Comment: The proposed implementation plan allowing compliance schedules for effluent limits to attain the criteria to be placed in permits may not pass the antidegradation test either. CBE believes EPA recognizes that permit schedules which allow continued impairment of fishing and aquatic life uses are improper (See e.g., section 1311(b)(1)(C), section 1314(l)(1)(D), section 1342(o)(1) and (3) and section 1313(d)(4)(A) of the Clean Water Act). In the alternative case, however, a schedule allowing discharge of these persistent pollutants to waters attaining the criteria will result in the accumulation of pollutants and will degrade water quality. This degradation is unnecessary as the state has accommodated important economic and social development for years while placing compliance schedules in administrative enforcement orders, and is thus impermissible under 40 CFR section 131.12(a)(2). Indeed, existing California dischargers have been made aware of the need to meet similar or more restrictive criteria since at least 1991, and further extension of time for more pollution should be done through schedules in enforcement orders. Any desire to avoid the administrative effort of continuing to prepare these enforcement orders is easily outweighed by the public interests in clean water and public participation afforded.

In sum, EPA's weaker criteria shown in Table 2 do not protect designated uses of water based on sound scientific rationale, and even if this were true for some toxics in some areas of the Bay, the weaker criteria are not necessary to allow important economic or social development. Therefore, revision of water quality standards by adopting these criteria would not meet the tests set forth by 40 CFR section 131.11(a)(1) and section 131.12 and the Clean Water Act provisions these regulations implement, Further, incorporating schedules allowing polluters to harm fishing and aquatic life in water quality standards and effluent limits is improper, and there is no legitimate need for schedules allowing degradation of water quality and restricting public participation to be in permits instead of putting them in administrative enforcement orders as is done today. Thus EPA's proposal may, by failing to provide equal protection for people of color who fish for food and unfairly restricting public participation, also conflict with the Executive Order on environmental justice and civil rights law.

Response to: CTR-002-010a

See legal response to CTR-002-009. EPA disagrees that compliance schedules will prevent antidegradation requirements from being met. First, the antidegradation policy at 40 CFR 131. 12 requires, as an absolute minimum, that existing uses (those uses established on or after November 28, 1975) must be fully protected in all waters. Secondly, the antidegradation policy allows some degradation in high quality waters (i.e., those waters whose quality exceeds levels necessary to support fishable/swimmable uses) provided that any such degradation would not reduce water quality to such levels below that needed to maintain the fishable/swimmable uses. Before allowing any degradation in

high quality waters, the State must ensure that all statutory and regulatory requirements for point sources and all cost-effective and reasonable best management practices are achieved. Furthermore, in allowing degradation to high quality waters the State must provide for public participation and intergovernmental coordination in demonstrating that the lowering of water quality is necessary for important economic and social advancements in the area that the discharge is located. Thirdly, no degradation (other than short term or temporary lowering of water quality) is allowed in waters classified as Outstanding National Resource Waters (ONRWs). ONRWs include the highest quality waters in the U. S. Additionally, the ONRW classification offers special protection for waters of "exceptional ecological significance, " i.e., those waters that are important, unique, or of ecological importance, but whose water quality, as determined by traditional parameters such as dissolved oxygen or pH, may not be particularly high.

Thus, although EPA notes that there is some degradation allowed to certain waters under the antidegradation policy, EPA believes that a compliance schedule can be complementary to the antidegradation provisions. The Agency has supported reasonable compliance schedules based on new or reviewed water quality standards adopted after July 1, 1977. A compliance schedule will accommodate the practical real world problems in meeting a new effluent limit where it is adequately justified. The whole basis for a compliance schedule is when a facility needs to invest in capitol improvements to install the additional treatment technologies necessary to meet more stringent effluent limitations. Furthermore, EPA is not aware of any specific instances where the State has either allowed any unnecessary degradation or allowed degradation to occur to a degree that is inconsistent with 40 CFR 131.12. Moreover, the commenter did not provide any analysis to demonstrate that antidegradation provisions are not being met or not being appropriately implemented in the State of California. Furthermore, although the antidegradation provisions are essential in maintaining and protecting water quality, those provisions are outside of the scope of today's rule.

Comment: 1 . DESIGNATED USES AND ANTIDEGRADATION POLICY

The DFG is concerned with the issues of "designated uses" and an "antidegradation policy" as they apply to the formation of water quality standards. It is our understanding that water quality standards are comprised of, or defined by, three components: 1) designated uses, 2) numeric water quality criteria, and 3) an antidegradation policy. The CTR is not clear on which designated uses are being identified and when they were established. The rule needs to identify what designated uses are being assigned and when these uses were or should be attained. At issue is which uses should be maintained and protected, and what the baseline should be for designating the various beneficial or designated uses for inland freshwater and bay and estuarine waters of the state. We believe that any baseline for applying the antidegradation policy should establish what the quality of the water would have been historically in the absence of human impacts. Under the Porter Cologne Act, the State's primary water quality statute, the

discharge of waste into state waters is not a right but a privilege. Since the discharge of waste is not considered a beneficial use, it should not be permitted in public waters unless it is determined that all beneficial uses, especially publicly entrusted fish and wildlife resources, are fully protected. This is especially true for wetlands throughout the State. The proposed rule is not clear as to when the baseline starts (i.e., historical vs. statutory). The DFG believes that, to the extent practicable, designated uses should be reflective of what has been realized in the past. If the CTR is utilizing a statutory date for which baseline designated uses were identified, then the CTR needs to include a justification for such a date.

With respect to antidegradation, it is not clear whether or not the proposed rule is subject to these requirements. It is our understanding that when a proposed action would allow less stringent criteria than previously proposed or adopted, and if that action would result in more loading of a particular constituent into waters of the State, then an appropriate antidegradation analysis shall be required. It is not clear what process EPA has undertaken to adequately address antidegradation issues related to the proposed new criteria. It may be that the applicability of the antidegradation policies are more pertinent with respect to site-specific criteria that may be included in the final rule. We recommend that the CTR adequately address this issue and apply the antidegradation policy where necessary.

Response to: CTR-026-001a

The scope of today's rule is to establish numeric criteria to bring California into compliance with CWA Section 303(c)(2)(B). Section 303(c)(2)(B) requires adoption of numeric criteria for priority toxic pollutants contained in CWA Section 307(a) for which EPA has issued Section 304(a) criteria guidance and where those pollutants could reasonably be expected to interfere with the designated uses of state waters. In today's action, EPA is relying on the use designations developed by the State of California, the State's existing antidegradation policy, and the criteria promulgated in this action to ensure that adequate water quality standards are in place to protect the waterbodies identified in the State's Regional Basin Plans. The adoption of criteria sufficient to protect designated uses is not an action which in and of itself results in any change in water quality. Thus, antidegradation implementation and baselines for applying the antidegradation policy are outside of the scope of today's rule.

Comment: The Center for Marine Conservation (CMC) is a nationwide, nonprofit advocacy group dedicated to the conservation and enhancement of coastal and ocean life and resources. CMC submits these comments on behalf of its 16,000 members in California and over 120,000 members nationwide.

CMC applauds EPA's efforts to bring California into compliance with the Clean Water Act section 303(c)(2)(B). Implementing numeric criteria that will protect the beneficial uses of California's waters is

of great importance to the health of coastal and marine ecosystems, and so to CMC and its members. The reliance in many areas of the state on narrative criteria threatens the health of most of the state's waters, thereby impacting both human health and the health of the state's economy that relies on clean water.

While CMC strongly supports the swift adoption of an Enclosed Bays and Estuaries Plan and an Inland Surface Waters Plan that contain numeric criteria for toxic pollutants, CMC also is concerned that many of the specific criteria contained in the proposed rule are weaker than those contained in published guidance. CMC also believes that the proposed rule can better protect certain subpopulations from harm caused by consumption of contaminated fish and shellfish. Finally, CMC is concerned that the economic analysis of the proposed rule over-emphasizes costs and under-reports the many benefits of improving water quality throughout the state. These three points are reviewed below.

Use of the Majority of the State's Waters Is Threatened or Impaired by Pollution

Increasing pollution seriously jeopardizes the health of the state's waters. The most recently available data shows that pollution threatens or impairs the use of 98% of California's tidal wetlands, 93% of its bays and harbors, 90% of its estuaries, 88% of its freshwater wetlands, 79% of its lakes and reservoirs, and 74% of its rivers and streams.(*1)

Where specific toxics data are available, they demonstrate that these contaminants are particularly significant threat to the health of the state's waters. For example, use of 98% of the state's tidal wetlands, 85% of its estuaries, 72% of its freshwater wetlands, 72% of its groundwater, 68% of its bays and harbors, and 52% of its rivers and streams are threatened or impaired by toxic pollutants.(*2)

Significantly, these figures represent only water bodies whose water quality has been measured. The health of many waters in the state is unknown. For example, the water quality of only 9% of the state's rivers and streams has been assessed.(*3) Moreover, even when a water body is reported as being "monitored," it may only be tracked for one or a handful of contaminants, leaving its overall health unclear. In other words, the number of water bodies known to be contaminated is only the minimum; actual pollution problems may be far greater.

In light of these statistics, it is imperative that the state move forward swiftly in implementing strong numeric controls on the discharge of toxics into our waterways. It is unacceptable California is the only state in the nation in substantial noncompliance with Clean Water Act section 303(c)(2)(B), and CMC welcomes EPA's extensive efforts in helping California work towards compliance.

These statistics, however, also call for the strongest criteria supportable by science. The significant threats demonstrated by the statistics show that the proposed rule's move backwards from published criteria documents should be viewed with an extremely critical eye.

(*3) Id. at p. 2.

Response to: CTR-029-001

EPA acknowledges that the criteria in the proposed CTR appeared in some instances to be inconsistent with EPA's published criteria recommendations. EPA explained in the preamble to the proposed CTR that EPA's policy has always been to utilize the latest toxicity information in IRIS when evaluating criteria. In this regard, EPA disagrees with the commentor that the criteria in the CTR are inconsistent with published EPA guidance. Since the proposed CTR, EPA has updated its National 304(a) published criteria to include the latest IRIS toxicity values (see 63 FR 68353 published on 12/10/98 and 64 FR 19781 published on 4/22/99). The values in the final CTR are now consistent with EPA's published criteria recommendations.

Comment: The Center for Marine Conservation (CMC) is a nationwide, nonprofit advocacy group dedicated to the conservation and enhancement of coastal and ocean life and resources. CMC submits these comments on behalf of its 16,000 members in California and over 120,000 members nationwide.

CMC applauds EPA's efforts to bring California into compliance with the Clean Water Act 303(c)(2)(B). Implementing numeric criteria that will protect the beneficial uses of California's waters is of great importance to the health of coastal and marine ecosystems, and so to CMC and its members. The reliance in many areas of the state on narrative criteria threatens the health of most of the state's waters, thereby impacting both human health and the health of the state's economy that relies on clean water.

While CMC strongly supports the swift adoption of an Enclosed Bays and Estuaries Plan and an Inland Surface Waters Plan that contain numeric criteria for toxic pollutants, CMC also is concerned that many of the specific criteria contained in the proposed rule are weaker than those contained in published guidance. CMC also believes that the proposed rule can better protect certain subpopulations from harm caused by consumption of contaminated fish and shellfish. Finally, CMC is concerned that the economic analysis of the proposed rule over-emphasizes costs and under-reports the many benefits of improving water. quality throughout the state. These three points are reviewed below.

In Light of Significant Threats to Water Quality, the Proposed Rule Should Contain the Most Stringent Criteria That Are Scientifically Defensible

Many of the criteria in the proposed rule are weaker than criteria in current published guidance. The proposed rule summarily states that the difference between the proposed, weaker criteria and the published guidance documents is "insignificant"(*4); however, in light of the current contamination

problems in California's waters today, any move backwards, particularly when spread out over the state, must be viewed as significant.

Any weakening of the criteria should be subject to close scrutiny and the most rigorous analysis, which the proposed rule itself does not do. Among other things, the criteria in the proposed rule may be under protective because additive and synergistic effects were not considered; and because the effects on wildlife, which can be particularly significant for bioaccumulative chemicals, were ignored.(*5) In addition, the proposed rule contains dissolved rather than total recoverable metals criteria, despite the fact that EPA acknowledges that total recoverable metals criteria are "scientifically defensible" and that they are more protective than dissolved metals criteria because they consider "sediment, food-chain effects and other fate-related issues," rather than simply water column impacts.(*6)

Clean Water Act section 303(c)(2)(B) mandates the development of numeric criteria that will "support such designated uses [that are adopted by the State]." The statistics available on the health of the state's waters indicates that their use already is significantly threatened or impaired by toxics. The strongest criteria supportable by science are necessary to reverse this trend and begin to restore the state's waters.

Comment: EPA should defer to the State's prior technical decisions to establish metals criteria based on total recoverable metals. EPA should defer to the State's prior determinations on dioxin and mercury as well as fish consumption rates. In establishing water quality standards under the federal Clean Water Act, neither EPA nor the States can factor in the anticipated economic burden which may result from implementation of the standards. The standards must be based solely on science and the needs of the beneficial uses established for the particular waters. The only reason that the State's promulgation of many of the requisite criteria in 1991 was overturned in state court was because of a flawed economic analysis pursuant to provisions unique to state law. EPA had approved many of those final criteria as technically sound and within the State's delegated discretion. EPA should not backslide on that prior

determination at this late date but instead should be attempting to close the gap in criteria by deferring to its previous approval.

Response to: CTR-039-002

EPA believes that in promulgating the criteria in today's rule, the Agency is not backsliding on criteria that were previously approved in California. Rather, in taking this action, the Agency intends to establish numeric criteria for priority toxic pollutants as required by CWA Section 303(c)(2)(B) until such time that California can adopt such criteria sufficient to protect the designated uses of the waters that are subject to this rule. The criteria included in today's rule are largely the same criteria that were adopted by the State. However, there are some differences. For example, because the criteria included in today's rule have been updated by EPA to reflect the Agency's latest scientific recommendation, the criteria values may be different from those adopted by State in the Inland Surface Waters Plan and Enclosed Bays and Estuaries Plan. EPA notes that the State, in the future, is not precluded from adopting criteria for total recoverable metals (instead of dissolved), adopting human health criteria that are based on higher fish consumption rates, or from adopting criteria for dioxin that are based on toxicity equivalents since these provisions are viewed as risk management decisions. The basis for EPA's use of metals criteria based on dissolved rather than total recoverable is discussed in the responses CTR-026-004, CTR-039-003a, and CTR-065-005, a record document entitled "Discussion of Use of Dissolved Metals in the CTR," and elsewhere in the record for the rule.

Comment: I . APPLYING DISSOLVED METALS CRITERIA AS PROPOSED VIOLATES THE ANTIDEGRADATION POLICY FOR SAN FRANCISCO BAY AND OTHER WATERS OF THE STATE

The practical effect of EPA's decision to rely on dissolved metals criteria is to allow higher levels of total recoverable metals to be discharged from point sources into San Francisco Bay as well as other waters of the State. Since 1991, many permits in the Bay area and else where have been issued applying the State Water Resources Control Board's technically-based and EPA approved numeric criteria for numerous toxic pollutants. For at least three years, permits throughout the State were required to be issued using the duly-promulgated criteria established by the State Water Resources Control Board ("SWRCB"). After the Sacramento court vacated the criteria on economic grounds, numerous permitting decisions were made by local regional boards and their staffs applying the previously applicable standards using their best professional judgement ("BPJ") in order to assure the protection of beneficial uses. Each of the permitting decisions based directly or deferentially on the SWRCB's criteria would be more stringent than permits for the same parameters authorized by EPA's proposed rule where a discharger opts to follow the Water Effects Ratio protocol for translating the criteria into a permit limit. BayKeeper would

not anticipate that many, if any, dischargers will opt for the default WER of 1.0 Thus, for many regulated dischargers, EPA's proposal will lead to major increases in the total metals they are allowed to discharge into the Bay and other waters of the State. This massive increase in the total pollution proposed to be allowed to be discharged into the Bay and other State waters is completely inconsistent with the State's and EPA's antidegradation policies mandating that existing water quality be maintained and protected. As the State's policy sets forth:

Whenever the existing quality of water is better than the quality established in policies as of the date on which such policies become effective, such existing high quality will be maintained until it has been demonstrated to the State that any change will be consistent with maximum benefit to the people of the State, will not unreasonably affect present and anticipated beneficial use of such water and will not result in water quality less than that prescribed in the policies.

SWRCB Resolution No. 68-16. Under the federal version of the policy:

[w]here the quality of the waters exceed levels necessary to support propagation of fish, shellfish, and wildlife and recreation in and on the water, that quality shall be maintained and protected unless the State finds, after full satisfaction of the intergovernmental coordination and public participation provisions of the State's continuing planning process, that allowing lower water quality is necessary to accommodate important economic or social development.

40 C.F.R. 131.12(a)(2). The antidegradation policies apply both to permit decisions as well as decisions establishing water quality standards. See, e.g., In The Matter of the Petition of Remmon C. Fay , SWRCB Order No. WQ 86-17 (Nov. 20, 1986). In the case of EPA's proposed rule, throughout California the rule, if adopted, will allow more pollution to be discharged than is currently allowed by permits validly issued to numerous dischargers throughout the State without any consideration of the policies, including the intergovernmental coordination and public participation requirements, required by the antidegradation policies.

Of course, in addition to that procedural problem, BayKeeper is opposed to the proposed reliance on dissolved numbers, especially in the Bay area, because it will in fact allow more pollution to be discharged into the State's waters than is currently allowed today and likely will prove detrimental to beneficial uses. See Comments of Communities For A Better Environment. BayKeeper also is very concerned about the burdens and uncertainty placed on the public by the need for translators in order to apply the dissolved criteria in permit limits that must be based on total recoverable numbers. As noted above, BayKeeper does not anticipate that many dischargers will opt for EPA's proposed WER default of 1.0 BayKeeper views this proposal as an invitation for dischargers to prepare site-specific limitations based on their own studies which will frustrate the public' s ability to participate effectively in the formulation of effluent limits. Further, the proposal will present a moving target for the public to understand and will burden the resources of regional board staff to a degree that may undermine the quality of those site by site determinations.

Response to: CTR-039-003b

See response to CTR-026-004. First, EPA disagrees with the contention that the CTR will result in massive increases in the total pollution allowed in the San Francisco Bay. See response to CTR-002-003 for a detailed response to this same comment.

EPA disagrees that the dissolved criteria will violate California's or EPA's antidegradation provisions contained in 40 CFR 131.12. The use of dissolved criteria in establishing aquatic life criteria for metals

is based on EPA's determination (with widespread support and input from experts in the scientific community) that dissolved metals more accurately approximates the portion of the metals in water that is biologically available to cause toxicity to aquatic organisms.

The antidegradation policy at 40 CFR 131.12 and the State's antidegradation policy ensures full protection of existing uses (those uses established on or after November 28, 1975) and provides a means to assess the impacts of discharges to high quality waters. There is some degradation allowed to high quality waters (see response to CTR-002-010a), provided certain procedures are implemented and certain provisions are met. However, EPA does not support the notion that dissolved metals will violate the antidegradation policy. EPA contends that the use of dissolved metals will provide a greater degree of accuracy in protecting aquatic ecosystems.

Furthermore, the adoption of criteria sufficient to protect designated uses is not an action which in and of itself results in any change in water quality. The implementation of such criteria may raise antidegradation issues in specific instances in the future, but this rule does not.

Comment: PROPOSED RULE ALLOWS SIGNIFICANT AND UNACCEPTABLE INCREASES IN TOXIC POLLUTANT CONCENTRATIONS IN BAYS AND ESTUARIES

Our initial review indicates that the proposed criteria for a number of toxic constituents are unacceptably high and will allow more pollution of bays and estuaries by several orders of magnitude. If adopted as proposed, the CTR will allow a 900% increase of dioxin, 140% increase of PCBs, 325% increase of mercury, 2760% increase of zinc, 23,000% increase of lead, and a stunning 430 million % increase for total PAH, some of the most problematic pollutants in San Diego Bay. The CTR only improves (i.e. strengthens) criteria for only 3 of 64 pollutants. This does not square with new studies that show reasons for concern about the synergistic and long-term effects of exposures to these toxic pollutants. In sum, the CTR proposes weaker criteria for 58% of the pollutants and no change for 37% of the criteria. This kind of action will not bring us closer to our goal of cleaner water containing healthier organisms in the future.

Comment: Now, I won't go through each of the pollutants one by one here. I want to give some other speakers some time.

But to summarize on the criteria point, EPA's proposal criteria ranges from slightly less to more than a thousand percent weaker than the state's previous proposal for 37 of the 64 pollutants of concern identified by the San Francisco Estuary Project -- that's according to our preliminary analysis -- or 58 percent of these pollutants, as compared with previous EPA-approved state standards.

Time and again, when environmental standards required action to prevent pollution, and this was done right, this resulted in long-term economic benefits rather than costs.

And I have an antidegradation question here: Will EPA allow these pollutants to degrade water quality when your own economic analysis shows no evidence of widespread economic concern?

And our data show that in fact doing it right and preventing pollution could save jobs and provide long-term economic benefits, as well as environmental health benefits.

Comment: (*1) As you know, several storm water systems have requested additional time to comment on the proposed rule, a request in which the ACCWP has joined. Additional time is particularly important given the interdependence between the CTR and the recently proposed "Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California," ("State Implementation Policy" or "SIP") released by the SWRCB on September 12, 1997, just two weeks before the comment deadline an the CTR. The way in which the CTR is implemented is central to its effects on storm water dischargers, as discussed below. Unfortunately, the State Implementation Policy does not fully correct or moderate the critical problems created by the proposed CTR.

Response to: CTR-001-001

EPA acknowledges that many dischargers have requested a longer comment period than was provided for the proposed CTR. The proposed CTR was published in the Federal Register on August 5, 1997 and the public comment period ended on September 26, 1997. This gave the public an opportunity of 52 days (over 7 weeks) within which to review and draft comments. The document was available through the Internet at EPA's website. EPA believes that this was a reasonable and sufficient time within which to complete a thorough review and to draft and submit comments to the Agency. The proposed CTR was not substantially different from California's prior law or the National Toxics Rule; it proposed to establish water quality criteria for priority toxic pollutants in the State of California and a compliance schedule provision for permits based on the proposed criteria. These provisions were not extensive or new; similar provisions have been in existence for the State of California and elsewhere in the country for many years.

The comment period is intended to provide commenters with a chance to substantively review the merits of the proposed action. For the proposed CTR, EPA expected and received comments on the scientific sufficiency of the criteria values and their underlying derivations, and on the compliance schedule provision. Comments concerning the implementation of the criteria should have been, and were, directed to the State of California. The State had proposed an implementation plan on September 12, 1997, during the public comment period of the proposed CTR. The comment period for the proposed implementation plan ended in December of 1997. The State's plan was also available to the public through the Internet.

Many commenters requested a longer comment period for the proposed CTR, to extend the time within which to review both the proposed CTR and the State's proposed implementation plan. The comment period for the proposed CTR overlapped with the first two weeks of the comment period for the State's

proposed implementation plan. EPA believes this was a reasonable and sufficient time within which to determine and comment on any issues concerning the proposed CTR criteria and compliance schedule provision due to the State's action. Commenters had several additional weeks to thoroughly review and comment on the State's specific implementation provisions in light of the proposed CTR criteria values. Although the CTR criteria and the State's implementation plan are related, the issues for comment are distinctly different and should have been directed to the respective appropriate entity. The CTR proposed water quality criteria which are scientifically-based and do not take economics into account; implementation procedures are not necessary in order to comment on the scientific underpinnings of the proposed water quality criteria.

The CTR and the State's implementation plan were not proposed together; they are separate phases of a comprehensive water quality control plan for the State of California and as such, can be commented on in phases. Both the EPA and the State published economic analyses which looked at the economic impacts of implementation of the respective proposed regulations. EPA's analysis for the proposed rule looked at the potential economic impacts of implementation of the proposed criteria using current State implementation procedures. The State's economic analysis for its proposed plan looked at the economic impacts of specific proposed implementation procedures.

Comment: Dear Ms. Frankel, Regional Administrator Marcus and Administrator Browner:

CBE believes that adoption of EPA's "California Toxics Rule" as proposed might represent the biggest step backward in toxics policy for San Francisco Bay in the twenty-five year history of the Clean Water Act.

The Rule would allow far more pollution than state water quality standards criteria EPA is trying to replace for most of the toxic pollutants of concern in the Bay. It would allow levels of dioxin compounds, mercury, polycyclic aromatic hydrocarbons, and toxic metals that already harm the fishing public and aquatic life to increase. Despite EPA's admission of soaring cancer risk and other toxic threats to Bay anglers, it would fail to protect people who fish for food unless they eat only starvation rations of one-seventieth of a pound of fish per day. Its dioxin criteria deregulate sixteen of the seventeen most toxic compounds known to science. It ignores proof of mercury bioaccumulation and evidence that its weaker copper criteria allow pollution levels that wiped out aquatic populations. It then proposes a system of "permits to pollute" above even-these inadequate standards for up to ten years. Many of these problems extend state-wide beyond the Bay.

EPA's analysis in the proposed Rule ignores protection of fishing people of color who are disproportionately imperiled by toxic pollution it would allow, and evidence EPA asked us for showing

that stronger rules than EPA'S drive pollution prevention which results in economic benefits to the manufacturing base. The proposed Rule does not appear to comply with federal laws which require protection of public health, fishing and aquatic life and equal protection under the law.

The massive scope of this policy change suggests the need for maximum public involvement. Unfortunately, EPA staff report receiving only one "public" comment to date. We believe that this critically important environmental health decision is not receiving adequate public scrutiny.

Accordingly, we request that EPA extend the comment period for the Rule beyond the present September 26, 1997 deadline, revise the toxics criteria to address the concerns detailed in our enclosed comments, and require present state implementation procedures instead of allowing permit schedules which could grant "permits to pollute."

We have begun to discuss these concerns with EPA staff, and hope to continue this process with you, Regional Administrator Marcus, and Administration environment officials, in order to seek ways in which we can move forward together to solve the serious toxic pollution problems affecting people and aquatic life in San Francisco Bay and throughout California. We propose a meeting at your offices at 2 p.m. or later on Wednesday, October 1, 1997 as a next step in these discussions.

Response to: CTR-002-001

In response to the comment requesting an extension of the comment period, please refer to response to CTR-001-001. In response to the comment requesting present state implementation procedures instead of allowing permit schedules as proposed in the CTR, the State's implementation procedures were overturned by a State Courtruling in 1994. Thus, the State does not have a comprehensive set of implementation procedures. Each of the Regional Water Quality Control Boards implements water quality-based effluent limitations based on varying procedures, some of which have been formally adopted and others which have not. The Regional Boards may always implement any State adopted, federally approved water quality criteria through a State adopted, federally approved compliance schedule provision.

Comment: As stated above, most of the SBSA's concerns with the CTR, relate to the uncertainty of how the objectives will be implemented in permits. The CTR comment period should be extended to 90 days to allow sufficient time to review the draft implementation policy recently released by the state.

SBSA appreciates the opportunity to comment on the proposed rule. Please call me at (650) 594-8411 ext. 124 if you have any questions regarding the SBSA comments or need any additional information.

Sincerely,

James B. Bewley Manager

Comment: 4. It is the District's understanding that the State Water Resources Control Board's ("SWRCB") implementation policy for the CTR will include a policy determination on which criteria will be used in mixing zones i.e. fresh or salt water. If this is indeed the case (which the District does not know because it has not yet received its copy of the implementation policy) then the District requests that the comment period be extended in order to evaluate the CTR with the SWRCB's implementation policy.

Response to: CTR-007-005

Comment: In particular, Sunnyvale supports CASA/Tri-TAC's request for additional time in which to evaluate the potential impacts of the CTR in conjunction with the implementation plan being proposed by the State of California (the "State Proposal"). Sunnyvale obtained the State Proposal from the Internet as soon as it became available, yet Sunnyvale has had little time to digest the massive proposal and analyze its potential impacts on the implementation of the CTR. We suggest that most other California dischargers are in the same position and we strongly urge the Agency to reconsider its unfair and probably illegal decision to provide only a few days to assess and comment on what amounts to a joint promulgation by EPA and the State.

Response to: CTR-021-001

CROSS REFERENCES C-16

Comment: Some of the concerns noted above could be addressed through the implementation provisions of the CTR. As you know, the State Water Resources Control Board has just made available for public review the Proposed Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California (Proposed ISWP/EBEP Policy), the implementing document for the CTR. Because of the length of the document (several hundred pages) and the fact that it has only

recently become available, there has been insufficient time for thorough review. Yet, this document is crucial to understanding the practical impact of the CTR.

Metropolitan strongly requests that U.S. EPA extend the comment period on the CTR to December 10, 1997, the end of the comment period for the Proposed ISWP/EBEP Policy. This would allow drinking water suppliers and others affected by the CTR to evaluate the CTR in the context of its implementation. Without workable implementation provisions, the operational and economic impacts on drinking water suppliers could be significant and may need to be taken into account in the CTR. If the comment period is not extended, we ask that U.S. EPA fully consider the impacts of the freshwater aquatic life criteria on the operation and maintenance activities of drinking water suppliers and the effect on water reclamation activities and to modify the CTR, as necessary, so that these activities can continue to be undertaken in an economically feasible manner.

The CTR forms the backbone of the water quality regulatory process and Metropolitan urges U.S. EPA to review the proposed criteria in light of regulatory requirements of the California/Federal SDWA and the operating and maintenance requirements of drinking water suppliers. If you have any questions regarding Metropolitan's comments, please feel free to call Marcia Torobin of my staff at (213) 217-7830.

Response to: CTR-025-006a

In response to the comment requesting an extension of the comment period, please refer to response to CTR-001-001. In response to the comment concerning the CTR's impact on drinking water suppliers, EPA notes that the criteria in the CTR do not impose any cost on anybody or entity. It is only when they are implemented through the State's process that economic impacts may be felt. The CTR's criteria legally apply only to water quality-based effluent limits in NPDES permits. The State on its own accord may apply the water quality criteria in other contexts and/or in other programs, and those applications may cause economic impacts.

Comment: d. The proposed CTR and the recently released proposed State Implementation Plan must be fully integrated, internally consistent, and their combined effect thoroughly assessed. However, EPA has allowed only one week of overlap between the proposals for stakeholder review.

The EPA concedes within the proposed CTR that the criteria themselves lack substance without the corresponding implementation measures. EPA also acknowledges that the economic impact of the CTR can not be fully evaluated without consideration of the ISWP. However, the EPA can not simply abdicate its responsibility to assess the impact of its proposal, nor can it expect stakeholders to accept the

proposed CTR without full understanding of its implementation.

All stakeholders require the opportunity to evaluate the proposed CTR and Implementation Plan together as a comprehensive, cohesive body of regulation.

Comment: The Southern California Alliance of Publicly Owned Treatment Works, or SCAP, is pleased to submit comments to the Environmental Protection Agency (EPA) regarding the Proposed Rule Regarding Water Quality Criteria for Toxic Pollutants for California (known as the California Toxics Rule, or CTR) SCAP's members include 47 public agencies that provide wastewater treatment services in Southern California.(*1) Collectively, our member agencies serve over 16 million residents of Southern California. Our member agencies range in size from very small to very large, and include wastewater treatment facilities that discharge to inland surface waters, bays and estuaries, and the ocean. Most of our members are also involved in water reclamation activities. We appreciate the opportunity to comment on the proposed California Toxics Rule.

As noted in SCAP's testimony at EPA's public hearing held on September 18, 1997 in Los Angeles, we would like to request that EPA re-open the comment period on the CTR. We would, like the opportunity to more fully review the proposed rule and supporting documentation, and believe that the extra time would afford us the opportunity to develop additional meaningful comments on the proposed regulation and its potential impacts on the POTW community in southern California.

(*1) SCAP's members are located in the following counties: Santa Barbara, Ventura, Los Angeles, San Bernardino, Riverside, Orange, and San Diego

Comment: We are writing on behalf of Tri-TAC and the California Association of Sanitation Agencies (CASA), which are California-based organizations comprised of members from public agencies responsible for wastewater treatment. Tri-TAC is an advisory group which includes representatives from CASA, the California Water Environment Association, and the League of California Cities. CASA is comprised of over 80 agencies responsible for the operation of publicly owned treatment works (POTWs). The constituency base for Tri-TAC and CASA encompasses most of the sewered population of California.

We have reviewed the draft rule containing proposed water quality criteria for toxic pollutants for California ("California Toxics Rule" or "CTR") that was published in the Federal Register on August 5, 1997. We have numerous specific comments on the proposed rule. Our specific comments are contained in two attachments. Attachment 1 contains our comments on specific sections of the draft regulation and the Economic Analysis. Attachment 2 is a critique of the Economic Analysis prepared by M.Cubed, a resource economics consultant to Tri-TAC, CASA, the Southern California Alliance of POTWs (SCAP), and the Bay Area Dischargers Association (BADA). We would like to highlight several priority concerns below.

First, we would like to reiterate our previous requests (see letters of July, 21, 1997 and August 12, 1997) that EPA reopen the comment period for the proposed rule in order to facilitate a more complete review by the public, and in particular, by those in the POTW community. EPA's own analysis shows that POTWs are the sector most affected by the rule (according to the Preamble. POTWs will incur 67 percent or 96 percent of costs under the low and high cost scenarios, respectively) (62 Fed. Reg. 42189). We believe that it is common practice for the Agency to provide 90 days -- or even longer -- for comment periods on proposed rules, particularly if there is no court order dictating a promulgation schedule (and we are not aware of any court decision requiring a specific schedule for promulgation of the CTR). It is our understanding, for instance, that EPA provided a 150-day comment period for the Great Lakes Initiative in 1993.

In addition, as we noted in our previous letters, we understand that EPA and the State Water Resources Control Board (SWRCB) are promulgating the criteria and Statewide Implementation Policies in a collaborative manner. We respectfully request that you provide an extension in order to facilitate a more complete review of the SWRCB's Draft Implementation Policy, which was released on September 12. Because of the impending deadline for comment on the CTR, we have not had time to conduct more than a cursory review of the SWRCB's proposal. Therefore our comments by and large do not take into account the draft Implementation Policy of the SWRCB, which may after our interpretation of some aspects of the CTR.

Further, we believe that EPA has an obligation under Section 6(a) of Executive Order 12866, which requires all federal agencies, including EPA, to provide a "meaningful opportunity to comment on any

proposed regulation, which in most cases should include a comment period of not less than 60 days." (emphasis added). While we believe that the CTR is a "significant regulatory action," the comment period requirement applies even if EPA does not agree. The Agency is also required under the Unfunded Mandates Reform Act of 1995 (2 U.S.C.A. 1511 et. seq.) to provide "meaningful and timely review" by small governments. Aside from the fact that EPA has not provided the minimum of 60 days on the proposed CTR itself, the State Water Resource Control Board did not make its proposed implementation plan (the "State Proposal") available until September 12 (with effective distribution delayed for several days), which means that the public will have a period of less than two weeks to review the State Proposal, relate its provisions to the proposed CTR and formulate comments. This is obviously an inadequate time period in which to review a package of approximately 200 pages, which contains many proposals on a variety of complex matters which could substantially alter the potential impacts of the CTR.

We believe that the State Proposal is an integral part of the CTR; this belief is supported by the dozens of references to the future exercise of regulatory authority by the State of California scattered throughout the Preamble to the CTR (see, for instance, pp. 42173, 42174, and 42185, as well as numerous references in the Economic Analysis). The EPA even concedes (at p. 42188): "A more precise measure of costs and benefits may not be known until the State adopts its implementation provisions." In short, the CTR may have many significant impacts on the regulated community, the nature of which are dependent upon the contents of the State Proposal, and yet EPA is not willing to give the affected community the time to analyze and comment meaningfully upon the EPA rule, as proposed to be implemented by the State. This is, we believe, a violation of the Executive Order and the Unfunded Mandates Reform Act. We do not believe that EPA can justify its comment deadline by the requirement of Section 303(c)(4) to promulgate the final rule within 90 days after the proposal, since EPA has already signaled its Intention to take longer than 90 days to finalize the rule. EPA thus has no obvious reason to object to allowing additional time for review of the CTR nor has EPA offered any reasonable explanation for its lack of compliance with Executive Order 12866 and the Unfunded Mandates Reform Act.

Response to: CTR-035-001

In response to the comment requesting an extension of the comment period, please refer to response to CTR-001-001. In response to the comment concerning the Great Lakes Initiative (GLI), the GLI was a much more complex rulemaking than the CTR. The GLI applied to eight states and promulgated water quality criteria and many implementation procedures. In contrast, the proposed CTR promulgated criteria for only one state and had only one implementation procedure - a compliance schedule provision. The proposed CTR was not substantially different from California's prior law or the National Toxics Rule. Although the GLI comment period may have been substantially longer, the complexity of the rule was much greater, warranting the longer time frame. EPA's usual comment period is 45 days; EPA extended this to over 50 days for the proposed CTR to ensure that a reasonable overlap of time existed with the comment period for the State's proposed implementation plan.

In response to the comment concerning Executive Order (E.O.) 12866 and the Unfunded Mandates Reform Act, each of which discusses comment periods for proposed rulemaking activities, see the preamble to the final rule. EPA believes that over 7 weeks to review and comment on this proposed straightforward and basic water quality rule was adequate, especially because this rule was not substantially different from California's prior law or the National Toxics Rule. Although E.O. 12866 states that in most cases, agencies should afford a comment period of not less than 60 days, in this case, EPA provided 52 days because it thought this period adequate (for reasons stated above) and because EPA had a statutory deadline to promulgate 90 days after proposal.

Comment: 4. EPA has not provided sufficient time to review and comment on all of the changes that it is making in various water quality criteria. Only 7 weeks were provided to comment on over 20 different criteria, when EPA is providing almost 9 weeks to comment on one criterion (TBT, Aug. 7 - Oct. 6, 1997). This magnitude of change requires at least a 180 day comment period. Therefore the comment period should be extended, at a minimum, to February 1, 1998.

Comment: The Sacramento Regional County Sanitation District (District) appreciates the opportunity to submit these comments on the proposed California Toxics Rule (CTR). The District provides wastewater treatment service to approximately one million people in the Sacramento metropolitan area. The Sacramento Regional Wastewater Treatment Plant (SRWTP) discharges approximately 160 million gallons per day of treated wastewater to the Sacramento River.

Our response has been limited due to the limited comment period. We are also concerned about not having time to analyze the CTR with the State Water Resources Control Board's draft policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California which was released on September 12. It is essential that sufficient time is provided to conduct a detailed review of the CTR and to assess its impact on the draft implementation policy by the State. As we have previously requested, the comment period should be extended.

CROSS REFERENCES

Comment: WateReuse believes that the designation of the relatively short comment period proposed of fifty days does not afford a comprehensive and complete public review of the rule. It is our opinion that should a decision be made to reopen and/or extend the public comment period on this subject, USEPA and the rulemaking process will benefit from the additional input of appropriate and valuable information. This would allow for, and include, a more thorough review and coordination of public comment with the lengthy Draft Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California just released by the State Water Resources Control Board (SWRCB) on September 12, 1997. We therefore would request that the comment period for the draft CTR be reopened and/or extended to reflect the weight of this proposed rule, the impact it will have on all statewide stakeholders, and the need for better coordination of comments with the just released draft state plan.

Response to: CTR-049-001

Comment: The Authority acknowledges the importance of the CTR and the efforts that went into its creation. EPA has taken several years to prepare the CTR, yet has given the public only a 45 day period in which to develop comments. In addition, the State Water Resources Control Board issued its Draft Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California (Implementation Plan) on September 12, 1997. The Authority received its copy on September 16, 1997. Thus there has been less than two weeks to review both documents to determine the potential impact on the Authority, its member agencies, and the public which they serve. On July 17, 1997, requested an extension of the public comment period, and that request was denied.

In the short time available to review the CTR and the EA, it has been determined that the CTR, as currently proposed, will have tremendous economic impacts on our ratepayers. In addition, it appears that the EA is so seriously flawed from both a cost and benefit perspective, that EPA's justification for promulgating the CTR is seriouslyquestioned. The CTR and the EA briefly discuss "relief options" for dischargers that will be available through the State. We have been so preoccupied with reviewing the CTR that there has been no opportunity to properly review the Implementation Plan. In view of the cost implications, more time is needed to provide adequate review time for the Implementation Plan as it relates to the CTR and the EA. Therefore, I again repeat my request for EPA to reopen the public comment period. It should be reopened through December 10, 1997 to coincide with the comment period for the Implementation Plan.

Response to: CTR-052-001

Comment: The comment period should be extended to 90 days. The rule is critical to California and it is essential that all parties have ample time to review it in detail and to assess its impact based on the draft implementation policy recently released by the State. There is no reason to rush the final version of the rule.

Response to: CTR-054-001

In response to the comment requesting an extension of the comment period, please refer to response to CTR-001-001.

Comment: First, like many other agencies submitting public comment, EBMUD requests that EPA give serious consideration to reopening the comment period for the CTR to provide affected dischargers sufficient time to conduct a thorough review of the proposed rule. This is especially of concern to the EBMUD in the context of having to also review the recently published, "Policy for Implementation of

Toxics Standards for Inland Surface Waters and Enclosed Bays, and Estuaries of California" and "Functional Equivalent Document" [September 11, 1997]. For POTWs, the only way to completely evaluate the regulatory and economic impacts of the CTR is to review both documents together. Because of the limited time in which to conduct such a review, and in recognition that EPA has provided extensions for past rulemaking (e.g. a 150-day comment period for the Great Lakes Initiative in 1993), this request is reasonable and will result in a more complete review by the public.

