V.2, T.44 at 706 ("a PCB TMDL still remains a tool and will be necessary if ongoing toxics reduction strategies do not result in compliance with water quality standards.").

E. EPA's April 12, 2013, Letter Determining That Ecology Has Not Renounced Establishing a Spokane River PCB TMDL If One Is Required and That EPA Is Therefore Not Required to Establish Such a TMDL Under Plaintiffs' Constructive Submission Theory

Plaintiffs' original, one-count Complaint in this action (Dkt. No. 1, ¶¶ 23-26) alleged that Ecology's failure to finalize a PCB TMDL for the Spokane River constitutes its intent to never complete such a TMDL and thus the constructive submission of no PCB TMDL, the disapproval of which by EPA would create a mandatory duty under the CWA citizen suit provision for EPA to establish a PCB TMDL for the Spokane River. On November 6, 2012, this Court held that review in this case is limited to the administrative record. Dkt. No. 49. Thereafter, in December 2012, Plaintiffs submitted two letters to EPA, attaching numerous documents not in EPA's administrative record, for EPA to review administratively. V.1, T.B & C. These documents included several internal Ecology draft documents, many of which are described above. Based on these documents, Plaintiffs contend that Ecology has disavowed submitting an actual PCB TMDL for the Spokane River, thereby constructively submitting no TMDL; Plaintiffs thus requested that EPA approve or disapprove that constructive submission, and if disapproved, to establish a PCB TMDL. *Id.*

EPA reviewed the full administrative record in this case, including the new documents submitted by Plaintiffs, and on April 12, 2013, issued its administrative determination, concluding that "Ecology's decision to delay completion of a PCB TMDL for the Spokane River is within the discretion of the State of Washington" and that "Ecology has not renounced completion of a PCB TMDL for the Spokane River if one is required." V.1, T.A, at 1 (internal citation). EPA thus concluded that there has not been a constructive submission by Ecology of a PCB TMDL and that EPA is not "required to issue such a TMDL in lieu of Ecology." EPA also detailed the bases for its findings. EPA first noted that Ecology has "demonstrated its commitment to develop and implement" a robust TMDL program under Section 303(d) of the Act over the past fifteen years, and that "Ecology is continuing to establish large numbers of TMDLs each year in accordance with its judgment of how best to protect the environment and allocate its limited resources." *Id.*

Ecology established and EPA approved 1372 TMDLs since 1999 using EPA's national counting system. *Id. & n.1*. EPA further explained Ecology's priority-setting process, and noted that in December 2012 EPA approved Ecology's 303(d) list and found "that the state's process for targeting waters for TMDL development in this period is appropriate." *Id.* at 2 (internal citation).

In its administrative determination, EPA expressed support for Ecology's use of interim, supplemental approaches to achieve water quality standards, especially for those WQLSs for which a TMDL will not be issued in the near term, in an effort to reduce pollution and achieve water quality standards. This approach is reasonable because "[i]f water quality standards are attained through implementation of such interim, supplemental approaches, development of a TMDL [for that WQLS] would not be necessary." *Id.* EPA explained that Ecology's use of the Task Force to make progress achieving the applicable PCB standards represents such a measure, and that EPA supports the Task Force's work. *Id.* at 3.

EPA also explained its support for the Task Force's reasonable goal of completing the work outlined in its work plan by 2016 to reduce PCBs, *id.*, Ecology's commitment in its May 2012 letter (V.1, T.1 at 1-2) that it will in five years "evaluate progress in reducing PCB contamination in the Spokane River," and Ecology's acknowledgment that "[i]f Ecology determines that the [Task Force] is failing to make measurable progress toward meeting applicable water quality criteria for PCBs, Ecology . . . will proceed with development of a TMDL in the Spokane River for PCBs if necessary." V.1, T.A at 3. EPA further reviewed Ecology's acknowledged commitment to proceed with development of a TMDL for PCBs in the Spokane River if necessary, and explained that this "leads EPA to conclude that Ecology has not repudiated its legal obligation to develop a PCB TMDL if needed." *Id.* at 4.

EPA noted that a "straight to implementation" ("STI") project is a type of interim approach used by Ecology, *id.* at 2-3 (describing such approaches), and that Ecology may have once intended to develop an STI project for the Spokane River, but that as Ecology further developed its STI program, it appeared that the Task Force was not an STI. *Id.* at 2-3. EPA noted, however, that the name given to a particular project or project type is not important, so long as it remains

"an interim, supplemental tool that does not displace ultimate TMDL development if needed." *Id.* at 3 n.10.

EPA also reviewed Ecology's decision to defer the continued development and completion of a PCB TMDL for the Spokane River at this time, and found them reasonable. In particular, EPA highlighted the significant information gaps that led Ecology not to finalize its draft PCB TMDL, and Ecology's experience of lengthy delays and large resource expenditures establishing the dissolved oxygen TMDL for the Spokane River. *Id.* at 4. "These factors support Ecology's decision not to finalize a PCB TMDL for the Spokane River prematurely, e.g., before adequate information and resources are available." *Id.* Further, the Task Force has "the potential to fill the existing data gaps and to achieve PCB reductions until such time that a needed PCB TMDL is issued." *Id.*

Finally, EPA explained that Ecology's approach reflects its priorities to "balance[] its available resources for issuing TMDLs with other effective tools to reduce pollution within its borders where TMDLs have not yet been issued." *Id.* at 4. EPA thus concluded that it would not be appropriate "in these circumstances for it to usurp Ecology's authority by issuing a PCB TMDL for the Spokane River at this time." *Id.* EPA therefore concluded that "Ecology has not constructively submitted to EPA a PCB TMDL for the Spokane River, and to the extent that such a constructive submission could be considered to have occurred, EPA declines to disapprove such a constructive submission." *Id.* EPA explained that it will monitor Ecology's efforts to reduce PCB pollution in the Spokane River, including "its ongoing progress in issuing TMDLs for other water bodies," and that it "may reconsider this decision if significant relevant circumstances change." *Id.*

After EPA issued this determination, Plaintiffs filed an amended complaint on April 22, 2013, which retained Plaintiffs' original constructive submission claim under the Clean Water Act citizen suit provision, Dkt. No. 61 ¶¶ 36-39, and added a new, second claim challenging EPA's April 12, 2012, determination under the Administrative Procedure Act. *Id.* ¶¶ 41-42.

F. The Pollution Control Hearing Board's July 2013 Decision

In 2011, Ecology issued the Spokane County Regional Water Reclamation Facility an NPDES permit for discharges into a water-body segment that is not listed as impaired for PCBs under Washington's 303(d) lists. Plaintiffs in this case challenged that permit before the Washington Pollution Control Hearing Board (the "Board"), alleging that it unlawfully authorized PCB discharges. Board Decision pg.1 (attached hereto as Exhibit A). The Board agreed with Ecology that the available data was not adequate for preparation of a numeric effluent limit for PCBs in the permit, *id.* pg.22, that the permit therefore required best management practices, or narrative effluent limits, *id.*, and that any narrative limits used in such a circumstance must "require defined steps towards compliance with standards." *Id.* at p.24. Therefore, the Board remanded the matter to Ecology with instructions, among other things, that Ecology (a) include deadlines and mandatory requirements for identification and implementation of measures to reduce PCBs coming into the treatment facility, (b) identify the expected reductions in toxicant loadings and the schedule for initiating such reductions; and (c) requiring the use of ongoing monitoring data to set a numeric effluent limitation at the earliest possible time. *Id. at* p.27. In so ruling, the Board reviewed the important role of the Task Force and stated that it "finds that the creation of the Task Force is a positive step toward bringing the Spokane River into compliance with water quality standards for PCBs" and that "the actions undertaken by the Task Force are necessary to address the water quality problems in the Spokane River . . . ." *Id.*

STANDARD OF REVIEW

I. EPA'S DECISION MUST BE UPHELD UNLESS PLAINTIFFS ESTABLISH THAT EPA'S ACTION WAS ARBITRARY AND CAPRICIOUS.

Under the Administrative Procedure Act, EPA's final agency actions under the Clean Water Act must be upheld unless they are "arbitrary, capricious, an abuse of discretion, or otherwise not in accordance with law." 5 U.S.C. § 706(2)(A). The scope of review under this standard is narrow, and a court may not substitute its judgment for that of the agency. *See Motor Vehicle Mfrs. Ass'n v. State Farm Mut. Auto Ins. Co.*, 463 U.S. 29, 43 (1983); *Citizens to Preserve*

Overton Park v. Volpe, 401 U.S. 402, 416 (1971). Rather, "Congress has assigned the courts perform 'only the limited, albeit important, task of reviewing agency action to determine whether the agency conformed with controlling statutes,' and whether the agency has committed 'a clear error of judgment.'" *Maryland Dep't of Human Resources v. U.S. Dep't of Agric.*, 976 F.2d 1462, 1475 (4th Cir. 1992) (quoting *Baltimore Gas & Elec. Co. v. NRDC*, 462 U.S. 87, 97 (1983), and *Overton Park*, 401 U.S. at 416).

The party asserting an APA challenge bears the burden of demonstrating that the agency's actions were arbitrary or capricious. *Nw. Ecosystem Alliance v. U.S. Fish & Wildlife Serv.*, 475 F.3d 1136, 1140 (9th Cir. 2007). This standard is a "highly deferential, presuming the agency action to be valid." *Id.* "The court may not set aside agency action as arbitrary or capricious unless there is no rational basis for the action." *Friends of the Earth v. Hintz*, 800 F.2d 823, 831 (9th Cir. 1986).

Under this deferential standard the agency's factual determinations are entitled to substantial deference. *Arkansas v. Oklahoma*, 503 U.S. 91, 112 (1992); *Central Arizona Water Cons. Dist. v. EPA*, 990 F.2d 1531, 1539-40 (9th Cir. 1993). As long as the agency's factual determinations are supported by the administrative record they should be upheld, even if there are alternative findings that could also be supported by the record. *Arkansas*, 503 U.S. at 112. Even an agency decision "of less than ideal clarity" may be upheld by the court "if the agency's path may reasonably be discerned." *Dioxin/Organochlorine Center v. Clarke*, 57 F.3d 1517, 1525 (9th Cir. 1995) (quoting *Motor Vehicle Mfrs. Ass'n v. State Farm Mutual Ins.*, 463 U.S. 29, 43 (1983)). Further, when examining agency scientific findings made within an area of an agency's technical expertise, a reviewing court must generally be at its most deferential. *Marsh v. Oregon Natural Resources Council*, 490 U.S. 360, 376-77 (1989).

II. JUDICIAL REVIEW IS LIMITED TO THE ADMINISTRATIVE RECORD AND IS CONDUCTED THROUGH A SUMMARY JUDGMENT PROCEEDING.

In a case such as this, judicial review is limited to the administrative record prepared by the agency for its decision. *Overton Park*, 401 U.S. at 419-20; *Vermont Yankee Nuclear Power Corp.*

v. NRDC, 435 U.S. 519, 549 (1978). This rule implements the well-settled principle that judicial review of agency action is confined to review of the record that was before the agency when it made its decision, and not extra-record material that was not considered by the agency at the time that it took final action. *Federal Power Comm'n v. Transcontinental Gas Pipe Line Corp.*, 423 U.S. 326, 331 (1976). Extra-record declarations, however, may be submitted by the Agency to clarify or explain information contained in the record. *See Camp v. Pitts*, 411 U.S. 138, 142-43 (1973). This Court has held that review in this case is limited to the administrative record. Dkt. No. 49.

Finally, because review is limited to the administrative record, resolution of this case is proper through summary judgment. *Adams v. United States*, 318 F.2d 861, 865 (9th Cir. 1963). In such a proceeding, the district court "is not required to resolve any facts in a review of an administrative proceeding. Certainly, there may be issues of fact before the administrative agency. However, the function of the district court is to determine whether or not as a matter of law the evidence in the administrative record permitted the agency to make the decision it did." *Occidental Eng'g Co. v. INS*, 753 F.2d 766, 769 (9th Cir. 1985). The Parties to this matter have stipulated that all claims for relief in this case will be resolved through the instant summary judgment proceedings. *Infra* at 30 n.15.

ARGUMENT

I. ECOLOGY HAS NOT MADE A CONSTRUCTIVE SUBMISSION FOR A SPOKANE RIVER PCB TMDL, AND THEREFORE PLAINTIFFS' COMPLAINT SHOULD BE DISMISSED WITH PREJUDICE AND SUMMARY JUDGMENT ENTERED FOR EPA.

A. The Constructive Submission Theory May Not, As a Matter of Law, Apply Where, As Here, the State Has a Robust Program for Establishing TMDLs.

Plaintiffs invoke the nondiscretionary duty prong of the CWA citizen suit provision, 33 U.S.C. § 1365(a)(2), alleging that Ecology has constructively submitted no PCB TMDL for the Spokane River, and that this triggers EPA's nondiscretionary duty under CWA § 303(d)(2), *id.* § 1313(d)(2), to approve or disapprove that submission. Plaintiffs and the Spokane Tribe thus invoke the constructive submission doctrine in an effort to circumvent and undermine Ecology's

decisions as to how best to protect the environment, by targeting a particular TMDL that they believe should be established before all others. As discussed below, the constructive submission theory is inapplicable where, as here, the State has a robust program for establishing TMDLs.

1. The Constructive Submission Caselaw Supports EPA's Interpretation.

Plaintiffs' claim depends on a novel, and untenable, reading of the CWA and the applicable caselaw that would expand the constructive submission theory well beyond the limited circumstances in which it applies. The Ninth Circuit explained in San Francisco Baykeeper v. Whitman, 297 F.3d 877, 881 (9th Cir. 2002), that the doctrine was created by the courts to address the narrow situation in which a State has submitted no TMDLs at all for a prolonged period of time, *id.* at 881 (i.e.,"a complete failure by a state to submit TMDLs"), and this State inaction is "construed as a constructive submission of no TMDLs, which in turn triggers the EPA's nondiscretionary duty to act." *Id.* If EPA disapproves the constructive submission of no TMDLs, EPA then becomes obliged to establish the TMDLs pursuant to section 303(d)(2). If EPA approves the constructive submission of no TMDLs, that decision is reviewable under the Administrative Procedure Act. *Hayes v. Whitman*, 264 F.3d 1017, 1023 (10th Cir. 2001) (citing *Scott*, 741 F.2d at 995 & 997). In *Baykeeper*, the Ninth Circuit concluded that California's actions, having submitted at least eighteen TMDLs, "preclude any finding that the state has 'clearly and unambiguously' decided not to submit any TMDLs." *Id.* at 883 (citing *Hayes*, 264 F.3d at 1024).