Response to: CTR-056-001

In response to the comment requesting an extension of the comment period, please refer to response to CTR-001-001 and CTR-035-001.

Comment: We also wish to emphasize the need for additional time to review the proposed Rule in light of the State Water Resources Control Board's (SWRCB) Draft Implementation Policy for Toxics Standards, which was released for general distribution less than two weeks ago. Because these proposed plans involve complicated issues that may significantly increase our treatment costs, and because we have not had sufficient time to review the State's draft document, we may submit additional comments based on further analysis of the CTR as it relates to the SWRCB's September 12, 1997 draft document.

Response to: CTR-057-002

Comment: We are also deeply concerned that EPA has given a relatively short comment period on this very lengthy and complex rulemaking. EPA has taken years to develop these rules. We see no reason for EPA's failure to grant an additional 30 days for comments on this important rule since the promulgation and implementation of this proposal is many months away, and considering that stakeholders have had only a few days to obtain and consider the state's implementation policy which is a parallel rulemaking.

Response to: CTR-058-002

Comment: The Sanitation Districts would greatly appreciate additional time to review the proposed rule. As discussed above, the rule will clearly have significant impacts on our facilities and on the residents and businesses in our service area, as well as on numerous other POTWs and local governments in California. While EPA has minimized the significance of the rule in its analysis, the bottom line is that the rule will promulgate some 190 water quality criteria for California for about 70 different pollutants. While a few of these criteria have previously been promulgated by EPA through the 1992 National Toxics Rule (NTR), approximately 70 of them have been recalculated, modified, or added by EPA since the 1992 NTR, To adequately review these changes requires a great deal of time and effort, especially since only a few of the changes are discussed in the Preamble and many of the supporting documents cannot be readily accessed outside of EPA. Therefore, the Sanitation Districts respectfully request that EPA provide at least 30 additional days for public review and comment.

Response to: CTR-059-003

In response to the comment requesting an extension of the comment period, please refer to response to CTR-001-001. In response to the comment concerning records, a complete record of supporting documents is available at the U.S. EPA Region 9 office in San Francisco, and many of the important documents are available at the U.S. EPA Headquarters Office in Washington, D.C. The availability of these documents was published on the first page of the preamble to the proposed CTR.

Comment: While I do not know how long it would take the US EPA to conduct the required analyses of the urban stormwater runoff costs and real water quality benefits, it would seem appropriate that taking a few months to accomplish this could, in the long term, represent a time and resource savings in terms of ultimately correcting the significant technical problems that exist today in regulating urban stormwater runoff. I recommend the following:

Urban stormwater dischargers as well as other interested parties should be provided a several-month period during which a preliminary assessment of the potential costs and water quality benefits associated with having to meet CTR criteria as standards in the receiving waters for stormwater runoff of concern to the discharger, is conducted and reported to US EPA Region 9.

The US EPA should take several months to develop an amended draft CTR that provides a reliable economic analysis of costs and potential benefits covering the current regulatory approach for regulating chemical constituents urban stormwater runoff which involves a ratcheting down of BMPS to achieve the ultimate goal of only one exceedance of a water quality standard every three years in the receiving waters for stormwater runoff.

The public should be given a two-month period during which to review and comment on the adequacy of the US EPA's economic analysis of costs and benefits of achieving the currently mandated goal of using CTR criteria as standards for receiving waters for regulated urban stormwater runoff.

Adoption of this approach will send a clear signal to the public that the US EPA is finally willing to meaningfully address the heart of the urban wet-weather runoff water quality management problem. With the Agency's, for the first time, reliably developing information on costs and true water quality benefits, the public, Congress, regulators and the regulated will begin to understand the need to change how urban and highway stormwater runoff is regulated to protect the designated beneficial uses of waterbodies without significant unnecessary expenditures for chemical constituent control.

Comment: The District has done its best to stay up-to-date on happenings surrounding the CTR and have attempted to complete our review of the proposed rulemaking. However, given the nature of this rulemaking and the companion pieces currently being pursued by the State Water Resources Control Board, it is practically impossible for us to give you anything more than preliminary comments on the CTR. Extensive work has been done by your agency to fill the void left by the litigation that overturned the State Board's rulemaking, and that has resulted in a significant period of time for both your staff and others to complete this rulemaking. It is our belief that you should allow adequate time for medium-sized agencies such as ours to be able to hire consultants or other technical professionals to assist us in this very important rulemaking. In addition, the information related to the economic analysis associated with this is difficult at best and we have not been able to hire anyone to assist us in completing our evaluation. Consequently, we would request a significant extension of either 90 or 150 days to allow us to complete our analysis. We will also be preparing our NPDES permit renewal request in the next six months and expect that many of the issues that will come out of our review of the CTR will relate directly to our activities on the permit. As a consequence, we would request that this extension in time be allowed for all agencies in the state.

The District fully supports EPA and the State Water Resources Control Board (SWRCB) program to promulgate both the criteria and statewide Implementation Policies in the collaborative manner currently being approached. However, because of the late release of the Implementation Policy by the state, we are not able to have reviewed both that policy and the CTR for conformance and detail. We have only had a short 14 days to complete this analysis and that just has not been adequate to complete the response. We believe that the state's comment period lasting until December, 1997, is far more equitable and reasonable given the substantial nature of the criteria being established. We would further request that EPA and SWRCB give serious consideration to establishing a blue ribbon technical committee to assist with this collaborative effort so that concerns and needs of the regulated community can be thoroughly considered so that there will be broad public acceptance of the results of this most important work.

Response to: CTR-066-001

In response to the comment requesting an extension of the comment period, please refer to response to CTR-001-001. In response to the comment concerning the blue ribbon technical committee, the State, during its redrafting process of the implementation plan, convened numerous task force groups with a number of different stakeholder representatives on each task force, to solicit comments and ideas concerning the issues. EPA was fully represented on each task force, and listened to all comments concerning the State's water quality control plans. EPA hopes the commenter had the opportunity to participate in these task force groups.

Comment: Having just completed such a costly time consuming project, OVSD requests that EPA extend the comment period on the CTR. Allowing an extended comment period would provide for a more thorough review of the proposed rule and supporting documentation, and allow OVSD .adequate time to develop specific comments on the rule relative to its impact on our new treatment plant and our residents. In addition, an extended comment period would allow EPA the opportunity to work more closely with the State Water Resources Control Board (SWRCB) in developing simultaneous comment periods and joint final promulgation, since EPA acknowledges that the impacts of the CTR criteria depend greatly on the State's approach to implementation. This would provide the added benefit that a more streamlined and effective CTR and Statewide Implementation Policy be developed, potentially reducing the resistance by dischargers upon promulgation and implementation. Thus, OVSD asks that EPA extend the comment period until December 10, 1997, the SWRCB's public comment deadline, or at a minimum, for 30 (thirty) days.

Response to: CTR-067-001

Comment: We find ourselves in a quandary over the timeline for commenting on this proposed rulemaking package. The Environmental Protection Agency is allowing only 50 days for public comment on a proposal whose complexity really warrants more time. A public comment period spanning the summer months further exacerbates the situation by ensuring that only a minimal staff would be available to review the proposal.

We are further concerned that our members have had virtually no time to obtain the state's proposed implementation policy, which is parallel rulemaking to this one, as it has just been released for public review. Given the potential enormous impacts of this rulemaking, it is not unreasonable to suggest extending the deadline for comments.

The California Chamber of Commerce, on behalf of its members, requests that you consider extending the deadline for comments for at least another 30 days and preferably 60 days to accommodate the business community's concerns on this important package.

Response to: CTR-068-001

In response to the comment requesting an extension of the comment period, please refer to response to CTR-001-001. In response to the comment that since the comment period spanned the summer months which exacerbated the situation since minimal staff were available, EPA had no intention of proposing during aninconvenient time period. This was the time period after which the Agency obtained it internal administrative and OMB approval to propose the rule. EPA notes that the comment period ran through September 26, 1997, a month in which most people have returned from summer vacations.

Comment: The subject rule has a significant impact on our facility discharge and the citizens of the City. We therefore present the following comments for your consideration to re-open the comment period for this rule in order to facilitate a more complete review by public and in particular by those in the POTW community:

* Even though the EPA is not obligated to provide more than 30 days for public comment, it has been common practice for the agency to provide comment periods of 90 days or longer for significant rules. As an example, your agency provided a 150 day comment period for Great Lakes Initiative in 1993.

* The request for extension of the comment period for this rule is really necessary and justified to facilitate a complete review of the State Water Resources Control Board's (SWRCB's) Draft Implementation Policy which was released on September 12, 1997. As the USEPA and STWRCB are simultaneously promulgating the CTR and Criteria and Statewide Implementation Policy, the POTW's did not have adequate time to review the CTR, State Implementation Policy and supporting discussion which are quite lengthy and voluminous. As a result any comments we have, by and large don't take into account the draft implementation policy.

Comment: While the draft regulations demonstrate clear progress on these and other issues, there remain some unresolved problems that could compromise our ability to serve our customers. We offer these comments in the hope of minimizing those potential impacts.

Adequacy of the 30-Day Public Comment Period

The CTR is a major revision of the regulations governing the discharge of toxic pollutants throughout the state. While not required by law, we respectfully request that the USEPA extend the draftt CTR public comment period to at least 90 days. We believe this is justified and necessary given the scope, length, and technical content of the proposed regulations. In particular, due to the limited time to review these regulations, we were unable to closely examine the proposed State Implementation Policy (SIP), which provides detailed guidance to the state's Regional Water Quality Control Boards, which must enforce these new regulations.

SUMMARY

We hope these comments will help to make the final CTR a better document and a better law. Overall, the draft CTR reflects substantial thought and effort on how best to implement the Clean Water Act's mandate of reducing pollutant discharges to the nation's receiving waters. The draft CTR clearly advances this goal, but our hope is that those agencies and parties most-directly affected by it will be

allowed additional time to review it to their satisfaction. We strongly encourage a more detailed assessment of the actual economic impacts that could result from these new regulations. The ability of public utilities to fund new projects has never been louver, and every rate increase requires sound and well-founded justification. No ratepayer should be asked to shoulder the cost of new regulations without a clear and detailed explanation of what it is going to cost, and what benefits will result. State mandated costs require state funding.

We appreciate this opportunity to comment on the draft California Toxics Rule. Please do not hesitate call myself or Dr. Randal Orton in our Resource Conservation and Public Outreach Department to tell us how we can help you further.

CROSS REFERENCES

Comment: SAIC has reviewed the draft rule proposing water quality criteria for toxic pollutants for California (California Toxics Rule) that was published in the Federal Register on August 5, 1997 and believe that the breadth and complexity of the draft CFR and the accompanying economic impact analysis warrant an extension of the comment period for an additional 30 days.

SAIC is a diversified, scientific, engineering, research, and development company that provides technical and management services and products to private industry and the Federal government. SAIC was organized in 1969 to apply the techniques successfully employed in high technology areas to major national and international programs. Over the past 28 years, SAIC's team of professionals has grown from a handful to more than 22,000 employees throughout 250 locations in the United States and abroad.

SAIC is making this request to ensure that sufficient time is available to the public to coordinate the review of the CFR with an evaluation of the State of California's anticipated proposal of implementation policies for the criteria, which is scheduled to be released September 12, 1997. Providing overlapping comment periods will allow interested parties to understand the full contents and implications of the regulations, which are being partially adopted by the US EPA and partially developed by the State in 303 (c)(2)(b) of the Clean Water Act.

If you have any questions, please call me at 650-604-0924. Thank you for your consideration of our request.

Comment: Thank you for the opportunity to comment on the proposed California Toxics Rule. The City's comments are related to five main concepts:

5. Additional time is needed to assess the specific impacts that the proposed Rule will have on the City of Modesto system.

Specifically, the City submits the following comments:

H. Although Modesto's wastewater treatment system and storm water disposal system is not entirely

unique to most Central Valley communities, it is one of the more complex systems in the state. It is among the top 20 in size in a state with nearly 500 POTWs. In order to best evaluate the effect of The California Toxics Rule on Modesto, additional comment time is needed. Also, more time is needed to facilitate a more complete review of the State Water Resources Control Board's (SWRCB) draft implementation policy, which was released September 12, 1997. By and large, these comments do not take into account the draft implementation policy of the SWRCB.

Response to: CTR-096-005

Comment: We are writing to you on behalf of Tri-TAC and the California Association of Sanitation Agencies regarding the forthcoming publication of the proposed Water Quality Standards for Toxic Pollutants for California ("California Toxics Rule") and release of draft state implementation policies and functional equivalent document. As you are aware, Tri-TAC and CASA have supported the decisions of the U.S. Environmental Protection Agency (EPA) and the State Water Resources Control Board (SWRCB) to eliminate duplication in state and federal water quality rulemaking activities through the pursuit of a collaborative approach. Our understanding is that, through this approach, EPA will adopt water quality criteria for toxic pollutants that will apply in California and the SWRCB will adopt implementation policies that will guide the Regional Water Quality Control Boards in the implementation of those criteria. In a later phase, the SWRCB intends to adopt state criteria that will replace the federal criteria.

We have been informed recently by EPA staff that publication of the draft California Toxics Rule is imminent and is expected to take place by the end of July. According to staff, a 50-day public comment period will be provided. We have heard from SWRCB staff that they plan to release the proposed state implementation policies and FED on September 12. We have asked each agency to provide an overlapping comment period for these draft regulations, and have been informed that the current schedule will provide about one week of overlap, assuming that both agencies release their drafts on schedule. We are quite concerned about this situation in several respects. First, we believe that a one-week overlap does not provide sufficient time for a meaningful review and comparison of the regulations (and comparative analysis of the economic impact analyses, which depend heavily on the implementation policies). We believe that a minimum of 30 days is necessary for the overlap review period, and that the slight delay that this would create for EPA is warranted and would have a negligible impact on the timing of the overall rule promulgation process. Second, we are very concerned about whether the SWRCB will meet its projected release schedule. While we believe that sufficient time has been available to prepare

the draft policies and FED, it is imperative that the SWRCB do everything possible to meet its commitment to move forward in a timely manner, and that any extension of EPA's comment period not be used to adjust the state's schedule. Third, we understand that both EPA and the SWRCB plan to hold public hearings regarding their respective proposals this fall. We believe that it is important that representatives of both agencies attend and participate in the hearings that each agency holds, and that an explanation be provided regarding both the CTR and the implementation policy.

In short, we request that EPA and the SWRCB carefully review their efforts to coordinate both the development and release of the California Toxics Rule and State implementation Policies, and specifically, we request that EPA provide a comment period sufficient to ensure that a 30-day overlap will occur with the SWRCB's release of the FED for the State Implementation Policies. More generally, we hope that both agencies will offer flexibility in the promulgation process so that the various scheduling and review needs can be met. We hope that your respective agencies will continue to move forward with a collaborative rulemaking process, and are concerned that cooperation not break down due to institutional barriers at this point in the process.

Thank you for your consideration of our comments. We would be happy to discuss these issues further at your convenience.

Response to: CTRE-001-001a

In response to the comment requesting an extension of the comment period, please refer to response to CTR-001-001. In response to the comment concerning the coordination of public hearings, the State was invited to speak about its proposed implementation plan at EPA's public hearings on the CTR. Although they did not make any formal presentation, they were available to answer questions and in fact did answer questions posed to them concerning the implementation policy.

Comment: I am writing on behalf of Tri-TAC and the California Association of Sanitation Auencies (CASA), which are California-based organizations comprised of members from public agencies responsible for wastewater treatment. Tri-TAC is an advisory group which includes representatives from CASA, the California Water Environment Association, and the League of California Cities. CASA is comprised of over 85 agencies responsible for the operation of publicly owned treatment works (POTWs). The constituency base for Tri-TAC and CASA encompasses most of the sewered population of California. Representatives of CASA and Tri-TAC have met with EPA staff over the past several years to discuss the development of the proposed rule, and appreciate the Agency's efforts to inform the regulated community about the pending regulation.

We have reviewed the draft rule proposing water quality criteria for toxic pollutants for California ("California Toxics Rule" or "CTR") that was published in the Federal Register on August 5, 1997 and believe that the breadth and complexity of the draft CTR and the accompanying economic impact analysis warrant an extension of the comment period for an additional 30 days. In particular, we are making this request to ensure that sufficient time is available to the public to coordinate the review of the CTR with an evaluation of the State of California's anticipated proposal of implementation policies for the criteria which is scheduled to be released September 12, 1997. Providing overlapping comment periods will allow interested parties to understand the full contents and implications of the regulations, which are being partially adopted by EPA and partially developed by the State in order to achieve full compliance with Section 303(c)(2)(b) of the Clean Water Act.

I would appreciate it if you would notify me at the above address of your decision. Thank you very much for your consideration of our request.

Response to: CTRE-001-002

Comment: I wish to follow up on yesterday afternoon's US EPA Region 9 hearing on the draft California Toxics Rule (CTR) criteria to reinforce the comments made by a number of urban stormwater dischargers about the need to extend the deadline for receipt of written comments. I have been involved in water quality criteria development and implementation since the mid-1960s where I have worked with federal, state and local governmental agencies and/or the regulated community. I find that it would be a serious error on the part of US EPA Region 9 and US EPA headquarters to proceed with the September 26, 1997 deadline for receipt of written comments on the CTR. There are many reasons for providing at least a 30- to 45-day extension of the date by which the written comments should be received. These include the fact that it took the USEPA Region 9 several years to develop the Califoniia Toxics Rule criteria beyond when they were due. To now not grant politically important entities, such as the major urban stormwater dischargers, adequate time to develop the information that needs to be developed and that should have been developed by the US EPA Region 9 as part of promulgating the draft California Toxics Rule would, in my opinion, be viewed as extremely short-sighted on the part of US EPA Region 9 and US EPA headquarters.

Comment: As I testified at yesterday's hearing, the issue of urban stormwater runoff water quality management is in chaos. This situation has been well understood for at least five years. While attempts are being made to address these issues through the US EPA headquarters' various wet weather committees, thus far the fudainental issue that was raised yesterday at the hearing by urban stormwater discharger after discharger has not been adequately addressed, i.e. ultimately having to achieve water quality standards based on CTR criteria in the receiving waters for the discharge through ever-increasingly more stringent BMPS. While the proposed CTR does not specify a time period over which the BMP ratcheting-down process will occur, there can be no doubt that this time period will be set by the courts through litigation brought by envirorunental groups who will assert that an NPDES-permitted stormwater discharger is not making adequate progress toward achieving the ultimate goal of only one violation of a water quality standard every three years for regulated constituents. Because of the uncertainty of how the courts will handle this matter, stormwater dischargers could be faced with having to achieve water quality standards in the discharge waters within five to ten years. Clearly there is need to understand the cost and benefits associated with achieving these standards as part of adopting the CTR as it is applied in regulating urban stormwater runoff water quality.

As part of my comments on the significant technical deficiencies in the CTR as drafted, I will be providing a discussion of technical back-up to these issues from the published literature. Many of my papers and reports on this topic are available from my web site (http://members.aol.com/ gfredlee/gfl.htm).

It is my recommendation that US EPA Region 9 and US EPA headquarters should postpone any adoption of the California Toxics Rule until the US EPA properly presents and discusses the potential costs and the potential benefits in terms ofreal improvements in designated beneficial uses of receiving waters that will likely accrue as the result of regulated urban stormwater discharges ultimately having to comply with water quality standards based on CTR criteria. The US EPA Region 9 should allow the starmwater dischargers tlte opportunity to provide information on the cost and benefits arising from applying these criteria to stormwater discharges as required by the Clean Water Act when it becomes clear that BMPs of the type that are readily available today win not eliminate the administrative exceedances ofwater quality standards numerically equal to the aquatic life criteria set forth in the. CTR. After allowing the urban stormwater dischargers to provide this information, the US EPA then, in turn, should develop an economic analysis that rcliably presents and discusses these issues. As I testified, this process is the necessary first step to correcting the significant chaos that now exists in the urban stormwater runoff water quality management field.

While I do not know how long it would take the US EPA to conduct the required analyses of the urban stormwater runoff costs and real water quality benefits, it would seem appropriate that taking a few months to accomplish this could in the long term represent a time and resource saving in terms of ultimately correcting the sigiifflcant technical problems that exist today in regulating urban stomlwater runoff.

I recommend the Following:

* Urban stormwater dischargers as well as other interested parties should be provided a several-month period during which preliminary assessment of the potential costs and water quality benefits associated with having to meet CTR criteria as standards in the receiving waters for stormwater runoff of concern to the discharger is conducted and reported to US EPA Region 9.

* The US EPA should take several months to develop an amended draft CTR that provides a reliable economic analysis and the potential benefits covering the current regulatory approach for regulating chemical constituents in urban stormwater runoff which involves a ratcheting down of BMPs to achieve the ultimate goal of only one exceedance of a water quality standard every three years in the receiving waters for stormwater runoff.

* The public sould be given a two-month period upon which to review and comment on the adequacy ofthe US EPA's economic analysis of costs and benefits of achieving the currently mandated goal of using CTR criteria as standards for receiving waters for regulated urban stormwater runoff.

Adoption of this approach will send a clear signal to the public that the US EPA is finally willing to meaningful address the heart of the urban wet weather problem. With the Agency for the first time reliably developing information on costs and true water quality benefits, the public, Congress, regulators and the regulated will begin to understand the need to change how urban and highway stormwater runoff is regulated to protect the designated beneficial uses of waterbodies without significant unnecessary expenditures for chemical constituent control.

If you have questions on these conunents, please contact me. I hope that those who control US EPA Region 9 activities associated with CTR development will address the highly significant deficiencies that exist now in how US EPA Region 9 and US EPA headquarters developed the draft CTR relative to urban stormwater runoff water quality issues. If I can be of assistance in this matter, please contact me.

Response to: CTRE-002-005

EPA did not include benefits or costs of controlling nonpoint sources or storm water dischargers in its estimates of benefits and costs of the CTR. EPA believes that the final rule will not have a direct effect on sources not permitted under the NPDES program (e.g., nonpoint sources) or NPDES sources not typically subject to numeric water quality-based effluent limits (e.g., wet weather discharges). Any potential indirect effect on nonpoint sources and wet weather discharges, such as runoff from farms, urban areas, and abandoned mines, and contaminated sediment, is unknown at this time. Many of the programs developed to control nonpoint sources and wet weather discharges are already in place. Costs due to these programs have already been incurred or will soon be incurred owing to existing federal, State, and local environmental programs.

EPA also acknowledges that nonpoint sources and wet weather discharges are technically difficult to model and evaluate costs because they are intermittent and highly variable. Nonpoint source and wet weather discharges also occur under different hydrologic or climatic conditions than continuous

discharges from industrial and municipal facilities, which are evaluated under critical low flow or drought conditions. Thus, evaluating agricultural nonpoint source discharges and storm water discharges and their effects on the environment is highly site-specific and data intensive.

See also response to CTR-040-004.

For analysis of the final CTR, EPA updated its Economic Analysis to reflect the most recent data and information for each sample facility and also increased the sample size for minor facilities. Based on this revised analysis, EPA estimated that minor POTWs will incur costs of approximately $5,000 per facility per year under the low cost scenario and $7,800 per facility per year under the high cost scenario. Comment: The Bay Planning Coalition represents approximately 200 maritime industry, shoreline businesses, local governments and Bay users along the S.F. Bay shoreline and is most significantly affected by the proposed California Toxics Rule. One of our primary interests is the economic analysis which under the EPA's model estimates a range of annual costs of $14.9 to $86.6 million.

We believe the annual costs for implementation of the Rule statewide exceed the EPA estimate range. We are particularly concerned because it appears that the economic impact analysis did not include the costs of compliance for the NPDES stormwater permit applicants. In order for us to provide EPA with sufficient detail on our economic analysis and cost projection as well as the impact of the Rule on small business under the Regtory Flexibility Act, we request an extension of time to respond. A 30-day extension from September 26 to October 27, 1997 would be acceptable. Thank you so much for your consideration.

Response to: CTRE-003-001a

In response to the comment requesting an extension of the comment period, please refer to response to CTR-001-001. In response to the comment concerning the Regulatory Flexibility Act, the proposed CTR did not itself establish any requirements that were applicable to small entities, and thus, the EPA Administrator certified that the proposed rule would not have a significant economic impact on a substantial number of small entities. The final CTR likewise did not establish any requirements that were applicable to small entities and thus, the EPA Administrator certified that the regulation would not have a significant economic impact on a substantial number of small entities. Thus, no initial regulatory flexibility analysis was conducted.

Response to: CTRE-003-001b

EPA's EA, which uses many conservative costing assumptions, indicates that the cost of the State implementing water quality standards based on the proposed criteria in the CTR is likely to be below $100 million per year. Benefits are also estimated to be below $100 million per year. These estimates indicate that the action is not "significant" under E.O. 12866, under the provision concerning annual effects on the economy.

Criteria, by themselves, do not directly impose economic impacts. Criteria are one of three parts of a water quality standard. A water quality standard is comprised of: a criterion, a designated use, and an antidegradation requirement. The CTR promulgates criteria for priority toxic pollutants. When these criteria are combined with State adopted designated uses and antidegradation requirements, water quality standards will be created. When the State implements these water quality standards, costs may be imposed. However, in the spirit of the intent of E.O. 12866, EPA prepared the EA which looks at the costs and benefits of the State's implementation of the resulting water quality standards based on the CTR criteria into the NPDES permit program.

The Unfunded Mandates Reform Act of 1995 (UMRA) in general requires federal agencies to assess the effects of their regulatory actions on State and local governments, and on the private sector. The agency must prepare a written statement including a cost-benefit analysis for actions with a "federal mandate" that may result in expenditures to State and local governments, in the aggregate, or to the private sector of $100 million or more in any one year. The CTR does not contain any federal mandate that may result in expenditures by State and local governments, or the private sector, of $100 million or more in any one

year. The CTR imposes no direct enforceable duties on the State, local or private sector; rather the rule promulgates water quality criteria which, when combined with State-adopted designated uses and antidegradation requirements, will create water quality standards. The CTR does not directly regulate or affect any entity and therefore is not subject to the requirements of UMRA.

The Regulatory Flexibility Act in general requires federal agencies to describe the impact of their regulatory actions on small entities as part of the rulemaking. If the Administrator certifies that the action will not have a significant economic impact on a substantial number small entities, the agency is not required to prepare the analysis. The Administrator certified in the proposed rule, and is certifying again today that the rule will not have a significant economic impact on a substantial number of small entities. EPA's promulgation of water quality criteria will assist the State in establishing water quality standards. The State will, in turn, implement the resulting water quality standards in its water quality regulatory programs such as the NPDES permit program. The State has discretion in deciding how to meet the water quality standards and in developing discharge limits as needed to meet those standards. While the State's implementation of water quality standards based on federally-promulgated criteria may result in new or revised discharge limits being placed on small entities, the criteria or standards themselves to not apply to any discharger, including small entities. Thus, EPA's action today does not impose any of these as yet unknown requirements on small entities.

CROSS REFERENCES G-08

Comment: The Victor Valley Wastewater Reclamation Authority (VVWRA) respectfully requests that the comment period deadline be extended for the California Toxics Rule (CTR). The current comment period deadline is September 26, 1997. We request that the latter deadline be extended for at least 60 days so that we can fully evaluate the potential impact on VVWRA

The reasons for our request are as follows:

1. VVWRA discharges to the Mojave River, which is considered by the Lahontan RWQCB as an impaired waterway. Although portions of the Mojave exhibit year-round surface flow, the River directly above VVWRA does not exhibit consistent surface flow. However, the Lahontan RWQCB considers the Mojave an underflow stream, which is often considered as surface flow. Whether an underflow stream would be considered under the CTR for receiving stream dilution has yet to be determined;

2. It is difficult if not impossible to evaluate the impacts of a proposed regulation without considering the mechanism by which it will be implemented. The SWRCB is not expected to release the

implementation plan until September 12, 1997. Therefore, VVWRA takes exception to the imposition of a regulation with an undefined implementation plan;

3. Because of the latter unknowns and the complexity of the regulation V has not had sufficient time to evaluate the potential economic impacts, if any, of the proposed regulation.

Response to: CTRE-004-001a

In response to the comment requesting an extension of the comment period, please refer to response to CTR-001-001.

Comment: The Western States Petroleum Association (WSPA) is a trade association, which represents a majority of the petroleum-related interests in the western United States. These interests include production, transportation, refining, and marketing of petroleum and petroleum based products. WSPA appreciates to opportunity to provide comments on the proposed rule regarding "Water Quality Criteria For Toxic Pollutants For California." Upon review, it has become clear that the limited time available for preparing meaningful comments is too short. This is a significant and complex rule development, which will impact our operations. We therefore, would like to request an additional 30 days to review the proposal and provide written comments. These concerns over timing are worsened by the anticipated September 12, 1997, release of the State of California's proposed implementation policies for the criteria. Due to their inter-relationship, it is important that interested parties be given the opportunity to review both of these proposals together.

Response to: CTRE-005-001

Comment: I am writing on behalf of the Sanitation Districts of Los Angeles County regarding the public comment period for the Proposed Rule Regarding Water Quality Criteria for Toxic Pollutants for California, which was published in the Federal Register on August 5, 1997. As noted in the Federal Register notice, the public comment period is scheduled to close on September 26, 1997. The Sanitation Districts requests that EPA extend the comment period for 30 days from that date.

We have reviewed the draft rule, and believe that its importance and complexity warrant an in-depth review, including an assessment of the rule's impacts on the seven water reclamation plants owned and operated by the Districts that will be affected by the rule. In addition, we believe that an extra 30 days is necessary to enable us to review the State of California's anticipated proposal of implementation policies for the criteria, which is not expected to be released until mid-September. As has been discussed with your staff and State Water Resources Control Board staff, we believe that a sufficient overlapping review period is necessary to fiilly implement the collaborative process embarked upon by EPA and the SWRCB last year.

Response to: CTRE-006-001

In response to the comment requesting an extension of the comment period, please refer to response to CTR-001-001.

Comment ID: CTRE-007-001
Comment Author: SCAP

CROSS REFERENCES

Comment: I am writing on behalf of the Souther California Alliance of Publically Owned Treatment Works (SCAP) to request an extension of the comment period for the proposed rule regarding water quality criteria for toxic pollutants for California (the California Toxics Rule) for 30 days. SCAP is a non-profit organization formed in 1992 to provide a common voice for the Southern California community of municipal nwastewater treatment agencies in expressing our interest in promotng reasonable regulations that are in the public's best interest. We have forty-six member agencias serving a combined population of over 10 million people.

CAP has reviewed the draft rule and believes that an extension of the comment period for an additional 30 days is warranted to ensure that sufficient time is available to review the changes made in the water quality criteria in the CTR from the National Toxics Rule, which was promulgated several years ago. In addition, the extension is necessary to provide sufficient overlap for a meaningful review and comparison of the proposed regulations and the State Water Resources Control Board's draft policies regarding the implementation of the CTR. We understand that the State plans to release proposed policies and draft

Functional Equivalent Document on September 12, 1997. We believe that our comments on the CTR will be more informed if there is an adequate opportunity to review the State's proposal before the close of the federal comment period. Therefore, we request that the comment period be extended until at least October 27, 1997.

Response to: CTRE-007-001

In response to the comment requesting an extension of the comment period, please refer to response to CTR-001-001. In response to the comment that additional time was necessary to review the changes in criteria values from the National Toxics Rule (NTR), EPA provided a table in the preamble to the proposed CTR which outlined all the changes in aquatic life numbers from the NTR. The text that followed explained the changes in detail. EPA believes that the comment period was sufficient time within which to review and comment on these changes from the NTR.

Comment: The Cupertino Sanitary District is a wastewater collection agency which transports approximately 4.5 MGD of wastewater to the San Jose/Santa Clara Water Pollution Control Plant. The San Jose/Santa Clara Water Pollution Control Plant is a regional treatment facility capable of treating 167 MGD. The staff at the plant have begun a review of the draft rule for toxic pollutants for California, as published August 5, 1997, in the Federal Register. The complexity of the document, however, and the need to compare our plant's assessment with other wastewater agencies, leads me to ask for a 30-day extension of the comment period. This additional time will allow for a concurrent evaluation of the state's implementation policies for the numeric criteria.

Thank you very much for considering this request.

Comment: The County Sanitation Districts of Orange County, California (Districts) operates the third largest wastewater agency west of the Mississippi River, having the responsibility for collecting and safely treating wastewater for 2.1 million residents and businesses in metropolitan Orange County. We are members of the California Association of Sanitation Agencies (CASA) and Tri-TAC (an advisory group for CASA, California Water Environment Association, and the League of California Cities), and through these groups we have met with EPA staff to discuss the development of the proposed rule.

We appreciate the Agency's efforts to inform the regulated community about the pending regulation, however, we believe the complexity of the draft "California Toxics Rule" that was published in the Federal Register on August 5,1997 and the accompanying economic impact analysis warrant an extension of the comment period for an additional 30 days. We are making this request to ensure that sufficient time is available to the public to coordinate the review of the "California Toxics Rule" with an evaluation of the State of California's anticipated proposal of implementation policies for the criteria, which is scheduled to be released September 12, 1997. This overlapping comment period will provide the interested parties the opportunity to understand the contents and implications of the regulations, which are being partially adopted by EPA and partially developed by the State in order to achieve full compliance with Section 303(c)(2)(b) of the Clean Water Act.

Should you have any questions regarding this request for extension, please call Nancy J. Wheatley, Director of Technical Services, or me at (714) 962-2411.

Comment: The California Council for Environmental and Economic Balance (CCEEB) has been advised

that the State Water Resources Control Board (SWRCB) staff is planning to release the proposed State Implementation Policies on September 12, 1997. Since the release of these policies may indeed have an effect on the proposed California Toxics Rule, the Council is concerned that there may not be sufficient time provided for comment prior to the release of these policies.

At this time, we would like to request that EPA provide a comment period of the draft California Toxics Rule sufficient to ensure that adequate time is given prior to release of the State Implementation Policies.

Furthermore, we trust that EPA and SWRCB will be flexible in the promulgation process in order that everyone's scheduling and review needs can be met.

Comment: Concern has been raised by various agencies in California (i.e., Tri-TAC and CASA) about the above-referenced proposed Rule which could have a sizable monetary impact on California agencies involved with wastewater treatment. Considerable more time is required to thoroughly study the proposed Rule and its economic impacts on California agencies.

As an agency involved with wastewater treatment, I hereby request that at least a 30 day extension of time be allowed for further review and comment.

Comment: The City of Riverside is requesting a 30 day extension in the comment period for the proposed California Toxics Rule. As the City was used as a case study for the economic analysis we feel that it is our responsibility to review these documents in some detail. Further, revelations regarding the status of the Santa Ana River Use Attainability Analysis and the site specific objectives that came out of that study, require considerable evaluation and consensus building within the watershed prior to comment.

Thank you for your consideration of this matter. Should you agree with our request, we would appreciate a notice of your decision.

Response to: CTRE-014-001

Comment: Oro Loma Sanitary District is a P.O.T.W. located in Alameda County between San Leandro and Hayward. We are also a member of the California Association of Sanitation Agencies (CASA) which actively monitors legislation and regulatory rule making.

We have reviewed the draft rule proposing water quality criteria for toxic pollutants for California ("California Toxics Rule" or "CTR") that was published in the Federal Register on August 5, 1997 and believe that the breadth and complexity of the draft CTR and the accompanying economic impact analysis warrant an extension of the comment period for an additional 30 days.

We are making this request to ensure that sufficient time is available to the public to coordinate the review of the CTR with an evaluation of the State of California's anticipated proposal of implementation policies for the criteria, which is scheduled to be released September 12, 1997. Thank you for your consideration.

Response to: CTRE-015-001

Comment: On behalf of the League of California Cities, I am writing to respectfully request a 30 day extension to the comment period on the draft rule proposing water criteria for toxic pollutants for California ("California Toxics Rule" or "CTR"). That rule was published in the Federal Register on August 5 1997.

The League agrees with others who have requested an extension of the comment period that the complexity and breadth of the draft CTR, and the accompanying economic impact analysis, warrant additional time for comment. In addition, it is necessary to ensure that sufficient time is available to the public to coordinate the review of the CTR with an evaluation of the State of California's anticipated proposal of implementation policies for the criteria, which is scheduled to be released September 12, 1997. We believe that the quality of the public comment submitted will benefit by providing an overlapping time period in which interested parties can evaluate both sets of proposals.

For these reasons, the League of California Cities respectfully requests an extension of the public comment period for the draft CTR. Thank you for your careful consideration of our request.

Response to: CTRE-016-001

Comment: On behalf of the Bay Area Stormwater Management Agencies Association (BASMAA), I am writing to respectfully request an extension of the comment period for the California Toxics Rule for an additional 30 days.

The Bay Area Stormwater Management Agencies Association is a consortium of the seven municipal storm water programs in the San Francisco Bay Area representing 89 agencies, including 78 cities and 5 counties. BASMAA is focused on regional challenges and opportunities to improving the quality of urban runoff to the San Francisco Bay and Delta.

BASMAA is working with its member agencies and the California Stormwater Quality Task Force to expedite its review of the proposed CTR. However, the completion of our review is complicated by the planned release on September 12 of the State Board's draft policy for implementing the numeric criteria included in the CTR. Providing more overlapping conunent periods for the CTR and the implementation policy will facilitate more coordination between storm water programs on their review and comments, likely saving a significant amount of time for both USEPA and State Board staff in the long run.

Thank you for consideration of our request, and for notifying us of your decision.

Comment: I am writing in support of Tri-TAC and the California Association of Sanitation Agencies (CASA), which are California-based organizations comprised of members from public agencies responsible for wastewater treatment.

The Crockett-Valona sanitary Distrilct is attempting to obtain a copy of the California Toxics Rule so that we may properly review and comment on this important regulatory document. To do so, and with the belief that the breadth and complexity of the draft CTR and the accompanying economic impact analysis alone warrant an extension of the comment period, we request an extension of 30 days.

In particular, we are making this request to ensure that sufficient time is available to CASA and Tri-TAC to coordinate the review of the CTR with an evaluation of the State of Californials anticipated proposal of implementation policies for the criteria, which is scheduled to be released September 12. Providing overlapping comment periods will allow interested parties to understand the full contents and implications of the regulations, which are being partially adopted by EPA and partially developed by the State in order to achieve full compliance with Section 303(c)(2)(b) of the Clean Water Act.

Comment: The Bay Area Dischargers Association (BADA) is comprised of 10 POTWs in the San Francisco Bay Area. Our five largest charter members include the Central Contra Costa Sanitary District, City and County of San Francisco, City of San Jose, East Bay Dischargers Authority, and East Bay Municipal Utility District. Together BADA agencies provide wastewater service to most of the Bay Area.

BADA requests that the U.S. EPA allow at least 90 days for public review of the proposed California Toxics Rule (CTR). We understand the proposed rule will be published in the Federal Register toward the end of this month. The reasons for our request are as follows:

1. The CTR could have a significant economic impact on California municipalities and businesses. In

order to properly assess the impacts of the proposed CTR standards, it is necessary to know how the standards are to be implemented. Yet, the proposed implementation provisions being developed by the State Water Resources Control Board will not be available until September 12, 1997. The several days of overlap are insufficient for California municipalities and businesses to assess the economic and environmental impacts of the proposed standards. At least 45 days of overlap is needed.

2. The U.S. EPA has spent more than three years developing the proposed CTR, in part because of its importance. It is therefore, reasonable to provide at least 90 days for the public to review and comment on the rule, especially considering its potential economic impact on the State and the unavailability of the implementation provisions

3. It is recommended that the EPA work closely with the SWRCB during the review period to define the implementation policy and procedures that the EPA would be likely to approve.

For these reasons, BADA urges you to issue a notice extending the review period from 45 days to 90 days.

CROSS REFERENCES

Comment: The Sacramento Regional County Sanitation District (District) understands that the proposed California Toxics Rule (CTR) will be published in the Federal Register at the end of this month. The District also understands that there will be a 45-day period set for public review and comment on this document. The District strongly requests that the period for review and comment be extended to a minimum of 90 days. The reasons for our request are as follows:

1. Previous studies have shown that the specific numeric values set for water quality criteria on metals such as mercury could have a major economic impact on the District. The key conclusion of these studies is that removal of mercury from the District's effluent could cost, more than $1 billion, but would only result in removing a very small percentage of the mercury being discharged to the Sacramento River from unregulated nonpoint sources in the watershed.

2. In addition, the CTR could have a significant economic impact on many California municipalities and businesses without providing any measurable water quality benefits. This statement is based on in-state studies of the attainability of the U.S. EPA recommended water quality criteria that will be incorporated

into the CTR.

3. The District believes it is necessary to know how the standards are to be implemented, in order to properly assess the impacts of the proposed CTR standards. However, the proposed implementation provisions being developed try the State Water Resources Control Board (SWRCB) will not be available until mid-September, 1997. The few days of possible overlap with a 45-day comment period are insufficient for California municipalities and businesses to assess the economic and environmental impacts of the proposed standards. In our opinion, at least 45 days of overlap are needed.

4. The U.S. EPA has spent more than three years developing the proposed CTR, in part because of its importance. The District believes it is unreasonable to provide only 45 day for the public review and comment on such an important rule, especially in light of both its significant potential economic impacts on the entire State and the unavailability of the SWRCB implementation provisions.

For these reasons, the District urges you to issue a notice extending the review period from 45 days to 90 days.

CROSS REFERENCES

Comment: The East Bay Dischargers Authority is a joint powers public agency providing wastewater treatment and disposal services for approximately 600,000 people in southern and eastern Almeda County, California. The Authority's members include City of San Leandro, City of Hayward, Oro Loma Sanitary District, Castro Valley Sanitary District, and Union Sanitary District.

The Authority and its member agencies have been following the process of U.S. EPA's development of the California Toxics Rule (CTR) and the State Water Resources Control Board's effort to develop implementation provisions for the CTR. We have been informed that the CTR will be published in the Federal Register late this month, and we are very dismayed by reports that there will only be a 45 day comment period. In addition, the comment period may not overlap with the release of the State Board's implementation provisions.

The Authority and its member agencies request that U.S. EPA allow at least 90 days, and preferably 120 days, for public review of the CTR. The reasons for our request include the following:

1. U.S. EPA has taken more than three years to develop the proposed CTR. It is unreasonable to provide only 45 days for the public to review and comment on the rule, especially considering the fact that the rule and its implementation could have significant economic consequences on the Authority and its member agencies.

2. In order to properly analyze the impacts of the CTR, it is imperative that the State Board's implementation provisions be examined concurrently. Yet the proposed release date of the implementation provisions is September 12, 1997. With a 45 day comment period, there is essentially no overlap, which is unacceptable from a public policy perspective.

3. An economic analysis of the CTR and the implementation provisions must be conducted concurrently. Such an analysis, by the parties most effected, must be allowed adequate time to be both accurate and meaningful. You will recall that the State Plans were invalidated in part because of a poor economic analysis by the State Board. We are skeptical that U.S. EPA and the State Board will have performed the necessary economic analyses and require adequate time to perform them ourselves.

The Authority and its member agencies believe that it is in the best interests of U.S. EPA, the State Board, the regulated community, and the public that the comment period for the CTR be extended to at least 90 days. Your consideration of this request is appreciated. Please feel free to contact me if you have any questions or need additional information.

Comment: That gets me to my next point. We got this thing about two weeks ago here. The task force is struggling on this. Our key people have been working on it around the clock for the last week. I'm looking at Mac Walker; he's been doing that. We really are very pressed by the shortage of the time we've got here. And other people have been asking for this, too.

I think it's only reasonable that we would get more time to look at this, time to perform economic analysis of the impact of this, and have a chance to do a little noodling. Forty-five days would be an absolute minimum extension on this thing.

We've waited a long time to get this. It wouldn't hurt us to extend it just that much longer to be able to look at the issues of this thing, rather than getting the numbers off the back of somebody's envelope.

That's really the last point.

Comment: MR. BOBEL: Thank you, Steve.

I'm Phil Bobel. I represent Tri-TAC, an organization of sewage treatment plants, the POTWs as we call them, made up of three groups: CASA, the California Association of Sanitation Agencies; the League of Cities; and the California Water Environment Association.

And later this afternoon you're going to hear from Bob Reid who represents CASA. And our comments are essentially the same, so I'm going to not repeat and just summarize a couple things.

I was even going to say you guys had done a really good job. But in light of all the previous speakers, I deleted that part of my testimony.

I will try to be positive and constructive. I promised to do that. In describing the nature of my comments on your little form, I put that I would be constructive. So I will do that.

The first point I'd like to make is positive. I think that the coordination you're doing with the state is great. The fact that we're going to have coordination with the feds focusing on the numeric criteria, the state focus on the implementation policy, working to come up with a system that will serve us all, is a good way to use resources of both organizations.

I applaud you for that and hope you will be able to pull that off. This is different than what we've tried to do before, and it will require some creativity.

One specific thing that I think would help if we did, is to allow all of us to see both what the state is proposing and what the feds are proposing, so we need a little more time in this comment period.

We've appealed before and been told no, but I still put that on the table as a good idea for the ultimate goal of a coordinated, consolidated, as much as possible, federal and EPA approach to this thing.

If you don't do that, or even if you do do that, I think it's going to require some other kinds of creativity as

we move out of -- away from your hearing and toward a final rule.

And in that period of time, I would ask you and the state to sit down together and see what kind of a process you can use to take the comments that you'll hear from your federal regs and the comments you hear on the state plan, and put those together, hear more back from folks that are interested and come up with a package that makes sense.

You're going to need some way of going back to interested parties over a longer period of time -- communicating, coordinating -- and I would refer you to the process that the state used on their task force approach and suggest that we need something like that as we move to the future. Creativity is going to be needed.

CROSS REFERENCES E-01d

Comment: MR. GUERRA: My name is Julio Guerra with the City of Merced. And in my capacity with the City of Merced, I function as NPDES compliance coordinator and have to directly deal with these issues .

I did serve on the Inland Surface Waters Task force as a POTW representative to the agricultural waters subgroup, and so I am somewhat familiar with the issues at hand.

The first thing I would like to say is that the high-end cost estimated in the economic analysis done in the case study that was part of the California Toxics Rule background work was $4 million a year, $13 million capital expense. Characterized in the toxics rule is that the plants, of which Merced was one, was deemed to be representative of the proportionate facilities located within the different California regional water control boards.

Now, if we are representative, then you could assume that a plant such as Merced without a heavy industrial base would be typical of a lot of plants in the state, which would lead to the conclusion that perhaps the $87 million per year figure was a projection that did not match what could actually happen.

The city of Merced discharges to an ephemeral stream. The effluent is dominated at certain times of year by agricultural waste water, and stormwater-dominated at other times of the year. We provide the only treated water to that stream.

The ephemeral stream is dammed about a half mile further down by a farmer who uses all of the -- as much of the water as he can. He has water rights to about 15 million gallons a day. We can only discharge between 4 and 5 million gallons a day to that stream.

Our operating budget is between 2 and $3 million a year. If the assumptions were all correct, and we had to -- had to expend an additional $4 million a year to meet these standards, we would be spending an awful lot of money to take care of our neighbor.

The other side of that issue is that my cursory review of the economic impact work there leads me to observe that certain interpretations of our -- the data were not properly applied. And I would be most willing to work to get a more accurate picture of it to the EPA people.

And it would really take longer than the remaining comment period to do that, and so I would also add my voice to those asking for extension of the comment period.

Response to: CTRH-001-0211b

See response to CTR-021-008.

EPA acknowledges that evaluating the impact of each individual direct discharger to inland waters, enclosed bays, and estuaries within the State of California would be the most accurate method to determine impacts of the CTR. However, the resources that would be required to perform such an analysis for each of the over 1,241 direct dischargers are beyond the resources typically available for development of environmental regulations.

In developing the methodology for estimating the compliance costs for the proposed CTR, time and budget constraints limited EPA's costing review to a subset of the regulated community. However, EPA believes that the sample selected adequately represents the various types of direct dischargers in the State.

EPA acknowledges that minor dischargers were under sampled as compared to the major dischargers. However, by definition, under the NPDES permit program, facilities classified as minor would not be expected to discharge toxic pollutants in toxic amounts. Since the CTR addresses only toxic pollutants, EPA would not expect significant, if any, impact to minor dischargers.

In analyses of the final CTR, EPA increased the sample of minors by five randomly selected facilities to bolster its analysis. EPA estimated costs of $872 per minor facility under the low scenario, and $2,682 per minor facility under the high scenario due to the CTR.

EPA also replaced Silvergate with South Bay in the sample in order to improve the estimate of the impacts of the CTR on the electric utility industry. The draft CTR cost analysis included costs for Silvergate, but the facility had closed and the data available was over five years old. The addition of South Bay, an electric utility facility with no costs, to the sample results in a more realistic, lower overall cost estimate for the electric utility industry.

CROSS REFERENCES

Comment: I'm Robert Reid, manager of the Sanitation District of Santa Clara County. I'm here today representing CASA and to present CASA's comments.

CASA is the California Association of Sanitation Agencies and represents more than 80 publicly owned treatment works in the State of California, I'll keep my comments brief as CASA will be submitting detailed written comments prior to the close of the public comment period.

We have four main issues to which we would like to draw your attention today.

First, as has been said many times over today, because the state's Draft implementation Policy was issued only last Friday, the comment period for this proposed rule should be extended by 45 days, or at least 30 days, to allow adequate time for analysis of the proposed rule as it will be implemented by the state.

Our comments are going to focus on the contents of the CTR only and its potential impacts, without consideration for the state's implementation policy and how those may change those impacts, because we have not yet had time to really evaluate the draft implementation policy.

Response to: CTRH-001-036

In response to the comment requesting an extension of the comment period, please refer to response to CTR-001-001.

Comment: MR. BATTS: Thank you.

I'm Charles Batts. I am Plant Operations Department Manager at the Central Contra Costa Sanitary District, a publicly owned treatment works, and I'm here today as chairman for the Bay Area Dischargers Association, a group of the five largest municipal dischargers to the San Francisco Bay, serving approximately three and a half million people. Our goal is only to protect the environment and to provide cost-effective service for our rate payers.

We are very appreciative of the work done by EPA on the California Toxics Rule. I hope my comments today will be of help in developing regulations that will continue to protect the waters of the state, and that everyone can live with.

First, I think I need to get in line and ask as everyone else has and as I asked earlier by letter, for the period of comment to be extended to 90 days.

There is no reason to rush the final version of these rules. The impact of state plans which are already out will not be greatly impacted beyond the extent they already have been. This will allow the state plan to reflect the changes and comments or modifications that may come out of your toxics rule.

Response to: CTRH-001-043

Comment: We would ask the EPA to extend the comment period to encourage further comments.

We would encourage you to look at actual agencies' calculations, that all translators be reviewed to ensure accuracy, even if special studies are required by individual dischargers.

Response to: CTRH-001-045a

In response to the comment requesting an extension of the comment period, please refer to response to CTR-001-001. In response to the request that we look at actual translators to ensure accuracy in our economic analysis, the economic analysis for the proposed rule and for the final CTR is a broad-brushed analysis. EPA neither had the time nor resources to look at individual translators for individual pollutants for each of the sample facilities used in its analysis. However, where information was available on a particular pollutant and its translator, EPA reviewed the information and considered its application where appropriate.

Comment: Secondarily and thirdly -- these two are tied together, the whole -- all our members that comply and have to secure the stormwater permits, we have been looking at how much it would cost us to build facilities to do some kind of end-of-pipe treatment to actually meet some of these numeric criteria for stormwater.

We don't think the economic evaluation that EPA has done is valid. Basically, there are a lot of shortcomings to it, and you have already heard today some of the numbers. The actual amount of money needed to build new facilities is way beyond the $86 million estimate that you have indicated in your analysis.

And based on this very serious economic evaluation shortcoming, I am recommending that at least a 30-day time limit be provided so that you can hear from the permit applicants regarding the statement to show you what the costs really are, and we'd like some more time to do that.

Those are essentially the substance of my comments today. Thank you.

Comment: Conclusion:

In conclusion, we believe that there are significant and fundamental issues associated with the proposed rule that require serious consideration.

We recommend an extension of the public review period for the proposed rule is requested to allow EPA, municipalities, industry, and others to further evaluate the wet weather discharge requirements of the rule and the resulting legal and economic impacts in light of the recently released Inland Surface Waters and Enclosed Bays and Estuaries plans.

Response to: CTRH-002-007

In response to the comment requesting an extension of the comment period, please refer to response to CTR-001-001. In response to the issue concerning wet weather discharge requirements, the preamble to the proposed CTR had a detailed discussion concerning application of the proposed criteria to wet weather discharges. See the discussion at 62 FR 42186. See also the discussion on wet weather flows in the preamble to the final rule. A complete discussion of wet weather flows and potential economic impacts is also included in this Response to Comments document after the specific comments concerning potential economic impacts from wet weather flows.

Comment: MS. ONLUND: I'm Lisa Ohlund. I'm an associate with the Southern California Alliance, a Publicly Owned Treatment Works. My business address is 30290 Rancho Viejo Road, San Juan Capistrano, 92675. I am here today representing SCAP. SCAP is comprised of 47 public agencies that provide wastewater treatment services in Southern California. Collectively, our member agencies serve over 16 million residents of Southern California. We appreciate the opportunity to testify on the proposed California Toxics Rule.

Before I make any substantive comments, I would like to reiterate the request that EPA extend or reopen the comment period on this CTR for an additional 30 days. We are still reviewing the proposed rule and its potential impacts on Southern Californials POTWs, and I believe that the number of changes proposed to the national water quality criteria and the extensive documentation that accompanies and explains the rule warrants the extension of the comment period.

In addition, as we noted in our letter requesting an extension, we would also appreciate the opportunity to review the CTR in the context of the State Water Resources Board's draft Implementation Policy which was just released last Friday, which I happen to have a copy here.

We're asking for an extension until at least October 27.

Comment: As you are aware, the California Policy for Implementation of Toxics Standards for Inland Surface Water, Enclosed Bays, and Estuaries of California, the proposed policy, was issued a few days ago. EPA and State essentially had the same objective to establish water quality criteria that are implementable for the water of California. Therefore, it is necessary for regulators and dischargers alike to fully comprehend the consequences of these rules on similar issues but from perhaps a different perspective.

Consequently, we strongly urge EPA to allow for additional 30 days for you and for us to fully review both documents together. We also urge EPA and State to coordinate these two rule-making process to minimize inconsistencies that might otherwise occur, EPA is the final focal point of this concern because

the process of State's obtaining EPA approval of ISWP and EBEP will be greatly enhanced if EPA and State can work together; and without EPA's approval, State's plan will be no good. So I think it will be ideal if CTR and the State's proposed policy can be promulgated simultaneously.

Thank you again for the opportunity to address you.

Comment: Proposed mercury criteria ignore the concentration of mercury in the food chain and site specific field data in a scientifically insupportable manner. One reason EPA's criterion allows mercury to harm Bay fishing, as shown above, is that EPA's proposed "bioconcentration factor" predicts that I part per trillion (ppt) of mercury in water results in 7,374 ppt in fish eaten by the public. EPA rejected "bioaccumulation factors" from the Great Lakes which-predict that the same I ppt in water results in 27,900 to 140,000 ppt mercury in fish eaten by the public. This decision weakens the criterion drastically by ignoring mercury's most dangerous aquatic property.

EPA's rejection of data on mercury concentration in the aquatic food chain is scientifically insupportable. The fact that mercury concentrates strongly in aquatic food chains is beyond dispute. However, EPA's bioconcentration factor includes data on the "uptake and retention of a substance. from water only." EPA'S criterion thus fails to protect against human exposure to all mercury that gets into fish from the food the fish eat, which comprises most of this human mercury exposure. (The statement that EPA's "PBCFs take into account uptake from food as well as water" appears to mean food and water consumption by humans, and should not be read to obfuscate this problem.)

EPA's rationale for rejecting mercury bioaccumulation data for protection of San Francisco Bay is incorrect. The proposal states that. "Lacking the data, it is difficult to determine if the [bioaccumulation factors] used in the [Great Lakes Initiative] represent the potential for mercury bioaccumulation in surface waters in California." However, numerous high quality field measurements of San Francisco Bay water and fish eaten by the public demonstrate mercury bioaccumulation comparable with Great Lakes estimates and far greater than EPA'S "bioconcentration factor.(*3) (*16) These data are summarized in Table 7. It is unscientific to ignore high quality, consistent field data showing mercury concentration in aquatic food webs while proposing a criterion which allows harm to fishing.

Response to: CTR-002-007b

EPA acknowledges concerns expressed by the commentors about mercury bioaccumulation and the protectiveness of the mercury human health in the final rule. EPA is well aware of the adverse human health and environmental effects associated with mercury exposure and the role that bioaccumulation plays. Several reports have been published recently documenting EPA's concern for, and guidance on, protection from mercury exposure. These documents include: Mercury Study Report to Congress, (EPA-452/R-97-008); The National Survey of Mercury Contamination in Fish. Database Summary 1990-1995. September 29, 1997; 1995 Updates: Water Quality Criteria Documents for the Protection of Aquatic Life in Ambient Water, (EPA-820-B-96-001); and Final Water Quality Guidance for the Great Lakes System: Final Rule. Fed Register, 60(56):15366-15425 (March 23, 1995). As noted in these documents and many other publications, mercury bioaccumulation is a very complex process that is not fully understood. Methylmercury is the most toxic and readily bioaccumulated form, but mercury methylation and bioaccumulation varies from location to location due to biological, physical, and chemical factors that are not completely understood. Much additional research is need to characterize these factors so that accurate predictions of methylmercury bioaccumulation can be made. EPA is working to improve the body of knowledge on mercury bioaccumulation, toxicity, and risk management, which will lead to improved protective mercury criteria. For example, EPA's Office of Research and Development is sponsoring a multi-year, several million dollar, Science to Achieve Results (STAR) research grant program to specifically investigate the fate and transport of mercury in the aquatic environment. Grants and funding will be awarded to successful applicants beginning in 1999.

In addition to these research activities, EPA is reviewing the basis for the human health mercury criterion and is conducting a comprehensive review of its overall human health criteria methodology. In 1998, Congress directed the National Academy of Sciences (NAS) to review the toxicological basis for EPA's reference dose (RfD) for mercury. NAS will review toxicological data generated from studies conducted in the Faroe and Seychelles Islands and assess its appropriateness for use in the RfD derivation. This review is scheduled to begin in mid-1999 and be completed in July, 2000. EPA plans to update the National 304(a) criteria once the review is complete, and then subsequently update criteria for California.

EPA believes the 304(a) mercury criteria will also be improved once the recently proposed revisions to the Ambient Water Quality Criteria Derivation Methodology Human Health (EPA-822-B-98-005) are final and ready for use in deriving National recommended criteria. Proposed changes to the human health methodology affect both the reference dose derivation and exposure assessment applicable to mercury. As recommended by a number of commentors, the proposed revisions to the human health methodology would use bioaccumulation factors (BAFs) rather than bioconcentration factors (BCFs) or practical bioconcentration factors (PBCFs), to derive water quality criteria in the future. EPA has received public comment on the proposed revisions to the health methodology and held an external peer review workshop in May,1999. EPA believes that such peer review is essential to maintaining the scientific defensibility of its water quality criteria. Once the methodology is finalized based on reviewers' comments, new National recommended mercury criteria for human health and aquatic life can be derived, and then subsequently criteria for California can be updated.

Any revision to either a National or California mercury criterion will include an evaluation of all relevant bioaccumulation data. The data in the GLWQI is specific to the Great Lakes region and its applicability to California waters has not been finally determined. The GLWQI BAFs alone cannot be directly applied

to California because the biological, chemical, and physical factors that influence mercury bioaccumulation will be different in California when compared to the Great Lakes region. Examples of these factors include: foodchain interactions, physicochemical parameters (e.g. pH, temperature, dissolved and particulate organic matter), and size and type of watershed. Additionally, the GLWQI BAFs were developed for lakes only, whereas the waters affected by mercury in California include rivers and estuaries, for which very little data on the bioaccumulation potential of mercury is available. Virtually nothing is known about the applicability to rivers or estuaries of BAFs which are based on lake ecosystems. However, EPA is currently gathering bioaccumulation data on lentic (lakes), lotic (streams, rivers) and estuarine environments in order to assess the nature and extent of bioaccumulation in different water bodies and the application of BAFs across ecosystems. Although the bioaccumulation data cited by the commentors for San Francisco Bay and Clear Lake appear to be quality data, the development of any California-specific BAFs would require more than these few limited studies.

In summary, EPA agrees that mercury in the environment is a problem and has clearly documented its adverse effects to humans and ecological receptors. Regulatory controls are need to protect humans, wildlife, and aquatic life from exposure to mercury. However, there are a number of issues that must be considered and resolved before EPA can conduct a revision of the National 304 (a) mercury criteria and promulgate revised values for California. The dominant issues are:1) finalize the overall Ambient Water Quality Criteria Derivation Methodology for Human Health, 2) within the human health methodology, finalize the approach for deriving bioaccumulation factors, and 3) wait completion of the NAS review and subsequently revise the National human health criteria for mercury. For these reasons EPA is at this time promulgating mercury criteria of 0.05 ug/L (consumption of water and organisms) and 0.051 ug/L (consumption of organisms only) as proposed in the CTR, rather than promulgating revised criteria based on partially peer reviewed methodologies, evolving science, and incomplete understandings of the factors that affect mercury bioaccumulation. Once this comprehensive review is complete, the mercury criteria will be revised as appropriate, supported by scientifically defensible and peer reviewed methodologies and data.

Comment: 9) The use of a $200 and $500 per toxic pounds-equivalent as a upper end cost basis seems arbitrary. From our perspective, there is no reason to assume that an alternative regulatory approach to toxics compliance will or, where uses may have been previously obtained, can be made available to the City at no cost. Although we disagree with EPA guidance, it clearly states that a minimum of 1-2% of median household income must be spent prior to relief based on economics. Relief may be available for expenses above that level. Assuming a median disposable household income of $30,000 the ceiling would be $300 - $600 per year. Since households are now spending $156.60 a year, that means that costs could go up $143.40 - $443.40 per household before the EPA would consider it an economic hardship. For 110,000 households, that is an increase of $15,774,000 - $48,774,000 per year for the City of

Riverside alone. When performing an economic analysis the EPA should be consistent with its own guidance.

Comment: The Natural Resources Defense Council strongly opposes the Region 9 EPA proposal to raise the allowable mercury criterion for continuous concentration in water from 0.012 parts per billion (ppb) to 0.770 ppb for aquatic life. This proposal is difficult to justify from the point of view of science and of public health. On behalf of our over 350,000 members nationwide and our over 55,000 California

members, we are writing to register our opposition to the EPA proposed rule.

Mercury is a highly poisonous metal which results in toxicity to the brain and nervous system and toxicity to human reproduction. In addition, in sediments, mercury is bio-transformed into the even more toxic form, methyl mercury, which has resulted in some of the largest epidemics of neuro-developmental poisoning known to mankind. Methyl mercury bioaccumulates in the food chain and thereby results in greatly concentrated exposures to humans, because we eat off the top of the food chain. Underestimates of the toxicity and bioaccumulation of mercury have led to major mistakes in the past. The Minamata Bay disaster in Japan was caused by a failure to predict the potency of mercury and the extent of human exposure through fish. U.S. EPA's Draft Mercury Study Report to Congress documents that children of high-end fish consumers in the U.S. may be exposed to enough mercury to cause adverse neuro-developmental effects.

In this setting it is anomalous to relax the standards for mercury contamination in California water. Furthermore, the scientific reasoning behind the Region 9 EPA decision to relax the mercury standard 60-fold is fraught with errors. NRDC's major concerns with this approach are summarized below.

*Extrapolation for the Reference Dose (RfD) should start at a NOAEL, not at a level of 10% increased risk. *An additional 10-fold safety factor should be added in deriving the RfD to account for the vulnerability of fetuses, infants, and children. *The body weight in the calculation should be for a child, not an adult male. *The Fish consumption rates for those who do eat fish should be used instead of rates for the entire population including those who do not eat fish. *Average fish consumption quantities greatly understate the risk to those who eat a lot of fish. Instead, fish consumption for the top 5% of the population should be used.' *Bioaccumulation is known to be 10 to 100 fold greater than the estimate used by EPA. *California's waters are already too polluted with mercury.

Insufficiently Protective Reference Dose

The risk assessment used the-current reference dose (RfD) from U.S. EPA's Integrated Risk Information System (IRIS) which contains several problems that make it likely to be too high to be health protective. The starting point for the extrapolation was the dose which conferred a I 0% increased risk to exposed humans. This is certainly not a No Observable Adverse Effects Level (NOAEL), and in fact, a 10% increase in risk is quite significant in scientific and public health terms. Despite the fact that the NOAEL was not used as a starting point for derivation of the RfD, only a 10-fold uncertainty factor was added to derive the RfD. This was presumably a half-log of 10 for within human variability and a half-log of 10 for lack of a two generation reproductive study. A half-log of 10 is clearly insufficient to account for the wide range of human variability. In fact, the effects of mercury on the developing nervous system and the appearance of clinical mercury toxicity at much lower doses in children make it highly likely that fetuses, infants, and children are far more than an order of magnitude more susceptible to the effects of mercury intoxication than are adults. Thus an additional factor of at least 10 should be added to account for the disproportionate susceptibility of children.

Incorrect Choice of Body Weight

The body weight used in the equation for the mercury criterion is 70 kg. This is an average adult male body weight. Average female body weight is around 60 kg and a child would weigh less than 10 kg (7.5 kg is a common choice in risk assessment). It is extremely odd to use an adult male body weight in the risk calculation when the populations of interest are pregnant women and children. It is a fact that adult males are simply at much less risk for the adverse health effects of mercury. Choice of an excessively large body weight leads to a larger predicted tolerable dose. Such a large dose might well be tolerable to

an adult male, but in the case of mercury, we are concerned with a different population at risk. Therefore the calculation should use the body weight of the lightest member of the population at risk, ie. the weight of a child, in the equation if there is any hope that the result of the calculation will provide any health protection for a child.

NRDC strongly urges Region 9 EPA to reassess the proposed standard for mercury. Recalculation of the reference dose to accommodate the known disproportionate impact of mercury on fetuses, infants, and children will require addition of at least another 10-fold safety factor. The starting point for RfD calculation should be a true NOAEL. The body weight calculation should use an average weight for a child. Fish consumption data should reflect the "high-end" consumer. Finally, the outdated and unsupportable bioaccumulation factor of 7300 should be discarded in favor of a BAF which is supported by the current science in California.

Response to: CTR-006-001a

Regarding the choice of body weight, EPA disagrees that the use of a 70 Kg body weight is inappropriate for the calculation of the mercury criterion. Although the use of a 70 kg assumption results in a slightly less stringent value, the Agency disagrees that this represents an excessively large body weight. The comment author is also incorrect in the statement that the 70 kg assumption only represents adult males. The 70 kg assumption is, in fact, based on the combined average body weights of adult males and females according to data from the Second National Health and Nutrition Examination Survey (NHANES II). These data indicate that the average body weight for adult females of childbearing age is 65 kg. EPA does not believe that an adjustment of 5 kg would result in a significant change in the mercury criterion. However, EPA is developing a revised methodology for deriving water quality criteria to protect human health and is considering different default body weight recommendations for women of childbearing age and children (see draft revisions published August 14, 1998, Federal Register, Vol. 63, No. 157). EPA is currently reviewing public comments and is awaiting the results of a peer review on the draft methodology revisions. As part of this effort, EPA also intends to consider the more recently published NHANES III data for the same gender and age categories. Until these reviews are complete, it would be inappropriate to change the 70 kg assumption used to calculate the human health criteria for mercury.

EPA disagrees that the body weight of a child should be used for the calculation of the mercury criterion. The effect of concern is a developmental effect which is caused by exposure of the female to mercury and the transmigration of the mercury into the developing fetus to cause the developmental neurotoxic effect. Thus, if the exposure to the pregnant female is reduced to a level which is not toxic to the fetus, then the fetus is protected. This is achieved by calculating a maternal exposure level that corresponds to a NOAEL for developmental effects in the fetus, and in doing so, the weight of the pregnant female is the appropriate number on which to base the calculation.

For issues concerning the derivation of the Reference Dose and safety factors, see the response to CTR-006-002a. Regarding the fish consumption rate, see the response to this issue in CTR-002-002a. Regarding the bioaccumulation issue, see the response in CTR-002-007b.

Comment: Dear Ms. Frankel,

The Natural Resources Defense Council strongly opposes the Region 9 EPA proposal to raise the allowable mercury criterion for continuous concentration in water from 0.012 parts per billion (ppb) to 0.770 ppb for aquatic life. This proposal is difficult to justify from the point of view of science and of public health. On behalf of our over 350,000 members nationwide and our over 55,000 California members, we are writing to register our opposition to the EPA proposed rule.

Mercury is a highly poisonous metal which results in toxicity to the brain and nervous system and toxicity to human reproduction. In addition, in sediments, mercury is bio-transformed into the even more toxic form, methyl mercury, which has resulted in some of the largest epidemics of neuro-developmental poisoning known to mankind. Methyl mercury bioaccumulates in the food chain and thereby results in greatly concentrated exposures to humans, because we eat off the top of the food chain. Underestimates of the toxicity and bioaccumulation of mercury have led to major mistakes in the past. The Minamata Bay disaster in Japan was caused by a failure to predict the potency of mercury and the extent of human exposure through fish. U.S. EPA's Draft Mercury Study Report to Congress documents that children of high-end fish consumers in the U.S. may be exposed to enough mercury to cause adverse neuro-developmental effects.

In this setting it is anomalous to relax the standards for mercury contamination in California water. Furthermore, the scientific reasoning behind the Region 9 EPA decision to relax the mercury standard 60-fold is fraught with errors. NRDC's major concerns with this approach are summarized below.

*Extrapolation for the Reference Dose (RfD) should start at a NOAEL, not at a level of 10% increased risk. *An additional 10-fold safety factor should be added in deriving the RfD to account for the vulnerability of fetuses, infants, and children. *The body weight in the calculation should be for a child, not an adult male. *The Fish consumption rates for those who do eat fish should be used instead of rates for the entire population including those who do not eat fish. *Average fish consumption quantities greatly understate the risk to those who eat a lot of fish. Instead, fish consumption for the top 5% of the population should be used. *Bioaccumulation is known to be 10 to 100 fold greater than the estimate used by EPA. *California's waters are already too polluted with mercury.

Insufficiently Protective Reference Dose

The risk assessment used the-current reference dose (RfD) from U.S. EPA's Integrated Risk Information System (IRIS) which contains several problems that make it likely to be too high to be health protective. The starting point for the extrapolation was the dose which conferred a I 0% increased risk to exposed humans. This is certainly not a No Observable Adverse Effects Level (NOAEL), and in fact, a 10% increase in risk is quite significant in scientific and public health terms. Despite the fact that the NOAEL was not used as a starting point for derivation of the RfD, only a 10-fold uncertainty factor was added to derive the RfD. This was presumably a half-log of 10 for within human variability and a half-log of 10 for lack of a two generation reproductive study. A half-log of 10 is clearly insufficient to account for the

wide range of human variability. In fact, the effects of mercury on the developing nervous system and the appearance of clinical mercury toxicity at much lower doses in children make it highly likely that fetuses, infants, and children are far more than an order of magnitude more susceptible to the effects of mercury intoxication than are adults. Thus an additional factor of at least 10 should be added to account for the disproportionate susceptibility of children.

Incorrect Choice of Body Weight

The body weight used in the equation for the mercury criterion is 70 kg. This is an average adult male body weight. Average female body weight is around 60 kg and a child would weigh less than 10 kg (7.5 kg is a common choice in risk assessment). It is extremely odd to use an adult male body weight in the risk calculation when the populations of interest are pregnant women and children. It is a fact that adult males are simply at much less risk for the adverse health effects of mercury. Choice of an excessively large body weight leads to a larger predicted tolerable dose. Such a large dose might well be tolerable to an adult male, but in the case of mercury, we are concerned with a different population at risk. Therefore the calculation should use the body weight of the lightest member of the population at risk, ie. the weight of a child, in the equation if there is any hope that the result of the calculation. will provide any health protection for a child.

NRDC strongly urges Region 9 EPA to reassess the proposed standard for mercury. Recalculation of the reference dose to accommodate the known disproportionate impact of mercury on fetuses, infants, and children will require addition of at least another 10-fold safety factor. The starting point for RfD calculation should be a true NOAEL. The body weight calculation should use an average weight for a child. Fish consumption data should reflect the "high-end" consumer. Finally, the outdated and unsupportable bioaccumulation factor of 7300 should be discarded in favor of a BAF which is supported by the current science in California.

Response to: CTR-006-001b

With respect to the bioaccumulation factors see response to CTR-002-007b. With respect to the mercury aquatic life criteria, EPA is not promulgating these criteria in today's rule (see the preamble of today's rule for further explanation). For an explanation why EPA does not believe today's rule will worsen water quality see response to CTR-002-003.

With respect to EPA's risk assessment procedures see responses to CTR-006-001a and CTR-006-002a.

Comment: Dear Ms. Frankel,

The Natural Resources Defense Council strongly opposes the Region 9 EPA proposal to raise the allowable mercury criterion for continuous concentration in water from 0.012 parts per billion (ppb) to 0.770 ppb for aquatic life. This proposal is difficult to justify from the point of view of science and of public health. On behalf of our over 350,000 members nationwide and our over 55,000 California members, we are writing to register our opposition to the EPA proposed rule.

Mercury is a highly poisonous metal which results in toxicity to the brain and nervous system and toxicity to human reproduction. In addition, in sediments, mercury is bio-transformed into the even more toxic form, methyl mercury, which has resulted in some of the largest epidemics of neuro-developmental poisoning known to mankind. Methyl mercury bioaccumulates in the food chain and thereby results in greatly concentrated exposures to humans, because we eat off the top of the food chain. Underestimates of the toxicity and bioaccumulation of mercury have led to major mistakes in the past. The Minamata Bay disaster in Japan was caused by a failure to predict the potency of mercury and the extent of human exposure through fish. U.S. EPA's Draft Mercury Study Report to Congress documents that children of high-end fish consumers in the U.S. may be exposed to enough mercury to cause adverse neuro-developmental effects.

In this setting it is anomalous to relax the standards for mercury contamination in California water. Furthermore, the scientific reasoning behind the Region 9 EPA decision to relax the mercury standard 60-fold is fraught with errors. NRDC's major concerns with this approach are summarized below.

*Extrapolation for the Reference Dose (RfD) should start at a NOAEL, not at a level of 10% increased risk. *An additional 10-fold safety factor should be added in deriving the RfD to account for the vulnerability of fetuses, infants, and children. *The body weight in the calculation should be for a child, not an adult male. *The Fish consumption rates for those who do eat fish should be used instead of rates for the entire population including those who do not eat fish. *Average fish consumption quantities greatly understate the risk to those who eat a lot of fish. Instead, fish consumption for the top 5% of the population should be used. *Bioaccumulation is known to be 10 to 100 fold greater than the estimate used by EPA. *California's waters are already too polluted with mercury.

Use of Average Fish Consumption is not Health Protective

The assumption used by Region 9 EPA for fish consumption relies on the average fish and shellfish consumption in the entire general population, along with the average intake from each body of water. It is quite clear that fish consumption follows a highly skewed, or Poisson distribution in the population (see attachment from the U.S. EPA Draft Mercury Study Report to Congress, Appendix H, p. 20). Many people eat little or no fish, but a smaller, yet highly significant segment of the population eats a very large amount of fish. Surely EPA should strive just as hard to protect the health of those who eat fish frequently as it does to protect the health of those who do not eat fish.

In fact, this analysis adequately protects only those who eat little or no fish. The average which was used in the Region 9 EPA analysis appears to derive from the "per capita" data from the USDA Continuing Surveys of Food Intake by Individuals (CSF 11) from 1989-91 for males ages 15-44 years. (See attached tables from U.S. EPA Mercury, Report, Appendix H, pp. 8 & I 1). In fact, this average is highly influenced by those individuals who consume little or no fish. Non-fish-consumers, however, are not the population of interest for purposes of this analysis. Instead, if an average is to be used, it should be the average fish consumption rate for those people who do eat fish. This is substantially higher, at 53.7 g/day for males ages 15-44 years, and 41.4 g/day for females in the same age range. Furthermore, the average fish consumption will likely underestimate the fish consumption rate for the "high end" fish

consumer by many orders of magnitude. For example, in the case of females ages 15-44 years, average fish consumption (among those who do eat fish) is 41.4 g/day, while fish consumption by the top 5% of the population of these women of childbearing age is about 112 g/day, or more than double the average consumption rate.

The implications of not adequately protecting the high fish consumer are not trivial. The population of California is nearly 30 million, of whom overall 31% would be expected to be fish consumers according to the CSF II survey. This represents over 9 million people who would be at disproportionate risk. The top 5% of that population consists of nearly half a million people in California who would be expected to eat fish at nearly 10-times greater quantity than the EPA calculations would predict. 10 times greater consumption would translate into roughly 10-times greater risk from the mercury in the fish. EPA is not adequately protecting this substantial portion of the California population from mercury hazards.

NRDC strongly urges Region 9 EPA to reassess the proposed standard for mercury. Recalculation of the reference dose to accommodate the known disproportionate impact of mercury on fetuses, infants, and children will require addition of at least another 10-fold safety factor. The starting point for RfD calculation should be a true NOAEL. The body weight calculation should use an average weight for a child. Fish consumption data should reflect the "high-end" consumer. Finally, the outdated and unsupportable bioaccumulation factor of 7300 should be discarded in favor of a BAF which is supported by the current science in California.

Response to: CTR-006-002a

The commenter criticizes the current RfD on IRIS in several respects. While EPA intends to develop a revised IRIS value, once it receives recommendations from the National Academy of Sciences (see discussion in response to CTR-030-007 and CTR-002-007b), EPA strongly believes that some level of protection needs to be in place for mercury because of its toxicity to humans and aquatic life (see response to CTR-002-007b). Therefore, EPA thinks it is reasonable to keep in place the human health value based on the current RfD, which it believes is scientifically defensible based on the state of the science at the time it was derived.

The EPA disagrees with the comment that an RfD should be calculated by selecting the NOAEL and applying the appropriate safety factor in the case of mercury due to the nature of the data. The data base for mercury allow for the use of continuous human data (i.e., there are no dose groups and no NOAEL as it is defined for a controlled animal study) on the most sensitive subpopulation which is the fetus.

In regard to the methodology used to calculate the Reference Dose (RfD), the following discussion is intended to clarify why the Benchmark Dose (BMD) approach is the most appropriate method to use for the mercury data. Traditionally, when assessing the human health hazard and dose response relationship for a toxicant which produces a non-cancer effect in humans or animals following exposure, a No Observed Adverse Effect Level (NOAEL) and the Lowest Observed Adverse Effect Level (LOAEL) is selected for the critical effect from among all the available data, and a series of uncertainty factors are applied as appropriate to determine the Reference Dose. This methodology is widely used by regulatory agencies as the first step in assessing potential human health risk from exposure to the substance in question. As more refined mathematical models are developed and better scientific data on toxicants are generated, there is the opportunity to calculate a BMD which more closely approaches the true NOAEL because more of the data and the characteristics of the data are utilized in the analysis. When the data base is robust and such refinements are possible, it is incumbent upon the risk assessors to generate these more realistic estimates of human health hazard for the reasons listed below.

People often misinterpret the NOAEL that is selected from a critical study as the actual level of exposure at which no adverse effects are observed, but actually, it is only the highest level at which no adverse effects are observed in that particular study or in a group of studies. The NOAEL is a function of study design, (i.e., the number of animals tested, the number of doses, the spacing between doses, the duration of exposure, and the route of administration). If the study design has adhered to the toxicity testing guidelines and Good Laboratory Practice (GLP) requirements, the NOAEL actually represents an effect level because of the number of animals used. As the number of test animals increases and more dose levels are tested, the power of the study and its ability to detect a toxic effect increases; the data generated are more robust and the NOAEL decreases as it approaches the real value. Studies with higher power result in lower NOAELs, smaller RfDs and a greater confidence in the level of safety. Also, NOAELs are often controversial since scientific judgment is applied to reach the conclusion that what is observed at the LOAEL is really adverse in nature; and the selection of one number for the NOAEL disregards valuable information gained
from looking at the whole study and the slope of the dose response curve (There is a higher level of concern when the slope is steep because a small change in dose/exposure produces significant changes in the effects noted. Shallow slopes indicate that exposures can be increased over a broader range and the increase in the number or severity of the effects will be less dramatic). Consequently, there are many disadvantages to this methodology, but it is nevertheless frequently used due to the lack of better and more data on the toxicant under review.

However, some toxicants have presented a high level of interest to the scientific community and the regulatory programs and there exists an abundance of toxicology data (often times human data) from which to calculate risk. In these situations, it is preferable to use as much of the data as possible and to select an appropriate model for the data which allows the analyst to determine a Benchmark Dose (BMD). To do this, EPA chooses among a series of appropriate mathematical models. EPA fits each of these to the data. EPA then uses a statistical procedure to select the model that gives the best fit to the data. A BMD is a statistical lower confidence limit on the dose that produces a selected level of change in response rate in comparison to untreated control animals (e.g., 5% or 10% change in response when compared to the background response) (EPA 1995). In other words, the BMD approach selects a data point (point of departure at which there is a certain response level, in this case a 10% response level) and selects the appropriate mathematical model for the data which takes into account the slope of the dose response curve and the variability of the data. For mercury, the BMD thus represents the lower confidence limit for the dose that is estimated to produce the 10% level of change in response in the study population. The BMD thus represents the probability that 95% of the time, the dose producing the given level of response will be higher than the BMD. This approach is well suited to the data base for mercury since the human
data are continuous, i.e., there is a response associated with all exposure levels and there is no non-exposed group. The BMD approach is a newer and more robust analysis which utilizes all the data and the special characteristics of these data, and the Agency would be errant in its mission if it did not utilize state of the art methods in risk assessment to achieve its goals of public health protection. Using this methodology improves the resulting non cancer risk assessment because it uses the dose response data to select an appropriate model which does not extrapolate to doses below the experimental range. The BMD can either be less than or greater than the corresponding NOAEL, it is not restricted to one of the experimental dose levels, and it accounts more appropriately for sample size and dose-response characteristics (Crump 1984, Dourson et al. 1985, Kimmel and Gaylor 1988). In deriving an RfD using this method, the BMD is then divided by the appropriate uncertainty factors. Where the data are appropriate and lend themselves well to the use of a BMD as in the case of the type and quantity of data on mercury, the Agency would be errant in its mission of public health protection if it assessed the hazard of mercury by using the simplistic NOAEL/LOAEL approach.