In its decision adopting the constructive submission theory, the Ninth Circuit carefully reviewed the caselaw, and explained that since its first formulation in *Scott v. City of Hammond*, 741 F.2d 992 (7th Cir. 1984), the theory has been narrowly interpreted and applied "only when 'the state fails to submit any TMDLs and has no plans to remedy this situation.'" *Baykeeper*, 297 F.3d at 882 (explaining and quoting the district court's interpretation of *Scott*); *id.* (concluding that "the district court's ruling is consistent with how other circuits have interpreted and applied *Scott*"). Thus the Ninth Circuit concluded that the doctrine may apply only where no TMDLs have been submitted by the State over a prolonged period of time and the State has no plan to remedy this situation. *Baykeeper*, 297 F.3d at 881-883.

In this case, there is no dispute that Ecology has an ongoing, robust program for establishing TMDLs, having submitted 1372 TMDLS to EPA since 1999. *Supra* at 9-10. Even where States have submitted far fewer TMDLs, the courts have declined to find a constructive submission. *See Baykeeper*, 297 F.3d at 882-83) (citing cases). Moreover, where the doctrine has been found to apply, the State has submitted no, or only very few, TMDLs over a prolonged period of time and had no intention of remedying that situation.[11]/

The theory is not available here, as a means to alter Ecology's priorities regarding the order or timing in which particular TMDLs should be established or how limited State resources should be allocated. Although Plaintiffs prefer that Ecology establish a PCB TMDL for the Spokane River immediately, a claim for such relief is simply not available. The Tenth Circuit stated in *Hayes,* 264 F.3d at 1024, the "constructive-submission theory is not designed to challenge the timeliness or adequacy of the state's TMDL submissions . . . ." *See also Sierra Club v. Browner,* 843 F.Supp. 1304, 1314 (D.Minn.,1993) ("the Act does not set deadlines for the development of a certain number of TMDLs."). And in the Ninth Circuit the law is clear that the theory may apply only where the State has submitted no TMDLs. *Baykeeper*, 297 F.3d at 882.

Plaintiffs' contend that the *Baykeeper* case is inapposite, because it involved what Plaintiffs call a "programmatic" challenge where the "plaintiffs complained of a state's overall failure to submit any or an adequate number of TMDL," Pl Br. at 24-25, whereas Plaintiffs here are concerned with one particular TMDL. Such a distinction cannot evade the rule in *Baykeeper.* A necessary corollary to the *Baykeeper* holding, *i.e.*, that an ongoing State TMDL program that has already established 18 TMDLs precludes finding a constructive submission, is the Ninth Circuit's acknowledgment that there are many more TMDLs in that State (California) to be established. For these remaining TMDLs, whether taken as a group or individually, the constructive submission doctrine cannot be used to upset the State's priorities and resource allocations. As explained in

---

[11]/ *E.g., Kingman Park Civic Ass'n v. EPA*, 84 F. Supp. 2d 1, 6 (D.D.C. 1999) ("An eighteen-year failure to calculate and submit any TMDLs constitutes constructive – if not outright – determination that no TMDLs are necessary."); *Alaska Center for the Environment v. Reilly,* 762 F. Supp. 1422, 1426-27 (W.D. Wa. 1991) (holding that failure by state to submit to EPA any TMDL for over ten years was constructive submission).

section B below, the reason for so limiting the theory is clear. Courts quite properly are not willing to invoke the constructive submission theory, and the necessarily narrow nondiscretionary duty prong of the CWA citizen suit provision,[12]/ in order to second-guess and supersede discretionary policy choices Congress reserved to States to prioritize waters under their 303(d) programs and to allocate limited State resources as the State believes appropriate to protect the environment. That is why *Hayes* concluded that a constructive submission theory cannot challenge "the timeliness" of a State's TMDL submissions or their content, and the Ninth Circuit concluded that the doctrine may apply only where no TMDLs have been submitted.

Plaintiffs' reliance (at 25) on three other cases for their overly expansive view of the constructive submission theory is unavailing. Although the claim in *Scott* concerned TMDLs for only Lake Michigan, it arose in a context in which the State had submitted no TMDLs at all over a prolonged period, 741 F.2d at 996-97, and it is that circumstance that the Court explained that the theory may apply. *Id.* Here, Ecology has already submitted and EPA has approved 1372 TMDLs statewide and, for the Spokane River watershed alone, Ecology has already submitted and EPA has approved 73 TMDLS. *Supra* at 9-10. Moreover, as explained in *Baykeeper*, 297 F.3d at 882, the *Scott* court remanded the case to the district court instructing it "to proceed as if the states had submitted proposals of no TMDL's" and still left open the possibility that a constructive submission may not be found. *Scott*, 741 F.2d at 997 n.11.

Plaintiffs' reliance on *Hayes* is also misplaced. While the Court in one part of its opinion describes the constructive submission theory in the singular, referring to the clear intent to submit no TMDL for a particular waterbody, in others places it speaks in the plural, referring to the submission of no TMDLs needed to trigger the theory. 264 F.3d at 1023 (the theory applies "[o]nly upon this determination that the states' inaction was so clear as to constitute a 'constructive submission' of no TMDLs"). Moreover, as the Ninth Circuit in *Baykeeper*

---

[12]/ Claims against EPA under citizen suit provisions are limited to "'clear-cut' nondicretionary dut[ies]." *Farmers Union Cent. Exchange, Inc. v. Thomas*, 881 F.2d 757, 760 (9th Cir. 1989) (reviewing the similar citizen suit provision under the Clean Air Act). Thus, the CWA citizen suit provision "cannot be employed to challenge the substance or content of an agency action." *Scott*, 741 F.2d at 996; *see also Sierra Club v. Thomas*, 828 F.2d 783, 791 (D.C. Cir. 1987).

explained, the key fact in *Hayes* for why no constructive submission was found was not the focus on a particular TMDL, but the fact that Oklahoma had submitted between three and twenty-nine TMDLs with a commitment for more. *Baykeeper*, 297 F.3d at 882. Accordingly, the Ninth Circuit explained that *Hayes* should be construed to mean the constructive submission theory may apply only when no TMDLs are submitted. *Id.* Finally, in *City of Arcadia v. EPA*, 411 F.3d 1103, 1105 (9th Cir. 2005), also relied upon by Plaintiffs, the court described the constructive submission theory using the singular, but it did so only in passing, in a background section, and the holding of the case did not involve application of the theory at all. This passing reference carries no weight whatsoever. In sum, Plaintiffs have not cited a single case in which the constructive submission theory has been applied to compel establishment of a single, particular TMDL from among the many that may ultimately be required, and EPA is not aware of such a case.

2. EPA's Reasonable Interpretation is Fully Supported by the CWA

EPA's interpretation is also fully supported by the CWA § 303(d) provisions regarding State TMDL prioritization and the cases interpreting it. The CWA vests States with authority to exercise their own judgment as to when particular TMDLs should be established and how their limited resources should be allocated, without the threat of judicial intervention requiring that EPA usurp that State discretion and decisionmaking. For example, while the CWA requires that States establish a priority ranking for TMDLs, EPA is not required to pass judgment on that prioritization or approve or disapprove the State's order. Although CWA § 303(d)(1)(A) requires that "[e]ach State shall identify those waters within its boundaries . . . * * * [and] establish a priority ranking for such waters," 33 U.S.C. § 1313(d)(1)(A), the CWA only requires each State "from time to time" to submit to EPA for approval "the waters identified and the loads established." *Id.* § 1313(d)(2) (emphasis added). Thus, the CWA is specific and clear: EPA must review only the 303(d) list (the "waters identified") and the TMDLs (the "loads") once they are submitted to EPA. Conspicuously absent from Section 303(d)(2) is any mention of EPA approval of priority rankings set by the States under Section 303(d)(1)(A). "Where Congress includes particular language in one section of a statute but omits it in another section of the same Act, it is generally-presumed

that Congress acts intentionally and purposely in the disparate inclusion or exclusion." *Russello v. U.S.*, 464 U.S. 16, 23 (1983).

Accordingly, the courts that have reviewed this question have agreed that EPA is not required to review and approve the particular priority ranking States establish for TMDL development. The Court in *Potomac Riverkeeper, Inc. v. EPA*, 2006 WL 890755, at 10 (D. Md. 2006), explained as follows:

> While a state's § 303(d) list must list waters 'targeted' for TMDL development within the next two years, this requirement is a form of goal setting. This requirement does not, however, require EPA, prior to approval, to ascertain, based on the state's historic average number of impairments resolved per year, whether the state can actually complete the 'targeted' TMDLs in the next two years. In addition, there is no provision that requires EPA to approve or disapprove a state's priority rankings.

Id. at 10 (footnote omitted).[13]/

Plaintiffs' theory in this lawsuit, therefore, contradicts the CWA's clear text and structure and is not supported by applicable caselaw. The constructive submission theory may not, as a matter of law, be used, as Plaintiffs' intend here, to supersede and reorder the State's priorities and decisions.

This limitation on the constructive submission theory is a corollary to the prohibition on its use to challenge the timing or content of State TMDLs, *Scott*, 741 F.3d at 995, and the Ninth Circuit's holding that the theory may apply only if no TMDLs have been submitted and the State

---

[13]/ EPA also notes that, in *Sierra Club, Inc. v. Leavitt*, 393 F.Supp.2d 1263, 1273 (N.D. Fla. 2005) (N. D. Fla. 2005), *aff'd and rev'd in part; judgment vacated in relevant part*, 488 F.3d 904 (11th Cir. 2007), the district court declined to second-guess the State's particular priority ranking for completing TMDLs in a case challenging EPA's approval of a 303(d) list, explaining:

> No requirement is present that EPA approve the [States'] rankings. Importantly, in its Decision Document, while the EPA specifically approves or disapproves [the State's] decision to list, not list, or delist waters, the section discussing prioritization does not "approve" or "disapprove" [the State's] ranking; it merely concludes that Florida did, in fact, rank its waters and set a TMDL schedule accordingly. Because there is no requirement that the EPA actually approve or disapprove of a state's priority rankings, . . . summary judgment is granted in favor Defendants

On appeal, the Eleventh Circuit concluded that plaintiffs did not actually challenge the particular ranking of listed waters, and thus it did not address that issue and vacated district court's summary judgment on that claim and remanded. 488 F.3d at 917-918. Nevertheless, the district court properly addressed this issue.

has no plan to remedy that situation. *Baykeeper*, 297 F.3d at 882. This limitation also follows from the discretion CWA § 303(d) preserves for the States. A contrary ruling would open the floodgates to numerous lawsuits against EPA by groups dissatisfied with how limited State or federal resources were allocated, in an effort to redirect development to their preferred TMDL in lieu of other environmental projects or TMDLs in other communities. Such "special pleading" lawsuits on behalf of those groups' narrow priorities would ensnare the courts in disputes they are ill-suited and not authorized by statute to resolve, *i.e.*, second-guessing the States' judgments about how to best protect the environment in the face of limited resources. These are precisely the types of claims the CWA and caselaw foreclose.[14]/

EPA's interpretation is fully consistent with the plain meaning of Section 303(d) and the applicable caselaw. However, even were the statute ambiguous, EPA's construction is reasonable, and should be upheld. Accordingly, EPA has not failed to perform a nondiscretionary duty under the CWA citizen suit provision, and thus Plaintiffs' and the Tribe's complaints should be dismissed and summary judgment entered for EPA.

B. Plaintiffs Have Waived Their Right to Challenge EPA's Determinations That Ecology Has Not Renounced Establishing a PCB TMDL for the Spokane River If Necessary and That Ecology Has Thus Not Constructively Submitted Such a TMDL.

Even assuming, arguendo, that a constructive submission claim could be used to compel EPA to establish a particular TMDL, Plaintiffs have waived their right to raise such a claim here. As discussed *supra* at 18-20, on April 12, 2012, EPA reached its administrative determination that Ecology has not disavowed establishing a Spokane River PCB TMDL if needed and that Ecology has not therefore constructively submitted such a TMDL. In their amended complaint, Plaintiffs include an additional claim (claim two) against EPA under the Administrative Procedure Act challenging EPA's April 12, 2012, determination, alleging that EPA's "determination that Ecology has not submitted a Spokane River PCB TMDL is arbitrary, capricious, an abuse of discretion, and

[14]/ EPA does not here opine on what recourse Plaintiffs may have on claims in State court directly against Ecology regarding its priorities under State law or regulations. That matter is not before the Court.

not in accordance with law, and their refusal to approve or disapprove the TMDL, and, if disapprove, to establish a TMDL as required by 33 U.S.C. § 1313(d)(2) constitutes agency action unlawfully withheld or unreasonably delayed." Dkt. No. 61¶ 41. Because Plaintiffs have elected not to argue their second claim to challenge EPA's determination in their motion for summary judgment, that claim is waived in accordance with the caselaw and the parties' stipulated agreement and the Court's Scheduling Orders that all claims in this case will be resolved by these summary judgment proceedings.[15]/

The rule in this Court is clear that such claims must be dismissed with prejudice. *See, e.g.,Wild Bainbridge v. Mainlander Services Corp.* 544 F. Supp. 2d 1159, 1167 (W.D. Wash. 2008) ("Pursuant to the parties' agreement that all claims against the federal defendants will be resolved by summary judgment, all claims not raised in Wild Bainbridge's summary judgment motion are dismissed as to the Corps."); *Thunderbird Trading v. U.S. Bureau of Alcohol, Tobacco and Firearms*, No. C92-5181, 2007 WL 1128810, at *10 (W.D. Wash. Ap. 16, 2007) (where all parties agreed that all issues are to be decided on summary judgment, on those issues in the Plaintiff's complaint not raised in the Plaintiff's brief "the Court presumes that Plaintiff has abandoned them. Therefore, to the extent that Plaintiff makes claims, if any, regarding these issues, Plaintiff's claims should be dismissed with prejudice and summary judgment for the Defendants should be granted.").[16]/

Accordingly, because Plaintiffs elected not to pursue its challenge to EPA's April 12, 2012, determination, the determination necessarily stands intact.