In the EPA RfD calculation for mercury, an estimate of a NOAEL was used; namely the lower 95% confidence limit on a dose corresponding to a 10% effect level for all reported neurodevelopmental effects reported in a population of 81 Iraqi children reported in Marsh et al. 1987. The 10% effect level refers to the dose which produces the defined effect in 10% of the study population. A Weibull model was fit to the data as recent research suggests that it may be the best model for developmental toxicity data (Faustman et al. 1994). Other research indicates that the lower confidence limit on the dose which produces a 10% response level (i.e., the BMD) is the appropriate choice when correlated with the NOAEL for developmental effects in controlled animal studies (Allen et al. 1994a, b). In the case of the mercury RfD, the 10% effect level was determined to be the most appropriate regarding the aforementioned discussion on compariosn to background response (i.e., statistical significance) and when correlated to the NOAEL. It should be noted that the data on developmental effects in the Iraqi children are continuous with respect to dose. That is, there are no dose groups and no NOAEL as it is defined for a controlled animal study. The benchmark dose modeling procedure provides a reasonable approach to determining the exposure at which effects are observable above background.

EPA also disagrees with the comment that the adult males are at much less risk for the adverse health effects of mercury, and that the RfD should be recalculated with the addition of at least another 10 fold safety factor to accommodate the known disproportionate impact of mercury on fetuses, infants and children. In regard to the sensitivity of adult males vs fetuses, infants and children, the original RfD of 0.3 @g/kg/day was based on paresthesia in Iraqi adults exposed to methylmercury in grain. This is within a factor of three of the current RfD (0.1 @g/kg/day based on developmental neurotoxicity in the same population. According to EPA, an RfD is defined as "an estimate (with uncertainty spanning perhaps an order of magnitude)"of a daily exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effect during a lifetime. Thus, by this "order of magnitude" standard, the RfD based on adult effects overlaps that based on developmental endpoints. In the most recent publications on the poisonings in Minamata, exacerbation or onset of neurological symptoms have been noted as the population has aged.

In regard to the addition of another safety factor for fetuses, infants and children, the scientific community agrees that when deriving an RfD for methylmercury using sensitive developmental neurotoxic endpoints that the data represent the effects in children and fetuses. Thus, an additional 10 fold factor would be redundant. In calculation of the RfD, a composite uncertainty factor of 10 was used to account for a number of uncertainties related to the data. First, this uncertainty factor was applied for variability in the human population, in particular, the wide variation in biological half-life of methylmercury and the variation that occurs in the hair to blood ratio for mercury. In addition, the factor accounts for lack of a two-generation reproductive study and lack of data for possible chronic manifestations of the adult effects (e.g., paresthesia that was observed during gestation). EPA also considers whether to incorporate a modifying factor to address limitations on the data used (e.g., number of animals, sex of animals). The default value of one was used for the modifying factor. Additional discussion regarding the uncertainty factor based on the Marsh et
al 1987, is excerpted from the Mercury Study Report to Congress, 1997, see "Addendum" for this information.

The fish intake rate of 6.5 gm/day is from a national, 30-day survey (the National Purchase Diary), based on an empirical distribution, where 6.5 gm/day represents the average value for the general population. Regarding the fish consumption analysis, the commenter is incorrect on several points.
First, although EPA agrees that fish consumption distributions do tend to be skewed, the Agency disagrees that they follow a Poisson distribution. Nor has the commenter demonstrated that fish consumption follows a Poisson distribution. On the contrary, numerous studies have shown that average fish consumption rates are generally approximated by log-normal distributions. This is specifically true

for the CSFII survey data that the commenter references. The commenter is also incorrect that "many people eat little or no fish." According to the National Purchase Diary (NPD), the basis of the 6.5 gm/day intake rate, 94 percent of the survey respondents stated that they eat some fish. It is not EPA's intention to specifically protect non-consumers of fish. However, survey designs generally, and the referenced CSFII survey in particular, do not allow segregating the data to isolate consumers from non-consumers. The only determination that can be made from the CSFII data is whether a respondent did or did not eat fish during the three consecutive survey days. Therefore, the extrapolation made by the commenter that only 31 percent of the population are fish consumers is incorrect. The commenter is also incorrect that the basis of the chosen intake rate is for males ages 15-44 years. The 6.5 gm/day is based on all respondents from the NPD and, therefore, is representative of males and females in the general population. Further, the "per capita" data submitted by the commenter (from the 1996 draft version of the Mercury Study Report to Congress) are based on rates that include marine species (not used in the water quality criteria derivations), in additon to the estuarine/freshwater species that do comprise the value used in deriving water quality criteria. For additonal discussion regarding the basis of the fish consumption rate, including the exclusion of marine species, see the response to this issue in CTR-002-002a.

Regarding the choice of body weight, see response to CTR-006-001a. Regarding the issues on bioaccumulation, see response to CTR-002-007b.

Comment: Dear Ms. Frankel,

The Natural Resources Defense Council strongly opposes the Region 9 EPA proposal to raise the allowable mercury criterion for continuous concentration in water from 0.012 parts per billion (ppb) to 0.770 ppb for aquatic life. This proposal is difficult to justify from the point of view of science and of public health. On behalf of our over 350,000 members nationwide and our over 55,000 California members, we are writing to register our opposition to the EPA proposed rule.

Mercury is a highly poisonous metal which results in toxicity to the brain and nervous system and toxicity to human reproduction. In addition, in sediments, mercury is bio-transformed into the even more toxic form, methyl mercury, which has resulted in some of the largest epidemics of neuro-developmental poisoning known to mankind. Methyl mercury bioaccumulates in the food chain and thereby results in greatly concentrated exposures to humans, because we eat off the top of the food chain. Underestimates of the toxicity and bioaccumulation of mercury have led to major mistakes in the past. The Minamata Bay disaster in Japan was caused by a failure to predict the potency of mercury and the extent of human exposure through fish. U.S. EPA's Draft Mercury Study Report to Congress documents that children of high-end fish consumers in the U.S. may be exposed to enough mercury to cause adverse

neuro-developmental effects.

In this setting it is anomalous to relax the standards for mercury contamination in California water. Furthermore, the scientific reasoning behind the Region 9 EPA decision to relax the mercury standard 60-fold is fraught with errors. NRDC's major concerns with this approach are summarized below.

*Extrapolation for the Reference Dose (RfD) should start at a NOAEL, not at a level of 10% increased risk. *An additional 10-fold safety factor should be added in deriving the RfD to account for the vulnerability of fetuses, infants, and children. *The body weight in the calculation should be for a child, not an adult male. *The Fish consumption rates for those who do eat fish should be used instead of rates for the entire population including those who do not eat fish. *Average fish consumption quantities greatly understate the risk to those who eat a lot of fish. Instead, fish consumption for the top 5% of the population should be used. *Bioaccumulation is known to be 10 to 100 fold greater than the estimate used by EPA. *California's waters are already too polluted with mercury.

The Bioconcentration Factor is Incorrect

The proposed EPA rule calculates a bioconcentration factor (BCF) in fish of 7300. Available data from the state of California indicates that this factor is wrong by between IO and I 00-fold. In the Great Lakes, mercury has been shown to accumulate with bioaccumulation factors (BAF) of 27,900 for trophic level 3 fish and 140,000 for trophic level 4 fish. Despite this evidence, EPA rejects these data for use in California and calculates a BCF more than 10-fold lower based on a model created 27 years ago. In fact, current data are available on bioaccumulation in California fish.

The San Francisco Bay Regional Monitoring Program has found BAFs of 60,000 to 200,000 in bivalves and research in California lakes has found a calculated BAF of over 500,000 fold. These data have been presented elsewhere in the rulemaking record by researchers from the University of California at Santa Cruz. Underestimating by one to two orders of magnitude the amount of bioaccumulation that will occur in the environment is a major error with potentially devastating public health implications. The potential result is that water will contain "permissible" concentrations of mercury while fish will be contaminated at levels too high for safe human consumption.

California is already Suffering from Mercury Pollution

Numerous water bodies in the state of California are already under fish advisory for mercury. These include Clear Lake, Lake Berryessa, the San Francisco Bay and Delta, Lake Herinan, Guadalupe Reservoir, Calero Reservoir, Almaden Reservoir, Guadalupe River, Guadalupe Creek, and Lake Nacimiento. In the face of this widespread environmental pollution with mercury, all incentives should be driving toward further reduction of mercury emissions and releases to water sources. By relaxing the mercury standards for water, U.S. EPA is heading in absolutely the wrong direction. Increases in allowable levels of mercury in the environment can only lead to more contaminated fish, more fish advisories, more pregnant women and children potentially exposed to this toxic metal, and more risks to public health.

NRDC strongly urges Region 9 EPA to reassess the proposed standard for mercury. Recalculation of the reference dose to accommodate the known disproportionate impact of mercury on fetuses, infants, and children will require addition of at least another 10-fold safety factor. The starting point for RfD calculation should be a true NOAEL. The body weight calculation should use an average weight for a child. Fish consumption data should reflect the "high-end" consumer. Finally, the outdated and unsupportable bioaccumulation factor of 7300 should be discarded in favor of a BAF which is supported

by the current science in California.

Response to: CTR-006-003

Regarding the commenter's statements on the Reference Dose (RfD), refer to the responses on this same issue in CTR-006-001a and CTR-006-002a. Regarding the bioaccumulation issue, see response to CTR-002-007b.

Comment: Comments on the Proposed Mercury Criteria

The Regional Board supports the use of the current Reference Dose from IRIS in deriving the proposed mercury criteria, but we do not agree that the proposed weighted practical average BCF is appropriate for several reasons.

First, is has been our experience that accurate models of bioaccumulative metal uptake require detailed understandings and representations of biogeochemical cycling in aquatic environments. In the absence of a much more detailed, criteria derivation method that accounts for differences between aquatic environments, the Board agrees with current EPA policy that the BAF model used in the Great Lakes Initiative is a more technically sound approach for addressing bioaccumulative substances than approaches using BCFs.

Second, we disagree with EPA's conclusion that data are lacking to determine if the Great Lakes' BAFs are appropriate for use in California. There are ample data sets for derivation of BAFs for coastal waters and the major estuary in the State, as well as detailed water column, invertebrate, and fish tissue data available for mercury in the Sacramento River watershed and reservoir systems affected and unaffected by mercury.(*1) The Board encourages EPA to conduct the same level of analysis for the State of California as it did for the Great Lakes Region using existing data. Towards that end, we have calculated BAFs for two trophic levels for the San Francisco Bay Estuary using data from the San Francisco Buy Regional Monitoring Program according to the methodology outlined in the Great Lakes Initiative. For bivalves (trophic level 3), the field-measured BAF is 23,435; for trophic level 4 fish species typically caught by local fishermen, the field-measured BAF is 144,335.(*2)

The next set of comments relates specifically to the proposed "weighted average practical BCF" method. As written, we believe this method would be appropriate if the goal were to calculate the maximum marginal increase in mercury dose that a population could receive without exceeding the RfD. In other words, this approach allows the weighted dietary average to "dilute" the effects of high levels of mercury in individual water bodies. We do not believe that such an approach is appropriate for the derivation of

criteria that will be used to determine whether mercury levels are affecting uses of individual water bodies in California. Instead, consideration should be given to protecting established beneficial uses that rely on water quality in one stream segment. Our second comment is that it is not clear why EPA is including data for open ocean levels of mercury in the derivation of criteria for inland and estuarine waters. Third, it is also not clear whether the referenced BCFs pertain to the dissolved mercury fraction, or total recoverable and if the latter, why the proposed criteria are in terms of the dissolved fraction. Nor is it clear that the data used to derive the early BCFs were obtained using the ultra clean sampling techniques necessary to obtain true water column concentrations. Improper sampling and analytical techniques would yield higher water column values and lower BCFs than the true measurements.

In summary, the Regional Board requests that EPA calculate an appropriate set of BAFs for mercury applicable to the State of California and not adopt the criteria derived using the proposed method. The proposed mercury criteria are under protective of California waters by several orders of magnitude, and the implicit public concern being protected (average diet of the state's population) is inappropriate. For example, San Francisco Bay is currently listed as a water quality limited segment due to high levels of mercury in fish tissue. The mean dissolved mercury concentration in San Francisco Bay is 0.0019 ug/I and no samples have ever exceeded EPA's proposed standard of 0.05 ug/l.

(*1) It is our understanding that extensive data sets exist for at least Clear Lake, Lake Nacimiento, Cache Creek, Walker Creek, Marsh Creek, the Sacramento River, and the New Almaden mining area. These water bodies encompass most of the types of aquatic systems where mercury levels pose water quality threats in the State.

(*2) Both of these calculations are based on high quality data sets and report wet weight tissue concentrations and dissolved mercury concentrations. Because of the time constraints for comments, they are, however, first-cut estimates using mean reported values. The derivation of a BAF for San Francisco Bay can be made much more precise by separating out location, time, specific species, deployment variables (such as size, growth, and post-deployment bioaccumulation), and available TOC using this data base.

Response to: CTR-016-007

EPA acknowledges the San Francisco Bay Regional Water Quality Board's agreement with EPA's position that a BAF model better represents bioaccumulation potential than a BCF. As noted by the commentor, the issue of mercury bioaccumulation is very complex. EPA is working to improve the knowledge base on mercury bioaccumulation and is in the process of updating its overall method for assessing bioaccumulation and deriving BAFs. EPA's National human health water quality criteria are based on national averages of fish consumption from all relevant sources, which is why the PBCF is based on a weighted average that includes open ocean data. The mercury PBCFs and criteria for human health protection are based on total mercury, not the dissolved total form. Only the freshwater and saltwater CMC and CCC are based on the dissolved inorganic form (Hg-II). For further response to the bioaccumulation issue, refer to response to CTR-002-007b.

Comment: II. Use of New Scientific Information

The City acknowledges and supports EPA's update of several water quality criteria including those for mercury, cadmium and arsenic. While a number of criteria were updated to reflect current scientific information, there are a few notable exceptions.

The following briefly addresses the key updates and omissions that should be addressed in the final publication of this rule.

A. Criteria that Fail to Reflect Updated Scientific Information

1. Mercury

Mercury criteria were significantly corrected, and the City supports this action. The acute criteria were changed to the dissolved form, the misclassified chronic criteria were changed from 0.012 ppb to 770 ppb, and the human health fish tissue-based criteria were raised from 12 parts per trillion ("ppt") to 50 ppt and now apply at harmonic mean flows. These corrections appear to reflect the latest available scientific information. EPA indicated that the human health criteria were based upon fish tissue contaminant levels. Because the underlying basis for the criteria is an assumed fish tissue contamination level, the human health criteria should either (1) allow for adjustment of the criteria where it is apparent that fish tissue levels are acceptable but the criteria may be exceeded or (2) specify that information on fish tissue contamination may be used as a screening tool to determine if the discharge has a reasonable potential to cause exceedance of the criteria. If the fish tissue data indicate that the existing discharge is acceptable, no limitation should be included in the permit.

Response to: CTR-020-004a

EPA acknowledges the commenter's support for the criteria reflecting the latest scientific information, notwithstanding the fact that the commenter has incorrectly referred to the previous aquatic life criterion of 12 ppt as the previous human health value. Regarding the two options that the commenter presents for human health criteria when the underlying basis is a fish tissue concentration, EPA disagrees that the first option is a plausible scenario, given the BCF-based calculation. EPA believes the reverse scenario is far more likely (i.e., when the fish tissue levels are not acceptable but the water column value is not exceeded). For the second option, EPA agrees that the use of fish tissue is more acceptable for back-calculating from fish tissue concentrations to ambient concentrations in order to determine remaining assimilative capacity.

Comment: PROVISIONS OF THE PROPOSED RULE WE SUPPORT

Not withstanding the above comments, we believe there are certain elements of the proposed rule with respect to establishing water quality standards that we can support:

* Metal criteria expressed in the dissolved fraction rather than expressed in the total recoverable fraction.

* Metal criteria that are developed as a function of the water-effect-ratio (WER).

* The current proposed human health criterion for mercury.

* The current preamble language regarding metal translators and mixing zones.

We believe the above provisions provide a more acceptable, scientific approach to the water quality-based pollution control approach. We recommend these provisions of the current rule remain as proposed.

Response to: CTR-027-012c

EPA acknowledges the commenter's support of the rule.

Comment: B. The Proposed Mercury Human Health Criterion is Technically Deficient

EPA proposes a human health criterion for mercury of 50 nanograms per liter for California. 62 Fed. Reg. at 42,194. This criterion, while substantially less stringent than that applied in the Great Lakes Water Quality Rule, is technically deficient because assumptions used in developing the criterion are not scientifically defensible. For example, the Bioconcentration Factor (BCF) used in the criterion equation assumes a "steady state" relationship between mercury levels in the water column and mercury levels in fish. In fact, the California proposal's preamble states "the BCF is defined as the ratio of chemical concentration in the organism to that in the surrounding water." 62 Fed. Reg. at 42,179, col. 3. The preamble also references EPA's water quality criteria document for mercury, which stipulates that "These [BCF] calculations depend upon a number of assumptions. The basic assumption is that, on the average, the concentration of methylmercury in fish muscle is related to the concentration of total mercury in water. This might be true if (1) methylmercury on the average is a constant fraction of total mercury in water . . . " Ambient Water Quality Criteria for Mercury, EPA 440/5-80-058 (October 1980) (Mercury Criteria Document) at C-25 to C-28. However, the ratio of mercury in the water column to mercury

levels in fish is not a "steady state" but can vary by as much as a factor of 100, particularly in streams and littoral areas of larger bodies of water. This variability is described at length in the Proceedings of the Third International Conference on Mercury as a Global Pollutant, reprinted in Water, Air and Soil Pollution Journal 80 (1-4) 1995 (Proceedings of Third International Conference). The preamble to the California proposal does not address the variability of totalmercury concentrations in the water column, but acknowledges the variability in the ratio of methylmercury to total mercury concentrations in the water column, stating:

To a considerable degree the magnitude of the BAF for mercury in a given system depends on how much of the total mercury in that system is present in the methylated form. Methylation rates vary widely from one aquatic system to another for reasons that are not fully understood.

62 Fed. Reg. at 42,180, cols. 1-2. Having acknowledged that methylation rates vary widely, EPA should not employ a model which is preconditioned on the existence of constant methylation rates.

UWAG also notes the following additional questionable assumptions of the proposed criterion.

* The criterion does not adequately acknowledge fate and transport processes such as evasion and deep sediment burial, which in many aquatic systems can remove 90 percent or more of the available mercury. Although the California proposal incorporates the concept of mixing zones, mixing zones only provide for partial consideration of the fate and transport mechanisms which reduce water column concentrations of mercury. Fate and transport processes - particularly evasion - take place over several days whereas mixing is a more instantaneous process. Since fish bioaccumulate mercury over their lifespan, it is the range of mercury concentrations that fish experience over their entire life (and not the concentration at the edge of a mixing zone) which is of concern. A subcommittee of EPA's Science Advisory Board (SAB) has criticized EPA's fate and transport models for ignoring evasion. In its recent report, the Subcommittee states: "It is unfortunate that soil and water loss degradation constants were not incorporated in the model. Several recent studies have shown that (elemental) Hg production and evasion are common processes in soils and surface waters." SAB, Report of the Mercury Review Subcommittee, Executive Committee Review Draft, dated June 30, 1997, p. 30.

* The RfD is inappropriate because it is based on a chronic exposure study done in Iraq under poor field conditions. Newer and much better data are available from a number of studies, including those conducted in the Seychelles Islands. (See 11 papers presented in Neurotoxicology Vol. 16, no. 4 (1995)). These data should be evaluated and should result in a larger RfD.

* The California proposal's BCFs (*2) are not valid because they use erroneous water column concentrations and arbitrary fish concentrations. The open ocean mercury concentration of 15 ng/l apparently was taken from an outdated 1979 report by Fitzgerald. In more recent peer-reviewed literature, Fitzgerald identifies the open ocean mercury concentration as more than ten fold less than the cited values (see Proceedings of Third International Conference, particularly "Methylation and Elemental Mercury Cycling in Surface and Deep Ocean Water of the North Atlantic" by Mason, Rolfus and Fitzgerald). The 17 ng/l estuarine and 40 ng/l fresh water values are similarly off by a factor of ten.(See Proceedings of Third International Conference, particularly "Mercury Speciation in the Scheldt Estuary" by Leermakers et al., and "Mercury Concentrations in Two Great Waters" by Cleckner et al.) Moreover, the range of concentrations between water bodies is great and prompted the SAB Subcommittee to conclude that BAFs (and, presumably, BCFS) can only be derived and used on a site-specific basis. The Subcommittee similarly concluded that fish mercury concentrations between various species in a given body of water vary dramatically.

* Furthermore, the BCFs are not valid for use in the California proposal because they were developed primarily on the basis of species from the Eastern half of the United States and the Atlantic Ocean (e.g., sardines). See Mercury Criteria Document.

For all of these reasons, UWAG believes the proposed human health mercury criterion is fundamentally flawed and should be subject to rigorous reevaluation by the Agency.

(*2) The term BCF is used inconsistently in the California proposal's preamble and in the Mercury Criteria Document. In the preamble, BCF is defined as fish uptake of mercury by respiration alone and specifically excludes mercury uptake through ingestion of food. The preamble goes to considerable length to explain that uptake by both respriation and ingestion is a different process defined as bioaccumulation. The preamble explains that a criterion based on bioaccumulation is not being considered at this time but may be incorporated into future rulemakings. The preamble then explains how its bioconcentration values were taken from the Mercury Criteria Document. That document, however, uses the term "bioconcentration" in a completely different sense. Bioconcentration, as used in the Mercury Criteria Document, is actually bioaccumulation as defined in the 1997 preamble. The Mercury Criteria Document derives its bioconcentration values from actual fish levels measured in ocean and lake fish caught for commercial purposes. Consequently, those fish were exposed to mercury both from the water column and from their food sources. Bioconcentration factors (as the term is defined in the 1997 preamble) can only be obtained from fish reared in carefully constructed laboratory experiments where the diet is purposefully devoid of the naturally occurring mercury commonly found in natural forage.

Response to: CTR-030-006

EPA agrees with the commenter that considerable variability can exist in both total and methymercury concentrations in the water column. However, predicting the amount of methylmercury present for a given concentration of total mercury is very difficult. The amount of methylmercury formed is affected by numerous chemical, physical, and biological factors which are not well understood. Examples of these include: foodchain interactions; physicochemical parameters (e.g., pH, temperature, dissolved and particulate organic matter); and size and type of watershed. It is readily acknowledged that mercury is toxic, causing a variety of adverse effects to both humans, fish, and wildlife. Thus, methods are need to assess mercury exposure and effects, and to control its release to the environment. These issues are discussed in the Mercury Study Report to Congress, (EPA-452/R-97-008); The National Survey of Mercury Contamination in Fish. Database Summary 1990-1995. September 29, 1997; 1995 Updates: Water Quality Criteria Documents for the Protection of Aquatic Life in Ambient Water, (EPA-820-B-96-001); and Final Water Quality Guidance for the Great Lakes System: Final Rule. Fed Register, 60(56):15366-15425 (March 23, 1995). EPA is not aware of any method to accurately predict concentrations of methylmercury in the water column and subsequent bioaccumulation in aquatic biota, nor does the commenter suggest any method. Although there are a few fate/transport models that could be used to assess the fate of mercury in the environment, these models are still in developmental stages, have only been applied under a narrow range of environmental and biological conditions, and will require validation before they are ready for use on a broad scale. Therefore, EPA believes that the use of BCFs represents the most appropriate method at this time for use in the CTR. Furthermore, as suggested by the commenter, EPA is currently undergoing a comprehensive review of the human health mercury criteria, in addition to the overall hman health criteria derivation methodology. Once this review is complete, EPA intends to revise its National human health mercury criteria, and subsequently update California's mercury criteria. For further response to the bioaccumulation issue, refer to response to comment for

CTR-002-007b.

Regarding comments on the Reference Dose (RfD), EPA has on two occasions published RfDs for methyl mercury which have represented the Agency consensus for that time. These are described in the sections below. The original RfD of 0.3 @g/kg/day was determined in 1985. The current RfD of 0.1 @g/kg/day was established as Agency consensus in 1995, based on the study by Marsh et al. 1987. The Agency is aware of all the additional data that have become available since the calculation of the current RfD. At the time of the generation of the Mercury Study Report to Congress, it became apparent that considerable new data on the health effects of methyl mercury in humans were emerging. Among these are large studies of fish, or fish and marine mammal, consuming populations in the Seychelles and Faroes Islands. Smaller scale studies are in progress which describe effects in populations around the Great Lakes.

However, as much of this new data have either not yet been published or have not yet been subject to rigorous peer review, it was decided that it was premature for EPA to make a change in the 1995 methyl mercury RfD at this time. This decision was approved by the Science Advisory Board (SAB), a public advisory group providing extramural scientific information and advice to the Administrator and other officials of the EPA. The SAB is structured to provide balanced, expert assessment of scientific matters relating to problems facing the Agency. Their report makes the following statement.

"In general, from the standpoint of looking at human health effects and the uncertainties, the draft report is a very good document and an important step forward in terms of bringing the relevant information together into one place for the first time. The current RfD, based on the Iraqi and New Zealand data, should be retained at least until the on-going Faroes and Seychelles Islands studies have progressed much further and been subjected to the same scrutiny as has the Iraqi data."

The SAB report continues:

"Investigators conducting two new major prospective longitudinal studies--one in the Seychelles Islands the other in the Faroe Islands--have recently begun to publish findings in the literature and are expected to continue releasing their findings during the next 2-3 years. These studies have advantages over those cited in the previous paragraph in that they have much larger samples sizes, a larger number of developmental endpoints, potentially more sensitive developmental endpoints, and control a more extensive set of potential confounding influences. On the other hand, the studies have some limitations in terms of low exposures (to PCBs in the Faroes) and ethnically homogenous societies. Since only a small portion of these new data sets have been published to date and because questions have been raised about the sensitivity and appropriateness of the several statistical procedures used in the analyses, the Subcommittee concluded that it would be premature to include any data from these studies in this report until they are subjected to appropriate peer review. Because these data are so much more comprehensive and relevant to contemporary regulatory issues than the data heretofore available, once there has been adequate opportunity for peer review and debate within the scientific community, the RfD may need to be reassessed in terms of the most sensitive endpoints from these new studies."

An inter-agency process, with external involvement, will be undertaken for the purpose of reviewing these new data, their evaluations, and the evaluations of existing data. An outcome of this process will be an assessment by EPA of its RfD for methyl mercury to determine if a change is warranted.

Comment: C. EPA Should Delay Promulgation of a Mercury Human Health Criterion Until SAB Subcommittee Comments

In forming a SAB subcommittee to comment on its draft Mercury Report to Congress, EPA has engaged a group of very knowledgeable scientists to assist it in understanding the fate and transport of mercury. That subcommittee has prepared draft comments and will finalize those comments within the next few months. EPA should review and evaluate the Subcommittee's final comments before promulgating mercury criteria for California.

Response to: CTR-030-007

EPA has reviewed and incorporated all of the SAB subcommittee's final comments that are possible to incorporate at this time. However, there are further analyses on mercury that are in progress. EPA has entered into an 18-month agreement with the National Academy of Sciences (NAS) to resolve outstanding issues with the mercury risk assessment. Additionally, EPA is in the process of developing methods to more accurately measure bioaccumulation, as part of the revisions to the human health methodology for deriving water quality criteria. After finalization of the methodology and completion of the NAS agreement, EPA intends to update its criterion for mercury. Until that time, EPA believes that the proposed CTR criteria value for mercury is appropriate and reflects the best available scientific information.

Comment: Mercury Criteria

The District supports the proposed revised human health criteria for mercury based on updated IRIS information. The District also supports EPA's decision (CTR P. 42180) not to apply the bioaccumulation factor (BAF) developed for the Great Lakes Initiative to the CTR mercury criteria. We agree that mercury methylation rates vary widely and are not well understood, particularly for amalgam related

mercury. We believe that adoption of a national BAF under consideration as part of the "Mercury Study Report to Congress: SAB Review Draft" is inappropriate for California, particularly for the complex San Francisco Bay system. CDA recommends that EPA direct the State to develop a site specific objective (SSO) for mercury for San Francisco Bay based on a site specific BAF and data on natural cleanup processes and methylation processes. The proposed CTR criteria should serve as interim criteria until the SSO is developed and adopted.

Response to: CTR-032-006a

EPA acknowledges the commenter's support of the rule. Regarding the recommendation for a "site-specific objective" for mercury in San Francisco Bay, EPA always advocates that states develop site-specific criteria when local data are available. However, EPA also believes that protective defaults are appropriate.

Comment: Second, we commend EPA for its inclusion in the CTR of several innovative and flexible regulatory approaches, such as metals criteria expressed as dissolved rather than total recoverable concentrations, and the revised human health criterion for mercury. In addition, in light of the issues surrounding the human health criteria for arsenic we support EPA's decision not to promulgate human health criteria at this time. With respect to implementation issues discussed in the Preamble, we support EPA's policies and guidance regarding the application of mixing zones and dilution credits. the use of interim permit limits while Total Maximum Daily Loads (TMDLs) and other special studies are being performed, and EPA's guidance to Regional Water Quality Control Boards (RWQCBs) that they may use any of the methods described in EPA's guidance document on the use of translators. We also support EPA's proposal to create a rebuttable presumption for Water Effects Ratios (WERs), allowing the RWQCBs and SWRCB to develop site-specific WERs that can be approved by EPA during the NPDES permit approval process. We believe that this approach will help facilitate the development of appropriate site-specific adjustments for metals criteria.

Response to: CTR-035-002b

EPA acknowledges the commenter's support of the rule.

Comment: pp. 42179-42180 -- Mercury Criteria We support EPA's promulgation of revised human health criteria for mercury based on updated IRIS information We also support EPA's decision not to apply the bioaccumulation factor (BAF) developed for the Great Lakes in the Great Lakes Initiative to the CTR mercury criteria. We agree that there is insufficient evidence at this time to substantiate whether this is an appropriate BAF for California. Further, we question whether a single BAF should be developed in the future for California, given the varied nature of the water bodies in the State -- ranging from the Bay-Delta in northern California to concrete-lined effluent-dominated streams and the saline, agricultural drainage-dominated Salton Sea in southern California -- as well as the variation in methylation rates and the amount of methylated mercury in these varied ecosystems. For these reasons, we also doubt that it is possible to derive a valid national BAF for mercury.

Response to: CTR-035-026

EPA acknowledges the comment on the Agency's choice not to use a BAF for the mercury criterion. EPA believes that the use of a BCF is most appropriate at this time for the CTR. EPA further understands the complexity surrounding the issue of bioaccumulation and is currently working on improving its methodology, including evaluating the impact that the type of water body has on bioaccumulation.

Comment: III. EPA'S PROPOSED MERCURY NUMBER IS FLAWED BECAUSE IT IGNORES RELEVANT DATA REGARDING ITS POTENTIAL TO BIOACCUMULATE

EPA's proposed mercury number, in addition to using an inappropriate fish and shellfish consumption rate, also fails to factor in bioaccumulation of mercury into fish tissue. Assuming EPA is accurate in that it does not know the specific potential for mercury to bioaccumulate in waters of the State of California, it is certain that some rate of bioaccumulation is occurring. Unfortunately, EPA only applies a bioconcentration factor, ignoring the mercury that is entering fish through their own food consumption. In fact, in at least one region of the State -- the San Francisco Bay area -- there is ample data from which an accurate bioaccumulation factor can be determined. See Comments of Communities For A Better Environment. That factor is comparable to the rate of bioaccumulation observed in Great Lakes fish, which is from four times to 20 times greater than EPA's proposed bioconcentration factor.

Response to: CTR-039-005

EPA acknowledges the comments made on the use of BCFs. EPA believes that this represents the most appropriate method at this time for use in the CTR. EPA further understands the complexity surrounding the issue of bioaccumulation and is currently working on improving its methodology. Regarding the fish consumption rate, see the response to this issue in CTR-002-002a. Regarding bioaccumulation and available data from the San Francisco Bay area, see response to CTR-002-007b.

Comment: PROVISIONS SUPPORTED

We support a number of provisions of the Rule, including: (1) adoption of metals criteria as dissolved concentrations; (2) expression of the metals criteria as a function of the water-effect ratio; (3) adoption of the proposed new human health criterion for mercury- and (4) the Preamble discussions regarding metals translators and mixing zones. These provisions provide a firmer scientific base for the water quality-based approach to pollution control and are a marked improvement over the old Inland Surface Waters Plan. We would urge EPA to retain these provisions in the final Rule.

Response to: CTR-040-002b

EPA acknowledges the provisions of the rule supported by the commenter.

Comment: Third, the District strongly supports the revised human health criteria for mercury, and EPA's recognition that bioaccumulation factors (BAF) from the Great Lakes are highly unlikely to be applicable in the diverse California environment. Consequently, the District does not believe that the proposal to develop a national BAF for mercury is scientifically sound. The use of most recently available and applicable data from EPA's resources to revise the human health criteria is the type of sound scientific procedure that should be used. Similarly, EPA's recognition that mercury methylation, the key to the magnitude of the BAF for a given system, is widely variable and not understood is also welcomed and supported. Given these statements in the proposal, however, EPA's subsequent proposal to develop a national BAF has little merit and is not supported by the District.

Response to: CTR-041-004

EPA disagrees that its effort to derive national default bioaccumulation factors for mercury are inappropriate. EPA acknowledges the complexity of mercury biogeochemical cycling and bioaccumulation in aquatic ecosystems, but believes that need to control mercury risks to humans

warrants the development of national, default human health criteria that reflect the latest science on mercury toxicity and bioaccumulation. EPA is aware of only one comprehensive model on mercury cycling and bioaccumulation that has been developed (the Mercury Cycling Model) and believes, at this time, that the model cannot be extrapolated with sufficient certainty to ecosystems that differ substantially upon which it was based (i.e., northern oligotrophic lakes). This model was specifically developed with northern oligotrophic lakes and reservoirs in mind, and EPA believes at this time it can not be extrapolated with sufficient certainty to ecosystems that differ substantially from this (e.g., streams, rivers, estuaries), and for which mercury bioaccumulation is also an important issue. This uncertainty exists partly because the model represents ecosystem dynamics rather simplistically, though more because of limitations in the science than by preference. Mercury bioaccumulation to higher order trophic levels influenced heavily by the type of food chain (i.e. benthic or pelagic based) and complexity of food chain interactions. The model must make assumptions about food chain interactions that limit the models predictive capability. Uptake and depuration of mercury in natural systems is also difficult to measure and predict, the model must make assumptions about these processes that limit its predictive capability. In order to minimize the effect that model assumptions have on predicting mercury uptake for a given application, it is necessary to have some local hydrological, physical, and biological data to calibrate the model. In most cases, such data is not available. Such limitations are common for most predictive models. Terefore, given the state of the science for the few available models, and because EPA must address mercury bioaccumulation for a broad range of aquatic ecosystems (e.g. lakes, streams, estuaries), EPA believes at this time it is most appropriate to derive BAFs for mercury. EPA is currently collecting data on bioaccumulation for all aquatic ecosystems, however, it is unclear whether BAFs will be developed separately for each type of aquatic system or if one value will be derived for application to all aquatic systems. Therefore, EPA anticipates the need to develop BAFs for mercury which have applicability to a broad range of aquatic ecosystems (rivers, lakes, estuaries). At this time, it is unclear whether BAFs will be developed separately for each type of waterbody because EPA is currently collecting and evaluating mercury bioaccumulation data.

Comment: 2. Additional Strong Reasons to Maintain use of Dissolved Metals and Mercury Criteria

The District also has significant economic reasons to support the use of dissolved metals and the updated mercury criteria. Previous District studies have shown that adoption of metal criterion as total recoverable would cost the District more than $50 million a year while reducing metal loads in the Sacramento River by several percent. Likewise, if old mercury criteria were adopted it would cost the District over $100 million a year while reducing mercury loads in the Sacramento River by several percent.

Response to: CTR-041-007a

EPA acknowledges the commenter's support, however the commenter did not provide enough information for EPA to comment on its cost estimate related to total recoverable criteria and the old mercury criteria.

Comment: We have reviewed the proposed CTR and offer the following comments:

2. The following provisions of the rule are supported:

(1) adoption of metals criteria as dissolved concentrations;

(2) expression of the metals criteria as a function of the water-effect ratio;

(3) adoption of the proposed new human health criteria for mercury; and

(4) the Preamble discussions regarding metals translators, mixing zones, and interim permit limits.

Were the old human health criterion for mercury (0.012 ug/ l) to be adopted, the City would have to remove its discharge from Tule Canal and go to land disposal. The capital cost to do this would be $22.1 million and the total present worth cost would be $23.1 million (see Exhibit B, Required Capital improvements and Costs for Beryllium and Mercury). This would translate to an annual cost of $3.1 million per year (at 7% over 10 years) and would require that monthly sewer service charges be increased by more than 100%.

Comment: Mercury

The proposed mercury criteria are not appropriate for California waters and could seriously undermine ongoing regulatory and watershed efforts to address regionwide mercury concerns. In the Central Valley Region, existing ambient concentrations of dissolved mercury are two orders of magnitude lower than the proposed criteria, yet there are widespread beneficial use impairments that result form elevated mercury levels in fish. There are consumer advisories in effect in the Delta, Clear Lake and Lake Berryessa because of elevated fish tissue levels of mercury. There is widespread concern about mercury bioaccumulation in fish and wildlife. Mercury cycling and transfer through the ecosystem is very complicated. More research is needed to determine which sources and forms of mercury, in California, are important in controlling how much mercury is concentrated in aquatic systems. Also, use of national orstatewide fish consumption values are inappropriate. Subsistence fishing is practiced by many of California's subpopulations. Protection of these subpopulations necessitates establishing site specific consumption estimates upon which to base a criterion. For the reasons stated above, the proposed criteria for mercury should not be adopted.

Please call me at (916)255-3087 or Jerry Bruns at (916)255-3093 if you have any questions regarding these comment.

Response to: CTR-051-003a

EPA disagrees that its program to derive national default criteria is inappropriate. EPA understands that conditions vary from state to state and can vary among different site-specific locations within a given state. However, under Section 304(a) of the Clean Water Act, EPA is required to develop, and from time to time revise, such default criteria to help protect human health and designated uses of the nation's water bodies. As such, EPA believes that the criteria program is necessary and appropriate. The State will be translating the state's narrative criteria, site-specifically, to better account for exposure to mercury. The State will also develop regulatory controls that will protect designated uses. If there is widespread beneficial use impairment, then these waterbodies will appear on EPA's 303 list for TMDL development and protective target goals for the waterbodies will be addressed as part of that process. In addition, EPA will be updating its human health water quality criteria methodology to better reflect exposures through the food chain.

Regarding the fish consumption values chosen, see response to CTR-002-002a.

Comment: BADA supports the adoption of the proposed new human health criterion for mercury. Several of the BADA agencies would have serious attainability problems with the old EPA human health criteria for mercury, whereas none have a problem with the criteria proposed in the CTR. Although we concur with environmental groups testifying at the September 17 hearing that mercury is a major

problem, there is little to be gained through more stringent regulation of point sources. Mercury levels of concern in water and tissue are largely the result of unregulated nonpoint sources, namely abandoned mines and downstream sediments. The way to address mercury is through the watershed management approach and control of nonpoint sources. BADA's support for the new mercury criteria is not meant to imply that BADA agencies are unwilling to implement reasonable source controls aimed at reducing mercury levels in our discharges or to participate in watershed management studies aimed at reducing nonpoint sources of mercury. On the contrary our agencies support and are committed to such activities.

Comment: Mercury Human Health Criteria

EPA has proposed human health criteria for mercury for consumption of water and organisms (0.05 ug/L) and for consumption of organisms only (0.051 ug/L). We have a number of concerns about these criteria and recommend that EPA defer adoption or revise them for the final rule.

First, we can find no basis for the range of Bioconcentration Factors (BCFs) listed in the CTR Administrative Record Matrix (ARM). The ARM lists BCFs for mercury ranging from 3,765 to 9,000. No specific references are provided in the 1986 criteria document (the "Gold Book") for mercury for the derivation of the BCFs. EPA should provide information on the scientific basis for the derivation of the BCFs used to derive the mercury criteria. The discussion in the Preamble (p. 42179) indicates that there are three different BCFs for fresh water, estuarine waters, and the open ocean. This indicates that it would be most appropriate to calculate separate criteria for each type of water (i.e. fresh, estuarine, and ocean). More to the point, the Preamble also indicates that methylation rates vary widely from one aquatic system to another, thus making it difficult to know the actual potential for bioaccumulation in surface waters in California (p. 42180). Therefore, we believe that for mercury it is necessary for EPA to derive California-specific BCFs for different types of water bodies before adopting human health criteria for mercury in the CTR. At a minimum, separate freshwater and estuarine criteria should be developed. Alternatively, EPA could defer to the State for adoption of appropriate regional or site-specific mercury criteria by RWQCBs using local fish tissue concentration data.

Response to: CTR-059-009

The scientific basis for the range of BCFs is stated in the 1980 ambient water quality criteria document for mercury (Report No. EPA 440/5-80-058), which was part of the CTR Administrative Record Matrix. EPA acknowledges the comment on the differences between types of water bodies (i.e., fresh, estuarine, and ocean) and the Agency is currently evaluating the need to develop separate BAFs for such different water body types. For further response to the bioaccumulation issue, refer to response to CTR-002-007b.

Comment: PROVISIONS SDG&E DOES NOT SUPPORT

As described in the following comments SDG&E does not support the following provisions:

Mercury human health criteria is technically deficient

The mercury human health criterion has used unrealistic assumptions in developing the criterion, including: * the Bioconcentration Factor (BCF) used in calculating the criterion assumes a steady state condition between the mercury concentrations in the water column and fish. The preamble itself acknowledges that there is significant variability in the ratio of water column to fish concentrations (see 62 Fed. Reg. at 42,180, Cols. 1-2). Consequently, EPA should not endorse the use of a single BCF for all California waters. * the BCFs were developed primarily on the basis of species from the Eastern half of the United States and the Atlantic Ocean (e.g., sardines) (See Ambient Water Quality Criteria for Mercury, EPA 440/5-80-058, October 1980) and are not valid for use in the California proposal.