---

[15]/ Order, dated April 8, 2013 (Dkt. No. 58) (entering the parties Stipulation and Proposed Order to Modify Scheduling Order at 2 & 4 ¶ 7); Order, dated September 12, 2013 (Dkt. No. 78) (entering the parties' Stipulation and [Proposed] Briefing Schedule, at 4 ¶ 5); *see also* Order, dated December 23, 2013 (Dkt. No. 88) (entering the parties Stipulation and [Proposed] Modified Briefing Schedule).

[16]/ *Also Mountain States Legal Found. v. Espy*, 833 F. Supp. 808, 813 nn.4-6 (D. Id. 1993) (where the plaintiff agreed that all claims in its complaint would be resolved through summary judgment, claims not raised in its summary judgment motion were waived and dismissed with prejudice); *City of Santa Clarita v. Dep't of Interior*, No. 02-00697, 2006 WL 4743970 at *11 (C.D. Cal. Jan. 30 2006) (same), *aff'd*, 249 Fed. Appx. 748 (9th Cir. 2007).

C. The Court Should Uphold EPA's Reasonable Determined That Ecology Has Not Renounced Submitting a PCB TMDL for the Spokane River if Needed and That Such a TMDL Has Not Been Constructively Submitted to EPA.

1. The Administrative Record Supports EPA's Finding That There Has Not Been a Constructive Submission.

Assuming, arguendo, that Plaintiffs can overcome the legal bars discussed above to either of their claims, the Court should uphold EPA's reasonable determination and reject those claims. As explained in detail, *supra* at 18-20, EPA in its April 12, 2013, determination concluded that "Ecology's decision to delay completion of a PCB TMDL for the Spokane River is within the discretion of the State of Washington" and that "Ecology has not renounced completion of a PCB TMDL for the Spokane River if one is required." V.1, T.A, at 1. EPA thus determined that there has not been a constructive submission by Ecology of a PCB TMDL. These determinations are amply supported by the record.

As detailed above, Ecology has a robust, ongoing TMDL program, having issued 1372 TMDLs since 1999, including 73 TMDLs in the Spokane River watershed, and Ecology is committed to continuing this progress. *Supra* at 9-10. Although Ecology initiated the process to develop a PCB TMDL for the Spokane River, those efforts disclosed significant information gaps and the need for additional study and analysis, which prevented Ecology from completing that TMDL. *Supra* at 11-14; V.1, T.A at p.4; V.5, D.132 at 2671, 2675, 2683. Ecology also recently completed a lengthy, technically complex and contentious twelve-year process to establish a dissolved oxygen TMDL for the Spokane River, V.1, T.A at p.4, V.1, D.4 at 503; V.5, T.132 at 2671-72, and based upon lessons it learned there, Ecology was concerned that pressing forward on a PCB TMDL for that same water-body, especially given the significant gaps in information and the importance of a cooperative approach, would result in further, lengthy delays in establishing such a TMDL. *Id.; supra* at 16-17. Ecology thus determined to devote its limited resources to other TMDLs at this time, and to supplemental measures, including the Task Force, to fill data gaps and to achieve near-term PCB reductions. *Id.* EPA supports the work of the Task Force and other interim measures until such time that a PCB TMDL can be completed if necessary. V.1, T.A

at pp.2-3. Moreover, even if the Task Force or other measures fail to adequately reduce PCBs, the information gained by the Task Force would assist in the development of a TMDL. *Supra* at 15-16.

EPA also found reasonable Ecology's commitment to review the Task Force's progress in five years. V.1, T.A at 3. Ecology further committed to establish a PCB TMDL if the Task Force or other measures it may adopt fail to achieve applicable PCB water quality standards. V.2, T.44 at 706 ("a PCB TMDL still remains a tool and will be necessary if ongoing toxics reduction strategies do not result in compliance with water quality standards."); *also* V.1, T.1 at 2. If the applicable PCB water quality standards are met through supplemental measures, no TMDL would be required. EPA explained that this "leads EPA to conclude that Ecology has not repudiated its legal obligation to develop a PCB TMDL if needed." Id. at 4. EPA concluded that Ecology must retain discretion to manage and establish priorities for TMDL development, including how limited resources should be expended to reduce pollution where TMDLs have not yet been completed. *Id.*

In their effort to discredit Ecology's reasons for deferring a PCB TMDL, Plaintiffs argue that Ecology shared with EPA a "complete draft TMDL" to review, that this draft TMDL included all elements required in a TMDL for approval by EPA, and that Ecology's draft TMDL went through the public notice process required for TMDL development. This is incorrect. As an initial matter, the documents Plaintiffs contend are technically complete TMDLs are each marked "Draft . . . Do not cite or quote," V.3, T.90, at 1319; V.3, T.69 at 1102, which demonstrates that Ecology never believed them complete. Ecology also has not conducted the notice and comment proceedings required before a TMDL can be submitted to EPA. *Supra* at 13 n.9. Moreover, Ecology itself explained that significant gaps in information and need for additional new information prevented these preliminary drafts from being finalized. The background section of this brief details important areas where these draft documents are incomplete. *Supra* at 11-14, 17.

For example, the draft document that Plaintiffs and the Tribe contend is a complete and approvable PCB TMDL for the Spokane River could not identify the sources or categories of sources or otherwise account for 57% of the PCB loading in the relevant reach of the River. V.1, T.15 at 163 (figure 19); *supra* at 14. Further, in uncontested testimony in a proceeding before the

Pollution Control Hearing Board involving the same plaintiffs in this case, a spokesperson for Ecology explained as follows:

> Q And I believe you testified earlier that this draft TMDL failed to account or was unable to discover roughly 57 percent of the sources of PCB loading to the river?
> A Correct.
> Q Would Ecology develop a total maximum daily load for a pollutant if it didn't even know where 57 percent of the sources of that pollutant came from?
> A No.
> Q Why not?
> A It would leave too much uncertainty and I think it would require the dischargers to pay an inequitable amount of their resources to solve the rest of the PCB problem.

V.5, D.132 at 2683 (questions by counsel for Ecology; answers by Ecology employee Jim Bellatty); *id.* at 2671 (this large information gap "leaves a lot of unanswered questions and uncertainty with our ability to be able to do a TMDL"). This and the other record information readily rebuts Plaintiffs' conclusory assertions that political pressure prevented Ecology from finalizing the TMDL.

In sum, EPA fully explained the bases for its April 12, 2013, determination and the record amply supports EPA's findings. Plaintiffs' burden to demonstrate otherwise is particularly high in this case, where inherent in the State's decisions are judgments about how best to allocate limited resources to protect the environment.

2. Plaintiffs' Arguments Challenging EPA's Decision Are Without Merit.

Plaintiffs contend that a Memorandum of Agreement between EPA and Ecology in 1997 regarding Ecology's commitment to establish TMDLs, as well as Ecology's 303(d) lists from 1996 through 2010, required that Ecology have developed a PCB TMDL for the Spokane River by 2013. Pl. Br. at 26-27 & 34. This argument is flawed on several counts. First, neither that Memorandum of Agreement, V.1, T.34, nor the out-of-court settlement agreement that EPA entered in 1998 with two environmental groups regarding TMDL development, V.1, T.32, required Ecology to have established and submitted a Spokane River PCB TMDL to EPA by this time. Consistent with the CWA, those documents necessarily preserve Ecology's discretion to

select which particular TMDLs to develop and when to do so. For example, Attachment A to the Memorandum of Agreement and settlement agreement describes Ecology's 303(d) prioritization process for initiating development of TMDLs in different management area watersheds throughout the State over five-year cycles, V.1, T.33, including the Spokane area. It does not require that the TMDL on which Ecology initiates development in the Spokane area be for PCBs. *Id.* at 457. Similarly, the settlement agreement preserves Ecology's discretion to substitute between TMDLs it intends to develop from the State's different 303(d) lists. V.1, T.32 at 47-48 (¶ 7).

Nor is there anything to Plaintiffs' claim that Ecology has departed from its prioritization process and ignored the Spokane River and its tributaries. As explained above, since 1999, Ecology submitted and EPA has approved 1372 TMDLs, many of which were for WQLSs in the Spokane River and its tributaries. Further, on April 12, 2012, EPA approved an additional 57 TMDLs submitted by Ecology for the Little Spokane River watershed, for fecal coliform bacteria, temperature and turbidity. [Is the 57 Included in the total?] Thus, Ecology has not, as Plaintiffs' claim, departed from its prioritization process and ignored the Spokane River. Rather, Ecology has exercised its discretion by prioritizing and completing the particular TMDLs that in its judgment will best protect water quality most efficiently with the State's finite resources.

Plaintiffs further argue that because Ecology initiated development of a PCB TMDL for the Spokane River, Ecology was required to have already completed and submitted that TMDL to EPA. However, as explained above, Ecology has adapted its priorities based upon the circumstances, deciding to defer establishing a PCB TMDL for the Spokane River and to establish other TMDLs at this time, and to adopt interim, supplemental measures to reduce PCBs in the Spokane River. Nothing in the CWA or EPA's regulations precludes Ecology from altering course in this manner. Moreover, while EPA's regulations direct States to submit 303(d) lists every two years, and to include a priority ranking of waters "targeted for TMDL development within the next two years," 40 C.F.R. § 130.7(d)(1), this language plainly does not require completion of such TMDLs within that two-year period. Nor could it, since, as discussed above, the CWA preserves the State's discretion in this regard, requiring only that States submit TMDLs to EPA "from time

to time," 33 U.S.C. § 1331(d)(2). Rather than require TMDLs be submitted in two years, this language expressly preserves State discretion to determine when such TMDLs should be developed and submitted to EPA. Similar "time to time" language under a different Section 303 provision are construed precisely in this manner. *American Canoe*, 30 F. Supp. 2d at 923. Indeed, "courts have generally held that the use of the phrase 'time to time' does not create a nondiscretionary administrative duty." *Id.* [17]/

Plaintiffs argue that Ecology has decided to utilize a "straight-to-implementation project" ("STI") for reducing PCBs in the Spokane River, that STI projects necessarily preclude TMDLs, and that this demonstrates that Ecology has decided no PCB TMDL for the Spokane River will ever be established. Pl. Br. at 28. EPA reasonably addressed this in its April 2012 determination, explaining that STIs are a type of interim approach to identify PCB sources and practices to prevent contamination reaching the water body, and that Ecology's "definition and use of this term [i.e., STI] are changing over time." V.1, T.A at pp. 2-3. Further, while Ecology once appeared to refer to the Task Force or other measures to reduce PCBs in the Spokane as an STI, it no longer does so. *Id.* at p.3 n.10. The key point here, however, is that Ecology has committed to establish a PCB TMDL if it is ultimately needed, and that it therefore does not matter whether the Task Force, or any other interim, supplemental measures Ecology may adopt, may have once been or are called STIs. *Id.* Moreover, if Plaintiffs here intend to challenge STIs generally or in other contexts, that issue is not before the Court; neither the issues nor administrative record in this case provide the Court with the opportunity or ability to resolve whether STIs generally or in other contexts preclude TMDLs. And then, Plaintiffs depiction of STIs is incorrect, because an Ecology presentation in the record from 2011 states that an STI "does not preclude further TMDL

---

[17]/ *See, e.g., NRDC v. Thomas*, 885 F.2d 1067, 1075 (2nd Cir. 1989) (Clean Air Act provision requiring revision of a list of air pollutants "from time to time" does not impose a nondiscretionary duty); *Oljato Chapter of the Navajo Tribe v. Train*, 515 F.2d 654, 661 (D.C. Cir. 1975) (Clean Air Act provision imposing a duty in which EPA may from "time to time" revise certain standards does not impose a nondiscretionary duty). Rather, a nondiscretionary duty is typically one in which the statute requires performance by a date certain. *Sierra Club*, 828 at 791 (absent a readily-ascertainable deadline, "it will be almost impossible to conclude that Congress accords a particular agency action such high priority as to impose upon the agency a 'categorical[] mandat[e]' that deprives it of all discretion over the timing of its work.").

pathway." V.3, T.86 at 1307.

Eventually, Plaintiffs frankly concede in their brief, as they must, that Ecology has not renounced its obligation to establish a PCB TMDL if one is ultimately necessary, but they then argue that Ecology has not adequately identified what "measurable progress," "activities," or "metrics" would make the TMDL "unnecessary." Pl. Br. at 28-29. Plaintiffs confuse the issue and distort Ecology's position; it is undisputed that the TMDL will ultimately not be needed if and when the Spokane River meets the applicable PCB water quality standards. *See supra* at 5. Moreover, Ecology's point is that, for now, it has chosen to pursue various interim measures, such as the Task Force, to reduce PCBs in the Spokane River, while development of the PCB TMDL is deferred for the reasons discussed above. At the same time, Ecology has clearly committed that it will evaluate the Task Force's progress in five years, V.1, T.1 at 1-2, and if "measurable progress" is not being made and other measures are not available, "Ecology would be obligated to proceed with development of a [Spokane River PCB] TMDL . . . ." *Id.* at 2. Thus Ecology explained that "it is committed to proceed with a TMDL should it be necessary." *Id.* Further, if such a TMDL is needed, Ecology will have the benefit of the additional needed information gathered (based on the work of the Task Force) for developing the TMDL. *Supra* at 15-16; V.1, T.35 at 481-84 (data to be gathered). Based upon this, EPA reasonably concluded that "Ecology has not repudiated its legal obligation to develop a PCB TMDL if needed," *V.1 T.A*, at 4.

Plaintiffs next complain that the Task Force is not adequate, alleging that it is "controlled by the NPDES dischargers." Pl. Br. at 29. Such an attack, however, is incorrect, given that several governmental entities and other environmental groups are members of the Task Force. *Supra* at 15. Indeed, Plaintiffs as well as the Spokane Tribe were invited to participate in the Task Force, but declined. Although Plaintiffs doubt that the Task Force will achieve its goal, this is no reason to fault Ecology for pursuing interim measures to reduce PCB pollution, much less to equate Plaintiffs' projections of the Task Force's failure to Ecology constructively renouncing ever establishing a TMDL. Nor is it a proper criticism that the Task Force did not, up-front, identify measures it will adopt to reduce PCB pollution, given that it was only recently established and part

of its mission is to identify those measures. *Supra* at 15-16. Moreover, Plaintiffs inaccurately suggest that the Pollution Control Hearing Board was critical of the Task Force. To the contrary, while the Board merely concluded that participation in the Task Force is not a defense to NPDES permit compliance, Board Decision at p.27, a matter not at issue here, the Board stated that it "finds that the creation of the Task Force is a positive step toward bringing the Spokane River into compliance with water quality standards for PCBs" and that "the actions undertaken by the Task Force are necessary to address the water quality problems in the Spokane River . . . ." *Id.* at p.26.

Finally, Plaintiffs allege that absent a PCB TMDL for the Spokane River, NPDES permits issued by Ecology for PCB discharges into the Spokane River will be inadequate. Pl. Br. at 33. This argument is flawed for several reasons, and we address it in detail *infra* at 42-43 & 45. EPA highlights here that if Plaintiffs believe those State-issued permits are inadequate, the remedy is to challenge them through the State administrative process and court system, rather than improperly attempt to adjudicate their adequacy in this case. Plaintiffs' unsupported claims that NPDES permits will be inadequate thus provide no support for the claims in this case. Moreover, as explained *supra* at 7, even where a TMDL has not yet been established, States still must include effluent limits in NPDES permits as stringent as necessary to meet water quality standards, 33 U.S.C. § 1311(b)(1)(C); 40 C.F.R. § 122.44(d)(1)(vii)(A). Indeed, as explained below, the presence of a PCB TMDL may not result in any change in the stringency of NPDES permits.

In sum, Plaintiffs have not met the high burden to upset EPA's April 12, 2013, determination nad have not established that a constructive submission has occurred.

II. THE INTERVENOR SPOKANE TRIBE'S CLAIMS SHOULD BE REJECTED.

The Tribe in its second amended complaint asserts two claims for relief. In its first claim, under the CWA citizen suit provision, the Tribe incorporates portions of Plaintiffs' claim and alleges that "EPA breached its trust responsibility and fiduciary duty to the Tribe by failing to perform its nondiscretionary duties under 33 U.S.C. § 1313(d)(2)," Dkt. No. 74, Attach. 1 ¶ 22. The Tribe's second claim, after incorporating Plaintiffs' description, alleges that "EPA Defendants' April 12, 2013 determination failed to protect the interests of the Spokane Tribe, and

EPA Defendants have breached and will continue to breach their trust responsibility and minimum fiduciary duty owed to the Spokane Tribe because the April 12, 2013 determination is not in accordance with 33 U.S.C. § 1313(d)(2) and federal common law, and is in violation of 5 U.S.C. § 706(2)(A)&(D) [*i.e.*, APA standards of review]." *Id.* ¶ 24. This language explicitly limits the claims in this case to arguments that EPA's alleged failure to comply with the CWA, the APA, and any applicable common law, also constitutes a breach of EPA's alleged trust responsibility and fiduciary duty owed the Tribe.

In its brief, the Tribe argues that, for the downstream PCB-impaired water-body segment it administers within its jurisdiction, the Tribe has established PCB water quality standards that are more stringent than those adopted by Ecology for the upstream segments Ecology administers, to account for risks posed by the greater fish consumption assumed for Tribal members. The Tribe argues that unless PCBs upstream are adequately reduced, the Tribe's more stringent water quality standard in the downstream segment within its jurisdiction cannot be met. According to the Tribe, only an EPA-established TMDL for the upstream segment administered by Ecology will ensure NPDES limits within that segment that can accomplish PCB reductions downstream on the reservation, and that the general fiduciary duty weighs in favor of finding a constructive submission under the CWA citizen suit (claim one). In the alternative, the Tribe contends that EPA's determinations that Ecology has not renounced its obligation to establish a TMDL and that no constructive submission has occurred should be set aside under the Administrative Procedure Act (claim two). The Tribe's arguments miscast the nature of EPA's general trust responsibility and provide no basis to find a constructive submission or upset EPA's determination. As discussed below, there is no specific fiduciary duty owed the Tribe in this case. Moreover, nothing in EPA's decision undermines the Tribe's ability to enforce its tribal PCB standard.

A. EPA's Compliance with the CWA and its Regulations Satisfies its General Trust Responsibility.

Although the relationship between the United States and Indian tribes has been described as a trust, the scope of the federal trust responsibility is not defined by common law fiduciary

duties or those imposed on a private trustee. *United States v. Jicarilla Apache Nation*, 131 S. Ct. 2313, 2323 (2011). Rather, tribes must point to specific statues and regulations that "establish [the] fiduciary relationship and define the contours of the United States' fiduciary responsibilities." *Id.* at 2325 (citation omitted). Thus the only cognizable breach of trust claim is one founded upon a definite and express fiduciary duty imposed on the federal government by administrative regulation or Act of Congress. *United States v. Navajo Nation*, 537 U.S. 488, 511 (2003); *United States v. White Mountain Apache Tribe*, 537 U.S. 465, 477 (2003). Accordingly, the federal common law trust duties applicable to private beneficiaries, which the Tribe seeks to impute to the federal government, *see* Tribe Br. at 15, do not provide independent bases for the claims asserted by the Tribe. *See Pacific Coast Fed'n of Fisherman's Ass'ns v. United States BLM,* 2005 U.S. Dist. *LEXIS* 36035, *34 (N.D. Cal. Mar 8, 2005).

There is a "distinctive obligation of trust incumbent upon the Government in its dealings with [Indian tribes]." *Gros Ventre Tribe v. United States*, 469 F.3d 801, 810 (9th Cir. 2006) (quoting *United States v. Mitchell*, 463 U.S. 206, 225 (1983)). However, "[w]ithout an unambiguous provision by Congress that clearly outlines a federal trust responsibility, courts must appreciate that whatever fiduciary obligation otherwise exists, it is a limited one only." *Shoshone-Bannock Tribes v. Reno*, 56 F.3d 1476, 1482 (D.C. Cir. 1995). While that general trust relationship allows the federal government to consider and act in the tribes' interests in taking discretionary actions, it does not impose a duty on the federal government to take action beyond complying with generally applicable statutes and regulations. *Jicarilla,* 131 S. Ct. at 2325. Accordingly, in the absence of a specific duty that has been placed on the government with respect to the Tribe, the United States' general trust responsibility "is discharged by the agency's compliance with general regulations and statutes not specifically aimed at protecting Indian tribes." *Morongo Band of Mission Indians v. F.A.A.*, 161 F.3d 569, 574 (9th Cir. 1998); *Okanogan Highlands Alliance v. Williams*, 236 F.3d 468, 479 (9th Cir. 2000) (Bureau of Land Management's approval of gold mine satisfied trust obligations by the agency's compliance with NEPA); *Gros Ventre*, 469 F.3d at 814.

Here, the Tribe alleges in its CWA citizen suit claim that EPA breached fiduciary duties owed in the CWA by not establishing a TMDL. Second Amended Complaint ¶ 24 (Dkt. No. 73, Attach. 1). The Tribe does not identify where the CWA establishes a fiduciary duty mandating that EPA establish a PCB TMDL for the Spokane River, much less that a mandatory duty requires EPA do so at this time. Instead, the Tribe duplicates the arguments of Plaintiffs (which we refute above) based upon the government's general statutory and regulatory obligations under the CWA. Accordingly, EPA satisfied its general trust responsibility by its compliance with the CWA.

B. The Indian Law Canon of Construction Raise by the Tribe Does Not Apply, and Even if It Did, It Would Not Result in a Finding of a Constructive Submission.

The Tribe contends that an Indian law canon of construction requires that any statutory ambiguity be interpreted to benefit the Tribe, and that this canon is triggered in this matter because under CWA section 518(e), 33 U.S.C. § 1377(e), the Tribe has been granted the right "to be treated as a state," *id.*, for purposes of issuing water quality standards. Tribe Br. at 5-6. Even assuming arguendo this were accurate, this canon is inapplicable because, as demonstrated in Section 1.A above, the provision of the CWA at issue in this case is not ambiguous: the constructive submission theory does not, as a matter of law, apply in this case. And beyond that, the CWA calls for EPA to approve or disapprove TMDLs arises only if TMDL submissions (actual or constructive) have occurred, and there is no ambiguity in that statutory proposition. The canon of construction raised by the Tribe does not apply when the statue is clear. Thus the Court need not decide whether the canon cited by the Tribe applies here.

Even were the applicable law ambiguous, the referenced canon would not apply in this circumstance. This canon applies only to "'statutes passed for the benefit of dependant Indian tribes.'" *Hoonah Indian Ass'n v. Morrison*, 170 F.3d 1223. 1228 (9th Cir. 1999) (quoting *Bryan v. Itasca County, 426 U.S. 373, 392 (1976)).* Regardless of whether this canon may apply to ambiguous interpretations of the Tribe's authority under 33 U.S.C. § 1377(e), or the Tribe's administration of its own program, it certainly would not extend here to the Section 303(d) TMDL program administered by Ecology, *id.* § 1313(d), EPA's obligation to approve or disapprove a

TMDL once submitted, *id.* § 1313(d)(2), or the CWA provisions governing the Tribe's assertion that the Court must order EPA to establish a PCB TMDL and thereby usurp Ecology's role and substitute the Tribe's priorities for the State's reasonable pollution prevention and remediation plans. The latter generally applicable provisions of the CWA just discussed are the only provisions at issue in this case, and thus the referenced canon would not apply.

The Tribe also appears to rely upon the canon when recounting selected documents and information in the administrative record, which it construes in its favor, in an effort to establish that Ecology has renounced its obligation to issue a TMDL that may be necessary, and thus has constructively submitted a PCB TMDL to EPA. However, even if the canon somehow applied to the interpretation of the CWA, it does not apply to the judicial review of record information. Rather, the applicable arbitrary and capricious standard of the Administrative Procedure Act applies. The Tribe has not met its burden to demonstrate that EPA's determinations are arbitrary and capricious or contrary to law.

C. The Tribe's Arguments Based Upon Alleged Impacts to Its Fishing Rights Are Not Properly Before the Court, and Provide No Basis to Reject EPA's Determination.

In the context of its APA claim, the Tribe contends that EPA's April 12, 2013, decision is arbitrary, capricious or contrary to law because it "fails to preserve and protect the Tribe's fishing rights." Tribe Br. at 16. The Tribe appears to base its argument on its assertion that it has "a right to water quality that can sustain fish and other aquatic life." Tribe Br. at 6 (citing *United States v. Anderson*, 591 F. Supp. 1, 5 (E.D. Wash. 1982), *aff'd in part and rev'd in part*, 736 F.2d 1358 (9th Cir. 1984)). That case, however, involved an adjudication of the Tribe's water rights in the Chamokane Stream, and the Court addressed only "[t]he quantity of water needed to carry out the reserved fishing purposes" as it relates to "flow" and "water temperature." Moreover, this is far different than the circumstance here, where the issue is PCB contamination and the State's decision of how best to expend resources to reduce that pollutant. *See Hopi Tribe v. United States*, 113 Fed. Cl. 43, 49 (2013) (reserved water rights do not impose mandatory fiduciary duties on the United States to build drinking water infrastructure). This issue, however, is not properly before

the Court, regardless of what the scope of the Tribe's fishing rights may be, and should be dismissed. Plaintiffs' second amended complaint does not include a claim based upon alleged violation of fishing rights. Stipulations entered by the Parties and filed in Court further demonstrate that the Intervenor Tribe's complaint was not to so expand the claims in this case.[18]/

Even if this issue were properly before the Court, the Tribe has not made the necessary showing to support its assertion that the lack of an EPA-issued TMDL adversely impacts the Tribe's fishing rights. TMDLs are not self-executing and thus do not themselves reduce pollution.

---

[18]/ After this Court ruled that review in this case is limited to the administrative record, Dkt. No. 49, Plaintiffs requested that EPA review documents and approve or disapprove a constructive submission, V.1, T.B & C, which resulted in EPA's April 12, 2012, determination that no constructive submission had occurred, V.1, T.A, and the inclusion of additional documents in the record for judicial review. Dkt. No. 58 at 2, 4-5 (¶ 8) (Order dated April 8, 2013). Counsel for the Tribe did not, as part of that process, request that EPA consider or determine impacts to its fishing rights. *See id.* Moreover, Plaintiffs, and the Tribe, were to add an additional cause of action in their amended complaints only to secure their challenge to EPA's April 12, 2013, determination. That process, however, was not to enlarge the basic issues originally in this case. After the Tribe filed its First Amended Complaint, Dkt. No. 64, counsel for EPA contacted counsel for the Tribe and objected because the Tribe's new second and third causes of action added the claims that EPA failed to comply with certain specific alleged fiduciary duties, including primarily an alleged failure to consult with the Tribe as part of that process. *Id.* ¶¶ 19-23. Ultimately, to ensure no misunderstanding, through an exchange of emails and calls, the Parties' all agreed to the following:

> The Parties agree that in the Tribe's Second Amended Complaint, the Tribe is not raising a breach of trust/fiduciary duty claim based upon EPA's alleged failure to consult with the Tribe upon considering the additional documents and in issuing its April 12 letter. Thus, the Tribe, in the second claim of its second amended Complaint, may only challenge as a breach of trust/fiduciary duty the merits of EPA's decision that there has been no constructive submission.