EPA should delay promulgation of a mercury human health criterion until the Science Advisory Board (SAB) Subcommittee comments on EPA's report to congress on mercury

EPA has formed a SAB Subcommittee to comment on its draft Mercury Report to Congress. This Subcommittee is reviewing the fate and transport of mercury which are important factors in developing the mercury human health criterion. EPA should postpone the adoption of the proposed CTR criterion until the final report from this committee is available so that the SAB's findings can be reviewed and incorporated into the CTR criterion.

Response to: CTR-060-008

EPA acknowledges the complexity of issues associated with steady state assumptions when calculating criteria. EPA also believes that it has used appropriate assumptions based on the best methodologies currently in-place. EPA is currently working to enhance its methodology to address these complex issues. Further, once EPA develops the BAF-based human health water quality criteria, EPA will work with the State of California to adopt either that recommended value or a value that is consistent with the final methodology. For additional discussion, refer to responses on CTR-002-007b, CTR-030-007, and CTR-041-004.

Comment: Page 42168, third column, first paragraph, states, "The mercury criteria also differ in this proposal due to the Agency's movement away from aquatic life criteria based on the Final Residue Value (FRV) procedure of the 1985 Guidance." It has been learned that the proposed CTR's apparent raising of the Hg criterion for protection from excessive bioaccumulation from the current 12 ng/L to 50 ng/L total mercury is only temporary. The regulation of Hg is under review at the national level. The Agency should have indicated to the regulated community in the proposed CTR that the total Hg criterion for prevention of bioaccumulation will likely decrease from the current 12 ng/L set forth in the "Gold Book" to about 5 ng/L. This revised Hg criterion will cause most domestic wastewater discharges to be in violation of this criterion.

Rather than trying to regulate Hg in wastewater effluents and other sources based on the exceedance of the total Hg criterion to prevent excessive Hg bioaccumulation in edible fish tissue, Hg should be regulated based on excessive Hg concentrations in fish tissue. It is technically invalid to assume, as the US EPA has been assuming and proposes to continue to assume, that there is a constant bioconcentration factor that relates the total concentration of Hg in water to excessive Hg concentrations in fish tissue. The actual bioconcentration of total Hg is highly site-specific. To require that all POTWs and other dischargers or sources of Hg have no more than 5 ng/L in the discharge will grossly over-regulate Hg from many sources.

Response to: CTR-061-012

EPA notes that this response addresses what the commenter believes will be the national criteria recommendations for mercury and human health. EPA disagrees that the proposed criterion for mercury is inappropriate. The Mercury Study Report To Congress has been published and an Agency Mercury Action Plan is being developed. EPA has also begun work to develop a new criterion for mercury that will be based on the Mercury Study Report To Congress and upcoming proposed revisions to the human health methodology. In addition, EPA is evaluating the complexity of determining the BAF and how best to express its value for criteria-setting purposes.

Comment: CDA is a strong supporter of water quality and human health protection. CDA's primary goals in commenting on the draft CTR are to request that mercury criteria be based on sound science and that mercury regulation be implemented via a watershed management, phased TNML-type approach.

CDA is particularly concerned that the CTR does not adequately assess the economic impacts on indirect dischargers nor the extent to which there will be measurable water quality benefits solely from adoption of the proposed mercury criteria for point sources.

Mercury Criteria

CDA supports the proposed revised human health criteria for mercury based on updated IRIS information. CDA also supports EPA's decision (p. 42180) not to apply the bioaccumulation factor (BAF) developed for the Great Lakes Initiative to the CTR mercury criteria. We agree that mercury methylation rates vary widely and are not well understood, particularly for amalgamrelated mercury. We believe that adoption of a national BAF under consideration as part of the "Mercury Study Report to Congress: SAB Review Draft" is inappropriate for California, particularly for the complex San Francisco Bay system. CDA recommends that EPA direct the State to develop a site specific objective (SSO) for mercury for San Francisco Bay based on a site specific BAF and data on natural cleanup processes and methylation processes. The proposed CTR criteria should serve as interim criteria until the SSO is developed and adopted.

Response to: CTR-086-002

EPA agrees with the commenter's support of the proposed mercury criterion. EPA encourages the State or Tribe to utilize site-specific information on bioaccumulation when available to calculate criteria. For additional discussion on the complexity of BAF use in the mercury criterion, refer to response on this issue in CTR-041-004.

Comment: The draft California Toxics Rule (CTR) is clearly the product of substantial effort by USEPA staff, and we applaud this effort and its intent. On several issues of concern to public utilities, the CTR strikes a good balance between the need to promulgate standards and the need to base those standards on sound science. Examples include the use of dissolved concentrations rather than the total recoverable concentrations for metals, the deferral of human health criteria for arsenic until adequate information is available, and the revision of the human health criterion for mercury. We are also pleased with the CTR's guidance and flexibility, on mixing zones and dilution credits, total maximum daily loads (TMDLs), compliance schedules, and translators.

Comment: This comment addresses the mercury criteria for continuous concentration (CCC) proposed in

40 CFR, part 13 1(*1). The proposed aquatic health and human health criteria do not protect aquatic life or humans from mercury contamination. This is demonstrated by the scientific data presented herein. That information includes published and unpublished results from scientists with established reputations in environmental research.

The aquatic life mercury CCC is proposed to be raised sixty-fold, from the National Toxics Rule standard of 0.012 micrograms per liter (ppb) to 0.770 ppb. The human health criteria is proposed to be raised four-fold, from 0.0 12 ppb to 0.050 ppb. These proposed changes have potentially devastating economic and environmental costs that must be included in the EPA's cost-benefit analysis. Water treatment costs for the metals mercury, silver, and chromium account for 30% of costs projected in the, California Toxics Rule (CTR) economic analysis.(*2) However, the long term environmental and economic cost of mercury contamination may far exceed the short term economic savings resulting from an increase in the mercury CCC. This is especially true in California, a mining state that has devoted hundreds of millions of dollars to restoration and enhancement of commercial and sport fisheries by enactment of Proposition 204.

Four specific points are substantiated by data and-literature: (1) California should maintain the National Toxics Rule standard of 0.012 ppb for protection of both aquatic life and human health; (2) The proposed increase in CCC standards do not protect against uncontrolled point-source releases; (3) The proposed criteria of 0.77 ppb (aquatic life) and 0.050 ppb (human health) were derived using assumptions about mercury bioconcentration that are not scientifically justified ; and (4) Wetlands may require even more protective measures than open waterways.

The proposed aquatic life CCC offers no protection from mercury point sources, such as the acid mine drainage shown in Figure 1. The data from San Carlos Creek, above and below the New Idria mercury mine in San Benito County, California, indicate that this mine, which was at one time the second largest producer of mercury in North America(*3), represents an uncontrolled point source mercury release(*4). Acidic water from the abandoned mine mixes with the waters of San Carlos Creek, leading to elevated mercury concentrations below the mine opening.

Figure 2 shows dissolved mercury concentrations upstream and downstream of the mine opening. The existing standard, 0.012 parts per billion (shown by the heavy, black horizontal line), distinguishes between background mercury concentrations (upstream) and point source mercury contamination (downstream). The low concentrations from the two upstream stations reflect natural ambient dissolved mercury concentrations resulting from water drainage through mercury ore deposits in that region(*5). The elevated concentrations downstream of the mine opening clearly exceed the National Toxics Rule mercury criteria. The proposed 0.77 ppb criteria, shown in Figure 3, would not distinguish between natural ambient upstream water and the contaminated water downstream from the mine.

The aquatic life CCC is more than two times greater than concentrations toxic to aquatic life. A water concentration as low as 0.3 ppb inhibits invertebrate reproduction and egg hatching success, and impairs fish physiology(*6). Although the lower human health criteria of 0.05 ppb would apply to essentially all California surface waters(*7), establishment of an aquatic life criteria above toxic effect levels sets a poor precedent for environmental protection.

The New Idria mine is but one example of mercury point source contamination within the State of California; there are many others. Mercury contamination is part of this state's mining legacy(*8). Historically, cinnabar (mercury, sulfide) was mined in California from New ldria, New Almaden, and other mines, and purified to elemental mercury (quicksilver). Thousands of tons of quicksilver were used to amalgamate gold and silver during the late 1800's. It is estimated that 0.3 to 3 kg of mercury was lost,

via volatilization and spillage, for every ton of gold recovered during this period.(*8)

Recent measurements(*9) from California lakes, including Clear Lake, Davis Creek Reservoir, and Lake Nacimiento indicate that dissolved mercury concentrations were twenty to fifty times lower than the proposed human health criteria of 0.05 ppb. However, in each lake largemouth bass contained part per million tissue mercury concentrations which exceeded the National Academy of Sciences guideline for acceptable mercury concentrations in fish.

Part per trillion mercury concentrations in water may be magnified a million-fold, to health-threatening, part per million mercury concentrations in fish. The form of mercury which is most readily bioaccumulated is methylmercury, a form of organic mercury which is produced by bacterial metabolism. Organomercury compounds are highly toxic. Karen Wetterhahn, the prominent Dartmouth researcher who was recently studying mercury toxicity, spilled two drops of dimethylmercury on her hand. Three months later she died from neuralgic damage resulting from acute mercury poisoning(*10) (Figure 5). The disaster in Minimata Bay, Japan, resulted from bacterial conversion of inorganic mercury to methylmercury, and its subsequent bioconcentration.(*11) Birth defects and infant mortality were directly linked to consumption of contaminated fish which had accumulated organomercury.

Methylmercury accumulates in proteins and lipids(*12). So at each subsequent trophic level in a food web, the tissue concentration of mercury increase(*13) . Figure 4 illustrates mercury bioconcentration in a very simple, three-tiered food chain. Methylmercury in water is bioconcentrated by plankton, at the base of the food chain.(*14) Subsequent bioconcentration occurs as plankton are consumed by filter feeders, and again as the filter feeders are consumed by higher level predators. This is a simple food chain example; bioconcentration increases with increasing food web complexity and increasing numbers of trophic levels.

Figure 4 also highlights the importance of mercury in sediments. Sediment-bound mercury can serve as an additional source to filter feeders, as these zones represent the primary location of microbially mediated mercury-methylation in aquatic systems(*15). Wetlands and marshes may be particularly susceptible to mercury pollution. These areas typically have shallow water columns and a large inputs of organic matter to the sediment, which leads to enhanced bacterial activity and subsequently greater mercury-methylation rates(*15). Further, wetlands and marshes provide breeding habitat for diverse populations of fish, birds, and reptiles, and hence, are composed of tightly knit, complex food webs. The susceptibility of these types of environments to mercury pollution has been demonstrated in the Florida Everglades, where low dissolved mercury concentrations result in high concentrations in top level predators, including panthers and sport fish(*16,17,18).

The ratio of the mercury concentration in an organism to the mercury concentration in the organism's ambient water is defined as the bioconcentration factor(*19). Assumptions about the bioconcentration factor are critical to the way the currently proposed human health criteria were derived, because the principle dose of mercury to humans is attributed to contaminated fish. So the appropriate criteria depend on the accepted value of the mercury bioconcentration factor.

Table I compares the bioconcentration factors used in the currently proposed criteria to bioconcentration factors derived from recent research. The practical bioconcentration factor of 7342.6 used in the proposed water quality standards was derived from research that is now almost two decades old. Most mercury data, particularly aqueous dissolved mercury measurements, generated prior to 1988 are suspect. Technological advances in mercury quantification and the establishment of trace metal clean sampling procedures made it possible to accurately measure environmentally relevant mercury concentrations in water(*20,21). The EPA has recently recognized the need for adequate analytical methods and trace

metal clean techniques(*22,23,24). The 1980 bioconcentration factors were derived before trace metal clean techniques for mercury analysis were established. If the dissolved mercury concentration is overestimated due to contamination, the bioconcentration factor will be underestimated.

In the Federal Register discussion of bioconcentration factors, values derived from the Great Lakes Initiative are dismissed, "because it is uncertain whether the bioaccumulation factors of 27,900 and 140,000 are appropriate for use in California at this time..."(*1). However, California field data support bioconcentration factors equal to or greater than those of the Great Lakes Initiative. In 1995, the San Francisco Bay Regional Monitoring program reported tissue concentrations in bivalves that averaged 0.2 ppm. At the same time, aqueous dissolved mercury values ranged from 0.001-0.003 ppb(*25), resulting in a bioconcentration factor between 60,000 and 200,000. In the Gill and Bruland study of mercury in California lakes(*9), tissue and dissolved mercury concentrations lead to a bioconcentration factor between 300,000 and 800,000. Clearly, the bioconcentration factor of 7342.6 used to derive the proposed mercury standard is not appropriate to California.

To summarize, the proposed human health mercury CCC (0.05 ppb) does not sufficiently safeguard human health from mercury contamination. and the proposed aquatic life mercury CCC (0.77 ppb) offers no protection to aquatic life. The aquatic life CCC does not distinguish between contaminated and uncontaminated waters, and is two times higher than published toxic effect levels for mercury(*6). Even though the human health criteria will apply in California(*1,7), the 0.77 ppb criteria for protection of aquatic life sets a dangerous national precedent. In California, mercury concentrations twenty to fifty times lower than the proposed human health criteria lead to elevated concentrations in sport-fish. The aquatic life and human health criteria are based on faulty assumptions about mercury bioconcentration factors in the environment. Using bioconcentration factors appropriate to California would result in much lower mercury water quality criteria.

We ask that Region Nine of the Environmental Protection Agency maintain the established National Toxics Rule standard of 0.012 ppb. Furthermore, we strongly suggest that adequate regulation of mercury consider microbial mercury-methylation potentials and evaluate food web complexity to develop site-specific criteria.

Response to: CTR-091-001a

Regarding the protectiveness of the mercury criteria, refer to responses in CTR-029-002b, CTR-030-007 and CTR-051-003a. EPA recognizes the significance of the accumulation of toxic chemicals, particularly bioaccumulatives, in our nation's sediments. For this reason, EPA is in the process of developing "Equilibrium Partitioning Sediment Guidelines" for use in identifying contaminated sediments which are potentially toxic to benthic organisms. These chemical guidelines are calculated based on the organic carbon content of the sediment for nonionic organic chemicals and acid volatile sulfide content for divalent cationic metals. At this time, EPA has developed guidance for the calculation of bioaccumulation factors (BAFs) for a variety of chemicals. The BAFs are used to ensure that protective levels of water column contaminants are established. BAFs are based on the freely dissolved concentration of the bioaccumulative chemical, such as mercury. The use of BAFs, particularly those calculated based on field data, will provide a mechanism to address the accumulation of chemicals in organisms at higher trophic levels in the food web. For further discussion, refer to the response to CTR-002-007b.

EPA is also currently working to enhance its methodology to address the complex BAF issues. Further, once EPA develops the BAF-based human health water quality criteria, EPA will work with the State of California to adopt either that recommended value or a value that is consistent with the final methodology. By 2003, EPA will promulgate revised criteria for California for mercury based on a BAF for the protection of human health. As part of this process, EPA will evaluate all available published information, including data originating in California.

Comment: This comment addresses the mercury criteria for continuous concentration (CCC) proposed in 40 CFR, part 13 1(*1). The proposed aquatic health and human health criteria do not protect aquatic life or humans from mercury contamination. This is demonstrated by the scientific data presented herein. That information includes published and unpublished results from scientists with established reputations in environmental research.

The aquatic life mercury CCC is proposed to be raised sixty-fold, from the National Toxics Rule standard of 0.012 micrograms per liter (ppb) to 0.770 ppb. The human health criteria is proposed to be raised four-fold, from 0.0 12 ppb to 0.050 ppb. These proposed changes have potentially devastating economic and environmental costs that must be included in the EPA's cost-benefit analysis. Water treatment costs for the metals mercury, silver, and chromium account for 30% of costs projected in the, California Toxics Rule (CTR) economic analysis.(*2) However, the long term environmental and economic cost of mercury contamination may far exceed the short term economic savings resulting from an increase in the mercury CCC. This is especially true in California, a mining state that has devoted hundreds of millions of dollars to restoration and enhancement of commercial and sport fisheries by enactment of Proposition 204.

Four specific points are substantiated by data and-literature: (1) California should maintain the National Toxics Rule standard of 0.012 ppb for protection of both aquatic life and human health; (2) The proposed increase in CCC standards do not protect against uncontrolled point-source releases; (3) The proposed criteria of 0.77 ppb (aquatic life) and 0.050 ppb (human health) were derived using assumptions about mercury bioconcentration that are not scientifically justified ; and (4) Wetlands may require even more protective measures than open waterways.

The proposed aquatic life CCC offers no protection from mercury point sources, such as the acid mine drainage shown in Figure 1. The data from San Carlos Creek, above and below the New Idria mercury mine in San Benito County, California, indicate that this mine, which was at one time the second largest producer of mercury in North America(*3), represents an uncontrolled point source mercury release(*4). Acidic water from the abandoned mine mixes with the waters of San Carlos Creek, leading to elevated mercury concentrations below the mine opening.

Figure 2 shows dissolved mercury concentrations upstream and downstream of the mine opening. The existing standard, 0.012 parts per billion (shown by the heavy, black horizontal line), distinguishes between background mercury concentrations (upstream) and point source mercury contamination (downstream). The low concentrations from the two upstream stations reflect natural ambient dissolved mercury concentrations resulting from water drainage through mercury ore deposits in that region(*5). The elevated concentrations downstream of the mine opening clearly exceed the National Toxics Rule mercury criteria. The proposed 0.77 ppb criteria, shown in Figure 3, would not distinguish between natural ambient upstream water and the contaminated water downstream from the mine.

The aquatic life CCC is more than two times greater than concentrations toxic to aquatic life. A water concentration as low as 0.3 ppb inhibits invertebrate reproduction and egg hatching success, and impairs fish physiology(*6). Although the lower human health criteria of 0.05 ppb would apply to essentially all

California surface waters(*7), establishment of an aquatic life criteria above toxic effect levels sets a poor precedent for environmental protection.

The New Idria mine is but one example of mercury point source contamination within the State of California; there are many others. Mercury contamination is part of this state's mining legacy(*8). Historically, cinnabar (mercury, sulfide) was mined in California from New ldria, New Almaden, and other mines, and purified to elemental mercury (quicksilver). Thousands of tons of quicksilver were used to amalgamate gold and silver during the late 1800's. It is estimated that 0.3 to 3 kg of mercury was lost, via volatilization and spillage, for every ton of gold recovered during this period.(*8)

Recent measurements(*9) from California lakes, including Clear Lake, Davis Creek Reservoir, and Lake Nacimiento indicate that dissolved mercury concentrations were twenty to fifty times lower than the proposed human health criteria of 0.05 ppb. However, in each lake largemouth bass contained part per million tissue mercury concentrations which exceeded the National Academy of Sciences guideline for acceptable mercury concentrations in fish.

Part per trillion mercury concentrations in water may be magnified a million-fold, to health-threatening, part per million mercury concentrations in fish. The form of mercury which is most readily bioaccumulated is methylmercury, a form of organic mercury which is produced by bacterial metabolism. Organomercury compounds are highly toxic. Karen Wetterhahn, the prominent Dartmouth researcher who was recently studying mercury toxicity, spilled two drops of dimethylmercury on her hand. Three months later she died from neuralgic damage resulting from acute mercury poisoning(*10) (Figure 5). The disaster in Minimata Bay, Japan, resulted from bacterial conversion of inorganic mercury to methylmercury, and its subsequent bioconcentration.(*11) Birth defects and infant mortality were directly linked to consumption of contaminated fish which had accumulated organomercury.

Methylmercury accumulates in proteins and lipids(*12). So at each subsequent trophic level in a food web, the tissue concentration of mercury increase(*13) . Figure 4 illustrates mercury bioconcentration in a very simple, three-tiered food chain. Methylmercury in water is bioconcentrated by plankton, at the base of the food chain.(*14) Subsequent bioconcentration occurs as plankton are consumed by filter feeders, and again as the filter feeders are consumed by higher level predators. This is a simple food chain example; bioconcentration increases with increasing food web complexity and increasing numbers of trophic levels.

Figure 4 also highlights the importance of mercury in sediments. Sediment-bound mercury can serve as an additional source to filter feeders, as these zones represent the primary location of microbially mediated mercury-methylation in aquatic systems(*15). Wetlands and marshes may be particularly susceptible to mercury pollution. These areas typically have shallow water columns and a large inputs of organic matter to the sediment, which leads to enhanced bacterial activity and subsequently greater mercury-methylation rates(*15). Further, wetlands and marshes provide breeding habitat for diverse populations of fish, birds, and reptiles, and hence, are composed of tightly knit, complex food webs. The susceptibility of these types of environments to mercury pollution has been demonstrated in the Florida Everglades, where low dissolved mercury concentrations result in high concentrations in top level predators, including panthers and sport fish(*16,17,18).

The ratio of the mercury concentration in an organism to the mercury concentration in the organism's ambient water is defined as the bioconcentration factor(*19). Assumptions about the bioconcentration factor are critical to the way the currently proposed human health criteria were derived, because the principle dose of mercury to humans is attributed to contaminated fish. So the appropriate criteria depend on the accepted value of the mercury bioconcentration factor.

Table I compares the bioconcentration factors used in the currently proposed criteria to bioconcentration factors derived from recent research. The practical bioconcentration factor of 7342.6 used in the proposed water quality standards was derived from research that is now almost two decades old. Most mercury data, particularly aqueous dissolved mercury measurements, generated prior to 1988 are suspect. Technological advances in mercury quantification and the establishment of trace metal clean sampling procedures made it possible to accurately measure environmentally relevant mercury concentrations in water(*20,21). The EPA has recently recognized the need for adequate analytical methods and trace metal clean techniques(*22,23,24). The 1980 bioconcentration factors were derived before trace metal clean techniques for mercury analysis were established. If the dissolved mercury concentration is overestimated due to contamination, the bioconcentration factor will be underestimated.

In the Federal Register discussion of bioconcentration factors, values derived from the Great Lakes Initiative are dismissed, "because it is uncertain whether the bioaccumulation factors of 27,900 and 140,000 are appropriate for use in California at this time..."(*1). However, California field data support bioconcentration factors equal to or greater than those of the Great Lakes Initiative. In 1995, the San Francisco Bay Regional Monitoring program reported tissue concentrations in bivalves that averaged 0.2 ppm. At the same time, aqueous dissolved mercury values ranged from 0.001-0.003 ppb(*25), resulting in a bioconcentration factor between 60,000 and 200,000. In the Gill and Bruland study of mercury in California lakes(*9), tissue and dissolved mercury concentrations lead to a bioconcentration factor between 300,000 and 800,000. Clearly, the bioconcentration factor of 7342.6 used to derive the proposed mercury standard is not appropriate to California.

To summarize, the proposed human health mercury CCC (0.05 ppb) does not sufficiently safeguard human health from mercury contamination. and the proposed aquatic life mercury CCC (0.77 ppb) offers no protection to aquatic life. The aquatic life CCC does not distinguish between contaminated and uncontaminated waters, and is two times higher than published toxic effect levels for mercury(*6). Even though the human health criteria will apply in California(*1,7), the 0.77 ppb criteria for protection of aquatic life sets a dangerous national precedent. In California, mercury concentrations twenty to fifty times lower than the proposed human health criteria lead to elevated concentrations in sport-fish. The aquatic life and human health criteria are based on faulty assumptions about mercury bioconcentration factors in the environment. Using bioconcentration factors appropriate to California would result in much lower mercury water quality criteria.

We ask that Region Nine of the Environmental Protection Agency maintain the established National Toxics Rule standard of 0.012 ppb. Furthermore, we strongly suggest that adequate regulation of mercury consider microbial mercury-methylation potentials and evaluate food web complexity to develop site-specific criteria.

Comment: In summing up -- not summing up, just as a parting shot -- I do appreciate the fact that in

working up the toxics rule here that EPA has done certain things which in fact we see as improvements in actually making the standards fit with what we think -- have come to see as perhaps the actual impacts of the stormwater part of this. And by that, I'm referring to the dissolved metals criteria and the water effect ratio in there, and the human health criteria revisions for mercury and the other -- the other items.

I appreciate some of the stuff in there, and -- with the exception of the preamble language. And you really need to get that out of there. We're going to pursue this as far as we have to.

I appreciate your hearing me.

Response to: CTRH-001-003c

EPA acknowledges the comments made and their support of the rule.

Comment: Issues on mercury:

Bay fisherpeople report eating more mercury-tainted fish than the state says is safe for developmental neurotoxicity. EPA proposes a weaker standard that allows these mercury pollution levels in the vast majority of the bay rather than reducing this harm.

EPA says it has itself weakened the standard because EPA doesn't know whether mercury bioaccumulates here as much as it bioaccumulates in the Great Lakes. San Francisco Bay data show that it does. Will EPA use these data?

Response to: CTRH-001-013

The commenter is incorrect regarding the proposed standard for the San Francisco Bay. The previous standard of 0.025 ug/L will remain in effect for the San Francisco Bay. The commenter is also incorrect about EPA's position regarding bioaccumulation. EPA did not suggest that it did not know if mercury bioaccumulated as much in the Bay as in the Great Lakes. Rather, EPA stated that the Great Lakes data were not appropriate for use in the Bay. EPA is evaluating available bioaccumulation data to determine its appropriateness for use in California. EPA is also currently working to enhance its methodology to address these complex issues. Further, once EPA develops the BAF-based human health water quality criteria, EPA will work with the State of California to adopt either that recommended value or a value that is consistent with the final methodology. Within the next several years, EPA or the State will promulgate revised criteria for California for mercury based on a BAF for the protection of human health. For additional discussion on mercury bioaccumulation, refer to the response to CTR-002-007b.

Comment: MR. ABU-SABA: Good afternoon. My name is Khalil Abu-Saba. I'm a graduate student in chemistry at the University of California, Santa Cruz. I want to thank Kathleen Van Velsor of Coastal Advocates for having me here to speak today.

Today we'd like to address mercury criteria for continuous concentration as proposed in the California Toxics Rule. The facts I'll be presenting today come from the interpretations of a number of scientists of established reputation in environmental research. In the written transcript of this speech, there are 20 references giving the names of those authors, who reviewed this presentation before I submitted it.

The mercury criteria for continuous concentration is proposed to be raised from the National Toxics Rule standard of 0.012 parts per billion up to 0.770 parts per billion. That is a 60-fold increase in the mercury criteria. We will present the facts showing that allowing that level of mercury in fresh water has potentially devastating economic and environmental consequences.

We will show why mercury regulation should consider particulate as well as dissolved concentrations and why wetlands may require even more protective measures than open waterways.

Finally, we will demonstrate how the proposed standard was derived using assumptions about mercury bioconcentration that are scientifically unsound.

First, let's compare the current National Toxics Rule standard to mercury concentrations downstream from a point source. The preliminary measurements for this stream were provided by Priya Ganguli and Russ Flegal of University of California Santa Cruz and Rob Mason of the Chesapeake Bay Laboratory of the University of Maryland.

The data come from San Carlos Creek, above and below the New Idria mercury mine in San Benito County. This mine, which was at one time the second largest producer of mercury in North America, represents an uncontrolled point source mercury release.

Acidic water from the abandoned mine mixes with the waters of San Carlos Creek, leading to elevated mercury concentrations below the mine opening. The brown water you see in this slide is from metals precipitated after the acid mine drainage mixes with the clear water of San Carlos Creek.

The next graph we'll be showing you will be the part-per-billion concentrations of filtered mercury above and below the mine opening. These are filtered mercury concentrations consistent with the promulgated standard.

The point of this graph is that the existing standard, 0.012 parts per billion, shown by the heavy, black horizontal line, distinguishes between background regional processes and point source contamination. The two lowest mercury concentrations on the left are from water samples upstream of the mine opening in clear water; those concentrations represent mercury concentrations in water which could result naturally from drainage of mercury ore deposits in that region.

The concentrations downstream of the mine opening, in the brown water you just saw, clearly exceed the current National Toxics Rule standard of .012 parts per billion. In contrast, if we were to put the proposed continuous criteria concentration standard on the same scale with this graph, that standard would be two stories above our heads right now.

The next graph shows the same mercury concentrations from New ldria on scale with the proposed criteria of 0.77 parts per billion. Clearly, the proposed criteria does not distinguish between background processes and point source contamination. Mercury levels in the clear water and in the brown water are equal in the eyes of the proposed criteria.

That is the economic benefit that will be derived from raising limits on mercury in water. The citizens of California will be asked to ignore point source contamination of mercury. This is one example from within the State of California; there are many others.

Mercury contamination is part of our mining legacy in this state, we ignore it at our peril. In a 1990 publication in Environmental Science and Technology, Gary Gill and Ken Bruland show that Clear Lake, Davis Creek Reservoir, and Lake Nacimiento all had filtered mercury concentrations that were several hundred times lower than the 0.77 parts per billion proposed standard. Those lakes also had largemouth bass with part-per-million tissue mercury concentrations exceeding the National Academy of Sciences guideline for acceptable mercury concentrations in fish.

How are subpart-per-billion mercury concentrations in water magnified a million-fold to health-threatening part-per-million mercury concentrations in fish? To understand this, we have to recognize that not all mercury is created equal.

This is cinnabar or mercury sulfide. This is an example of inorganic mercury. This type of ore was mined in California at the New Idria and New Almaden mines, and roasted to make elemental mercury or quicksilver, which we're familiar with in the tip of a common thermometer.

Thousands of tons of elemental mercury were used to extract gold during the Gold Rush, distributing mercury throughout California. In the environment, bacterial action can convert inorganic mercury into organic mercury compounds, including methylmercury. The toxicity of mercury depends on its chemical form.

I didn't bring any organic mercury in today; it is too toxic to safely handle in public. I did bring in the obituary of Karen Wetterhahn. As most of you know, she was a prominent Dartmouth researcher who was studying mercury toxicity. This year, she spilled two drops of dimethylmercury on her hand. Three months later, she was dead from neurological damage resulting from acute mercury poisoning.

The disaster in Minimata Bay, Japan, resulted from bacterial conversion of inorganic mercury to methylmercury, and its subsequent bioconcentration.

Methylmercury accumulates in proteins, so at each level in a complex food web the tissue concentration

of mercury increases. This graph shows an example of mercury bioconcentration in a very simple, three-tiered food chain.

Methylmercury in water is bioconcentrated by plankton at the base of the food chain. Subsequent bioconcentration occurs as plankton are consumed by filter feeders, and again as the filter feeders are consumed by higher level predators. This is a simple food chain example; bioconcentration increases with increasing food web complexity.

This figure also highlights the importance of mercury in sediments. Sediment-bound mercury can serve as an additional source to filter feeders. Moreover, conversion of inorganic mercury to methylmercury is regulated by bacteria.

Extensive bacterial methylation occurs in sediments, which host bacterial communities. Wetlands and marshes are much more sensitive areas because intense bacterial activity leads to greater methylation rates, and because they have complex food webs.

This has already been demonstrated in the Florida Everglades, where relatively low dissolved mercury concentrations result in high concentrations in top-level predators, including panthers and sport fish.

Deriving a criteria for dissolved mercury alone and ignoring particulate mercury concentrations, bacterial metabolism, and ecosystem structure is inadequate to protecting the health of California citizens.

The magnification of mercury in water to tissue mercury can be qualified by a value referred to as bioconcentration factor. Assumptions about the bioconcentration factor are critical to the way the proposed criteria was derived because the primary source of mercury to humans is attributed to contaminated fish. So the appropriate criteria, depends on what we accept as a reasonable value for the mercury bioconcentration factor.

The bioconcentration factor of mercury is simply defined as the ratio of the mercury concentration in an organism to the mercury concentration in the organism's surrounding waters, just tissue mercury over water mercury.

In the justification of the proposed criteria, this table compares the bioconcentration factors used in the proposed criteria to bioconcentration factors developed from more recent research. The bioconcentration factor of 7,300 as used in the proposed criteria was derived from research now almost two decades old.

All mercury data and in particular water measurements generated prior to 1988 are suspect. The methods published in 1988 by Bloom and Fitzgerald, and the establishment of trace metal clean sampling procedures to avoid contamination made it possible to measure environmentally relevant concentrations of mercury in water.

The EPA has recognized in their own publications the need for adequate analytical methods and trace metal clean techniques. This is EPA method 1631, mercury in water by cold vapor atomic fluorescence spectrometry, April 1995. This is EPA method 1669, sampling ambient water for EPA water criteria levels. This method 1669 describes how to avoid contamination in trace metal analysis.

The 1980 bioconcentration factors used to derive the proposed criteria come from data generated before trace metal clean techniques were established. If you overestimate the water mercury concentration due to contamination, you will underestimate the bioconcentration factor, because the dissolved concentration appears here in the denominator.

In the Federal Register discussion of the bioconcentration factors, values derived from the Great Lakes initiative are dismissed, "because it is uncertain whether the bioaccumulation factors of 28,000 and 140,000 are appropriate for use in California at this time." That's a quote from the Federal Register.

We can compare the relevance of these bioconcentration factors by examining field data from California, as Greg Karras suggested. In 1995, the San Francisco Bay regional monitoring program reported tissue concentrations in bivalves that averaged 0.2 parts per million.

At the same time, quantifiable dissolved mercury values ranged from 0.001 to 0.003 parts per billion. If you just plug those numbers into the formula for bioconcentration factor, you get a bioconcentration factor between 60,000 and 200,000.

In the Gill and Bruland study of mercury in California lakes, tissue and dissolved mercury concentrations lead to a bioaccumulation factor between 300,000 and 800,000. Clearly, the bioconcentration factor of 7,300 used to derive the proposed standard is not appropriate to California.

To summarize, the proposed mercury standard of 0.77 parts per billion does not distinguish between contaminated and uncontaminated waters. The proposed standard is based on faulty assumptions about mercury bioconcentration in the environment.

The potential economic costs of this legislation far exceed any perceived benefits from ignoring mercury contamination. For example, one of the goals of Proposition 204 is the protection and enhancement of commercial and sport fishing in the State of California. To that end, hundreds of millions of dollars have been committed to water quality improvement and habitat restoration. A 60-fold increase in the permissible mercury limits can only hinder these goals.

We ask that Region 9 of the Environmental Protection Agency promulgating the California Toxics Rule maintain the established National Toxics Rule standard of 0.012 parts per billion. Furthermore, we strongly suggest that adequate regulation of mercury should incorporate particulate mercury concentrations and should consider the potential for bacterial activity and evaluate ecosystem complexity to develop site-specific criteria.

Comment: MR. ABU-SABA: Good afternoon. My name is Khalil Abu-Saba. I'm a graduate student in chemistry at the University of California, Santa Cruz. I want to thank Kathleen Van Velsor of Coastal Advocates for having me here to speak today.

Today we'd like to address mercury criteria for continuous concentration as proposed in the California Toxics Rule. The facts I'll be presenting today come from the interpretations of a number of scientists of established reputation in environmental research. In the written transcript of this speech, there are 20 references giving the names of those authors, who reviewed this presentation before I submitted it.

The mercury criteria for continuous concentration is proposed to be raised from the National Toxics Rule standard of 0.012 parts per billion up to 0.770 parts per billion. That is a 60-fold increase in the mercury criteria. We will present the facts showing that allowing that level of mercury in fresh water has potentially devastating economic and environmental consequences.

We will show why mercury regulation should consider particulate as well as dissolved concentrations and why wetlands may require even more protective measures than open waterways.

Finally, we will demonstrate how the proposed standard was derived using assumptions about mercury bioconcentration that are scientifically unsound.

First, let's compare the current National Toxics Rule standard to mercury concentrations downstream from a point source. The preliminary measurements for this stream were provided by Priya Ganguli and Russ Flegal of University of California Santa Cruz and Rob Mason of the Chesapeake Bay Laboratory of the University of Maryland.

The data come from San Carlos Creek, above and below the New Idria mercury mine in San Benito County. This mine, which was at one time the second largest producer of mercury in North America, represents an uncontrolled point source mercury release.

Acidic water from the abandoned mine mixes with the waters of San Carlos Creek, leading to elevated mercury concentrations below the mine opening. The brown water you see in this slide is from metals precipitated after the acid mine drainage mixes with the clear water of San Carlos Creek.

The next graph we'll be showing you will be the part-per-billion concentrations of filtered mercury above and below the mine opening. These are filtered mercury concentrations consistent with the promulgated standard.

The point of this graph is that the existing standard, 0.012 parts per billion, shown by the heavy, black horizontal line, distinguishes between background regional processes and point source contamination. The two lowest mercury concentrations on the left are from water samples upstream of the mine opening in clear water; those concentrations represent mercury concentrations in water which could result naturally from drainage of mercury ore deposits in that region.

The concentrations downstream of the mine opening, in the brown water you just saw, clearly exceed the current National Toxics Rule standard of .012 parts per billion. In contrast, if we were to put the proposed continuous criteria concentration standard on the same scale with this graph, that standard would be two stories above our heads right now.

The next graph shows the same mercury concentrations from New ldria on scale with the proposed criteria of 0.77 parts per billion. Clearly, the proposed criteria does not distinguish between background

processes and point source contamination. Mercury levels in the clear water and in the brown water are equal in the eyes of the proposed criteria.

That is the economic benefit that will be derived from raising limits on mercury in water. The citizens of California will be asked to ignore point source contamination of mercury. This is one example from within the State of California; there are many others.

Mercury contamination is part of our mining legacy in this state, we ignore it at our peril. Comment: For mercury, certainly I would concur with the previous comments, that the number should be -- that is appropriate is accumulation factors.

Now the bioconcentration factor, in deference to this state's consumption rates that have been determined are appropriate for California, I think using the average consumption rate for everyone in the country, by definition, lops off about half of the population. It seems to me that it doesn't account for those users of the bay who are the high consumption -- high fish-consumption users, which obviously there's a number of them, and that's not reflected in that average at all.

So I think that those bioaccumulation factors are important to the mercury number base data that we have for the bay for all the reasons stated earlier, and similarly for dioxin. It seems as if EPA would like to back away on that, the criteria that is listed.

Comment: The other point I want to make, we had a discussion about mercury today and that discussion doesn't address the issues properly. That discussion focused on the number -- I think it was .77 parts per billion, and that's not a human health criteria. That is the toxicity part. That's a dissolved mercury. As related to aquatic life, that number's about right.

Response to: CTRH-001-062

Comment: In another part of the Federal Register promulgating the rule, there is a statement about -- for human health, the number is proposed to be 50 nanograms per liter -- going from 12 nanograms per liter, now the current gold book number, to 50 under these criteria. But if you go further and you ask what does that mean really? Do I think mercury is less toxic? No way.

What it's headed for is that within two to six months to a year, as state and federal rules on mercury are developed through the Science Advisory Board review, so forth, it's a pretty good chance that's going to drop, 3 to 5.

You should understand we're headed for 3 to 5 nanograms per liter for total mercury as a number to protect from excessive bioaccumulation. That's where we're headed.

I'll stop at this point.

Comment: Proposed copper criteria ignore San Francisco Bay data that show damage to sensitive populations at lower dissolved copper concentrations and led the state to reject criteria that deregulate total copper in its water quality criteria. The proposed rule states that: "New data including data collected from studies for the New York/New Jersey Harbor and the San Francisco Bay indicated a need to revise the copper criteria documents to reflect a change in the saltwater" criteria. In contrast to this statement, many scientists involved in review of the San Francisco Bay study reached a very different conclusion.

Many scientists commented during the state's review that the data did not necessarily support a revised copper criterion. EPA scientists raised many questions regarding: inadequate seasonal sampling; departure from standard testing recommendations; interpretation of toxicity test endpoints and precision; interpretation of widely varying responses; failure to measure dissolved copper in key bioassays and sites; overestimation of the amount of copper producing an effect; significant problems with algal test interpretation; confusion of acute versus chronic exposure; unmeasured effects of filtration; joint toxicity of copper with other metals; multiple stresses; bioaccumulation; and, generally, how lab results will "mimic environmental reality."(*17)

Other scientists stated similar and stronger concerns, Dr. Michael Perrone commented that "there isn't a positive demonstration that dissolved copper is a good predictor" of environmental ion.(*18) The state's Department of Fish and Game also stated that "[t]otal copper can become protect unbound and available for uptake by organisms" in comments voicing many of the concerns listed above, and recommended: "Retain the existing criteria of 2.9 ug/L as total copper."(*19)

The weight of scientific opinion raised sufficient questions about how these laboratory studies "mimic environmental reality" to warrant analysis of field data. This showed species had responded to changes in Bay copper, and those bivalve shellfish and phytoplankton which are most vulnerable to copper toxicity were severely reduced in abundance although they once thrived here, and thrive in similar estuaries at dissolved copper levels of about I ug/L or less.(*1) Comparison of high quality data between estuaries further demonstrated S.F. Bay copper pollution similar to other polluted estuaries, and dissolved copper levels below 1 ug/L in unpolluted or less polluted estuaries where these copper-sensitive species thrive.(*2) There is a "reasonable probability" that copper levels in waters of the southern reach affect the ecosystem, and cutting copper pollution will likely benefit aquatic life.(*1)

Therefore, the state's review of all of this evidence led to a decision to adopt a criterion for total copper that would require reduced copper concentrations. The fundamental rationale for this was that cutting copper pollution was necessary in order to ensure the protection of aquatic life. In contrast, EPA's

proposed 3.1 ug/L dissolved copper criterion, which would not require less copper in most Bay waters as shown in Table 4, and which allows dissolved copper three times levels at which sensitive estuarine species are known to thrive, cannot ensure the protection of Bay aquatic life based on sound scientific rationale.