Emails dated September 6 and 9, 2013, Attachment A hereto. Based on this agreement, the Parties' filed a joint stipulation, Dkt. No. 73, which the Court entered on September 12, 2013, Dkt. No. 74, thereby authorizing the filing of the Tribe's Second Amended Complaint, to ensure that the claims in this action were not expanded. The stipulation filed by the Parties explained as follows:

> To resolve disagreements regarding the scope of the amended complaint filed by the Tribe, the Parties hereby stipulate to the Intervenor-Plaintiff Spokane Tribe of Indians filing a second amended complaint, which is attached (Attachment 1). This proposed second amended complaint is narrower than the Complaint previously filed by Intervenor-Plaintiff Spokane Tribe, and thus its filing will neither expand the claims in this lawsuit nor delay their resolution, while also resolving disputes the Parties had regarding the scope of the first amended complaint previously filed by the Spokane Tribe of Indians.

Doc. Nos. 73 & 74, ¶ 3 (emphasis added). Accordingly, the Tribe's arguments in its motion for summary judgment alleging fishing rights have been violated are not properly before the Court and must be dismissed.

Even if EPA were required to establish a PCB TMDL, it may not result in any reduction in PCBs in the River or in fish located within the Tribe's fishing grounds. The Tribe contends that the lack of an EPA-issued PCB TMDL has resulted or will result in State-issued NPDES permits that lack adequate PCB limits or will not make adequate progress reducing PCBs in the Spokane River. They offer, however, only speculative and conclusory assertions in this regard, and neither the issues nor administrative record in this case provide the Court with the authority, or basis, to assess the adequacy of such future permits. As explained *supra* at 7, the lack of a TMDL does not preclude the inclusion of appropriate effluent limits in NPDES permits. Regardless of whether a TMDL has been established, NPDES permits still must include effluent limits as stringent as necessary to meet water quality standards. 33 U.S.C. § 1311(b)(1)(C); 40 C.F.R. § 122.44(d)(1)(vii)(A). A PCB TMDL, therefore, would not necessarily make NPDES permits any more stringent. Moreover, the Tribe's theory of how of its fishing rights are impacted inappropriately assumes the Task Force will fail to reduce PCBs. Ecology, however, reasonably reached the contrary conclusion, and the Pollution Control Hearing Board concurred that the work of the Task Force is necessary to reducing PCBs and meeting water quality standards. *Supra* at 37.

The Tribe's argument also fails because the issuance of NPDES permits will also take into account the Tribe's PCB water quality standard. The Tribe's recourse for inadequate NPDES permits is to appeal them. Thus, the Tribe has not demonstrated that an EPA-issued TMDL is required to protect the Tribe's fishing rights.

The Tribe also appears to argue that EPA was under a mandatory fiduciary duty to take into consideration impacts to the Tribe's fishing rights in deciding that Ecology has not constructively submitted a Spokane River PCB TMDL. Tribe Br. at 15-16. As noted *supra* at 42 n.18, as part of EPA's consideration of Plaintiffs' administrative request, the Tribe did not request that EPA determine or consider any potential impact to its fishing rights, and that issue is not properly raised in this case. In any event, the Tribe does not point to a source of law containing a specific mandatory fiduciary duty that would require that EPA disrupt Ecology's priorities and efforts to reduce PCBs and establish a federal PCB TMDL for the Spokane River at this time.

In sum, the Tribe's fishing rights claim is not properly before the Court. Even if it were, the Tribe has not shown that its fishing rights have been adversely affected by EPA's determination that there has not been a constructive submission, or that there is a mandatory fiduciary duty for EPA to establish a PCB TMDL for the Spokane River.

III. PLAINTIFFS ARE NOT ENTITLED TO THE REMEDY SOUGHT.

Plaintiffs request that the Court order EPA to establish a Spokane River PCB TMDL "within 90 days." Pl. Br. at 32. Plaintiffs' requested relief is unfounded and impracticable. Thus, even assuming that Plaintiffs were entitled to some relief, the requested relief should be denied.

Injunctive relief may not be granted as a matter of course. *Weinberger v. Romero-Barcelo*, 456 U.S. 305, 311 (1982); *Amoco Prod. v. Gambell*, 480 U.S. 531, 546 n.12 (1982). The Supreme Court explained in a citizen suit case that "the court [must] 'balance[] the conveniences of the parties and possible injuries to them according[ly] as they may be affected by the granting or withholding of the injunction." *Weinberger*, 456 U.S. at 312; *Amoco*, 480 U.S. at 542. In formulating a remedy, "the court must be careful not to intrude upon the agency's realm of discretionary decision making." *Idaho Sportsmen v. Browner*, 951 F. Supp. 962, 968 (W.D. Wash. 1996).

To the extent that the Court determines that some injunctive relief is appropriate here, the CWA citizen suit provision provides that the remedy is limited to "order[ing] the Administrator to perform [the nondiscretionary] act or duty" 33 U.S.C. § 1365(a) (i.e., a remand to EPA to approve or disapprove the constructive submission). A constructive submission triggers a mandatory duty on the part of the EPA Administrator to either approve or disapprove the constructive submission. *Hayes*, 264 F.3d at 1023. Only if the Administrator disapproves the constructive submission is the EPA Administrator under a duty to establish a TMDL. *Id.; also Scott*, 741 F.2d 997. Accordingly, imposing a schedule on EPA to establish a PCB TMDL is not an appropriate remedy. *See also American Canoe Ass'n v. EPA*, 30 F. Supp.2d 908, 922 & n.17 (E.D. Va. 1998) ("the appropriate remedy for the plaintiffs' TMDL [complaint] would appear to be an order directing EPA to approve or disapprove Virginia's constructive submission within 30 days . . . .").

Furthermore, EPA's determination on remand could be challenged by Plaintiffs as final agency action; the Court's role would then be limited to reviewing EPA's approval or disapproval determination. *Hayes*, 264 F.3d at 1023; *American Canoe*, 30 F. Supp. 2d at 923 n.17 ("[i]f the EPA approved the [constructive] submission, this would appear to be a final agency action which could be challenged for abuse of discretion under the Administrative Procedure Act").

Even assuming the Court's authority extends to ordering EPA to establish a Spokane River PCB TMDL, Plaintiffs' have not shown that the injury to them if the relief is not granted outweighs the damage to EPA and the public interest if it is. For example, Plaintiffs contend that the lack of a PCB TMDL has resulted or will result in State-issued NPDES permits that lack PCB limits necessary to reduce PCB discharges and achieve water quality standards. As explained *supra* at 7, 37, 42-43, such assertions lack any foundation. As explained, NPDES permits must require effluent limits that ensure water quality standards will be met, regardless of whether a relevant TMDL has been established, 33 U.S.C. § 1311(b)(1)(C); 40 C.F.R. § 122.44(d)(1)(vii)(A), and Plaintiffs' recourse if they believe State-issued permits are inadequate is to appeal such permits in the appropriate State administrative or judicial tribunal. Nor have Plaintiffs demonstrated that the Task Force will fail to reduce PCBs or that the relief they seek would result in any, let alone quicker, PCB reductions.

Plaintiffs also make no showing that the public interest will not be harmed by the Order they seek, due to the diversion of resources from equally or even more important State or federal TMDL development effort or other environmental projects. In this regard, it should be recognized that the entire docket of EPA involves issues affecting health and welfare. An increase in resources devoted to the PCB TMDL sought by Plaintiffs and Intervenor would result in a concomitant re-direction of resources devoted to other EPA programs designed to protect health and welfare.

If the Court were to conclude that an order requiring EPA to establish a PCB TMDL is appropriate, EPA should not be ordered to comply with Plaintiffs' proposed schedule to establish a PCB TMDL within 90 days. While Plaintiffs argue that this is reasonable "because the work has

already been done to prepare a technically sound TMDL," Pl. Br. at 32, this is clearly not the case. As discussed above, there are significant gaps in the draft TMDL Ecology prepared that would require an extended period of time to address. In considering the time necessary for EPA to complete such a complex regulatory action, the Agency must have the time it reasonably determines necessary to investigate and develop the necessary information. Even once a complete proposal is prepared, for complex regulatory actions EPA must have the time to consider the "complex scientific, technological, and policy questions" raised, reach "considered results," and establish a defensible action that will protect the environment. *Sierra Club v. Thomas*, 828 F.2d at 798. "[B]y decreasing the risk of later judicial invalidation and remand to the agency, additional time spent reviewing a rulemaking proposal before it is adopted may well ensure earlier, not later, implementation of any eventual regulatory scheme." *Id*. at 798-99. Finally, EPA's consideration of what schedule might be possible would require the consideration of additional information well beyond that contained in the administrative record in this case.

In short, even if Plaintiffs prevailed under a constructive submission theory, they would not be entitled to any of the injunctive relief they seek.

CONCLUSION

For the reasons stated above, the Court should grant EPA's cross-motion for summary judgment and deny Plaintiffs' and Intervenor's motions for summary judgment.

Respectfully submitted,

UNITED STATES DISTRICT COURT
WESTERN DISTRICT OF WASHINGTON
AT SEATTLE

SIERRA CLUB; and CENTER FOR ENVIRONMENTAL LAW AND POLICY,

Plaintiffs,

and

THE SPOKANE TRIBE OF INDIANS,

Plaintiff-Intervenor,

v.

DENNIS MCLERRAN; GINA MCCARTHY; and UNITED STATES ENVIRONMENTAL PROTECTION AGENCY,

Defendants,

and

SPOKANE COUNTY; KAISER ALUMINUM OF WASHINGTON LLC; and STATE OF WASHINGTON DEPARTMENT OF ECOLOGY,

Defendant-Intervenors.

Case No. 11-CV-1759-BJR

MEMORANDUM ORDER REMANDING MATTER FOR FURTHER CONSIDERATION

This matter is before the Court on cross motions for summary judgment by Plaintiffs, Plaintiff-Intervenor, Defendants, and Defendant Intervenors. Plaintiffs Sierra Club and Center for Environmental Law and Policy (hereinafter "Plaintiffs") claim that Defendant EPA failed to perform a nondiscretionary duty under the Clean Water Act ("CWA"). Plaintiffs raise claims

under the citizen-suit provisions of the CWA, 33 U.S.C. § 1365(a)(2), and the Administrative Procedures Act ("APA"), 5 U.S.C. § 706. Plaintiff-Intervenor Spokane Tribe of Indians ("Spokane Tribe") incorporates Sierra Club's claims and asserts additional claims under the CWA, APA, and federal trust responsibility. Having reviewed the parties' briefs together with all relevant materials, the Court grants partial summary judgment for Defendant EPA and Defendant-Intervenors (collectively, "Defendants") and grants partial summary judgment for Plaintiffs and the Spokane Tribe. The Court's reasoning follows:

I. BACKGROUND

A. The CWA Statutory Framework

Congress passed the CWA to "restore and maintain the chemical, physical, and biological integrity of the Nation's waters." 33 U.S.C. § 1251. In order to achieve that objective, Congress declared as a "national goal" that the "discharge of pollutants into the navigable waters be eliminated by 1985." 33 U.S.C. § 101(a)(1).[1]

The CWA's regulatory program focuses on two potential sources of pollution: "point" sources and "nonpoint" sources. A "point" source is any "discernible, confined and discrete conveyance" from which pollutants are or may be discharged. *See id.* § 1362(14). A "nonpoint" source is any non-discrete source, such as runoff from stormwater or irrigation agriculture. *Id.* The CWA regulates point source pollution through the National Pollution Discharge Elimination System ("NPDES") permit process.[2] NPDES permits limit the discharge of pollutants through quantitative limits on the amount of pollutants released from each point source. *See id.* § 1342.

[1] Needless to say, this goal has proven optimistic.

[2] Most states, including Washington, are authorized to administer the NPDES permit program.

As part of its regulatory program, Section 303(d) of the CWA imposes duties on the states and the EPA. States are required, subject to federal oversight, to adopt water quality standards for each waterbody or waterbody segment within the state's boundaries. 33 U.S.C. § 1313. If a waterbody does not meet these standards or is not expected to meet them, the state must then designate that body as a "water quality limited segment." *Id.* § 1313(d)(1)(A); *see* 40 C.F.R. § 130.2. The list of "water quality limited segments" is known as the "303(d) list." After creating the 303(d) list, states must prioritize the water quality segments based on the severity of their pollution and their beneficial uses. *See* 33 U.S.C. § 1313(d)(1)(A). States are required to develop a "total maximum daily loads" (TMDL) for each pollutant impairing each water segment on the 303(d) list in accordance with these priorities. 40 CFR § 130.2 (f). A TMDL establishes the maximum amount of pollutants a water quality limited segment can receive daily without violating the state's water quality standards. TMDLs are supposed to be developed in accordance with their priority ranking on the 303(d) list. *See* 33 U.S.C. § 1313(d)(1)(C).

States must submit the ranked list of water quality limited segments and TMDLs to the EPA "from time to time." *Id.* § 1313(d)(2). The first such submission was due on June 26, 1979, just 180 days after the CWA was enacted. Once a submission is made, certain mandatory EPA duties are triggered. First, within 30 days of submission, the EPA must approve or disapprove of the water quality limited segments and the corresponding TMDLs. *Id.* If the EPA approves a submission, the submission is incorporated by the state into its continuing planning process and NPDES permitting. *Id*. at §303 (e) (3). If the EPA disapproves, the EPA must, within 30 days of the disapproval, make its own identification of appropriate water quality limited segments or establish its own TMDLs. *Id.* The CWA is silent as to the nature of the

EPA's obligations if a state fails to make any submissions or fails to make a particular submission.

B. History of Spokane River TMDL for PCBs

In the State of Washington, the 303(d) list and TMDLs are prepared by Intervenor Washington State Department of Ecology (hereinafter "Ecology"). This case concerns the regulation of polychlorinated biphenyls (PCBs) in the Spokane River.[3] It is undisputed that PCBs are industrial chemicals that are "persistent, bioaccumulative, and toxic." AR 14A at 487. The Spokane River has the worst PCB contamination in the state and has been subject to a Spokane County and Washington Department of Health fish consumption advisory since 1994 and 2003, respectively. AR 15 at 97; AR Supp. 5, 7. The 303(d) list Ecology submitted in 1996 identified five segments of the Spokane River that exceeded water quality standards for PCBs. AR 2710. The most current 303(d) lists, for 2008 and 2010, identify fifteen segments of the Spokane River that exceed water quality standards for PCBs. AR 80.[4] Ecology had also identified segments that exceed water quality standards for other pollutants in the Spokane River, and has developed TMDLs for other pollutants in the Spokane River and tributaries. AR 222-23. Of particular note was a recent group of nine TMDLs for dissolved oxygen in the Spokane River. AR 503. Ecology prepared this group of nine TMDLs over the course of 12 years; EPA approved them in 2010. AR 224.

[3] For convenience, the Court uses "Spokane River" to refer to the Spokane River itself, the lake into which it flows (Spokane Lake, also known as Long Lake), and the Little Spokane River. The parties generally group these waterbodies together and this action appears to target regulation of all three.

[4] Upon Sierra Club's request, and with no opposition by Defendants, the Court takes judicial notice of the 2010 303(d) list, and the EPA approval of that list, which occurred in 2012. Neither documents are part of the administrative record in this case. *Available at* http://www.ecy.wa.gov/programs/wq/303d/currentassessmt.html; http://yosemite.epa.gov/r10/water.nsf/tmdls/WA-303d-2010-approval.

No TMDLs for PCB have been submitted to EPA to date. Ecology conducted a TMDL assessment for PCBs in the Spokane River during 2003 and 2004. AR 1331. In 2006, Ecology produced a document entitled "Spokane River PCBs Total Maximum Daily Load [:] Water Quality Improvement Plan." AR 1319. The document was labeled "Draft – 6-19-06 – Do not cite or quote." *Id.* In the document, Ecology cited the statutory requirement that "[w]aters placed on the 303(d) list require preparation of [TMDLs]." AR 1333. Recognizing that fifteen segments of the Spokane River were on the 303(d) list for PCB pollutants, Ecology explained that "[a] TMLD has been determined to be the action needed to address these listings." *Id.*

There are several water quality criteria applicable to the Spokane River, including levels promulgated by the federal government, by Washington State, and by the Spokane Tribe. AR 1348. Ecology selected the most stringent water quality standard, the Spokane Tribe's, as the "the basis for calculating necessary load reductions and load allocations" for the draft. AR 1402. The parties agree that adopting the Spokane Tribe's water criterion would likely mean PCB load reductions of 95-99 percent. AR 1409. The draft document set load reductions for various dischargers on the Spokane River, with reductions of over 99 percent for some of the dischargers. AR 1409. In 2006, Ecology shared a draft TMDL with the EPA, the tribe, the state of Idaho, the dischargers, and interested members of the public.

The parties dispute whether this draft document contained sufficient information from which a final PCB TMDL could have been produced. Emails from Ecology staff members indicate that Ecology originally contemplated finalizing the TMDL at some point in 2007, and by mid-2008 was projecting a completion date of June 2009. AR 1062. Throughout this period, Ecology continued to collect data. Delays in the preparation of the dissolved oxygen TMDL caused some uncertainty as to when the PCB TMDL would be completed. AR 1071.

Eventually, Ecology issued a finalized version of the 2006 draft document, but with several significant revisions. The document title did not include any reference to Total Maximum Daily Load. Instead the document, released in April 2011, was retitled "Spokane River PCB Source Assessment 2003-2007." AR 63. Some introductory material explaining TMDLs was also excised. AR 63. Though the document still identified the target water quality level for PCBs and explained the overall loading reductions that would be needed to comply with that standard, it did not include permissible wasteload amounts for individual Spokane River dischargers.

The following month, Ecology released a second document, the "Spokane River Toxics Reduction Strategy," which set forth the agency's "strategy or 'road map' for reducing and removing toxic contamination in water, water sediments and soil in the Spokane River watershed." AR 485. That document contained the following explanation of Ecology's change in course:

> A draft Spokane River PCB TMDL was issued for public comment in June 2006 but was not completed because of the need for more data, including more accurate stormwater data, updated fish tissue sampling results, and the addition of new Spokane Tribe water quality standards for PCBs based on updated fish consumption rates. The draft TMDL was revised with this updated information in 2009 and issued as the Spokane River Source Assessment Report in 2011.
>
> ***
>
> Ecology is not currently planning to develop a PCB TMDL with wasteload allocations, but this is still a potential tool for the future. Setting wasteload allocations through a TMDL would set a target well below the 'background' PCB concentrations observed in remote bodies of water with no obvious source of contamination other than aerial deposition.
>
> In part because it would establish an impossible near-term target, and based on its experience with the Spokane River Dissolved Oxygen TMDL, which took 12 years to complete, Ecology is opting to proceed directly to implementing measures to reduce all toxics to the Spokane River. Those measures are described in this strategy. Such a *straight-to-implementation* plan is a recent strategy being

> adopted by the EPA and Ecology to address the many bodies of water that are on the list of polluted waters [called the 303(d) list] through tools other than TMDLs. Ecology plans to develop a straight-to-implementation plan for Spokane River toxics in 2012.

AR. 503 (emphasis in original). After 2010, Ecology renewed the permits of several Spokane River dischargers, and issued a new permit to Spokane County. None of these permits reflected the load reductions anticipated by the draft TMDL. However, Ecology did condition permits on permittee monitoring and permittee participation in a "Regional Toxics Task Force."

Sierra Club brought this action in October 2011. On May 25, 2012, Ecology submitted a letter to the EPA, stating:

> If Ecology determines that the Task Force is failing to make measurable progress toward meeting applicable water quality criteria for PCBs, Ecology would be obligated to proceed with development of a TMDL in the Spokane River for PCBs or determine an alternative to ensure water quality standards are met. Ecology remains committed to proceeding with a TMDL should it be necessary.

AR 1 at 2. In December 2012, Sierra Club submitted documents to the EPA for inclusion in the administrative record, and requested a determination from the EPA regarding whether Ecology had, through its conduct, made a "constructive submission" of the PCB TMDL, i.e. abandoned the TMDL, thereby triggering the EPA's duty to prepare a TMDL. AR B and C. The EPA responded on April 12, 2012, finding no constructive submission. AR A. The EPA determined that "Ecology's decision to delay completion of a PCB TMDL for the Spokane River is within the discretion of the State of Washington," and that "Ecology has not renounced completion of a PCB TMDL for the Spokane River if one is required." *Id.* In reaching this decision, the EPA noted that Ecology had submitted 1372 TMDLs since 1999. *Id.* The EPA cited the gaps in

information concerning PCBs, the lengthy delays associated with preparing a TMDL, and the scarcity of resources supporting Ecology's decision to defer the TMDL. *Id.* The EPA also observed that interim measures to achieve water quality standards are an acceptable alternative to a TMDL. *Id.* The EPA pledged to monitor the situation, along with Ecology's progress in issuing other TMDLs, and indicated that it "may reconsider this decision if significant relevant circumstances change." *Id.* Sierra Club then amended its complaint to include two APA claims challenging the April 2013 letter, in addition to its preexisting CWA citizen-suit claim.

II. DISCUSSION

A. CWA – Claim Based Upon Section 505(a)(2)

§505(a)(2) of the CWA authorizes citizens to institute actions in federal court against the EPA for failure to perform any act or duty under the CWA that is not discretionary with the EPA. 33 U.S.C. § 1365(a)(2). Plaintiffs contend that the EPA is subject to §505(a) liability because it breached a mandatory duty under § 303(d) of the CWA. According to Plaintiffs, the EPA's non-discretionary duty to either approve or disapprove a TMDL was triggered when Ecology "clearly and unambiguously" indicated that it will not be preparing a TMDL for PCBs in the Spokane River.

1. EPA Has a Non-Discretionary Duty to Act When a State Clearly and Unambiguously Abandons a Particular TMDL

Defendants argue that, as a matter of law, the EPA does not have a statutory duty to approve or disapprove a state's failure to submit a particular TMDL. In determining the scope of the EPA's mandatory duty under Section 303(d), the court is guided by the fundamental principles of statutory construction. "Proper statutory construction requires

more than linguistic examination and review of the rules of statutory construction. The interpretation should be reasonable, and where the result of one interpretation is unreasonable, while the result of another interpretation logical, the latter should prevail." *Sierra Club v. Train*, 557 F.2d 485 (5th Cir. 1977). A court must construe a statute's language so as to give effect to the intent of Congress. *Id*.

The mandatory TMDL process requires that states identify water segments that are below the state's relevant water quality limits; establish a priority ranking for those waters; and establish TMDLs in accordance with the priority ranking. The relevant text of the CWA is as follows:

> (2) Each state shall submit to the Administrator from time to time, with the first such submission not later than 180 days after the date of publication of the first identification of pollutants under §1314(a)(2)(D) of this title, for his approval, the waters identified and the loads established. . . . The Administrator shall either approve or disapprove of such identification and load not later than 30 days after the date of submission. If the Administrator approves such identification and load, such State shall incorporate them into its current plan . . . If the Administrator disapproves such identification and load, he shall not later than 30 days after the date of such disapproval identify such waters in such State and establish such loads for such waters as he determines necessary to implement the water quality standards applicable to such waters and . . . shall incorporate them into its current plan . . .

The statute clearly contemplates (somewhat naively as time has shown) that states will promptly submit TMDLs for their listed waterways and that the EPA's duty to prepare a TMDL would be triggered when it disapproved of a state's submitted TMDL. The problem with the statute has not arisen in the context of disapproved submitted TMDLs but in a state's failure to submit TMDLs. Notably, the CWA is silent as to the EPA's responsibilities when a state abdicates its responsibility to submit TMDLs. *See Alaska Ctr. for the Env't v. Reilly*, 762 F. Supp. 1422, 1425 (W.D. Wash. 1991). The

Seventh Circuit was the first Circuit to address the nature of the EPA's obligations in light of this silence. In *Scott v. City of Hammond, Indiana*, the Seventh Circuit held that, even in the absence of express language in the statute, the EPA has a duty to develop TMDLs for a particular waterbody when a state fails to comply with the CWA's submission requirements. 741 F.2d 992 (7th Cir. 1984). The *Scott* case involved a citizen suit against the EPA for failure to prescribe TMDLs for pollutants discharged into Lake Michigan after Illinois and Indiana failed to submit any draft TMDLs for Lake Michigan over the course of several years. *Id.* Finding it "unlikely that an important aspect of the federal scheme of water pollution could be frustrated by the refusal of states to act," the court rejected the EPA's argument that Congress did not intend to establish a statutory duty for the EPA in the case of state inaction. *Id*. Instead, the *Scott* court held "if a state fails over a long period of time to submit proposed TMDLs, this prolonged failure may amount to the constructive submission by that state of no TMDLs," thereby triggering the EPA's mandatory duty. *Id.* Since Indiana and Illinois had produced no TMDLs for the Lake Michigan waterbody, the court remanded the matter to the district court with instructions "to proceed as if the states had submitted proposals of no TMDLs unless [there is] evidence indicating that the states are, or will soon be, in the process of submitting TMDL proposals or some factor beyond the scope of the complaint has made TMDL submission impracticable." *Id*. at 997, n. 11.

In 2002, the Ninth Circuit expressly adopted the constructive submission doctrine in *San Francisco BayKeeper v. Whitman*. 297 F.3d 877, 883 (9th Cir. 2002). *BayKeeper* concerned a citizen suit alleging that California's failure to submit any TMDLs for any water bodies in California constituted a "constructive submission" of no TMDLs for the

entire state, thereby triggering the EPA's non-discretionary duty to prepare TMDLs for the entire state. *Id.* Citing *Scott*, the Ninth Circuit held that state inaction can amount to a constructive submission if a state "clearly and unambiguously" indicates that it will not submit any TMDLs. *Id.* However, in applying this standard, the court held that California had not clearly and unambiguously abandoned its TMDL program for the state. *Id.* This holding was premised on a finding that, since 1994, California submitted "at least eighteen TMDLs and . . . established a schedule for completing its remaining TMDLs." *See id.* at 883-84.[5]

Defendants assert that a constructive submission occurs only when a state produces few or no TMDLs for the whole state over a substantial period of time: If a state has a robust TMDL program, its decision to abandon a particular TMDL does not trigger the EPA's non-discretionary duty. Doc. No. 91 at 27. The Court questions this narrow interpretation of the doctrine for the reasons set forth below.

In making this argument, Defendants rely on *BayKeeper's* holding and language, which focused on the state-wide TMDL program. This reliance is misplaced. The issue in *BayKeeper* was whether California's failure to produce a significant number of TMDLs constituted a *programmatic* failure for the *entire* state. *Id.* at 880-82. Clearly, California's producing several TMDLs and committing to more demonstrates that California had not abandoned its TMDL program. *See id.* However, the question here is whether Washington has abandoned a specific component of its CWA obligations—a question that was not before the *BayKeeper* court and one not resolved by looking to a

[5] The *BayKeeper* court expressed no opinion on California's failure to submit TMDLs prior to 1994 and eschewed any "broad, generic determination of the point in time at which a state's inaction may be deemed a constructive submission." *Id.*

state's general compliance. Accordingly, the Court finds it insignificant that the Ninth Circuit did not address an issue not raised by the facts of the case. Moreover, far from foreclosing the application of the constructive submission doctrine to a particular pollutant or waterbody segment, the *BayKeeper* court cited with approval to *Scott*, which applied the constructive submission doctrine to TMDLs for a particular waterbody segment, Lake Michigan. *See BayKeeper*, 297 F.3d at 882 (characterizing ruling as "consistent" with *Scott*).