(*19) California Department of Fish and Game, 1992. Conunents on the Draft Final Report Entitled "Development of site-specific criteria for copper for San Francisco Bay." Letter from John Turner, DFG, to Steven R. Ritchie, RWQCB. July 14,1992.

Response to: CTR-002-008

EPA does not agree with the commenter's comment concerning a copper criterion of 1 ug/L. This issue was raised in 1992 when the San Francisco Bay Regional Water Quality Control Board (SF RWQCB) published its site-specific copper value (based on total copper). EPA agrees with the SF RWQCB's position, which it articulated in its October 21, 1992, "Responses to Comments - Site-specific Copper Objective" for the September 25, 1992, report titled "Revised Report on Proposed Amendment to Establish a Site-Specific Objective for Copper in San Francisco Bay". The SF RWQCB noted that the ambient concentrations in South San Francisco Bay were well above the 1 ug/L in Tomales Bay and then stated that, "the observation that some organisms are more abundant in Tomales Bay where concentrations are less than 1 ug/L does not mean that 1 ug/L is needed to insure protection of these organisms in San Francisco Bay." This would be setting a criterion "based on correlation rather than controlled experimentation, and does not account for the many other factors that can affect the distribution and abundance of organisms."

EPA believes that the weight of sound scientific evidence fully supports the protectiveness of its copper criterion. EPA does not consider the commenter's interpretation of reference 17 (1992 EPA comments on the site-specific modifications of the copper criterion for San Francisco Bay) relevant to the CTR copper criterion. The subject of reference 17 was not the CTR criterion, and the information available to EPA when it formulated its 1992 comments (the commenter's reference 17) was less than the information available to EPA in formulating the criterion in this rule. In its 1995 "Ambient Water Quality Criteria - Saltwater Copper Addendum", EPA examined the data available from the San Francisco Bay studies and utilized only the data with suitable quality into its revised national criterion (which was used in the CTR).

Concerning the comment about whether dissolved copper is a good predictor of environmental ion

(reference 18), EPA does not agree that such prediction is cogent. The intent of the copper criterion in the rule is to prevent copper toxicity, not to achieve any fixed concentration of free ionic copper.

Concerning the comment that "total copper can become unbound and available", EPA notes that unbound and available copper is covered by the criterion incorporated in the rule. Thus, EPA does not believe that this a concern. See also the response to CTR-026-004 concerning dissolved v. total recoverable metals criteria.

Comment: II. Use of New Scientific Information

The City acknowledges and supports EPA's update of several water quality criteria including those for mercury, cadmium and arsenic. While a number of criteria were updated to reflect current scientific information, there are a few notable exceptions.

The following briefly addresses the key updates and omissions that should be addressed in the final publication of this rule.

B. Outdated Science

1. Copper

The proposed copper criteria do not reflect the expected toxicity of this pollutant in the environment and will result in unnecessarily restrictive requirements throughout the state. Although required by the National Guidelines, the copper criteria fail to include an adjustment to account for binding with organic material such as that expected to occur in storm waters and in treatment plant effluents that renders this pollutant non-toxic (see enclosed article, Exhibit 5). Application of the criteria as a dissolved standard will likely result in many facilities being identified as in violation of the criteria. Few storm waters are expected to meet the acute criteria due to low hardness of such waters. The City's storm water monitoring has indicated that such waters exceed the proposed acute criteria. The typical Total Organic Copper ("TOC") level present in storm waters (8-20 mg/l) is well above the 3 mg/l value specified in EPA's Copper Criteria Document as indicative of significant organic complexing and the need to modify the criteria. Consistent with the available technical data and criteria development guidelines, the copper criteria must be modified to address organic binding as part of the criteria to avoid classifying many dischargers as toxic threats when no such threat actually exists. The following identifies the scope of concerns regarding proper application of copper criteria and the technical information that demonstrates EPA's copper criteria routinely overestimate actual aquatic life threats.

(a) Introduction

No single issue in the development and application of water quality criteria for metals is of greater importance to NPDES permittees than the accurate assessment of aquatic toxicity of copper. The infrastructure of the nation's drinking water supply depends on copper and copper alloy pipes. Along with drinking water conveyance, copper chemicals are widely used for algae control in drinking water supplies and reservoirs. Because of the intimate association between copper and the nation's water supply, it is inevitable that some form of copper will be discharged in wastewater and present in storm waters.

EPA's current approach to copper regulation assumes that the toxic form of the metal exists in biologically treated effluents and storm waters even when all scientific information confirms that it does not. This assumption causes permittees to conduct expensive studies to correct the standard to reflect the lack of environmental threat present. This approach (1) is wasteful of local resources, constituting an unauthorized, unfunded mandate; (2) penalizes small communities which have both limited budgets and access to updated scientific approaches; (3) is inconsistent with EPA's statutory mandates and guidance; and (4) violates regulatory principles outlined in the President's "Reinventing Environmental Regulation" initiative. Because EPA's approach does not reflect reality and easily implemented, less costly approaches exist to properly regulate copper discharges, this criteria should be withdrawn or, at a minimum, narrowed in its application. The following summarizes the scientific and regulatory bases for withdrawal and reconsideration of laboratory-derived numerical water quality criteria for copper to biologically treated effluents.

First, existing copper criteria are not appropriate for biologically treated effluents or situations where elevated TOC levels are known to exist (the typical case where the criteria are applied) because the database used to derive this criterion did not consider the dramatic detoxification of copper by constituents commonly present in biological waste treatment systems. Second, laboratory studies, field surveys, and water effects ratios conducted by regulatory authorities and independent researchers all confirm that copper rapidly binds ("complexes") with organic and inorganic matter (e.g., phosphates) during biological waste treatment, thus rendering copper non-bioavailable and hence non-toxic to aquatic life. Third, all field studies conducted by EPA and state agencies confirm that copper in biologically treated effluents is not toxic to sensitive species which were used to establish the federal copper criteria. This demonstrates that biologically treated effluents eliminate copper toxicity and should pose no threat to resident species instream after mixing.

Briefly, the current body of laboratory research on the detoxifying effects of organic and inorganic matter on copper, including total organic carbon, particulate matter, humic and fulvic and amino acids, explains why scientific field studies consistently show that copper in biologically treated effluents, and by extension storm waters, is not expected to be toxic to aquatic life. Current copper criteria application to treated effluents and storm waters is not appropriate or necessary to protect aquatic life. Use of acute daphnid whole effluent toxicity tests would be sufficient to regulate copper at a level of protection equivalent to the national criteria for copper and eliminate the need for expensive WER analyses.

(b) EPA Must Follow Its Guidance

EPA's national guidance for Clean Water Act Section 304(a) criteria development requires all relevant factors regarding toxicity of a pollutant to be considered in establishing water quality criteria for that pollutant.(*16) Because the current copper criteria are based on assessments of dissolved metal salts in laboratory water with little or no ability to complex copper, the commonly encountered dramatic detoxifying effect of treated effluent and other naturally existing substances present in storm waters were

not considered.

EPA guidance on implementing metals criteria expressly states that it is only the biologically available fraction of the metal that is intended to be regulated.(*17) Although recent guidance from EPA specifying that metals criteria assessed as "dissolved" may be a better approximation of the toxic fraction under some circumstances, measurements of filterable "dissolved" copper in biologically treated effluents or in storm water samples with high (greater than 5 mg/l) TOC levels are, to a certainty, not relevant to assessing the toxic fraction of copper. Such measurements erroneously assesses non-toxic filterable organo-copper complexes as "dissolved" which is the form in which the metal will be discharged from these facilities or will preferentially exist in the environment. Because the vast majority of facilities that discharge copper utilize biological treatment, it is apparent that widespread misapplication of the copper criteria may result from use of a dissolved metals approach. Similarly, storin waters typically contain TOC levels equivalent to well treated municipal effluent (5-20 mg/l TOC).

Comment: II. Use of New Scientific Information

The City acknowledges and supports EPA's update of several water quality criteria including those for mercury, cadmium and arsenic. While a number of criteria were updated to reflect current scientific information, there are a few notable exceptions.

The following briefly addresses the key updates and omissions that should be addressed in the final publication of this rule.

(e) Copper Criteria Development and Application

(1) Criteria Based on the Dissolved Metal Fraction Overestimate Bioavailable Copper

In 1992, the Pellston Conference of the Society for Environmental Toxicology and Chemistry recommended that water quality standards be established on the basis of bio-availability.(*18) On May 28, 1992, EPA released the Interim Guidance on Interpretation and Implementation of Aquatic Life Criteria for Metals ("Interim Guidance"), a final policy which modified all prior Section 304(a) criteria documents for metals and implemented this recommendation. In issuing its Interim Guidance, EPA acknowledged that only the biologically available fraction of metals is responsible for aquatic toxicity, and therefore is the proper focus of permit limit derivation:

The principal issue is the correlation between metals that are measured and metals that are biologically available.(*19)

In the Interim Guidance and contemporaneous correspondence, EPA acknowledged that expressing water quality criteria for metals as dissolved measurements is a conservative approach and that a state should consider further reductions in toxicity from complexing:

Alternatively, we are allowing States to apply criteria to dissolved metals only. However, we suspect that this may be a somewhat less accurate method of excluding "nontoxic" metal from regulation, because some dissolved metal exists in forms that have little toxicity (particularly copper, a pollutant of great concern to municipal dischargers)...(*20)

Following the January 1993 Annapolis Conference on the development and implementation of metals criteria, EPA modified its criteria implementation guidance to use dissolved metal (i.e., filterable through a 0.45 u membrane) concentrations in setting water quality standards "because dissolved metal more closely approximates the bioavailable fraction of metal in the water column than does total recoverable metal.(*21) Scientists at the Annapolis Conference emphasized that under certain circumstances, dissolved metal standards are conservative and may overstate the toxic fraction: "In some cases, even the dissolved concentration may overestimate the bioavailable fraction for metals that strongly complex to either inorganic or organic ligands (e.g., filterable carbon containing particles).(*22) Because the dissolved approach erroneously equates all "filterable" dissolved copper to bioavailable copper, dissolved metals measurements overstate the toxic metal fraction in biologically treated effluents.

(2) All Laboratory Studies Confirm Copper is Detoxified by Organic Substances in Sewage

The detoxifying influence of organic and inorganic complexation on copper was reported in EPA's 1984 Copper Criteria Document.(*23) Among the heavy metals, copper is particularly amenable to complexation with organic and inorganic matter to render this metal non-bioavailable and hence non-toxic to aquatic life. Aquatic organisms respond to free ionic metal and monohydroxy complexes as bioavailable forms.(*24) Rapid detoxification of copper in the presence of inorganic and organic substances occurs due to the high reactivity of this metal:

[t]he cupric ion is highly reactive and forms moderate to strong complexes with many inorganic and organic constituents of natural waters (e.g., carbonate, phosphate, amino acids and humates), and is readily sorbed onto surfaces of suspended solids.(*25)

EPA's 1984 criteria application guidance provided a criteria adjustment for hardness -- one of the many substances present in biologically treated effluents -- but omitted similar consideration of organic ligands, even though EPA recognized their greater importance in detoxifying copper:

Lind, et al., (Manuscript) measured the toxicity of copper to Daphnia pulicaria in a variety of surface

waters and found that total organic carbon (TOC) is a more important variable than hardness, with acute values varying approximately 30-fold over the range of TOC covered. Similar results were obtained with the fathead minnow. This indicates that the criteria should be adjusted upward for surface waters with TOC significantly above the 2 to 3 mg/L usually found in waters used for toxicity tests.(*26)

The scientific literature is replete with peer reviewed studies confirming that organic ligands similar to those in municipal effluents dramatically mitigate copper toxicity.(*27) Callahan, et al., concluded that most cupric salts are not readily water soluble and reported that inorganic and organic complexation and adsorption of copper reduce the level of soluble copper to very low values, even in the presence of total copper.(*28) The linear relationship between reduction in toxicity of total copper to rainbow trout with increasing concentrations of suspended organic solids was reported by Brown.(*29) This work reported that doubling the concentration of organic ligand from 4 mg/l to 8 mg/l approximately doubled the 96-hour LC50 for copper. Brown concluded:

toxicity to rainbow trout of a given total concentration of copper was quantitatively reduced in the presence of a good quality sewage effluent, of an amino acid, of humicsubstances, and of suspended organic solids.(*30)

Similar results were obtained by Sunda and Lewis, who reported complexation of 61 to 99 percent of free copper by river water containing natural organic matter at 22 mg/l.(*31) Erickson, et al., reported that copper complexed with organic ligands appears to be one-fifth as toxic as free ionic copper, and that addition of organic matter (humic substances) increased the LC50 of copper by 2.7. Morrison and Florence reported that copper toxicity to algae and Daphnia magna was decreased by sixty (60) percent in the presence of 5 mg/l fulvic acids and eliminated in the presence of 1.3 to 8 mg/l humic acid colloids.(*32) As noted previously, storm waters typically contain TOC levels in excess of these values.

The above laboratory studies conducted under conditions with relatively low levels of binding agents confirm that even when relatively high "dissolved" copper concentrations were measured, the toxicity of copper to sensitive species was greatly reduced or eliminated in the presence of organic and inorganic compounds. The amount of copper complexed in the presence of high concentrations of organic ligands in biological waste treatment systems or urban storm waters would, of course, be much greater. As the amount of ligands and other binding agents is, stoichiometrically, greatly in excess of the ionic copper for typical municipal and storm water conditions, no copper will be present in a toxic form. This fact was demonstrated by Allen and Hansen.(*33)

On the basis of over twenty years of observations and research on metal speciation chemistry and fate of metals in receiving waters and in treatment facilities, Dr. Allen concluded that virtually all copper in biologically treated effluent is non-toxic:

Following biological treatment, virtually all the copper present in a municipal treatment plant effluent would be in the form of soluble copper complexes or it would be sorbed to particulate material not removed from the effluent stream in the final clarifier. Certainly, as in any chemical equilibrium situation, there will be a finite concentration of free, ionic copper present in the effluent. However, this concentration will be very low and will not pose a toxicity risk. This is borne out by a lack of metal toxicity in treatment plant effluents when effluent monitoring studies have been conducted. As far as I know, such studies have not demonstrated that there is toxicity from metals in effluents.(*34)

Field studies of WERs have repeatedly confirmed laboratory observations and validate the total detoxification of copper by biologically treated effluents. DiToro, et al., performed WERs on the site-specific detoxification of copper in the Naugatuck River.(*35)

Very little difference in toxicity was observed between laboratory water with minimal complexing ability and river water from pristine segments. However, where river water contained treated municipal effluents, up to a twelve-fold reduction in copper toxicity was recorded, and it was concluded that the copper present in the municipal effluent was non-toxic. A 1992 summary of WERs for heavy metals compiled by Brungs showed that copper is up to 26 times less toxic in water influenced by municipal effluent.(*36) It should be noted that to have a WER significantly above one (1), the existing metal in the discharge must be complexed. The WERactually represents the excess binding capacity of the effluent.

The dramatic detoxification of copper in the presence of municipal effluent was also reported in a field study on Shayler Run by Geckler, et al.

It was suspected that the Shayler Run sewage treatment plant was discharging materials that were detoxifying copper in Shayler Run water. Bioassays, using diluent water from above and below the entrance of the effluent, indicated that copper was much less toxic in Shayler Run water below the plant. Additional toxicity tests, in which Shayler Run water was diluted with a reconstituted water similar in hardness and alkalinity, indicated that the reduction in toxicity was not due to hardness or alkalinity, but to some other detoxifying agent or agents being diluted.(*37)

The North Carolina Department of Environment, Health, and Natural Resources documented 78 cases in which total recoverable copper in effluents and in receiving waters was measured in excess of water quality criteria without observed chronic toxicity. Instream total copper ranged up to 378 ug/l. Bioassay testing was conducted using Daphnia magna, one of the most sensitive species to copper (see Exhibit 7). The Massachusetts Department of Environmental Protection confirmed the same results in their survey of 35 facilities. These documents have previously been provided to EPA as part of the public comments on the May 1995 National Toxics Rule revision. No public response to those comments was ever published. As a result of the extensive NWR analysis performed by the Connecticut Department of Envirom-nental Protection, it was demonstrated that water upstream from municipal dischargers exhibit a typical WER of three (3) while those downstream of publicly owned treatment works ("POTWs") exhibit WERs ranging from 8 to 25 (Exhibit 8). As expected, the higher WERs are associated with increased levels of municipal effluent and organic material.

The above field studies confirm the observations made by laboratory research and validate the rapid detoxification of copper in the presence of treated effluents and elevated TOC levels. Stockton is not aware of any reported instances that contraindicate copper in biologically treated effluent is non-toxic to sensitive species. Thus, it is apparent that there is no technical or environmental basis for concern regarding copper levels typically discharged by biologically treated facilities (copper ranging from 20 to 200 ppb). Nor is there any rational basis to be concerned with low level dissolved copper measurements in storm waters where TOC levels are capable of fully binding the available copper. The continued application of a dissolved criteria approach which would classify these effluents as problematic when they clearly are not is arbitrary and capricious and wastes local resources on problems that do not exist.

(3) Water Quality Criteria Must be Based on the Latest Scientific Information and the Proper Application of Science

The fundamental oversight in translating dissolved copper criteria into permit conditions is the failure to regulate only bioavailable metal. The laboratory conditions of the EPA criteria development experiments accurately reflect the maximum toxic impacts to highly sensitive species when exposed to a highly toxic dissolved, ionic form of copper in pure water having little or no complexing ability. Such conditions are

plainly unrelated to copper discharged from biological waste treatment systems. Because of the greater abundance of complexing agents present in biological treatment process, all copper in a discharge will be in a complexed and therefore non-bioavailable form. This is particularly true for effluent dominated, low dilution streams and storm waters where proper criteria application is most critical.

EPA must apply copper water quality criteria in the same manner in which they were developed. The National Guidelines prohibit application of the criteria in a manner not contemplated by that document:

Criteria must be used in a manner that is consistent with the way in which they were derived if the intended level of protection is to be provided in the real world... Concentrations, durations and frequencies specified in criteria are based on biological, ecological and toxicological data, and are designed to protect aquatic organisms and their uses from unacceptable effects.(*38)

Application of water quality standards for copper must reflect the pollutant form assessed in the criteria. The National Guidelines require revision of criteria whenever it is demonstrated that the national criteria "would probably be substantially over or under protective."(*39) As the dissolved approach has been demonstrated to be overprotective in all cases involving biologically treated effluents and elevated TOC, this procedure requires revision.

By allowing scientifically defensible biomonitoring/bioassay methods as an alternative method of developing water quality criteria and water quality-based effluent limitations, EPA would assure adequate protection of only the toxic or bioavailable fraction of copper. This approach is outlined in the most recent SETAC Conference report on proper application of metals criteria. Unlike standards expressed in terms of analytical measurements (e.g., "total recoverable" or "dissolved"), use of bioassay tests to directly evaluate the bioavailable fraction of copper is rationally related to the actual potential for aquatic life impacts to the species that drove the national criteria (ie., daphnids).

The language of EPA regulations makes it clear that the Agency's authority to develop criteria rests on the scientific accuracy by which those criteria relate to aquatic impacts:

Section 304(a) criteria are developed by EPA under authority of Section 304(a) of the Act based on the latest scientific information on the relationship that the effect of a constituent concentration has on a particular aquatic species and/or human health. 40 C.F.R. 131.3(c) (emphasis supplied).

Therefore, Agency endorsement of test methods that are known to exhibit little relationship to aquatic life protection needs exceeds the scope of the Agency's authority to develop and implement criteria.

(4) EPA Is Bound to Adhere to Published Guidance

Both the Clean Water Act and EPA's National Guidelines establish the underlying mechanism for establishing Section 304(a) criteria for metals. As previously discussed, the National Guidelines describe the various methods of justifying numerical criteria values that are protective of aquatic life uses and specify that all factors that significantly influence the toxicity of a pollutant must be taken into account. EPA's National Metals Policies all state that only the biologically available fraction is intended to be regulated. Unfortunately, a dissolved approach to copper does not meet that objective.

EPA is not free to wander from its published guidance and regulations when the result of such deviation adversely affects the substantive rights of an individual who relied on the Agency's published representations.(*40) In Massachusetts Fair Share v. Law Enforcement Assistance, 758 F.2d 708, 711-712 (D.C. Cir. 1985), the court reinforced the philosophy established in Morton v. Ruiz:

It has long been settled that a federal agency must adhere firmly to self-adopted rules by which the interests of others are regulated. This precept is rooted in the concept of fair play and in abhorrence of unjust discrimination, and its ambit is not limited to rules attaining the status of formal regulations. The Supreme Court has declared that'[w]here the rights of individuals are affected, it is incumbent upon agencies to follow their own procedures, even though the procedural requirement there spoken of had not been published in the Federal Register, and other courts have concluded similarly.

Both the CWA and EPA's published regulations require that criteria accurately reflect the latest scientific knowledge on aquatic life protection needs. See, 33 U.S.C. section 304(a). EPA's current criteria do not reflect the latest information on copper detoxification by treated effluents or in the presence of elevated TOC levels, the most common cases for applying the criteria. The continued application of current numerical copper criteria to such situations is inappropriate and unnecessary

(5) Conclusion

For all the foregoing reasons, EPA should ensure that the criteria-based water quality standard for copper is applied to the same pollutant form assessed in the Copper Criteria Document "bioavailable" or, in this case, ionic copper). Laboratory and field studies overwhelmingly support the conclusion that copper in storm waters and biologically treated effluents exists in organo-complexes and is not bioavailable. There is no information to the contrary. Current approaches to criteria development erroneously equate filterable copper to dissolved bioavailablemetal, and overstate the toxic fraction in treated effluents, wasting local and state resources on time consuming, administratively complex and expensive WER tests. Consistent with the National Guidelines and the "Reinventing Government" initiative, a less costly, more environmentally appropriate approach is required.

It is clear from the preceding discussion that the existing copper criteria requires amendment because the criteria, as implemented, are not limited to the toxic form of the metal. Since there are no approved analytical techniques to allow measurement of the toxic form of copper in state waters, EPA needs to establish a procedure to better define the toxic fraction and defer implementation of copper water quality criteria for any discharge that has demonstrated no acute toxicity to copper sensitive organisms. This approach is used by the State of North Carolina and is conceptually the same as the simplified water effect ratio approach EPA is developing. This methodology will provide significant benefit to EPA and better focus environmental resources. By establishing an objective basis to evaluate actual copper toxicity, EPA and the regulated community will better be able to define where real copper toxicity problems exist.

In a dispute between an American Indian and the Department of Interior's Bureau of Indian Affairs ("BIA"), the Supreme Court held that where the rights of individuals are affected, it is incumbent upon agencies to follow their own procedures. This is so even where the internal procedures are possibly more rigorous than otherwise would be required.

Response to: CTR-020-012

EPA agrees that the factors discussed in the comment strongly affect the toxicity of copper, but does not agree that the criteria formulas specified in the rule do not account for these factors. The freshwater copper criterion is expressed as formula having two parameters, hardness and the water-effect ratio. The saltwater copper criterion is expressed as a formula having one parameter, the water-effect ratio.

The water-effect ratio (WER) is a generalized parameter that accounts for the difference in biological activity or toxicity of the copper in the site water versus in laboratory water. EPA agrees that the WERs typically observed in waters carrying substantial amounts of municipal effluent are generally large enough that no copper toxicity is manifested in such waters. EPA also agrees that the organic carbon content of such waters plays a key role in rendering copper nontoxic. However, EPA does not believe that the facts set forth in the comment indicate that the WER concept incorporated into the rule is incapable of satisfactorily accounting for the effects that organic carbon and other site water factors have on copper toxicity.

The rule has cited EPA's current guidance on determining water-effect ratios. However, the rule does not require that WER determinations follow only this guidance. Rather, it allows "other scientifically defensible methods adopted by the state...and approved by EPA." EPA understands the concerns raised in the comment about the resources needed to complete a WER determination pursuant to its guidance. EPA is working with states and dischargers in developing more streamlined approaches for determining WERs using fewer toxicity tests. EPA has also been funding development of a biotic ligand modeling approach, which will predict a site WER for copper using chemical measurements of hardness, alkalinity, dissolved organic carbon, and pH, thereby eliminating the need for the side-by-side site water and lab water toxicity testing of the traditional WER determination. EPA also supports conventional regression techniques for developing a relationship between site chemical parameters, such as DOC, and the WER. EPA's approval of such alternative procedures will be based on their scientific merit. With the anticipated improvements in techniques for predicting the WER from chemical measurements, EPA believes that in many cases it may be simpler to implement than the whole effluent toxicity approach advocated in the comment.

Comment: The proposed CTR freshwater aquatic life criteria for copper are also problematical for many drinking water suppliers. Copper algaecides are a necessary element of algal control strategies for drinking water reservoirs and conveyances. Even with a comprehensive reservoir management program based on limnological principles, copper algaecides need to be part of the algal control arsenal. Algal growth, if uncontrolled, can lead to unacceptable levels of trihalomethanes (THMS) in treated water supplies, among other impacts.

The CTR proposes freshwater aquatic life criteria for copper which could severely hamper the ability of drinking water suppliers to use copper algaecides. The dosage of these algaecides which is effective for controlling algal growth could lead to periodic exceedances of the copper freshwater criteria. Yet, use of copper algaecides is sometimes necessary to protect drinking water beneficial uses, and there is currently no economically feasible alternative available. Drinking water suppliers have the difficult task of meeting conflicting requirements to protect drinking water beneficial uses while ensuring that aquatic life criteria for copper are met.

Response to: CTR-025-004a

EPA acknowledges the comment, but notes that tradeoffs between drinking water benefits and aquatic life benefits were not considered.

Comment: The application of the proposed copper criteria to municipal effluent is overly restrictive. Copper in municipal effluents have been demonstrated not to be toxic at higher levels than proposed due to the nature of the constituents in the effluent. Attached is a recent article that appeared in the Water Environment Federation Journal that highlights the rational for high copper limits in municipal effluent.

Comment: Separate, scientifically defensible, reasonably achievable aquatic life criteria for copper should be adopted for San Francisco Bay, or alternatively EPA should specify in the Preamble implementation policies for copper that will result in reasonable control measures actions. To comply with the Clean Water Act and EPA regulations, EPA is required to consider specific water bodies. To fulfill the spirit of Presidential Executive Order 12866 and the requirements of the Unfunded Mandates Reform Act, EPA is required to evaluate regulatory alternatives based on an analysis of costs and benefits. Based on BADA's analysis of costs and benefits, EPA should either adopt copper criteria that are reasonably achievable or alternatively specify implementation policies that will avoid costly end-of-pipe controls. Potential implementation measures that could be specified include use of the following in calculating effluent limitations: actual dilution based on modeling studies; copper translators; probability of compliance less than 99.9%; and water-effect ratios determined for different

segments of the Bay. Unless EPA specifies these or similar implementation policies in the rule, it is possible that the CTR could result in significant costs ($12 million per year to $78 million per year) while resulting in minor environmental benefit (a 1% reduction in copper loading to the Bay). In that case, the CTR would violate the Clean Water Act, EPA regulations, Presidential Executive Order 12866, the Unfunded Mandates Reform Act and the Regulatory Flexibility Act. (see the discussion under Item 11 below.)

Comment: PROVISIONS SDG&E DOES NOT SUPPORT

As described in the following comments SDG&E does not support the following provisions:

Copper criteria

The metal criteria, including copper, are based on toxicity tests run in relatively pure water. Naturally occurring elevated ambient concentrations of suspended organic matter in bays and estuaries can significantly reduce the bioavailable portion of the metal. Since the criteria do not account for the presence of organic matter, the proposed criteria for metals, including copper, will be unnecessarily over-protective. As provided, water effects ratios (WERs) can be developed to account for this effect. However, WER studies can be very costly (see comments below regarding the economic analysis).

EPA appears to have deviated from its standard protocol in developing the copper criteria. Normally, a criteria is based upon toxicity tests of multiple species. However, the proposed criteria appear to be based upon the single species (i.e., the blue mussel) with the lowest toxicity concentration. This has resulted in a somewhat lower criteria than would have otherwise been derived. The criteria should be recalculated to be based upon the results of multiple species.

Response to: CTR-060-013

Concerning the comment on water-effect ratios, see response to CTR-020-012. EPA does not agree that it has departed from its standard protocol in deriving the saltwater copper criterion. The criteria Guidelines provide that the criterion derived to protect the fifth percentile genus is to be lowered, if necessary, to protect recreationally or commercially important species. This has been done for the saltwater copper criterion.

Comment: The CTR proposes to establish a dissolved approach for copper with typical limits for a low flow stream ranging from 8 to 15 parts per billion (ppb). The preamble to the CTR recognizes that copper rapidly binds with organic materials and may not be toxic in municipal effluents. In fact, EPA has acknowledged in a number of forums that copper is not expected to be toxic in municipal effluents; nonetheless, the proposed CTR does not reflect this reality.

As explained by EPA criteria derivation guidelines, water quality criteria are required to reflect expected environmental impacts and are to be revised if they are determined to be significantly over or under-protective. EPA has in its possession an extensive amount of research data and field study results which demonstrate that copper is never toxic in municipal effluents. If copper is discharged to low flow streams, there is no influence of upstream water quality -and therefore, the toxicity of the copper will not be altered. The copper level in EID's discharge typically ranges from 20 to 40 ppb and has been found to be non-toxic to copper-sensitive organisms (i.e., daphnids).

The proposed copper criteria do not reflect the expected toxicity of this pollutant in the environment and will result in unnecessarily restrictive requirements throughout the state. Although required by the National Guidelines, the copper criteria fall to include an adjustment to account for binding with organic material such as that expected to occur in treatment planteffluents that renders this pollutant non-toxic (see enclosure).

Application of the criteria as a dissolved standard will likely result in many facilities being identified as in violation of the criteria. This proposed approach wastes scarce local resources, imposes an unauthorized, unfunded mandate on municipalities, penalizes small communities which have both limited budgets and access to updated scientific approaches, and is inconsistent with EPA's statutory mandates and guidance.

EPA should take one of two actions: (1) withdraw application of the copper criteria to municipalities, or (2) establish a screening level procedure which will only apply the criteria where copper-sensitive organisms indicate that copper is toxic.

We thank you for the opportunity to comment on this proposed rulemaking and look forward to EPA's reevaluation of the copper criteria as applied to municipalities.

Comment: PROPOSED COPPER CRITERION WILL CONTRIBUTE TO DEGRADATION OF SAN DIEGO BAY

EPA's proposed 3.1 ug/L dissolved copper criterion will allow copper three times the levels at which sensitive species are known to be impacted in an areas such as San Francisco Bay. San Diego Bay is already listed as impaired for copper. This criterion is too high and will allow more degradation of our water resources.

Comment: Validity Of The Proposed Copper Criteria For South San Francisco Bay

Attachment 3 to this letter is a technical report entitled "Development of a Site-Specific Water-Effect Ratio for Copper in South San Francisco Bay", dated September 1997 and prepared by the City of San Jose Environmental Services Department.

This attachment is also incorporated as part of our comments and is being submitted for inclusion in the record for this rulemaking. Because EPA is proposing to promulgate water quality criteria for all waterbodies in the State of California, we believe that it is required toconsider site-specific data to the extent that it is available, especially, where, as in the case of the submitted data, it appears that there is a less costly/appropriately protective alternative to the proposed criteria.

Comment: On copper, EPA says it has weakened the copper standards to allow copper levels which, again, now violate the state standard of 4.99 in most of the bay. And EPA says this is too tight because the new data shows the quantity standard for total copper is overprotective.

But the highest dissolved copper level found in the estuaries with less copper pollution, where species that are apparently decimated by copper pollution in parts of San Francisco Bay still thrive, is three times smaller than EPA's proposal.

Our question here is, will EPA prove that its proposal will protect these species in the bay before adopting it?

Comment: In this rulemaking, EPA proposes to set the freshwater acute aquatic life water quality criterion for nickel (the so-called "Criterion Maximum Concentration" or "CMC") at a level of 470 ug Ni/L, while the freshwater chronic aquatic life water quality criterion (the so-called "Criterion Continuous Concentration" or "CCC") would be set at a level of 52 ug Ni/L -in both cases expressed as the dissolved fraction of nickel in the water column corresponding to a water hardness of 106 mg/L as CaCO3- See 62 Fed. Reg. at 42169 (Table), 42194, These values are less than one-third of the CMC and CCC values that EPA has adopted for nickel in its National Toxics Rule, See 62 Fed. Reg. at 42169.

As explained in the rulemaking notice, the reason why the freshwater nickel aquatic life criteria proposed for California are so much lower than the values set forth in the National Toxics Rule is that the California values were "calculated using data published subsequent to the issuance of [the Clean Water Act section] 304(a) criteria document [for nickel]." Id. at 42168/3. In particular, eight sets of acute toxicity (LC50/EC50) data were added to the database for nickel. Seven of these eight LC50/EC50 values (adjusted to a water hardness of 50 mg/L CaCO3) ranged from 66,100 ug/L to 160,521 ug/L(*1). The eighth value, an LC50, for the snail species Physa gyrina, was 416 ug/L, more than two orders of magnitude lower than the values in the other seven studies.(*2) This value also was far below any other acute aquatic toxicity value for nickel that had been reported previously.(*3)

Since EPA calculates the CMC acute toxicity value by using the lowest four Genus Mean Acute Values for the chemical(*4), the LC50 of 416 mg/L reported for Physa gyrina replaced a Genus Mean Acute Value of 6,707 ug/L for the fathead minnow in the calculation of the CMC for nickel.(*5) This substitution of LC50 values caused the proposed California CMC for nickel to be 470 ug/L at a water hardness of 100 mg/L CaCO3, while the National Toxics Rule CMC for nickel corresponding to that water hardness is 1400 ug/L. See 62 Fed. Reg. at 42169. It also caused the proposed California CCC for nickel to be 52 ug/L at a water hardness of 100 mg/L CaCO3, compared to a National Toxics Rule CCC of 160 ug/L at that water hardness. See id. (The chronic toxicity CCC was affected by the change in acute toxicity data because, in the absence of sufficient chronic toxicity data for nickel, the CCC was derived by applying an acute to-chronic ratio to the acute toxicity data. See Nickel Criteria Document at K-1.)

The LC50 of 415 ug/L for Physa gyrina that is driving the reduction in the acute and chronic aquatic toxicity values for nickel in the California proposal is derived from a study by A.V. Nebeker, et al., "Effects of Copper, Nickel and Zinc on Three Species of Oregon Freshwater Snails, " Environmental Toxicology and Chemistry 5:807-811 (1986). For the reasons discussed below, we do not believe that data from this study (which was conducted in part to develop new test methods) should be used to calculate CMC and CCC values for nickel.

Under the methodology used by EPA to derive CMC values, "results of acute tests during which the test organisms were fed shall not be used, unless data indicate that the food did not affect the toxicity of the test material(*6). The article by Nebeker, et al. does not mention whether or not the snails were fed during testing. When a NiPERA scientist contacted the study's lead investigator in August 1993, she was informed that the investigator believed the snails had been fed. A subsequent check of the original data book for the 96-hour and 30-day Physa gyrina zinc test conducted as part of the same study disclosed that food had indeed been placed in each test container.(*7) The data book for the Physa gyrina nickel test could not be found (apparently some archived material was lost when the EPA laboratory was closed in 1985). In the absence of the data book, the study's author explained that while animals normally are not fed during acute (96-hour) tests, they may have been fed in this instance because the investigators "were developing new test methods, as well as obtaining criteria data.(*8) The authors of the study simply "have no way to verify" whether or not the snails were fed in the Physa gyrina nickel test.(*9)

In these circumstances, data from the Physa gyrina nickel test should not be used to set water quality criteria, particularly since the authors' data book clearly shows that the snails were fed in the 96-hour zinc test performed by the same investigators, in the same series of tests, in the same lab.(*10) Another reason why data from the Physa gyrina nickel study should not be used is that the loss of the primary data notebook makes it impossible to verify the experimental conditions and results of the study.

Apart from the possibility that the snails were fed, data from the test by Nebeker, et al. should be interpreted cautiously because these particular snails are very sensitive to heavy metals, especially copper.(*11) In one of the snail species tested by Nebeker (Lithoglyphus virens), the 30-day LC50 for copper was found to be <0.004 mg/L, while in a second test of the same species, 50% of the snails died at a copper concentration of 0.008 mg/L (the lowest level tested) at 96 hours.(*12) Overall, Nebeker et al. noted that the effect levels they observed were "in the lower range of those that have been reported," a result they attributed in part to the extreme softness of their test water (approximately 20 mg/L) and the resulting "higher percentage of biologically active metal species (e.g., more Cu++ in solution).(*13) It may be that exposure to low ambient levels of copper and other metals in this extremely soft test water had compromised the overall health of the snails and made them more sensitive to nickel.(*14) In the absence of positive control data (which are not reported in the article and which are not otherwise available given the loss of the primary data notebooks), one cannot determine whether the snails' health was compromised.(*15)

In sum, substantial questions exist as to whether the study by Nebeker et al. -which was conducted in part to develop new test methods -- satisfies EPA's methodological criteria for developing acute aquatic toxicity values. The possibility (indeed, likelihood) that the snails were fed during the 96-hour test, the apparent heightened sensitivity of the organisms resulting from exposure to low levels of copper in the soft water while the snails were held in culture prior to testing, and the absence of a data notebook that would make it possible to verify the experimental conditions and results all suggest that data from this study should not be used to set freshwater aquatic toxicity criteria for nickel. This is particularly true in light of the fact that the LC50 value for the only other snail species for which acute nickel toxicity data are reported (Amnicola sp.) was 12,770 ug/L (adjusted to a hardness of 50 mg/L), a value that is 30 times higher than the LC50 reported by Nebeker et al. for Physa gyrina.(*16) This striking disparity between the LC50 values for the two snail species is an additional reason for excluding the data from the Nebeker et al. study of Physa gyrina in calculating the acute water quality criterion for nickel.(*17) With those data excluded, the freshwater CMC for nickel would be 1400 ug/L (adjusted to a hardness of 100 mg/L as CaCO3), and the freshwater CCC would be 160 ug/L (adjusted to a hardness of 100 mg/L as CaCO3). Those values (and the corresponding water hardness equation from which they are calculated) should be adopted as the numeric freshwater aquatic life criteria for nickel in the State of California.

(*17) Cf 58 Fed. Reg. at 21017/3 ("Acute values that appear to be questionable in comparison with other acute and chronic data for the same species and for other species in the same genus must not be used. For example, if the acute values available for a species or genus differ by more than a factor of 10, rejection of some or all of the values is probably appropriate.").

Response to: CTR-063-001

EPA does not agree that the Nebeker et al. test results should be rejected. EPA does not believe that the question of whether the snails were or were not fed is of overriding importance. Feeding of organisms is not desirable in acute tests because the material in the food may reduce the biological availability of the toxicant, thus reducing its toxicity and raising its LC50, and because feeding is generally not necessary in a short test. Feeding of organisms is necessary in chronic tests, because of their longer duration. EPA does not believe that the feeding of organisms in a either an acute or chronic test has any effect on increasing the sensitivity of organisms to the toxicant, and likewise does not believe that feeding of organisms in the Nebeker et al. test, if it had been done (which is not known), would explain the results.

EPA does not expect lab books to be retained for perpetuity and does not consider loss of the original lab books to be grounds for discarding the data.

EPA agrees that Physa gyrina appears to be significantly more sensitive than other species. EPA recognizes that in general the chemical characteristics of the lab water affect the toxicity of metals in

ways not taken into account by the hardness normalization. However, EPA does not have information indicating that the characteristics of the (very soft) lab water used in the Nebeker et al. test are so unusual as to be unrepresentative of California waters.

EPA has considered whether the organisms may have been stressed by the chemical characteristics of the lab water. However, subsequent communications with Nebeker revealed that the organisms have been successfully reproducing for years in ponds feed by the same wells that provided the lab water (Alan Nebeker memorandum to Charles Stephan, January 6, 1995). EPA can thus find no reason to believe that the control organisms were stressed.

Consequently, although Physa gyrina, as tested by Nebeker et al., is substantially more sensitive than other tested organisms, EPA has not found a good reason to reject the data. The freshwater nickel criterion in the rule is therefore unchanged for the final rule.

Comment: Validity Of Proposed Nickel And Cyanide Criteria On A Statewide Basis

Attachment 1 to this letter is a technical report entitled "Task Report 1: Update and Recalculation of the Freshwater and Saltwater Cyanide Criteria", dated November 5, 1996 and prepared by Tetra Tech, Inc. for the City of San Jose. Attachment 2 to this letter is a technical report entitled "Final Report Recalculation of the Nickel Criteria for South San Francisco Bay", dated November 1, 1995 and prepared by Tetra Tech, Inc. for the City of San Jose. All of the attachments to this letter are incorporated as part of our comments and are being submitted for inclusion in the record for this rulemaking.

EPA has an obligation to consider the most current, scientifically defensible data in this rulemaking. EPA's obligations in this regard are particularly significant in light of its obligations under Executive Order 12866 and the Regulatory Flexibility Act (5 U.S.C.A. 601 et seq.) to consider a full range of cost effective alternatives to promulgation of the proposed Rule.

Although the title of Attachments 1 and 2 suggest that the data submitted relates only to San Francisco Bay, the data in fact relates to the entire state of California, and indicates that lessstringent cyanide and nickel criteria than are proposed by the Rule would adequately protect water quality in California. Under the Executive Order 12866 and the Regulatory Flexibility Act, EPA should include consideration of the these less stringent criteria in its Economic Analysis.