Defendants also argue that applying the "constructive submission" doctrine to a particular TMDL interferes with the state's discretion to prioritize its TMDLs. Unquestionably, state discretion is an important component of the CWA. Resource constraints compel difficult choices as to which TMDLs should be performed before others—a choice that states are often better situated to make. Perhaps in recognition of these constraints, the CWA provides no specific mechanism for reviewing this prioritization. *See* § 303(d)(1)(A). However, the state discretion argument is a red herring in this context for several reasons.

Applying the constructive submission doctrine to individual TMDLs does not invade state prioritization. A constructive submission occurs only when a state has clearly and unambiguously *abandoned* its obligation to produce a TMDL or TMDLs. *See, e.g., San Francisco BayKeeper*, 297 F.3d at 883; *see also Alaska Ctr. for the Env't*, 762 F. Supp. at 1427(constructive submission when Alaska clearly and unambiguously abandoned its TMDL obligation). It does not occur merely because a state has prioritized one TMDL over another. *See Hayes*, 264 F.3d at 1024.

Relatedly, applying the constructive submission in this instance does not encroach upon Washington's ability to prioritize its TMDLs. Ecology has not identified a specific TMDL which it is prioritizing over the TMDL at issue.[6] In fact, Ecology has treated the Spokane River as a priority and kept it as such for a prolonged period of time, producing at least 78 TMDLs for this very water segment. Ecology has already engaged in a significant amount of work with regard to this specific TMDL by compiling scientific data, preparing at least a preliminary TMDL draft, discussing its contents with the EPA, submitting it to other parties for some form of comment, and creating the Task Force for PCBs.

More importantly, while a state's failure to produce any TMDLs is perhaps the clearest indication that it has abandoned its statutory obligations, the Court finds nothing in the text of the CWA or its purpose to support Defendants' contention that a state's abandonment of a specific statutory obligation should be treated differently from a state's wholesale failure. To the contrary, a state's discretion to prioritize TMDLs over other TMDLs does not remove its ultimate obligation to produce a TMDL for each water pollutant of concern in every 303(d) water segment. *See* 33 U.S.C. § 1313(d) (2). In light of this statutory obligation, it would be absurd for the Court to hold that a state could perpetually avoid this requirement under the guise of prioritization; such an administrative purgatory clearly contravenes the goal and purpose of the CWA. 33 U.S.C.A. § 1251 (a)(1) ("it is the national goal that the discharge of pollutants into the navigable waters be eliminated by 1985"). Accordingly, the Court rejects Defendants

[6] Defendants assert that Ecology is currently producing other TMDLs; however, Defendants do not demonstrate that pursuing these other TMDLs precludes Ecology from pursing the PCB TMDL as well. *See* Doc. No. 91 at 12.

contention that the constructive submission doctrine cannot apply when a state abandons its obligations under the CWA by clearly and unambiguously indicating that it will not produce a particular TMDL.

2. No Constructive Submission Has Yet Occurred

In examining whether Ecology "clearly and unambiguously" decided not to submit a TMDL for PCBs in the Spokane River, the Court is confronted with an issue that has not been directly addressed by any other court: at what point does a state's failure to prepare a particular TMDL ripen into a constructive submission?

According to the EPA, Ecology's failure to submit the PCB TMDL is not a constructive submission because Washington has a robust TMDL program, which has produced 1,372 TMDLs statewide since 1999. While a healthy TMDL program is required to show that a state is prioritizing other TMDLs over the TMDL in question, it is not, on its own, sufficient. *See supra* II A 1. Naturally, a state that has publicly indicated, as Plaintiffs claim Ecology has, that it will not produce a specific TMDL has violated its statutory obligations with respect to that TMDL, no matter how robust its program otherwise is. *See* 40 CFR § 130.2 (f) (states shall produce a TMDL for each water segment on the 303(d) list regarding each pollutant of concern). Accordingly, the Court finds consideration of Washington's general TMDL program relevant but not dispositive in a case concerning failure to submit a particular TMDL.

Plaintiffs present Ecology's actions as an exceptional case, in which an agency essentially completed a TMDL and then abandoned the TMDL for an alternate course, actions which, according to Plaintiffs, unambiguously indicate Ecology will never comply with its statutory obligations, thus requiring the EPA to prepare the TMDL. Doc.

No. 101 at 9. The EPA and Ecology counter that information gaps, scarce resources, and lengthy administrative processes led Ecology to adopt an alternative approach, for the time being, without ruling out a TMDL in the future. Doc. No. 91 at 15-17. If, as Plaintiffs contend, the PCB TMDL was essentially complete and ready for submission, a last-minute pivot to an illusory alternative may indicate a decision to abandon the TMDL. By contrast, if information gaps persisted such that Ecology determined that it could not confidently issue a TMDL at any point in the near future, adopting an alternative may, under some circumstances, represent a reasonable interim measure rather than an abandonment of any future plans to prepare a TMDL.

The Court need not define the precise contours of this doctrine at this time. The facts in the record readily demonstrate that Ecology had sufficient reasons for not completing the TMLD: The Court finds that Ecology lacked sufficient scientific data and had not satisfied certain pre-submission requirements, i.e. public notice and consultation.

i. Scientific Data

Defendants assert that, far from being essentially complete, substantial work remained to be done before Ecology could submit the TMDL. First, Defendants argue that Ecology lacked sufficient scientific data to produce a complete TMDL. According to the EPA, Ecology did and still does not know the source of 57% of PCB loading in certain parts of the Spokane River. V. 1, T. 15 at 163. Similar information gaps existed in other segments. V.3, T.69 at 1205; V. 5, D. 132 at 2683. In light of this uncertainty, the EPA contends it would be unfair and unproductive to impose severe restrictions on only a fraction of identifiable polluters. Plaintiffs counter that scientific uncertainty regarding pollution sources is not a sufficient justification for delay because it is inherent

in the TMDL process. Plaintiffs' argument relies on language in the CWA stating that TMDLs should include "margins of safety." The Court rejects this argument. The "margins of safety" in the CWA are designed to take "into account any lack of knowledge concerning the *relationship between effluent limitations and water quality*." 33 U.S.C. §1313(d)(1)(C)(emphasis added). In other words, "margins of safety" address uncertainty over the effect pollutants at certain levels will have on water quality; they do not address a lack of knowledge regarding the *source* of the pollutants. *See Natural Resources Defense Council, Inc. v. Muszynski*, 268 F.3d 91, 101-02 (2d Cir. 2001). While there may be a point at which a state possesses enough scientific data that failing to submit the TMDL demonstrates intent to abandon that TMDL, the EPA did not err in finding that the uncertainty here does not rise to that level.[7]

ii. Procedural Gap

Defendants point out that Ecology also needed to perform certain procedural steps before submitting the PCB TMDL. An important preparatory step in the submission process is the public notice and consultation period. According to Plaintiffs, Ecology satisfied these requirements when it sent the draft to the following stakeholders for comment: Plaintiffs; Defendant-Intervenors; and certain EPA and Idaho state officials. Plaintiffs assert that Ecology admitted that the draft "was issued for public comment in June 2006" in its "Spokane River Toxics Reduction Strategy." AR 485, 503.[8]

[7] Plaintiffs assert that the CWA specifically contemplates that the states will, at least occasionally, submit incomplete TMDLs because it gives the EPA the authority to disapprove of TMDLs. The Court rejects this argument. While the CWA contains a mechanism for rejecting an incomplete TMDL, the mere existence of this mechanism is not a sufficient reason to compel submission when a significant amount of data is missing.

[8] Plaintiffs also cite an email exchange between members of the EPA and Ecology in which EPA provided Ecology with various feedback over technical and practical issues associated with the PCB TMDL. However, Plaintiffs do not demonstrate how these comments amount to a formal step in the process that would amount to proper notice.

Defendants counter that the draft TMDL was still in the preparatory stages and such informal comments and requests for feedback do not satisfy the formal notice requirements. According to Defendants, the draft TMDL was specifically designated as incomplete and preliminary; it was marked "Draft – 6-19-06 – Do not cite or quote." *See* AR 1331. Defendants further assert that Ecology contemplated several additional steps before formal public disclosure, including additional studies of stormwater runoff and drainage. *See* Spokane River PCB TMDL Stormwater Loading Analysis Final Technical Report, at v (Dec. 2007). Plaintiffs have not shown these additional studies were unnecessary. Accordingly, Ecology did not, as Plaintiffs contend, essentially complete the TMDL and withhold it without sufficient reason.[9] Therefore, Ecology's failure to submit the PCB TMDL did not clearly and unambiguously indicate its intent to abandon the PCB TMDL.

B. Violation of Section 706(1) of the APA

Plaintiffs' APA claim under Section 706(1) relies on the same operative facts asserted in the CWA claim. Plaintiffs allege that the EPA's failure to disapprove Ecology's constructive submission constitutes "agency action unlawfully withheld or unreasonably delayed." a violation Section 706(1) of the APA. This claim fails because it is premised on an assumption that Ecology's inaction amounted to a constructive submission. As set forth above, no constructive submission has occurred.

[9] Scientific uncertainty and procedural gaps indicate that Ecology has not clearly and unambiguously abandoned its TMDL obligations in this specific context because Ecology has engaged in significant work toward completing the TMDL. The Court need not decide whether these factors would be relevant in other scenarios, i.e. if Ecology had engaged in no (or very little) work on the PCB TMDL or if Ecology fails to make any scientific progress in the coming years.

C. Violation of Section 706(2)(A) of the APA

a. The EPA Abused its Discretion

Under the APA, final agency actions must be upheld unless they are "arbitrary, capricious, an abuse of discretion, or otherwise not in accordance with the law." 5 U.S.C. §706(2)(A). The scope of the court's review under the APA is narrow, and a court may not substitute its own judgment for that of the agency. *See Motor Vehicle Mfrs. Ass'n v. State Farm Mut. Auto Ins. Co.*, 463 U.S. 29, 43 (1983). The agency's factual determinations are entitled to substantial deference and should be upheld if they are supported by the administrative record. *Arkansas v. Oklahoma*, 503 U.S. 91, 112 (1992). When reviewing an examining agency's scientific findings made within the area of an agency's technical expertise, the court must be at its most deferential. *Marsh v. Oregon Natural Resources Council*, 490 U.S. 360, 376-77 (1989). The party asserting the APA challenge bears the burden of demonstrating that the agency's actions were arbitrary or capricious. *Nw. Ecosystem Alliance v. U.S. Fish & Wildlife Serv.*, 475 F.3d 1136, 1140 (9th Cir. 2007).

Plaintiffs allege that the EPA's finding no constructive submission is arbitrary and capricious. As discussed *supra*, the Court found that the EPA did not err in finding no constructive submission has yet occurred on the grounds that significant scientific information and procedural gaps remained.

Plaintiffs further allege that the EPA acted contrary to law and abused its discretion in approving the Task Force as an alternative to the TMDL. Doc. No. 84 at 16. The Court agrees with Plaintiffs; the EPA does not have the statutory authority to

approve a Task Force in lieu of a TMDL. States may pursue reasonable courses to reducing pollution in addition to establishing TMDLs. *See, e.g., City of Arcadia v. U.S. EPA*, 411 F.3d 1103, 1106 (9th Cir. 2005) ("states remain at the front line of combatting pollution"). However, nothing in the CWA provides that states may pursue these courses in place of, or as a means of indefinitely delaying, a TMLD. To the contrary, the CWA expressly requires states to produce a TMDL for each pollutant of concern in each 303(d) water segment. *See* U.S.C. § 1313(d)(1)(A); 40 CFR § 130.2 (f); *see also Alaska Ctr. for the Env't v. Reilly*, 762 F. Supp. 1422, 1425 (W.D. Wash. 1991) (states must submit TMDLs). Similarly, the CWA does not give the EPA authority to approve an indefinite delay; the CWA commands the EPA to ensure prompt compliance with the CWA. *See Scott v. City of Hammond*, 741 F.2d 992, 998 (Congress intended TMDLs be established "promptly"); *Idaho Sportsmen's Coalition*, 951 F. Supp. at 967 ("Congress prescribed early deadlines for the TMDL process;" those deadlines could be interpreted to mean "months and a few years, not decades."). Therefore, the EPA may not approve a task force as an alternative to a TMDL, i.e. a task force not designed to complete or assist in completing a TMDL. *See Alaska Ctr. for the Env't*, 796 F. Supp. at 1379 ("The responsibility of the court is to ensure prompt and attentive adherence to the mandate of the CWA."). The Task Force as presently proposed provides no way of determining if the Task Force has been effective in furthering the preparation of a TMDL.

In its letters, Ecology indicated that it is pursuing a Task Force in place of a TMLD because the TMDL would establish "an impossible near-term target." *See* AR 14A at 503. Ecology further stated that it views a TMDL as a "potential" "alternative" to be re-visited only if the Task Force fails to make "measurable progress." *See* AR 14A at

503 (Ecology is not "currently planning to develop a PCB TMDL"). Ecology did not, however, define what constitutes measurable progress, nor did it clearly illustrate how the Task Force would produce or assist in preparing a TMDL. Even more troubling, Ecology provides no firm deadline for when the Task Force will end and Ecology will submit a TMDL. Rather, Ecology states only that it would "monitor and assess the effectiveness of toxic reduction measures" in 2017. V. 1, T. 4, at 14; V. 1, T.A. at 3. Thus, there is no metric to measure success, no clear trigger after which Ecology would produce a TMDL, and no specific date on which such a TMDL would be submitted to the EPA. Compounding this uncertainty is the worrying lack of progress made with respect to the scientific data in recent years. The EPA found that scientific uncertainty prevents the submission of a TMDL, yet it is unclear how or whether the Task Force will resolve that problem.[10] The record indicates that the Spokane River has been on the 303(d) list since 1996 and after nearly 20 years still contains the worst PCB pollution in the state. Despite this known problem and Ecology's prioritization of the Spokane River PCBs, a substantial percentage of the pollution sources remain unknown. The failure to submit a TMDL also affects the ability of the Washington State Pollution Control Hearing Board to effectively limit pollutants and monitor water quality. Had a TMDL been established, any issuance of permits would have been tied to the wasteload allocations specified in the TMDL. 40 C.F.R. §122.44(d)(1)(vii)(B). Meanwhile, it is significant that no effective limitations have been put in place by the Board and the only significant condition imposed by the Board has been that point polluters participate in the Task Force.

[10] During oral argument, counsel for the EPA was unable to articulate precisely how the Task Force would resolve the scientific uncertainty.

There comes a point at which continual delay of a prioritized TMDL and detours to illusory alternatives ripen into a constructive submission that no action will be taken. With the Task Force as presently proposed, Ecology is coming dangerously close to such a point, and with EPA's support. Accordingly, the Court finds that the EPA acted contrary to law in finding the Task Force, as it is currently comprised and described, a suitable "alternative" to the TMDL. For the reasons set forth below, the Court remands the matter to the EPA for further consideration and consultation with Ecology. *See e.g., Idaho Sportsmen's Coal.*, 951 F. Supp. at 969 (finding EPA abused its discretion in approving insufficient TMDL schedule, even though no constructive submission occurred).

b. The Issue Is Remanded to the EPA

When an agency "does not reasonably accommodate the policies of a statute or it reaches a decision that is 'not one that Congress would have sanctioned,' . . . a reviewing court must intervene to enforce the policy decisions made by Congress." *Environmental Defense Fund v. EPA*, 852 F.2d 1316, 1326 (D.C. Cir. 1988) (citations omitted). An EPA regulation requires that "[s]chedules for submission of TMDLs shall be determined by the Regional Administrator and the State." 40 C.F.R. §130.7(d)(1). This regulation derives from Congress's direction that states submit TMDLs "from time to time" under 33 U.S.C. §1313 (d). Thus, the EPA has authority to set, with a state, a schedule to complete the TMDL process. *See Idaho Sportsmen's Coal. v. Browner*, 951 F. Supp. 962, 968 (W.D. Wash. 1996); *see also Dioxin/Organochlorine Ctr. v. Clarke*, 57 F.3d 1517, 1527-28 (9th Cir. 1995). A firm schedule and concrete goals are important in this

case, especially since the state is pursuing an alternative route that may delay an already delayed TMDL. *See* AR 90 at 1334; AR 132 at 2675-76.

Accordingly, the Court sets aside the EPA's decision and remands this issue to the EPA for additional consideration consistent with this order. Specifically, the EPA shall work with Ecology to create a definite schedule with concrete goals, including: clear statements on how the Task Force will assist in creating a PCB TMDL in the Spokane River by reducing scientific uncertainty; quantifiable metrics to measure progress toward that goal; regular checkpoints at which Ecology and the EPA will evaluate progress; a reasonable end date, at which time Ecology will finalize and submit the TMDL for the EPA's approval or disapproval; and firm commitments to reducing PCB production from known sources in the interim.

D. Spokane Tribe's Claims

The Spokane Tribe asserts that the EPA, in addition to its obligations under the CWA and APA, owed a trust responsibility to the Spokane Tribe. The EPA counters that it owes only a general trust obligation in this instance, which, according to the EPA, it discharged by complying with generally applicable law. There is a "distinctive obligation of trust upon the Government in its dealings with [Indian tribes]." *Gros Ventre Tribe v. United States*, 469 F.3d 801, 812 (9th Cir. 2006). This obligation alone, however, "does not impose a duty on the government to take action beyond complying with generally applicable statutes and regulations." *Id*. at 810; *Shoshone-Bannock Tribes v. Reno*, 56 F.3d 1476, 1482 (D.C. Cir. 1995) ("[w]ithout an unambiguous provision by Congress that clearly outlines a federal trust responsibility, courts must appreciate that whatever fiduciary obligation otherwise exists, it is a limited one"). Unless a specific duty exists, an agency's compliance with general regulations and statutes discharges

the agency's general trust responsibility to Indian tribes. *Morongo Band of Mission Indians v. FAA*, 161 F.3d 569, 574 (9th Cir. 1998). In order to create a specific duty, the statutory language must "go[] beyond a bare trust and permit[] a fair inference that the Government is subject to duties as a trustee and liable in damages for breach." *United States v. White Mountain Apache Tribe*, 537 U.S. 465, 474 (2003). This analysis involves an examination of whether specific rights are created by the statute—either creating a duty or imposing statutory or regulatory "prescriptions." *United States v. Navajo Nation*, 537 U.S. 488, 506 (2003).

In Count I, the Spokane Tribe asserts that the EPA breached its trust responsibility by failing to disapprove a "constructive submission" and not producing a TMDL. Doc. No. 64. The EPA counters that it discharged its trust responsibility by complying with generally applicable law, namely the CWA. The Court agrees with the EPA; the Spokane Tribe has not identified a specific duty in this context. The Spokane Tribe contends its status as a state for the purposes of the CWA and the EPA's approval of the Spokane Tribe's water quality standards imposed a heightened trust obligation on the EPA. AR Supp. 10 at paras 8-9. However, the Spokane Tribe cites to nothing that grants any specific rights to the Indian tribes. In the absence of a specific right or obligation, the EPA's responsibilities amount to no more than a bare trust obligation, which can be discharged by complying with generally applicable law. *See Gros Ventre Tribe*, 469 F.3d at 812 (observing that no breach exists where statutes and treaties only recognize a general or limited trust obligation to protect tribes on Reservation lands). The Court has already found that the EPA has not violated the CWA by failing to find a constructive submission. Accordingly, the EPA has not breached a trust obligation with respect to the CWA.

The Spokane Tribe further argues that the EPA owed the Spokane Tribe a trust duty regarding its April 12, 2013 approval of the Task Force as an alternative to the TMDL. Doc. No.

64. In addition to the APA obligations discussed *supra,* the Spokane Tribe asserts that the EPA had to consider the Spokane Tribe's fishing rights. Doc. No. 64. The EPA counters that "the [Spokane] Tribe's theory on how its fishing rights are impacted [by this decision] inappropriately assumes the Task Force will fail to reduce PBCs." Doc. No. 102 at 12. Since the Court has already found that the EPA violated generally applicable law with respect to its April 12, 2013 determination and will remand the matter to the EPA, the Court need not consider whether the EPA has any specific trust obligations at this time.

III. CONCLUSION

While the Court does not find that on the record before it there has been a constructive submission, the Court does find that EPA's approval of the Task Force without adequate assurances that it will result in a TMDL within a reasonable time is in violation of EPA's statutory duties and, therefore, contrary to law and arbitrary and capricious.

NOW THEREFORE, IT IS ORDERED AS FOLLOWS:

1. Plaintiffs and the Spokane Tribe's Motions for Summary Judgment are GRANTED with respect to their claims pursuant to § 706(2)(A) of the APA. EPA's approval of the Task Force as an alternative to the TMDL development, to extend over an indefinite period of time without adequate assurances that a TMDL will result, is held to be arbitrary and capricious, an abuse of discretion, and contrary to law;
2. This matter is remanded to the EPA with directions to consult with Ecology and file herein, within 120 days of the date of this order, a complete and duly adopted reasonable schedule for the measuring and completion of the work of the Task Force, including quantifiable benchmarks, plans for acquiring missing scientific

information, deadlines for completed scientific studies, concrete permitting recommendations for the interim, specific standards upon which to judge the Task Force's effectiveness, and a definite endpoint at which time Ecology must pursue and finalize its TMDL;

3. EPA's Motion for Summary Judgment is GRANTED, with respect to Plaintiffs' CWA claims and the Spokane Tribe's claims under the CWA and related claims under the federal trust doctrine;

4. Plaintiffs and Spokane Tribe's claims under the CWA and the Spokane Tribe's claim for EPA's breach of its federal trust responsibility are DISMISSED WITHOUT PREJUDICE;

5. The Court retains jurisdiction pending compliance with this order.

RE: Concerns with Idaho's Water Quality Standards Revision Process

Dear Mary Lou:

I am writing to clarify why the Kalispel Tribe does not currently support the process that Idaho has charted, and EPA apparently does not oppose, for revising the State's fish consumption rate ("FCR") and water quality standards. I want to emphasize at the outset that the Tribe has no interest in receiving any portion of the IGAP funds that EPA may be using to finance a fish consumption survey among the five tribes with reservations in Idaho. Our interest in this matter is to ensure that Idaho's revised water quality standards protect Kalispel people who eat fish that are harvested in Idaho or that are exposed to water pollution originating within Idaho. This is a very real concern to our members who harvest fish within the Tribe's aboriginal territory in Idaho, on lands owned by the Tribe in Idaho, or in Kalispel waters located downstream of Idaho. It is also a very real concern to our members who would harvest fish in these locales if it were safe to do so. The fact is that the FCR used to derive water quality standards in both Washington and Idaho has been outdated for more than a decade, resulting in elevated health risks for Kalispel people who eat more than 6.5 g/day of local fish or dietary avoidance of local fish. As both of these consequences are unacceptable to the Tribe, we cannot support further delay in adopting a more protective fish consumption rate.

The potential consequences of additional delay should not be underestimated. The process that Idaho has outlined will take at least three years from the date of EPA's disapproval of Idaho's water quality standards, which date was more than five years after the State submitted its water quality standards to EPA. Under the best case scenario, fifteen years will have passed from the date EPA published its 2000 Methodology requiring states to adopt an FCR of at least 17.5 g/day to the date that EPA approves an FCR in Idaho of at least 17.5 g/day. The cumulative delay of Idaho's proposed process accordingly amounts to an entire childhood, not a few years. To be clear, we are confronting a generational problem in terms of both unacceptable health risks for people who continue to eat fish and cultural destruction for those who do not.

02308

If EPA and the Idaho tribes believe that a new survey will be useful in helping Idaho develop more protective water quality standards, then we support that effort. We do not, however, think that the availability of funds and opportunity to develop new data should supplant the adoption of more protective state water quality standards right now. Idaho could defensibly adopt an FCR of at least 175 g/day tomorrow based on data supportive of the EPA-approved FCR in Oregon and more recent fish consumption surveys conducted by Washington tribes. The real issue at hand is not the absence of relevant fish consumption data, but how to manage the regulated community's effort to preserve its entitlement to pollute in a manner that is unsafe for people. That concern has no place in describing how much fish people eat or would like to eat, and should be addressed instead by developing an implementation schedule that protects human health and is reasonably fair to those who are regulated.

If EPA believes that it needs data from a new survey to be able to defend an FCR that is sufficiently protective of Indian people, we need to know that. And even if this belief turns out to be well founded, it does not justify leaving Indian people underprotected while these studies are designed and conducted. EPA guidance sets forth a national default FCR for subsistence fishers of 142.4 g/day that may be adopted without any new studies whatsoever. To demonstrate to the tribes that the goal of conducting a new tribal fish consumption survey in Idaho is to actually protect Indian people, EPA should insist that Idaho take a step in that direction by adopting an FCR of 142.4 g/day. The new survey will take at least three years to complete, so this FCR could be revised appropriately during the next triennial review.

The Tribe is also concerned that EPA has not developed parameters to ensure that the information derived from the IGAP survey will be used to protect Indian people. For instance, tribes need to know in advance that EPA will require Idaho to protect Indian people to a risk threshold that tribes support before the new survey is conducted. If EPA is not willing to provide this guarantee, then the regulated community may be able to manipulate data in a way that understates actual human health impacts to tribal members and other people who eat a large amount of fish. This effort is already underway in IDEQ's Negotiated Rulemaking Process. It is no defense that tribes will be able to adopt FCRs of their own because the bulk of toxic pollution originates from outside reservation boundaries.

During a December 11th phone call with EPA and the Idaho tribes, we specifically asked whether EPA would require subsistence fishers to be protected to the same extent as the general population. Christine Psyk responded that EPA would not because that requirement does not appear in EPA regulations or guidance. With all due respect, this response did nothing but reinforce our concern. EPA's 2000 Methodology states that it is acceptable for subsistence fishers to be protected at a 10^{-4} risk level as long as the general population is protected at a 10^{-6} risk level. If Idaho really has two orders of magnitude worth of wiggle room with which to "protect" subsistence fishers, we do not understand why EPA disapproved Idaho's standards in the first place, much less why it makes sense to spend $2 million on a tribal fish consumption survey. It is even more confounding to understand why people who eat the most fish are seen as dispensable in a risk assessment designed to protect the beneficial use of fishing. Frequent flyers certainly would not stand for this approach where airline safety is concerned, nor would there be many frequent flyers if 1 in 10,000 of them were involved in a plane crash.

EPA has curried some degree of regional support among tribes for its proposed use of the IGAP funds by saying that the IGAP survey will provide data that can be used by other tribes throughout the region. This is a spurious rationale, as EPA's actions in Idaho have demonstrated its unwillingness to require states to use relevant regional data. Instead, EPA is devoting millions to a new survey among Idaho tribes and supporting the State's decision to begin a new survey from scratch. The 2000 Methodology certainly does not require states or tribes to finance new surveys in the absence of available local or regional information, so Region 10 is effectively amending national policy to create a tremendous financial onus on any state or tribe wishing to adopt an FCR greater than the national default rate. The sounder policy choice here is to interpret EPA's permissive policy allowing states and tribes to set FCRs based on available local and regional informational as a mandatory requirement when such information demonstrates that vulnerable populations are underprotected. EPA arguably already made this policy decision in Oregon, and the result of that decision was an FCR of 175 g/day. If Idaho prefers devoting its scarce resources to financing a new survey rather than relying on regional data, it should adopt a rate of 142.4 g/day as suggested above during the pendency of the survey. EPA's disapproval letter did not clearly specify what was required of Idaho, so a clarifying letter would be helpful in outlining Idaho's range of options.

I would appreciate the opportunity to discuss these concerns with you in more detail in the near future.

Regards,

Deane Osterman