Comment: Dear Ms. Frankel:

The San Luis & Delta-Mendota Water Authority objects to the freshwater selenium criteria set forth in Environmental Protection Agency's ("EPA") proposed "Water Quality Standards: Establishment of Numeric Criteria for Priority Toxic Pollutants in the State of California" (Federal Register Vol. 62, #150, pages 42160-42208, Tuesday, August 5, 1997) on the following grounds:

1. The criteria are based on data assembled before 1987 (as reported in EPA 440/5-87-003 "Ambient Water Quality Criteria for Selenium - 1987"). Therefore, the criteria do not take account of more recent data on selenium toxicity.

2. In particular, the freshwater selenium criteria are scientifically inadequate because they fail to take account of the known interference between selenate and sulfate uptake in high sulfate waters like those in the San Joaquin Valley {see, e.g., Ogle and Knight, Arch, Environ. Contam. Toxical, 30, 274-279 (1996); Williams et al., Arch. Environ. Contam. Toxicol. 27,449-453 (1994); Hansen et al., Arch. Environ. Contam. Toxicol. 25, 72-78 (1993)]. This interference means that criteria based largely on effects observed in the low sulfate waters of Belews Lake, North Carolina, are probably overprotective for the high sulfate waters of the San Joaquin Valley. EPA itself (Federal Register Vol. 62, #150, page 42168, Tuesday, August 5, 1997) explicitly recognizes this inadequacy by stating "Chemical toxicity is often related to certain receiving water characteristics (pH, hardness, etc.) of a water body. Adoption of some criteria without consideration of these parameters could result in the criteria being overprotective."

The proposed California Toxics Rule should not be adopted without adequately addressing the difference for high-sulfate waters. The Rule should also not be adopted if it undercuts EPA's commitment to the cooperative review of appropriate long-term standards in the San Joaquin River Basin.

Response to: CTR-008-001

EPA agrees with the comment that the proposed acute freshwater criteria equation for selenium should not be promulgated, and has decided not to promulgate the proposed freshwater acute criterion, however, not for all of the reasons specified by the commenter. EPA's proposed acute criterion for the California Toxics Rule was revised in 1996 to reflect newer data supporting the additive toxicity of two predominant selenium forms (selenite and selenate) and is expressed as an equation. The acute criterion equation is designed to account for the additive toxicity of selenite and selenate in freshwater ecosystems and relies on assumptions of the relative toxicity and additivity of other forms of selenium since the

separate and combined toxicity of these other forms present in natural aquatic systems is not well defined. In 1996, the revised acute criterion underwent external peer review and was proposed for adoption under the Great Lakes Water Quality Initiative (GLI) (61 FR 58444-58449, November 14, 1996). This proposal has not yet been finalized because EPA is currently responding to public comments, which have called to attention a significant source of uncertainty in the expression of the relative toxicity of selenite and selenate in EPA's proposed acute criteria equation. Specifically, EPA is responding to the comment that the relative acute toxicity of selenite and selenate as expressed by the proposed individual CMCs (185.9 ug/L and 12.8 ug/L, respectively) is not consistent with the weight of toxicological data suggesting the opposite relative toxicity relationship and is an artifact of nuances in the selenate data set (i.e., its relatively small size combined with one extremely sensitive toxicity test result for the amphipod, Gammarus pseudolimnaeus).

EPA is currently responding to this comment by conducting additional toxicity tests on the relative toxicity of selenite and selenate to G. pseudolimnaeus and other acutely sensitive species. EPA is also updating its acute toxicity database with newer information, including newer data on the potential sulfate dependency of acute selenium toxicity. Therefore, because additional toxicity tests may result in substantial changes in the relative acute toxicity relationship of selenite and selenate that was proposed in the GLI and subsequently in the California Toxics Rule, EPA has chosen defer promulgation of acute, freshwater criteria for selenium until after the new toxicity data have been fully evaluated and incorporated. Further, EPA will consider in its forthcoming update of selenium freshwater acute criteria newer information since 1987 on the importance of sulfate and other factors on selenium freshwater acute toxicity.

EPA disagrees with the commenter that the chronic freshwater selenium criterion of 5 ug/L should not be promulgated as proposed. First, EPA believes that its chronic criterion is scientifically defensible, because having been based on field data, it incorporates principles and effects of bioaccumulation of selenium in aquatic ecosystems which are critical for estimating a long-term (chronic) toxicological threshold for selenium. Second, EPA does acknowledge that since 1987 (the latest revision of the selenium freshwater CCC), additional data are available that might be germane to the freshwater CCC for selenium. However, unlike the acute criterion, where the new data have been collected and almost certainly will change the criterion, EPA can not predict at this time the impact of any new data on freshwater CCC. Currently, EPA is in the early stages of reviewing this data and is addressing technical issues whose impact on the CCC is not easily predicted (e.g., the impact of basing chronic toxicity thresholds on tissue residue concentrations vs. water column concentrations). To facilitate this review of the freshwater CCC, and to address many of the technical issues associated with selenium bioaccumulation and toxicity, EPA conducted a peer consultation workshop in May 1998 with selenium experts external to the Agency to ascertain the degree of scientific basis and consensus on these issues (EPA-822-R98-007).

Regarding the comment that EPA should not promulgate the CCC of 5 ug/L total recoverable selenium because it does not account for sulfate dependency, EPA disagrees. EPA disagrees with this comment because at this time, EPA believes that insufficient data exist to quantify the effect of sulfate on the chronic toxicity of selenium to aquatic life. Specifically, none of the data referenced by the commenter quantify the effect of sulfate dependency on the chronic toxicity of selenium forms to aquatic animals. Rather, they apply to the effect sulfate on selenium acute toxicity and bioaccumulation in aquatic animals, and its toxicity to algae. EPA's assertion of insufficient data on sulfate dependency of chronic toxicity is supported by the opinion of experts at EPA's 1998 peer consultation workshop who concluded: "...insufficient information exists to correlate water quality characteristics (such as sulfate, pH and TOC)" (p. 9 in EPA-822-R-98-007). Furthermore, EPA considers application of sulfate-toxicity relationships based on acute toxicity or bioaccumulation to chronic toxicity to be highly uncertain and

unreliable. This conclusion is also supported by expert option, who concluded that toxicity relationships derived from acute toxicity studies cannot be reliably extrapolated to chronic toxicity, owing to the important influence of dietary exposure on selenium chronic toxicity (p. 9 in EPA-822-R-98-007). After EPA's review of the available information and expert opinions, EPA believes that it would be premature to withdraw its proposed CCC of 5 ug/L because it does not address possible effects of sulfate on selenium chronic toxicity.

Comment: At Federal Register page 42170, EPA begins its discussion about the derivation of its proposed Selenium criterion. This criterion is essentially based on a very few site specific field situations, and is applied, generally, to all situations regardless of how dissimilar they may be to the criterion spawning field incidents. The Kesterson Slough/Belews Lake type of problems and aquatic toxicity have not been found in other waters where Selenium is present in elevated concentrations, but that lack the sediment/food-chain conditions of these particular water bodies. Recent investigators found that Selenium water column concentrations were poor predictors of aquatic toxicity, and instead, posit a rationale for sediment-based toxicity criteria that EPA should consider as part of this rulemaking. (Selenium Sediment Toxicity Thresholds and Derivation of Water Quality Criteria for Freshwater Biota of Western Streams, Van Derveer and Canton, Environmental Technology and Chemistry and Selenium Toxicity to Aquatic Life: An Argument for Sediment-Based Water Quality Criteria, Canton and Van Derveer, Environmental Toxicology and Chemistry. Copies enclosed)

Response to: CTR-009-005

EPA derived its CCC for selenium using the Belews lake data in combination with laboratory data because laboratory toxicity data have been shown to consistently underestimate selenium effect levels compared to field situations. This underestimation of adverse effect levels by laboratory toxicity data is believed to be due to the bioaccumulation of selenium in aquatic food webs and subsequent exposure in top predator fish; a phenomenon which occurs in the field but not in routine laboratory tests. EPA acknowledges the conditions at Belews Lake that may differ from those at sites to which the CCC of 5 ug/L is applied. However, as discussed in EPA's response to CTR-058-006, EPA believes that the Belews lake data are reasonably consistent with adverse effect levels observed in other types of ecosystems and are scientifically defensible. For example, Hermanutz et al. (1992) and Schultz and Hermanutz (1990) studied the effects of chronic selenium exposure in large outdoor experimental streams in Minnesota on bluegill and fathead minnow, respectively. Despite the potential effect that the different hydrology of Belews lake and the Minnesota streams might have on selenium effect levels, the two stream studies showed adverse effects at levels similar to those observed in Belews lake (i.e., 10 ug/L). Furthermore, Lemly (1993) exposed bluegill in the laboratory to combined dietary (5.1 ug/g dry weight) and waterborne (4.8 ug/L) selenium and adverse effects including significant mortality in 60

days compared to fish in equivalent warm water exposures. Thus, EPA believes that the similarity between the adverse effect levels associated with Belews lake and the stream and laboratory studies supports the notion that EPA's CCC for selenium can be reasonably applied to other aquatic ecosystems.

Regarding sediment-based criteria, EPA believes that basing the CCC on concentrations of selenium in sediments is premature at this time because of the lack of scientific consensus on this issue and because of the preliminary nature and limited scope of the studies cited by the commenter. This assertion is generally supported by the opinions of experts at EPA's May 1998 peer consultation workshop on selenium who characterize the selenium/sediment toxicity database as sparse and largely limited to observations in western streams (p. 37-38 in EPA-822-R-98-007).

Comment: Comments on the Proposed Selenium Freshwater Acute Criteria

The Regional Board supports EPA's efforts to develop an acute criterion for selenium that takes into account the presence of several oxidation states in natural waters, and the different and additive nature of toxicity associated with these different forms. The Board also supports EPA's determination that the existing chronic aquatic life criterion should not be modified to include consideration of different chemical species and that selenium interconverts from one chemical species to another in ambient waters. There are several practical consequences associated with the proposed additive toxicity approach that we would like to address from the perspective of our experience with selenium-related environmental problems in the San Francisco Bay Region.

The first comment is that the bioaccumulative potential of different chemical forms of selenium appears to be precisely the reverse of the toxicity potentials. For example, selenite is much more easily taken up into the food chain (preliminary estimates derived here in the Region are that selenite is about 10 times more bioavailable than selenate) but the proposed toxicity-based calculation method indicates precisely the opposite--that about ten times more selenite than selenate can be in the water column without causing unacceptable effects. The proposed model may work in systems that quickly flush out selenium such as stream segments, but do not accurately reflect conditions where selenium concentrations are elevated and occasionally spike upwards towards levels where acute toxic effects may occur-in the latter, bioaccumulative problems are likely more sensitive environmental endpoints. Thus, as a practical matter, the side-by-side application of the proposed acute and existing chronic criterion could have the unanticipated effect of over regulating selenate- and underregulating selenite-related bioaccumulation problems. For this reason, we recommend not using the proposed toxicity-based approach for a new acute criterion without additional considerations.

Additional considerations that EPA could make before changing the acute criterion to address this

practical problem include (a) reviewing the chronic criterion with the intent of including information to distinguish the bioaccumulative potential (and interconversion) of different chemical forms of selenium; (b) developing an alternative method for the acute criterion that takes into account the effect of short-term increases in selenium in aquatic systems on sensitive ecological indicators such as bird reproductive effects; or (c) developing more detailed guidance on the application of the acute and chronic criteria that would distinguish between aquatic systems potentially stressed with elevated levels of selenium in the food chain and those where such stresses are not a concern and the acute criteria are appropriate indicators of short-term problems.

Response to: CTR-016-005

EPA agrees with the commenter that it would be premature to promulgate the proposed freshwater acute criteria for selenium, and has chosen to defer promulgation of freshwater acute criteria for selenium until such time EPA has completed its evaluation of additional data and response to earlier comments on the proposed CMC equation in (61 FR58444, November 14, 1996. For additional detail on why EPA has chosen to defer promulgation of the freshwater CMC equation, see EPA's response to CTR-008-001.

Comment: II. ISSUES NEEDING CLARIFICATION OR MAJOR SUBSTANTIVE CHANGES

A. EPA's Proposed Selenium Acute Criterion is Technically Deficient

EPA's consideration of the toxicity of selenium has rapidly evolved over the last several years. In the Great Lakes Water Quality Rule (60 Fed. Reg. 15,366 (Mar. 23, 1995)), EPA proposed a selenium acute criterion that failed to consider the differing toxicities of two prevailing types of selenium, selenite and selenate. UWAG and other industry groups challenged the selenium acute criterion, and EPA eventually agreed to a remand of the criterion. The Court, however, ordered that the criterion be vacated and remanded. Following the vacatur, in November 1996 EPA proposed a new Great Lakes selenium acute criterion, adjusted to account for the selenite/selenate differences. UWAG submitted comments on the proposal, which are attached and incorporated into this comment document. (Attachment A). In the California proposal, EPA proposes to apply a selenium acute criterion that is identical to that proposed for the Great Lakes. EPA is still considering the comments it received in response to its revised acute selenium criterion for the Great Lakes - it has not taken final action on the proposal. UWAG therefore believes it would be inappropriate to promulgate the selenium acute criterion for California until the Agency has thoroughly assessed the record for the Great Lakes selenium acute criterion, and has determined appropriate final action on the Great Lakes criterion.

In commenting on the Great Lakes selenium acute criterion, UWAG raised the following points:

(1) EPA should reexamine and expand the LC50 database underlying the criteria maximum concentration (CMC) for selenate, which as currently derived is inconsistent with the vast majority of the available toxicity data for selenate and selenite;

(2) EPA should acknowledge and provide guidance for taking into account the effect of varying sulfate levels on selenium toxicity;

(3) EPA should acknowledge and provide guidance for dealing with situations where simple additivity does not occur;

(4) EPA should acknowledge and provide guidance for distinguishing between organic forms of selenium and elemental selenium, which may be found in anaerobic water under reducing conditions;

(5) EPA should provide guidance on where in the waterbody the proportions of selenate, selenite, and organo-selenium will be determined; and

(6) EPA should avoid making unfounded assumptions about the effect of potential selenium bioaccumulation on the CMC, and should delete from its final guidance or rule any discussion of unproven methodologies taking such bioaccumulation into account.

All of these arguments apply with equal force to the proposed acute selenium criterion for California. For further elaboration of each of these points, see Attachment A.

Response to: CTR-030-005

EPA agrees with the commenter that it would be premature to promulgate the proposed freshwater acute criteria for selenium, and has chosen to defer promulgation of freshwater acute criteria for selenium until such time EPA has completed its evaluation of additional data and response to earlier comments on the proposed CMC equation in (61 FR58444, November 14, 1996. For additional detail on why EPA has chosen to defer promulgation of the freshwater CMC equation, see EPA's response to CTR-008-001.

Comment: Dear Mr. Morris:

On behalf of the Utility Water Act Group ("UWAG")(*1), we are writing to comment on EPA's "Proposed Selenium Criterion Maximum Concentration for the Water Quality Guidance for the Great Lakes System," published at 61 Fed. Reg. 58,444 (Nov. 14, 1996). UWAG appreciates the Agency's

decision to extend the comment period(*2) for the selenium criterion maximum concentration ("CMC"), in light of the important technical issues raised by this proposed rule.

After reviewing the proposal, UWAG has the following recommendations:

(1) EPA should re-examine and expand the LC50 database underlying the criteria maximum concentration ("CMC") for selenate, which as currently derived is inconsistent with the vast majority of the available toxicity data for selenate and selenite;

(2) EPA should acknowledge and provide guidance for taking into account the effect of varying sulfate levels on selenium toxicity;

(3) EPA should acknowledge and provide guidance for dealing with situations where simple additivity does not occur;

(4) EPA should acknowledge and provide guidance for distinguishing between organic forms of selenium and elemental selenium, which may be found in anaerobic waters under reducing conditions;

(5) EPA should provide guidance on where in the waterbody the proportions of selenate, selenite, and organo-selenium will be determined; and

(6) EPA should avoid making unfounded assumptions about the effect of potential selenium bioaccumulation on the CMC, and should delete from its final guidance or rule any discussion of unproven methodologies taking such bioaccumulation into account.

Each of these recommendations is discussed in greater detail below.

1. THE CALCULATED CMC FOR SELENATE IS INCONSISTENT WITH THE VAST MAJORITY OF THE SCIENTIFIC DATA. THUS, EPA SHOULD REEXAMINE AND EXPAND THE DATABASE UNDERLYING THE CMC FOR SELENATE BEFORE GOING FORWARD.

EPA's proposed equation for calculating a CMC for total selenium relies on CMCs for selenite and scienate that the Agency calculated in the "Ambient Water Quality Criteria for Selenium -- 1987" (EPA 440/5-87-008) (the "1987 Criteria Document") and in the "Great Lakes Water Quality Initiative Criteria Document for the Protection of Aquatic Life in Ambient Water (EPA-8200-B-95-004) (the " 1995 Criteria Document"). See 61 Fed. Reg. 58,447. The CMC for selenate, which is fourteen times lower than the CMC for selenite(*3), is particularly troublesome, given that the overwhelming weight of the toxicological evidence indicates that selenate is less toxic than selenite. See Attachment A to these comments. This is apparent both from the data cited in EPA's 1987 Criteria Document and from numerous published papers in which a given researcher compared selenate and selenite toxicity in paired tests. Looking at the entire EPA database for selenate and selenite for all species where there are LC, values for both oxidation states, Gammarus pseiidolimnaeus is the only genus with a selenite LC50, to selenate LC50, ratio of less than one (1). While the ratio for Gammarus is 0.024, the range of ratios for all other genera range from 1.46 (for Daphnia) to 5.53 (for A. hypnorum (snail)).

A review of the CMC for selenate indicates that this anomalous result is caused by a combination of three factors: (1) the inclusion in the LC50, database for selenate of a Genus Mean Acute Value ("GMAV") of 0.065 mg/l for Gammarus pseudolimnaeus; (2) the fact that the database for selenate is relatively sparse (consisting of only eight GMAVS); and (3) the application of EPA's standard statistical technique for calculating CMCS, which produces results that are highly conservative in situations where

data are sparse and there is a substantial gap between the most sensitive species and the next most sensitive species.

UWAG believes that this combination of factors has lead EPA to derive a CMC for selenate that is inconsistent with the vast majority of comparative toxicity data. As two of the peer reviewers who commented on the July 1996, Draft Addendum to the 1987 Water Quality Criteria Document for Selenium (the "Draft Addendum") noted, this result appears questionable at best. See Adams, W.J., "Review of Selenium Water Quality Criteria: Revised" at p. 9 (undated) ("Adams Comments") (Attachment B to these comments); and DeGraeve, G.M., and McIntyre, D.O., "Review of The 'Freshwater CMC for Selenium: Addendum to Ambient Water Quality Criteria for Selenite -- 1987'" at p. 2 (Aug. 16, 1996) (Attachment C to these comments).

For example, Dr. Adams noted that another freshwater amphipod, Hyalella azteca, followed the expected pattern of toxicity and was more sensitive to seleaite than selenate. Adams Comments at 9. As Dr. Adams notes, one would expect selenate to be less toxic than selenite, because selenate is more chemically stable and less likely to be metabolized as organo-selenium. Id.

Several technical concerns with the two studies of Gammarus pseudolimnaeus by Brooke, et al., on which the GMAV is based, could have affected the accuracy of the results. First, Brooke et al. did not report the background concentrations of likely contaminants in the City of Superior water used in the tests. Thus, it is not possible to assess whether such contaminants may have affected the test results.

Second, the researchers do not report the actual concentration of selenate (or selenite) during or after the test. Instead, they appear to have made the assumption that no conversion occurred. Such assumptions are inappropriate, as evidenced by EPA's protocol for the Water Effects Ratio procedure, which requires that both the total recoverable and dissolved forms of the metal be measured at the start and end of any static exposure test. U.S. EPA, 1994 Interim Guidance on Determination and Use of Water Effect Ratios for Metals, EPA-823-B-94-001, pp. 55-56.

Third, UWAG questions the propriety of the researchers' decision to prepare their own reference standard solution, which they apparently used both to calibrate their measurement instruments and to prepare the test dilutions. Such a procedure is not standard, and could lead to biased results.

In sum, EPA should not blindly use the Brooke, et al., data for Gammarus without further verification, nor should it apply the standard criteria derivation procedure to the available data without first considering the suitability of that procedure in light of the inconsistency between the result obtained and the overwhelming weight of the available evidence. UWAG understands that EPA has commissioned additional acute toxicity tests of three species -- Gammarus pseudolittviaeus, Daphnia magna, and Ceriodaphnia dubia -- with both selenate and selenite. UWAG applauds this effort. We urge the Agency to forego taking any final action on issuance of a selenium CMC for the Great Lakes until those tests are complete and have been subject to review and comment.

(*1) UWAG is a voluntary, ad hoc, non-profit, unincorporated group of seventy-three electric utility systems, which own and operate over fifty percent of the nation's total generating capacity. The Edison Electric Institute, the American Public Power Association, and the National Rural Electric Cooperative Association also are UWAG members.

(*2) 61 Fed. Reg. 66,007 (Dec. 16, 1996).

(*3) EPA appears to have reversed the CMCs for selenate and selenite in the discussion at 61 Fed. Reg. 58,446, col. 2 (Section B. 1.3.a. and b. of the proposal). In other places in the notice (e.g., 61 Fed. Reg. 58,445, col. 2), EPA correctly states that the calculated CMC for selenite is 185.9 ug/l and the CMC for scienate is 12.82 ug/l.

Response to: CTR-030-011

For reasons specified in the response to CTR-008-001, EPA agrees with the comment that the acute toxicity database for selenate should be reexamined prior to promulgating the proposed acute criterion for selenium. As described in the response to CTR-008-001, EPA is not promulgating its proposed freshwater acute criterion for selenium and is conducting additional acute toxicity tests on Gammarus pseudolimnaeus and two species of daphnids to confirm the relative toxicity of selenite and selenate.

Comment: Dear Mr. Morris:

On behalf of the Utility Water Act Group ("UWAG")(*1), we are writing to comment on EPA's "Proposed Selenium Criterion Maximum Concentration for the Water Quality Guidance for the Great Lakes System," published at 61 Fed. Reg. 58,444 (Nov. 14, 1996). UWAG appreciates the Agency's decision to extend the comment period(*2) for the selenium criterion maximum concentration ("CMC"), in light of the important technical issues raised by this proposed rule.

After reviewing the proposal, UWAG has the following recommendations:

(1) EPA should re-examine and expand the LC50, database underlying the criteria maximum concentration ("CMC") for selenate, which as currently derived is inconsistent with the vast majority of the available toxicity data for selenate and selenite;

(2) EPA should acknowledge and provide guidance for taking into account the effect of varying sulfate levels on selenium toxicity;

(3) EPA should acknowledge and provide guidance for dealing with situations where simple additivity does not occur;

(4) EPA should acknowledge and provide guidance for distinguishing between organic forms of selenium and elemental selenium, which may be found in anaerobic waters under reducing conditions;

(5) EPA should provide guidance on where in the waterbody the proportions of selenate, selenite, and

organo-selenium will be determined; and

(6) EPA should avoid making unfounded assumptions about the effect of potential selenium bioaccumulation on the CMC, and should delete from its final guidance or rule any discussion of unproven methodologies taking such bioaccumulation into account.

Each of these recommendations is discussed in greater detail below.

II. EPA SHOULD ACKNOWLEDGE AND PROVIDE GUIDANCE ON TAKING INTO ACCOUNT THE MODERATING EFFECTS OF SULFATE LEVELS ON SELENIUM TOXICITY.

The available evidence suggests that the toxicity of selenium to certain taxa decreases as sulfate concentrations increase. This relationship may be expected, because sulfur and selenium are chemically similar and follow many of the same physical, chemical, and biological pathways. Stadtman, T.C., 1974. Selenium Biochemistry. Scietice. 183:915-922. Thus, sulfur seems to directly compete with selenium at the molecular level.

For example, the relationship between sulfate concentrations and selenate toxicity was examined in a paper by Ogle and Knight (1996). The authors compiled all of the published data from acute toxicity tests on Daphnia magna in which sulfate was measured. They found a highly significant correlation (r-square value = 0.84) using untransformed data.(*4) This strong correlation clearly indicates that the toxicity of selenate decreases as the concentration of sulfur increases.

In its proposed addenda to the 1987 Criteria Document, EPA acknowledges that sulfate may decrease the toxicity of selenate and selenite.(*5) But UWAG believes that this issue specifically warrants more prominent discussion in the preamble to any final rule published by EPA. UWAG urges EPA to advise states, as part of this rulemaking, to consider the potential mitigating effects of sulfate on selenium toxicity, and to take those effects into account when establishing their own criteria.

In both the Draft Addendum and the September 1996 Addendum,(*6) EPA also says that the Water Effects Ratio ("WER") procedure for deriving site-specific criteria can be used to derive appropriate criteria in situations where sulfate levels affect selenium toxicity. While UWAG agrees that such a procedure could be an appropriate mechanism for taking into account the moderating effects of sulfate, it is not clear how EPA anticipates the WER procedure would be applied.

For example, would it be applied to develop site-specific CMCs for selenate and selenite respectively, which could then be used in EPA's equation? Or does EPA expect that the WER procedures would somehow be applied to examine the effect of sulfate on the toxicity of the mixture of several selenium forms? If the latter, it is not clear how the procedure would work, since application of the WER typically involves comparison of the toxicity of a given pollutant in source waters with toxicity exhibited in the laboratory tests on which the generic criterion is based. Because EPA's proposed selenium CMC is based not on toxicity tests of mixtures, but instead on an equation that relies on calculated CMCs based on laboratory tests of two distinct selenium oxidation states, EPA should explain how the WER should be applied in this situation.

(*1) UWAG is a voluntary, ad hoc, non-profit, unincorporated group of seventy-three electric utility systems, which own and operate over fifty percent of the nation's total generating capacity. The Edison Electric Institute, the American Public Power Association, and the National Rural Electric Cooperative Association also are UWAG members.

(*2) 61 Fed. Reg. 66,007 (Dec. 16, 1996).

(*4) An even higher correlation would be expected if the data were log-transformed (the procedure EPA uses when examining the relationship between metal hardness and acute toxicity).

(*5) Draft Addendum at p. 3-6; U.S. EPA, "The Freshwater CMC for Selenate: Addendum to Ambient Water Quality Criteria for Selenium -- 1987" (Sept. 30, 1996) ("September 1996 Addendum") at p. 6.

(*6) See July 1996 Draft Addendum at p. 3-6; September 1996 Draft Addendum at p.6.

Response to: CTR-030-012

For the reasons specified in the response to CTR-008-001, EPA is not promulgating its proposed freshwater acute criteria for selenium. EPA is currently generating and evaluating additional toxicity data (including those that evaluate sulfate dependency of acute toxicity) to facilitate its review of the acute criterion for selenium.

Comment: Dear Mr. Morris:

On behalf of the Utility Water Act Group ("UWAG")(*1), we are writing to comment on EPA's "Proposed Selenium Criterion Maximum Concentration for the Water Quality Guidance for the Great Lakes System," published at 61 Fed. Reg. 58,444 (Nov. 14, 1996). UWAG appreciates the Agency's decision to extend the comment period(*2) for the selenium criterion maximum concentration ("CMC"), in light of the important technical issues raised by this proposed rule.

After reviewing the proposal, UWAG has the following recommendations:

(1) EPA should re-examine and expand the LC50 database underlying the criteria maximum concentration ("CMC") for selenate, which as currently derived is inconsistent with the vast majority of the available toxicity data for selenate and selenite;

(2) EPA should acknowledge and provide guidance for taking into account the effect of varying sulfate levels on selenium toxicity;

(3) EPA should acknowledge and provide guidance for dealing with situations where simple additivity does not occur;

(4) EPA should acknowledge and provide guidance for distinguishing between organic forms of selenium and elemental selenium, which may be found in anaerobic waters under reducing conditions;

(5) EPA should provide guidance on where in the waterbody the proportions of selenate, selenite, and organo-selenium will be determined; and

(6) EPA should avoid making unfounded assumptions about the effect of potential selenium bioaccumulation on the CMC, and should delete from its final guidance or rule any discussion of unproven methodologies taking such bioaccumulation into account.

Each of these recommendations is discussed in greater detail below.

III. EPA SHOULD ACKNOWLEDGE AND PROVIDE GUIDANCE FOR DEALING WITH SITUATIONS WHERE SIMPLE ADDITIVITY DOES NOT OCCUR

EPA has not provided any guidance to the states on how to determine whether something less (or greater) than simple additivity might be occurring. While EPA notes in the September 1996 Addendum at p. 6 that the WER procedure might be used to account for "possible deviations from additivity," it does not explain how the WER could be used to accomplish this. For the reasons discussed above, it is not clear how the WER would be adapted for use in this context, where effects of a mixture under actual instream conditions are being compared to effects of separate metal oxidation states in laboratory tests.

UWAG believes that EPA has an obligation both to provide a more reasoned basis for its assumption that simple additivity occurs, and to explain what and how available procedures may be used to develop defensible criteria in situations where such additivity may not be occurring.

Comment: Dear Mr. Morris:

On behalf of the Utility Water Act Group ("UWAG")(*1), we are writing to comment on EPA's "Proposed Selenium Criterion Maximum Concentration for the Water Quality Guidance for the Great Lakes System," published at 61 Fed. Reg. 58,444 (Nov. 14, 1996). UWAG appreciates the Agency's decision to extend the comment period(*2) for the selenium criterion maximum concentration ("CMC"), in light of the important technical issues raised by this proposed rule.

After reviewing the proposal, UWAG has the following recommendations:

(1) EPA should re-examine and expand the LC50 database underlying the criteria maximum concentration ("CMC") for selenate, which as currently derived is inconsistent with the vast majority of the available toxicity data for selenate and selenite;

(2) EPA should acknowledge and provide guidance for taking into account the effect of varying sulfate levels on selenium toxicity;

(3) EPA should acknowledge and provide guidance for dealing with situations where simple additivity does not occur;

(4) EPA should acknowledge and provide guidance for distinguishing between organic forms of selenium and elemental selenium, which may be found in anaerobic waters under reducing conditions;

(5) EPA should provide guidance on where in the waterbody the proportions of selenate, selenite, and organo-selenium will be determined; and

(6) EPA should avoid making unfounded assumptions about the effect of potential selenium bioaccumulation on the CMC, and should delete from its final guidance or rule any discussion of unproven methodologies taking such bioaccumulation into account.

Each of these recommendations is discussed in greater detail below.

IV. EPA SHOULD ACKNOWLEDGE AND PROVIDE GUIDANCE FOR DISTINGUISHING BETWEEN ORGANIC FORMS OF SELENIUM AND ELEMENTAL SELENIUM.

EPA proposes to employ an equation for calculating a CMC for total selenium, in part to address the potential toxicity of certain organo-selenium forms, which EPA says may be more toxic than selenate or selenite. EPA proposes to "assume that half of the measured or derived concentration of 'other' selenium forms is as toxic as selenate and half is as toxic as selenite." 61 Fed. Reg. 58,446. This proposal is troubling because it suggests that EPA may intend to allow states to "derive" organo-selenium concentrations by (1) measuring total selenium, selenate, and selenite; (2) subtracting the amount of selenite and selenate from the amount of total selenium; and (3) assuming that the difference is all organo-selenium, which EPA assumes is always at least as toxic as selenite or selenate.

Yet recent reviews of selenium cycling data show that some of that "other" selenium is likely to be elemental selenium, especially in anaerobic waters under reducing conditions. Maier, K.J. and A.W.

Knight. 1994: Ecotoxicity of selenium in freshwater systems. Reviews of Environmental Contamination and Toxicology. 134:31-48. Because of its insolubility and affinity for anoxic sediments, elemental selenium is far less bioavailable and, hence, less toxic than other selenium forms.

EPA's assumptions regarding the toxicity of organo-selenium forms clearly are based on a very limited amount of data on certain organic selenium forms. EPA has no data showing that either elemental selenium, or organic forms of selenium other than those for which data are provided in the proposal, are as or more toxic than selenite or selenate. Thus, EPA should specify that only measured amounts of the organic selenium forms for which it has sufficient toxicity data are to be included in the calculation. Equally important, EPA should specify that elemental selenium should be excluded from the calculation.

(*1) UWAG is a voluntary, ad hoc, non-profit, unincorporated group of seventy-three electric utility systems, which own and operate over fifty percent of the nation's total generating capacity. The Edison Electric Institute, the American Public Power Association, and the National Rural Electric Cooperative Association also are UWAG members.

(*2) 61 Fed. Reg. 66,007 (Dec. 16, 1996).

Response to: CTR-030-014

For the reasons specified in the response to CTR-008-001, EPA is not promulgating its proposed freshwater acute criteria for selenium.

Comment: Dear Mr. Morris:

On behalf of the Utility Water Act Group ("UWAG")(*1), we are writing to comment on EPA's "Proposed Selenium Criterion Maximum Concentration for the Water Quality Guidance for the Great Lakes System," published at 61 Fed. Reg. 58,444 (Nov. 14, 1996). UWAG appreciates the Agency's decision to extend the comment period(*2) for the selenium criterion maximum concentration ("CMC"), in light of the important technical issues raised by this proposed rule.

After reviewing the proposal, UWAG has the following recommendations:

(1) EPA should re-examine and expand the LC50 database underlying the criteria maximum concentration ("CMC") for selenate, which as currently derived is inconsistent with the vast majority of the available toxicity data for selenate and selenite;

(2) EPA should acknowledge and provide guidance for taking into account the effect of varying sulfate levels on selenium toxicity;

(3) EPA should acknowledge and provide guidance for dealing with situations where simple additivity does not occur;

(4) EPA should acknowledge and provide guidance for distinguishing between organic forms of selenium and elemental selenium, which may be found in anaerobic waters under reducing conditions;

(5) EPA should provide guidance on where in the waterbody the proportions of selenate, selenite, and organo-selenium will be determined; and

(6) EPA should avoid making unfounded assumptions about the effect of potential selenium bioaccumulation on the CMC, and should delete from its final guidance or rule any discussion of unproven methodologies taking such bioaccumulation into account.

Each of these recommendations is discussed in greater detail below.

V. EPA SHOULD CLARIFY THAT THE PROPORTION OF SELENITE, SELENATE, AND ORGANO-SELENIUM FORMS ARE TO BE DETERMINED INSTREAM, UNDER FULLY MIXED CONDITIONS.

EPA's proposal does not specifically discuss where in the waterbody the determination should be made as to the relative amounts of selenite, selenate, and organo-selenium present. Because water quality criteria are designed to protect aquatic organisms from plausible exposures instream,(*7) it seems logical that states would make this determination under fully mixed instream conditions(*8).

While the proposal does not discuss this point, on p. 58,448 it refers to deriving the acute criteria for selenium "depending on the relative proportions of the various forms of selenium in a facility's discharge." EPA has provided no explanation or support for making the determination on a discharge-by-discharge basis, nor would such an approach be consistent with the purpose of EPA's water quality criteria. Moreover, such an approach appears inconsistent with EPA's statements about the potential for chemical conversion of different selenium forms in ambient waters and the effects of water chemistry on various selenium forms. See 61 Fed. Reg. 58,446. Thus, an approach which requires determination of relative proportions instream, under the exposure conditions that are likely to occur, would seem the more technically sound and logically consistent approach in most cases.

(*1) UWAG is a voluntary, ad hoc, non-profit, unincorporated group of seventy-three electric utility systems, which own and operate over fifty percent of the nation's total generating capacity. The Edison Electric Institute, the American Public Power Association, and the National Rural Electric Cooperative Association also are UWAG members.

(*2) 61 Fed. Reg. 66,007 (Dec. 16, 1996).

(*7) See, e.g., U.S. EPA, Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses (1985).

(*8) UWAG recognizes that, in some cases, the concentrations of various selenium forms instream may

be so low as to make accurate analysis infeasible. In such cases, it may be more appropriate to allow for testing of the different selenium forms at the discharge point, as long as factors that are likely to affect selenium chemistry instream are taken into account.

Response to: CTR-030-015

For the reasons specified in the response to CTR-008-001, EPA is not promulgating its proposed freshwater acute criteria for selenium. When EPA finalizes its freshwater acute criterion for selenium, EPA will consider providing additional guidance on the determination of the fractions of total selenium that exist in various forms.

Comment: Dear Mr. Morris:

On behalf of the Utility Water Act Group ("UWAG")(*1), we are writing to comment on EPA's "Proposed Selenium Criterion Maximum Concentration for the Water Quality Guidance for the Great Lakes System," published at 61 Fed. Reg. 58,444 (Nov. 14, 1996). UWAG appreciates the Agency's decision to extend the comment period(*2) for the selenium criterion maximum concentration ("CMC"), in light of the important technical issues raised by this proposed rule.

After reviewing the proposal, UWAG has the following recommendations:

(1) EPA should re-examine and expand the LC50 database underlying the criteria maximum concentration ("CMC") for selenate, which as currently derived is inconsistent with the vast majority of the available toxicity data for selenate and selenite;

(2) EPA should acknowledge and provide guidance for taking into account the effect of varying sulfate levels on selenium toxicity;

(3) EPA should acknowledge and provide guidance for dealing with situations where simple additivity does not occur;

(4) EPA should acknowledge and provide guidance for distinguishing between organic forms of selenium and elemental selenium, which may be found in anaerobic waters under reducing conditions;

(5) EPA should provide guidance on where in the waterbody the proportions of selenate, selenite, and organo-selenium will be determined; and

(6) EPA should avoid making unfounded assumptions about the effect of potential selenium bioaccumulation on the CMC, and should delete from its final guidance or rule any discussion of unproven methodologies taking such bioaccumulation into account.

Each of these recommendations is discussed in greater detail below.

VI. EPA'S ASSUMPTIONS REGARDING THE POTENTIAL EFFECTS OF SELENIUM "BODY BURDENS" ON THE ACUTE TOXICITY OF SELENIUM ARE NOT SUPPORTED BY SOUND SCIENCE, AND SHOULD BE DELETED FROM ANY FINAL RULE OR ADDENDUM EPA ULTIMATELY ISSUES.

In its proposal, EPA says that it is not proposing to amend the 304(a) criteria document for acute or chronic selenium embodied in the EPA document entitled "Ambient Water Quality Criteria for Selenium -- 1987" (EPA 440/5-87-0008). 61 Fed. Reg. 58,445, col. 1. Thus, EPA says, it does not intend to respond to any comments on that document. Yet on the same page, EPA also says that it is proposing to incorporate into the 1987 Criteria Document an addendum(*9) reflecting its new proposed approach for calculating a selenium CMC. 61 Fed. Reg. 58,445, col. 3. UWAG believes that EPA should clarify whether or not it intends by this rulemaking to affect the national criteria guidance document. If so, EPA should provide potentially interested persons appropriate notice and an opportunity to conunent on the implications of applying this approach beyond the Great Lakes.

UWAG agrees with EPA's decision not to go forward with any proposal based on the theory, set forth in the Draft Addendum and the September 1996 Addendum, that fish exposed to organic selenium may carry a "body burden" that makes them more sensitive to acute selenium exposure. We agree that there are no hard data Co support this theory and, thus, reliance on it would be indefensible. Although elevated bioaccumulation of selenium occurring as a result of long-term exposure has been associated with reproductive impairment and mortality in some environments, EPA has provided no technical support for the notion that a certain level of selenium "body burden" predisposes an aquatic organism to greater, or lesser, sensitivity to acute exposures.

Furthermore, even if there were some theoretical or experimental basis for the hypothesis that a "body burden" of selenium increases an organism's sensitivity to acute effects, there is no rational basis for its application to a Great Lake. Great Lakes waters typically contain undetectable concentrations of selenium. Low background concentrations, combined with the enormous size of the Great Lakes and the migratory nature of Great Lakes fish, do no provide the same opportunity for bioaccumulation which might theoretically exist in small, well-mixed water bodies. This premise is confirmed by actual selenium levels in Great Lakes fish, which do not contain elevated concentrations of selenium (Schmitt and Brumbaugh, 1990).(*10) A "body burden" model is therefore particularly inappropriate for the Great Lakes.

In the same vein, we agree with EPA's decision not to propose Guidance implementing an unsupported theory that pollutants should be placed in one of three categories, based on their potential to bioconcentrate and bioaccumulate, and that this potential be taken into account in deriving criteria. The theories contained in this section of the Addendum amount to pure speculation, supported by little or no empirical data. The relationship between body burdens and toxic effects is very controversial, and there is no scientific consensus that bioaccumulation per se results in adverse effects (e.g., Chapman, 1996).(*11) For example, Reash et al. (1996)(*12) showed that bluegills exposed to water selenium concentration, much higher than EPA's criterion continuous concentration ("CCC") of 5 ILglf resulted in elevated bioaccumulation of seleaium but these "body burdens" did not cause mortality or reproductive impairment in the population. Moreover, the presence of additional pollutants which contribute to the

entire "body burden" of pollutants in an organism makes the relationship between tissue levels of one pollutant and adverse effects quite unclear. Heinz (1996) sununarized these concerns when discussing the significance of selenium residues in birds:

Selenium's ability to interact with other enviroru-nental contaminants, especially other elements, also sometimes complicates an interpretation of toxic thresholds in tissues of birds . . . the reader needs to be aware that such interactions exist."

In summary, EPA's theory that a "body burden" of selenium could increase an organism's sensitivity to acute selenium exposure is interesting scientifically, but EPA currently has no mechanism to link the two processes. Furthermore, this concept makes little sense froi-ii an exposure viewpoint. Bioaccumulation occurs over a much longer period in an organism's life cycle relative to acute effects. Hence, UWAG strongly recommends that EPA keep the distinctions between acute and chronic exposure/effect unambiguous. Therefore, UWAG urges EPA to delete this discussion from any guidance or Addendum it issues for any selenium CMC.

(*1) UWAG is a voluntary, ad hoc, non-profit, unincorporated group of seventy-three electric utility systems, which own and operate over fifty percent of the nation's total generating capacity. The Edison Electric Institute, the American Public Power Association, and the National Rural Electric Cooperative Association also are UWAG members.

(*2) 61 Fed. Reg. 66,007 (Dec. 16, 1996).

(*9) It is not clear whether the September 1996 Addendum to which EPA refers is a draft or final document. If it is not a draft, then EPA's use of that document in its current form would appear to run contrary to the Agency's statements that the sections of the Addendum dealing with "body burden" and BAF/BCF issues are not being proposed for comment and will not be included in either the Great Lakes Guidance or the addendum to the criteria document. See 61 Fed. Reg. 58445, cot. 1, 58446, col. 2. For the sake of clarity, EPA should provide the public with the specific version of any addendum that itproposes to apply in any context.

Comment: Selenium

In 1996, the Regional Board amended the Water Quality Control Plan for the Sacramento River and San Joaquin River Basins, updating the selenium control program in the San Joaquin River watershed. The amendment contains water quality objectives and an implementation timetable for the San Joaquin River and numerous water bodies in the Grassland area. It was finalized earlier this year and has been forwarded to US EPA for approval. If approval of the 1996 amendments is not obtained before promulgation of the final Toxics Rule, the current federally recognized objectives will remain in place indefinitely. This will unnecessarily complicate a control program that is already complex in nature. Therefore, US EPA is urged to approve the 1996 amendment and recognize it as the appropriate selenium control effort for the affected water bodies.

Response to: CTR-051-002

The commenter expressed concerns that the selenium control program and implementation timetable contained in the 1996 amendments to the Water Quality Control Plan for the Sacramento River and San Joaquin River Basins (Basin Plan) would be overriden by the CTR. The commenter also expressed concerns regarding the selenium criteria contained in the CTR and the potential for complications that could result from having state and federal criteria for the same waterbodies. EPA disagrees with these concerns.

First, it should be noted that already there are federal selenium criteria in place for parts of San Joaquin River, Salt Slough, Mud Slough (north), etc. These criteria were promulgated as part of the NTR on December 22, 1992. (57 Fed.Reg. 60848,60921, December 22, 1992.) The current CTR action does not change the NTR standards for those waters.

For the other named waterbodies subject to the 1996 Basin Plan amendments (Appendix 40), EPA is promulgating selenium criteria as part of the CTR. EPA has not yet approved the 1996 amendments, and in the absence of EPA-approved, site-specific criteria, EPA must promulgate criteria for toxic pollutants, including selenium, to meet the requirements of CWA section 303(c)(2)(B).

As with other site-specific criteria, if EPA approves the State's site-specific criteria for selenium for San Joaquin River, Salt Slough, Mud Slough (north), etc., EPA can undertake rulemaking to stay the the applicable selenium criteria in the CTR as well as the NTR. In the meantime, where site-specific criteria have already been adopted by the State in accordance with State law, but not yet acted upon by EPA,

such State-adopted criteria are in effect under State law. If those criteria are more stringent than applicable federal (CTR or NTR) criteria, those would be the controlling criteria for CWA purposes even without a stay of the applicable CTR (federal) criteria and would thus be implementable by the State. (This would not be affected by the so-called "Alaska Rule" which EPA proposed July 9, 1999, 64 Fed.Reg. 37072. See p. 37076.) This is the case with the site-specific criteria for selenium adopted by the State for the San Joaquin River, Salt Slough, Mud Slough (north), etc. Since the State must use the most stringent criteria in effect for its water quality programs, the 1996 Basin Plan site-specific selenium criteria remain in effect notwithstanding the CTR and NTR fresh water aquatic life criteria for selenium. Moreover, the selenium control program and implementation timetable will continue to apply to the State's site-specific criteria.

Comment: 4. Acute Selenium Criteria. EPA's assumption that the toxicities of all forms of selenium are additive is not adequately supported.

In the Great Lakes Initiative rulemaking, at pp 61 FR 58444 and 58446, EPA states that new data indicate that all forms of selenium are additive, and therefore takes that conclusion into account in setting the CMC for selenium without any further discussion.

The basis provided by EPA to support this conclusion consists of studies reported by Hamilton and Buhl (1990) and Maier et al. (1993) [at p. 61 FR 58446]. Interestingly, these reports more accurately suggest that mixtures of different selenium forms may not always reflect "additive" effects in the classic sense where the effect of two chemicals is equal to the sum of the effects of the individual chemicals applied alone. Instead, these two studies suggest that the combined effect can be substantially less than or somewhat greater than the "simple additivity" which EPA assumes and on which it bases its proposed equation. Moreover, the 1987 criteria document data do not support the additivity assumption made by EPA.

EPA should either abandon its stated assumption or provide a scientifically defensible explanation for basing its assumption upon the two studies cited as authority.

Response to: CTR-058-005

For the reasons specified in the response to CTR-008-001, EPA is not promulgating its proposed freshwater acute criteria for selenium. Therefore, this comment is no longer applicable to the final rule. During its review of the acute criterion, EPA will be generating additional data on the additive toxicity of different selenium forms to sensitive aquatic organisms.

Comment: 5. Chronic Selenium Criterion, SF Bay. WSPA does not support the choice of a freshwater criterion for SF Bay, Suisun Bay, San Pablo Bay and adjacent waters.

The proposed rule makes no attempt to defend the choice of a 5 ug/L freshwater criterion for selenium in these marine waters. This approach is arguably arbitrary and capricious. EPA says, more or less, we set this site-specific criterion in these waters in a previous rulemaking and we won't change. EPA should defend the choice of a criterion based on freshwater data for these waters, and stakeholders should be allowed to comment on the basis for this approach once they can see and evaluate EPA's attempt to justify it.

Furthermore, we dispute the 5 ug/L freshwater chronic criterion, which we understand to be based on the anomalous data of the Belews Lake, North Carolina study. We know of no other study where such a low threshold of concern was supported and challenge the Agency to cite any. Belews Lake is a lake with a very little flushing which arguably will not model many or most of the reaches of water in California to which EPA wants this criterion to apply (specifically, river reaches as well as the San Francisco/San Pablo/Suisun Bay system). We do not know what sort of mechanisms may occur in Belews Lake to convert selenium from one form to a more toxic form. We do not know if this transformation takes several steps. Additionally, we do not know whether these mechanisms would occur in the more common well-flushed reaches to which EPA seeks to apply the criterion here in California. EPA should justify both the value of 5 ug/L and the use of a freshwater criterion in marine waters.

Response to: CTR-058-006

EPA promulgated the freshwater CCC of 5 ug/l for San Francisco Bay, Suisun Bay, San Pablo Bay, and adjacent waters as part of the National Toxics Rule [NTR](57 FR 60848-60921, December 22, 1992). EPA disagrees that this approach is arbitrary and capricious. EPA explained its rationale for this decision in response to comments for the NTR (57 FR 60898, December 22, 1992). The purpose of today's rule is to promulgate criteria that fill the gap created when previous State criteria were invalidated as a result of State litigation. The rule is not intended to change or supersede any criteria previously promulgated for California in the NTR, as amended (Administrative Stay of Federal Water Quality Criteria for Metals and Interim Final Rule, Water Quality Standards; Establishment of Numeric Criteria for Priority Toxic Pollutants; States' Compliance-Revision of Metals Criteria, 60 FR 22228, May 4, 1995). The freshwater CCC for selenium is re-printed in the text of the CTR for the convenience of the user.

EPA disagrees with the commenter that the Belews Lake data are "anomalous" and are therefore not appropriate for application to California waters. The selenium effects data of Belews lake are supported

by other more recent data indicating adverse effects on aquatic organisms at comparable levels. For example, in a year-long study of selenium effects on aquatic life in outdoor experimental streams, Hermanutz et al. (1992) report statistically significant reductions in adult bluegill survival during the final 98-d exposure period to 10 ug/L selenium (introduced as sodium selenite) and complete mortality at 30 ug/L during the same exposure period. Hermanutz et al. (1992) also report statistically significant reductions in embryo hatch and higher incidence of developmental abnormalities at 10 ug/L and 30 ug/L compared to controls. This level (10 ug/L) is the same as that associated with unacceptable effects in the Belews lake study upon which the freshwater CCC is based. A chronic test conducted by Schultz and Hermanutz (1990) on the effect of selenium on fathead minnow in the same outdoor experimental streams is also consistent with results from the Belews Lake data. Specifically, Schultz and Hermanutz (1990) report statistically significant differences in the incidence of developmental abnormalities (lordosis and edema) in larvae from fish exposed in 10 ug/L streams compared to controls. In a laboratory study, Lemly (1993) exposed bluegill exposed to combined dietary (5.1 ug/g dry weight) and 4.8 ug/L waterborne selenium and reported that a combination of elevated selenium and low temperature resulted in reduced feeding, depletion of body lipids and significant mortality in 60 days (termed winter stress syndrome) compared to fish in equivalent warm water exposures.

The Belews lake data and supporting studies used to derive the freshwater CCC for selenium indicate that adverse effects on bluegill occurred at about 10 ug/L (as was also observed in experimental streams by Hermanutz et al., 1992) and that bluegill were unaffected at concentrations of 5 ug/L or below. Therefore, EPA believes that the similarity between the adverse effect levels associated with Belews lake and those of Hermanutz et al. (1992), Schultz and Hermanutz (1990), and Lemly (1993), which involved very different exposure systems, demonstrates that the Belews lake data are not "anomalous" as the commenter stated and can be reasonably extrapolated to other types of waterbodies. Finally, EPA notes that because these and other new data have become available since EPA's publication of the aquatic life criteria for selenium in 1987, EPA is currently reviewing this new data for potentially revising as appropriate its 304(a) criteria for selenium.

Comment: PROVISIONS SDG&E DOES NOT SUPPORT

As described in the following comments SDG&E does not support the following provisions:

Selenium acute criteria is technically deficient

This rule proposes to adopt the proposed revised Great Lakes acute selenium criterion. EPA has yet to respond to comments submitted on this criterion during a previous comment period. Until such time as EPA reviews and responds to the comments submitted previously on this proposed criterion, it would be premature for EPA to adopt the criterion as proposed in the CTR.

Response to: CTR-060-007

EPA agrees with the comment that it should not promulgate its proposed acute freshwater criterion for selenium until after it completes its response to comments on a previous proposal that relies on the same criterion. For additional reasons specified in the response to CTR-008-001, EPA is not promulgating its proposed freshwater acute criteria for selenium.

Comment: The U.S. Environmental Protection Agency (EPA.) recently received a letter, directed to your attention, from Daniel G.Nelson (Executive Director of the San Luis & Delta-Mendota Water Authority) dated September 15, 1997. Mr. Nelson's letter presented an objection to proposed freshwater selenium criteria recently announced by EPA (California Toxics Rule; Federal Register Vol. 62 (150):42160-42208, August 5, 1997). Mr. Nelson asserts in his letter that the proposed "... freshwater selenium criteria are scientifically inadequate because they fail to take account of the known interference between selenate and sulfate uptake in high sulfate waters like those in the San Joaquin Valley...." Mr. Nelson then requests that EPA delay adoption of proposed water-quality criteria for selenium, pending review of the sulfate-interference issue.

The U.S. Fish and Wildlife Service (Service) recently reviewed our copy of Mr. Nelson's letter and does not see a scientifically substantive basis for justifying the delay and further review that Mr. Nelson requests. Sulfate-interference does not appreciably affect selenium bioaccumulation in real-world enviroruments and that has been known for at least 60 years.

Dr. Joseph Skorupa, of my environmental contaminants staff, has recently reviewed the issue of sulfate-interference and its relevance to establishment of freshwater selenium criteria and has concluded

that fish and wildlife toxicity thresholds for waterborne selenium are not sulfate dependent (Skorupa, in press). Mr. Nelson supports his view that sulfate-interactions should be an important regulatory consideration by citing recent laboratory bench studies (Hansen et al. 1993; Williams et al. 1994; Ogle and Knight 1996). Such studies often suffer from the so-called lab-to-field-dilemma (Landis and Yu 1995:28) because they are very simplified and environmentally unrealistic and cannot be extrapolated to the real world. The authors of the studies that Mr. Nelson cites are clearly aware of this important dilemma.

For example, Hansen et al. (1993:77) wrote:

"Thus, at this time, it does not appear that we have sufficient evidence to justify the consideration of sulfate as a factor in the regulation of Se in aquatic environments.

Williams et al. (1994:452) wrote:

"At present, there is little information available that allows us to assess how relevant this study's conclusions will be in natural waters containing a complex assemblage of selenium species.

Ogle and Knight (1996:278) reported that in the region of 5 ug/L waterborne selenium (the critical threshold region recognized in the California Toxics Rule):

"...the differences [in selenium bioaccumulation and toxicity] between extremely different sulfate concentrations are not significant.....

There is a clear record of highly relevant field data supporting Hansen et al.'s and Williams et al.'s cautions against extrapolation of their lab results. Field data show that simplistic selenate-sulfate lab bench results do not extrapolate well to real environments (Skorupa, in press). Realworld data unanimously support the conclusion that toxicity thresholds for seleniun are notsulfate dependent. In the absence of any new field data to the contrary, the objection raised in Mr. Nelson's letter must be viewed as inapplicable..

The findings of Dr. Skorupa's review can be summarized as follows:

As early as the 1930's (e.g., Hurd-Karrer 1937, 1938) competitive uptake interactions between selenate and sulfate had already been confirmed experimentally. In the same era it had also already been demonstrated that sulfate-interference did not apply to any form of environmental selenium other than selenate, and that the field significance of sulfate-interference was negligible. Sixty years ago, Beath (1937) concluded that the "...sulfur-selenium antagonism theory has not been found generally applicable tofarm and range practices [for ameliorating selenium toxicity to range animals] of the Rocky Mountain region." Thus, although recent experiments cited by Mr. Nelson (Hansen et al. 1993; Williams et al. 1994; Ogle and Knight 1996) provide useful information corroborating earlier work, it is inaccurate for Mr. Nelson to suggest that recent studies provide any fundamentally new conceptual insights not already known by 1987 when EPA derived the 5 ug/L chronic criterion for selenium.

Twenty years ago, Birkner (1978) came to essentially the same conclusion for aquatic habitats that Beath (1937) had reported for open range habitats. Birkner surveyed 30 freshwater sites in Colorado and Wyoming for waterborne, sediment, and foodchain selenium content. The sites that Birkner surveyed included levels of dissolved sulfate that ranged from 5-9,611 mg/L. Statistical analyses of his data led Birkner to conclude that levels of dissolved sulfate did not influence the level to which selenium is bioaccumulated by aquatic organisms.

The lack of sulfate dependency for selenium bioaccumulation in the real world was affirmed once again in the late 1980's and early 1990's. This time the Service collected eggs of waterbirds from agricultural evaporation ponds in California that varied in dissolved sulfate concentrations from 2,000-100,000 mg/L. Selenium concentrations in the bird eggs, which are directly related to the contamination of aquatic foodchains at each sampling site, were strongly predictable from waterborne concentrations of selenium regardless of variable sulfate concentrations that spanned three orders of maagnitude (Skorupa, in press). The Service's failure to find a sulfate-interference effect for bioaccumulation of selenium in bird eggs, was corroborated by studies of aquatic invertebrates (the food supply for birds) at the same sites by the California Department of Water Resources (John Shelton, unpubl. data). Combining Birkner's (1978) results with,the results from California evaporation ponds, no sulfate-interference effect could be detected in the real world for dissolved sulfate concentrations spanning from 5-100,000mg/L! Furthermore,the field-verified toxic threshold point of 3-4 ug/L waterborne selenium for birds at the high-sulfate ponds in California showed excellent correspondence with the field-verified toxic threshold point of 2-5 ug/L for fish residing in the low-sulfate waters of Belews Lake, North Carolina (Skorupa, in press).

Finally, a comprehensive review of the best documented case studies of selenium poisoning in nature revealed that 7 of 12 real-world toxic episodes occurred at sites with high-sulfate waters (Skorupa, in press). This rich body of real-world data on selenium toxicity to fish and wildlife affirmatively, and unequivocally, supported the conclusion that toxic thresholds for selenium arenot sulfate dependent.

Why are simple laboratory bench studies contradicted by field data? Bench studies confirm that high-sulfate waters can reduce bioaccumulation of selenate, but not eliminate it. Thus, even in the face of high concentrations of dissolved sulfate, over time, functionally significant amounts of waterborne selenate are nonetheless taken up by biota and transformed to other forms of environmental selenium that are not subject to sulfate-interference. Those other forms of selenium are far more bioaccumulative than selenate, are free of any interference from sulfate and, over time, come to dominate the bioaccumulation process (e.g., Besser et al. 1989). Recent 48-hr-96-hr lab bench experiments are simply too short in duration and too simple in design to mimic this progression from selenate-dominated water to a complex mixture of multiple chemical species of selenium that characterizes the ecotoxicology of selenium in the real world.

For example, drainage water in the San Joaquin Valley of California was found to contain selenium as selenate, selenite, and selenomethionine (Se-Meth) in a ratio of approximately 18:3:1 (Besser et al. 1989). Bioconcentration factors for periphyton, however, showed a reverse ratio of about 1:6:120 (Besser et al. 1989). Thus, the approximate ratio of selenium uptake from selenate, selenite, and Se-Meth would be 18:18:120. Therefore, only about 11 percent (18/156) of bioaccumulated selenium in the periphyton would be taken up directly from the inventory of dissolved selenate. Under these circumstances, even if a sulfate-interference effect as high as 50 percent were occurring it would have only about a 5 percent (0.5 x 0. 11) inhibitory impact on overall bioaccumulation of selenium. At toxic threshold exposures in the region of 2-5 ug/L waterborne selenium, a 5 percent effect would be very negligible in absolute terms. Even this example probably overestimates the contribution of selenate to bioaccumulation of selenium because it does not account for the cumulative loading of predominantly non-selenate species of selenium into aquatic sediments, which is another major bioaccumulation pathway that further devalues the relative importance of dissolved selenate selenimn. It is quite plausible that in real aquatic environments even where concentrations of dissolved sulfate are low, only a minute proportion of selenium bioaccumulation is due to direct uptake of selenate selenium.

Much of the technical information presented in this letter was also presented to the scientific consultants

retained b the San Luis & Delta-Mendota Water Authority during a meeting with Dr. Skorupa on July 19, 1995. If Mr. Nelson possesses fundamentally new data that are unequivocally relevant to the real-world, by all means the data should be evaluated by EPA. The studies that Mr. Nelson cites in his letter do not, however, constitute such data.

Questions regarding this letter may be directed to Drs. Joseph Skorupa or Steven Schwarzbach by contacting them at (916)-979-2110.

Response to: CTR-103-001

EPA agrees with the commenter that by itself, the current state of the science on the sulfate dependent toxicity of various selenium forms is not adequate justification to delay promulgation of freshwater selenium criteria in the CTR. However, EPA has chosen not to promulgate acute freshwater criteria for selenium for the reasons stated in EPA's response to CTR-008-001. EPA has chosen to proceed with promulgation of the freshwater CCC for selenium for the reasons stated in EPA's response to CTR-008-001. EPA will consider additional data on sulfate dependency of selenium toxicity, including those cited by the commenter, during its review of freshwater selenium aquatic life criteria.

Comment: II. Use of New Scientific Information

The City acknowledges and supports EPA's update of several water quality criteria including those for mercury, cadmium and arsenic. While a number of criteria were updated to reflect current scientific information, there are a few notable exceptions.

The following briefly addresses the key updates and omissions that should be addressed in the final publication of this rule.

2. Lead

The 1984 lead criteria establishes very stringent chronic criteria due to an artifact of EPA's criteria calculation procedure - where inadequate data are available, a lower criteria is calculated. Thus, even where it is apparent that less restrictive criteria should be developed, the calculation procedures produce a lower criteria. This anomaly of criteria calculation could have been rectified by updating the criteria to add additional organisms that were tested since the 1984 Lead Criteria Document was published. Unfortunately, EPA failed to update the lead chronic water quality criteria which would have increased the chronic value from about 1.5 ppb to 15 ppb. This update has been acknowledged by EPA Duluth representatives in a number of public forums as acceptable, and it was approved for the Delaware River Basin Commission, a quasi-federal entity in 1996 (Exhibit 9). EPA's failure to update the lead database for the CTR is arbitrary and capricious and needs to be corrected

(a) The Technical Basis for EPA's Lead Criteria is Flawed

EPA criteria for lead were first published in 1980 and revised in 1984. The database from which the criteria were derived is very limited. EPA assessed only ten freshwater species and eleven saltwater species. Consequently, the data used to develop the lead criteria do not meet the minimum data requirements set forth in EPA's guidelines. (*41) In addition, the analytical methodology (acid soluble metal) used to assess lead concentration in the toxicity tests used to develop the criteria was a rigorous digestion that measured non-toxic, as well as toxic, forms of the metal.

Because the tests used to develop the lead criteria measured non-toxic forms of metal, and lead salts tend to form carbonates and precipitate readily from solution, the criteria overestimated the toxic fraction of lead. Thus, the lead criteria are very conservative. In addition, statistical deficiencies in the underlying data base render the lead criteria significantly more uncertain thanother criteria derived using the requisite data. As a result, some states have deferred adoption of EPA's lead criteria; others have adopted

more appropriate lead standards that are scientifically supported. North Carolina, for example, adopted a 25 ug/l lead standard (as total recoverable) because:

We believe that a standard based on an acid-soluble equivalent value of 1.3 ug/l Pb is extremely and unnecessarily overly protective, especially when considering the vast differences in Pb concentration that can be measured from the same sample, as shown by EPA's data. Since these values can vary as much as 50-75 fold for Pb according to EPA's data, implementing a standard of 25 ug/l measured as total recoverable metal which is less than 20 times higher than the acid-soluble criterion of 1.3 ug/l) is sufficiently conservative and technically sound... (*42)

The geometric mean for water effect ratios reported for lead using C. dubia and fathead minnows are consistently greater than five (5), which confirms a reduction in lead toxicity in natural waters by a factor of five relative to laboratory water of minimal complexing ability. (*43) This is not surprising since lead is readily complexed by inorganic and organic ligands in natural waters. (*44) Pagenkopf reported that relatively low concentrations of humic acids readily detoxify lead:

If there is 1 mg/liter humic acid (HA) in the water with an effective gram formula weight of 1000, a sizable amount of lead could be complexed. With these conditions the HA concentration would be 10E-6M, and if the 108 stability constant were applicable, essentially all of the humic acid would complex PbE+2. This would raise the total nontoxic species concentration and in fact could cause a shift from apparent toxicity to nontoxicity. (*45)

Given the abundance of complexing agents in biologically treated effluents and storm waters, a dissolved lead standard based on EPA's criteria is overly conservative.

(b) Conclusions With Respect to Lead

EPA should withdraw the proposed lead standard as unnecessarily restrictive and recalculate the criteria to reflect the additional studies conducted since the criteria were issued. Given the prevalence of lead in virtually all municipal effluents and storm waters, a minor change in the lead criteria will significantly affect treatment requirements. EPA should not apply the lead chronic criteria to storm waters where elevated TOC levels are prevalent and will detoxify the metal present.

Response to: CTR-020-013

Although EPA agrees that the freshwater lead data set is less diverse by one taxon than the Aquatic Guidelines call for, EPA is retaining the criteria in the rule. EPA does not believe that the decreased taxonomic diversity in the data set is by itself a substantial shortcoming that would invalidate the criterion.

The comment about statistical deficiencies is not sufficiently specific for EPA to be able to identify to what the comment refers.

EPA is addressing the issue on bioavailability of different forms of lead (that is, the presence of "non-toxic" forms of lead) through expressing the criterion as dissolved lead and as function of a site-specific Water-Effect Ratio.

Comment: Page 42168, third column, near the bottom, states, "However, EPA believes that it is appropriate to propose criteria in this rule based on the most recent data." Following that statement is a table (located on the bottom of page 42168 and top of 42169) in which the proposed freshwater criteria (CMC) for Cr VI is 16 ug/L. That table also lists the CCC for Cr VI as 11 ug/L. I have reviewed the literature on Cr VI toxicity (see attached "Chromium Speciation: Key to Reliable Control of Chromium Toxicity to Aquatic Life ") and find that 11 ug/L will not protect zooplankton from toxicity. There is substantial reliable data in the literature which show that Cr VI is toxic to zooplankton at 0.5 ug/L. This situation should have been discussed in the proposed CTR so regulatory agencies, the regulated community and the public learn that an 11 ug/L Cr VI criterion will not prevent zooplankton toxicity and could thereby violate the narrative toxicity standard of no discharge of toxic chemicals in toxic amounts. The CTR should also discuss the fact that in many ambient water systems Cr III (which is allowed to be discharged at 50 ug/L) can convert to Cr VI resulting in concentrations of Cr VI above those that are known to be toxic to zooplankton.

Response to: CTR-061-013

EPA does not agree that the 11 ug/L criterion will not protect zooplankton from toxicity. EPA believes its criterion for chromium is adequately protective. EPA has examined the quotation appearing in the submitted document "Chromium Speciation: Key to Reliable Control of Chromium Toxicity to Aquatic Life". EPA believes that the comment's Elnabarawy et al. (1986) citation refers to those authors' data published in Environmental Toxicology and Chemistry (Vol 5, pp. 393-398), and has examined that reference.

This material dealt with additional toxicity testing data rather than the data EPA used to derive the criterion. The material does not have data on previously untested species. Consequently, even if EPA were to include the Elnabarawy et al. (1986) data, then the results would be averaged with other study results for the same species, in order to obtain new Genus Mean Acute Values and Acute-Chronic Ratios, and recalculate the CMC and CCC.

Furthermore, even if the Elnabarawy et al. (1986) data were acceptable and included in a new criteria derivation, under no circumstances would EPA's criteria derivation procedure allow setting the criterion to the lowest test result (0.5 ug/L) among replicate tests. The averaging of test results prevents the criteria from being unnecessarily influenced by experimental errors. Consequently, even if EPA were to update the criterion for this rule, it cannot be predicted whether the entire body of new data (as opposed to the lowest test results therein) would cause the criterion to go up or down, or leave it essentially unchanged.

An additional problem is that there is doubt as to whether EPA could judge the Elnabarawy (1986) data to be acceptable. Although all or nearly all treatment concentrations for Ceriodaphnia reticulata and Daphnia magna had reproductive success that was statistically significantly lower than the control response, essentially all treatments had the same response, only slightly lower than the control, despite 100 fold differences in concentration.

Data from Elnabarawy et al. (1986)

	Average number of young per adult			Adult survival percentage		
Cr (VI) ug/L	D.magna	D.pulex	C.reticulata	D.magna	D.pulex	C.reticulata
Control	85	53	23	100	100	100
0.5	76	44	16*	100	100	100
1.5	69*	44	16*	100	80	100
5.0	71*	45	16*	100	80	100
15.0	71*	45	14*	60	80	100
50.0	47*	42	14*	0*	50	100

* Significantly different from control, p less than or equal to 0.05.

The expected behavior for this experiment would be a sigmoidal concentration-response curve (in this case a backwards "S" shape) with the low concentrations displaying similar responses to the control, and the higher concentrations with more or less progressively lower reproductive or survival success. The character of Elnabarawy et al. (1986) data suggest that the somewhat depressed reproductive success for D. magna between 0.5 and 15.0 ug/L and for C. reticulata between 0.5 and 50.0 ug/L may not due to chromium.

Consequently, EPA cannot accept the comment's contention that new evidence has demonstrated that the CCC specified in the rule, 11 ug/L, would not adequately protect aquatic life uses.

With regard to the conversion of chromium (III) to chromium (VI), EPA does not agree that the rule, in setting forth criteria concentrations, needs any provision for interconversion of oxidation states. EPA believes that site-specific fate considerations are best handled during the waste load allocation or permitting processes, not during the state-wide standards setting process.

Finally it should be noted that in analyzing the toxicity tests underlying the CMC and CCC for chromium (III), EPA assumed that none of the chromium (III) was converted to chromium (VI). To the degree (if any) that chromium (III) was oxidizing to chromium (VI) in the underlying toxicity tests, the chromium (III) criterion would already account for that degree of conversion.

CROSS REFERENCES

Comment: Marine Cyanide Criteria. In 1996 WSPA submitted to the Washington Department of Ecology three reports in support of developing site-specific water quality criteria for cyanide. These reports were:

* Acute Toxicity of Cyanide to Two Species of West Coast Crabs, Cancer productus and Cancer gracilis;

* Literature Review of Cyanide Toxicity Data * Range and Distribution of Cancer branneri

These studies support an acute criterion of 9.4 ug/L and a chronic criterion of 1.5 ug/L using the EPA calculation procedures with data for C. irroratus being replaced by the Genus Mean Acute Value for four West Coast Cancer species. An acute to chronic ratio of 6.458 was used based on a recommendation by Mark Hicks of the Department of Ecology.

WSPA incorporates these studies into the record by reference (we will transmit the studies under separate cover) and urges EPA to review these data and support site specific marine cyanide criteria of 9.4 ug/L and 1.5 ug/L for California as well.

Response to: CTR-058-013

EPA agrees with incorporating the data generated for Cancer magister, C. oregonensis, C. productus, and C. gracilis into the data set underlying the cyanide saltwater criterion. The data for all tested species in genus Cancer are then as follows:

C. magister: LC50s 51.24 & 91.5 ug/L; SMAV 68.47 ug/L
C. oregonensis: LC50s 111.3 & 154.1 ug/L; SMAV 131.0 ug/L
C. productus: LC50 219 ug/L; SMAV 219 ug/L
C. gracilis: LC50 153 & 135 ug/L; SMAV 143.7 ug/L
C. irroratus: LC50s 4.2 & 5.7 ug/L; SMAV 4.893 ug/L

Within a genus, such as Cancer, in situations where toxicity data are available for some of the species, but not all of the species found in a state, data on tested resident species and data on tested non-resident species are both used to represent the untested species, when calculating site- or state-specific standards.

In contrast, for the State of Washington, where all resident Cancer species were tested (that is, C. magister, C. oregonensis, C. productus, and C. gracilis), EPA agreed that the GMAV for Cancer could be

recalculated after excluding C. irroratus, because (a) C. irroratus did not occur in Washington, and (b) it could not represent any untested Cancer species in that state since all resident Cancer species had been tested.

However, EPA has no data on the occurrence of Cancer species in California. Nor did the commenter submit any such data. As a result, EPA is unable to make the determination that C. irroratus could not represent any untested Cancer species occurring in California. That is, with the information available, EPA is not able to determine whether some Cancer species other than the above five occurs in California. If such Cancer untested species did occur in California, then C. irroratus would be considered as likely as any of the others above to represent the sensitivity of the untested Cancer species, and would thus not be deleted from the data set. Consequently, for this rule, the cyanide criterion was determined by considering all five of the above species.

The SMAV for C. irroratus is more than an order of magnitude less that the LC50 for any other species in the genus Cancer. The tests on C. irroratus were flow-through, measured tests at 20 degrees C. The tests on the other Cancer species were renewal, measured tests at 10 degrees C. EPA has not found any persuasive reason to believe the C. irroratus data to be in error. The observed difference between C. irroratus and the other Cancer species may be due to (a) genuine biological differences among species (although such large differences within a genus are not common), (b) reproducible differences stemming from different experimental conditions (flow-through test at 20degrees C versus renewal test at 10 degrees C), or (c) non-reproducible experimental variation.

The Aquatic Life Guidelines (the procedures EPA uses to derive criteria) discuss the situation where there are large differences among species in a genus. The Guidelines caution against taking a geometric mean of SMAVs when the values differ by more than a factor of 10, but do not precisely indicate what should be done in such cases. Generally, for other criteria included in the rule, when the SMAVs differed by more than a factor of 5, the GMAV was set equal to the lowest SMAV. When that is done for Cancer, the GMAV remains at 4.893 ug/L. The CMC and CCC thus remain unchanged from the proposed rule, both having the value of 1.0 ug/L.

Comment: Validity Of Proposed Nickel And Cyanide Criteria On A Statewide Basis

Attachment 1 to this letter is a technical report entitled "Task Report 1: Update and Recalculation of the Freshwater and Saltwater Cyanide Criteria", dated November 5, 1996 and prepared by Tetra Tech, Inc. for the City of San Jose. Attachment 2 to this letter is a technical report entitled "Final Report Recalculation of the Nickel Criteria for South San Francisco Bay", dated November 1, 1995 and prepared

by Tetra Tech, Inc. for the City of San Jose. All of the attachments to this letter are incorporated as part of our comments and are being submitted for inclusion in the record for this rulemaking.

EPA has an obligation to consider the most current, scientifically defensible data in this rulemaking. EPA's obligations in this regard are particularly significant in light of its obligations under Executive Order 12866 and the Regulatory Flexibility Act (5 U.S.C.A. 601 et seq.) to consider a full range of cost effective alternatives to promulgation of the proposed Rule.

Although the title of Attachments 1 and 2 suggest that the data submitted relates only to San Francisco Bay, the data in fact relates to the entire state of California, and indicates that lessstringent cyanide and nickel criteria than are proposed by the Rule would adequately protect water quality in California. Under the Executive Order 12866 and the Regulatory Flexibility Act, EPA should include consideration of the these less stringent criteria in its Economic Analysis.

Response to: CTR-092-012b

EPA does not agree that the nickel and cyanide site-specific criteria developed for South San Francisco Bay necessarily apply to the entire State of California. EPA has examined the two reports ("Final Report: Recalculation of the Nickel Criteria for South San Francisco Bay" and "Update and Recalculation of the Freshwater and Saltwater Cyanide Criteria") referenced in the comment, and could not find evidence that the analysis contained therein applies to or was intended to apply to the entire state. EPA is not claiming that it has evidence that the San Francisco Bay analysis is not valid in other parts of the state. However, because the comment provided no information to support its assertion that the cited data relate to the entire state, and because EPA has no information of its own to determine the occurrence of species in the state, EPA is not able to conclude that the South Bay analysis applies state wide. To adjust the nickel and cyanide criteria statewide, EPA would need a statewide analysis of the type done for South San Francisco Bay. These site-specific studies must first be reviewed and approved by State authorities; they may then come to approval. If approved, EPA would rescind the criteria for nickel and/or cyanide in the CTR for the South San Francisco Bay.

With respect to the commenter's suggestion that these studies should be considered in any costing analysis for the CTR under Executive Order (E.O.)12866 and the Regulatory Flexibility Act, EPA does not agree. EPA has made clear elsewhere in the record of the rule that these criteria are health-based and are not based on cost-benefit balancing. The E.O. 12866 is supplemental information that shows the indirect costs and benefits of CTR criteria; it is an indication of the magnitude of the costs and benefits of the resulting water quality standards implemented through the NPDES permit program. With respect to the RFA, EPA addresses this issue in the preamble to the final rule and elsewhere in the final record for the final rule.

[The remaining parts of the response were written by Region 9 and are not shown here because I do not have an electronic version of them. All issues with that portion of the response deal with regional matters outside the purview of the national program.]

Comment: II. Use of New Scientific Information The City acknowledges and supports EPA's update of several water quality criteria including those for mercury, cadmium and arsenic. While a number of criteria were updated to reflect current scientific information, there are a few notable exceptions. The following briefly addresses the key updates and omissions that should be addressed in the final publication of this rule.

3. Arsenic

Arsenic human health criteria have been deleted as not being based on reliable scientific information. (This action followed a petition for rulemaking to amend the NTR for Alaska.) In the preamble, EPA tries to promote use of a 5 ppb human health criteria which was never adopted by the state. The number routinely approved by the Agency for other states is 50 ppb. Based upon the Agency's recent discussion of the current scientific information regarding arsenic addressed in the modification of the National Toxics Rule for Alaska (62 Fed. Reg. 27707-27710), EPA should clarify that the 50 ppb drinking water objective is acceptable to meet all Clean Water Act requirements.

Response to: CTR-020-007

In the final rule, EPA is not promulgating human health criteria for arsenic. As stated in the preamble, EPA made the decision not to promulgate human health criteria in light of number of issues and uncertainties that have arisen concerning the effects of arsenic on human health. A discussion of these issues are contained in a document entitled "Issues Related to Health Risk of Arsenic" that is contained in the administrative record for this rule. EPA is currently completing a review of the risk assessment for arsenic in an effort to resolve these concerns.

Although the State did not adopt a human health criterion for arsenic, California has previously expressed its scientific and policy position by recommending the use of 5 ppb in providing human health protection. This value has been utilized by the State in implementing its narrative criteria. EPA expects that the State will continue to implement its narrative criteria to ensure that protections are in place for arsenic.

As the commenter noted, many states have adopted human health criteria for arsenic based on the maximum contaminant levels (MCL) under the Safe Drinking Water Act. In addition, many States have arsenic criteria in place that are based on EPA's existing Section 304(a) criteria guidance. As stated in EPA's December 12, 1988 guidance to states on complying with CWA Section 303(c)(2)(B) and in the Agency's policy on the use of Section 304(a) criteria and MCLs (published at 45 FR 79320, November

28, 1980), EPA encourages the use of MCLs for the protection of public water supplies. However, where fish consumption is an important activity in a waterbody, EPA recommends the use of the Section 304(a) criteria. EPA does not believe that any further clarification is needed.

Comment: C. EPA is Correct to Delay Promulgation of Human Health Criteria for Arsenic

Given the numerous uncertainties involved in developing scientifically defensible human health criteria for arsenic, UWAG supports EPA's decision to delay promulgation of such criteria in theCalifornia water quality standards. As noted in the preamble, those uncertainties include: (1) arsenic exposure evaluations, (2) metabolism and detoxification processes, (3) analytical methods, and (4) effects at low doses. 62 Fed.Reg. at 42,179, col. 1. EPA has prudently decided to await resolution of these uncertainties before promulgating additional arsenic human health criteria.

Response to: CTR-030-003

EPA acknowledges the numerous comments that support the Agency's decision not to promulgate human health criteria for arsenic in today's rule.

Comment: Second, we commend EPA for its inclusion in the CTR of several innovative and flexible

regulatory approaches, such as metals criteria expressed as dissolved rather than total recoverable concentrations, and the revised human health criterion for mercury. In addition, in light of the issues surrounding the human health criteria for arsenic we support EPA's decision not to promulgate human health criteria at this time. With respect to implementation issues discussed in the Preamble, we support EPA's policies and guidance regarding the application of mixing zones and dilution credits. the use of interim permit limits while Total Maximum Daily Loads (TMDLs) and other special studies are being performed, and EPA's guidance to Regional Water Quality Control Boards (RWQCBs) that they may use any of the methods described in EPA's guidance document on the use of translators. We also support EPA's proposal to create a rebuttable presumption for Water Effects Ratios (WERs), allowing the RWQCBs and SWRCB to develop site-specific WERs that can be approved by EPA during the NPDES permit approval process. We believe that this approach will help facilitate the development of appropriate site-specific adjustments for metals criteria.

Comment: p. 42179 - Arsenic Human Health Criteria We support EPA's decision not to promulgate human health criteria for arsenic at this time. However, in light of the scientific uncertainties identified by EPA, we strongly recommend that EPA remove from the Preamble the recommendation that State permitting authorities use 5 ug/l in evaluating and interpreting the narrative water quality criteria, since EPA's own scientific judgment is that there is an insufficient basis for setting valid human health criteria at this time. Instead, as an interim measure, EPA should recommend that the maximum contaminant level (MCL) for arsenic of 50 ug/l be used by permit writers, as has been approved as the human health criterion for the State of Alaska.

Comment: Fourth, for arsenic, the District strongly supports EPA's recognition that human health criteria should not be proposed at this time. The District is aware of the confusion in issues and the uncertainties that have developed concerning the measurement of the health effects of arsenic, and consequently the District supports the Agency's review of risk assessments for arsenic before promulgating criteria in any more states. In light of this reasoning, the District recommends that EPA withdraw its final sentence in this discussion recommending that permitting authorities in California refer to the State's criterion level of 5 ug/l in interpreting and evaluating narrative water quality criteria.

Comment: Arsenic Human Health Criteria

We support EPA's decision not to promulgate human health criteria for arsenic at this time in light of the scientific uncertainties regarding the risks posed by arsenic in water. EPA currently has two different human health values for arsenic in water: 0.018 ug/L for the ambient water criterion and 5 0 ug/L for the drinking water maximum contaminant level (MCL). In its own decision document for arsenic(*2), EPA states that "Having two very different criteria for arsenic (0.018 ug/L ambient water v 50 ug/L in drinking water) to protect human health drinking water exposures is very confusing to the public. These different values have been difficult to explain, defend, and implement in EPA and State Programs." Based on this discussion, we strongly recommend that EPA remove from the Preamble the recommendation that State permitting authorities use 5 ug/l in evaluating and interpreting the narrative water quality criteria. Instead, as an interim measure, EPA should recommend that the MCL for arsenic of 50 ug/l be used by permit writers, as has been approved by EPA as the human health criterion for the State of Alaska.(*3)

Comment: PROVISIONS SDG&E SUPPORTS

EPA has included in the proposed CTR provisions which are reasonable and with which SDG&E supports. These include:

Delay of arsenic human health criteria

The preamble states that EPA has decided to not propose human health criteria for arsenic in this rule due to a number of issues and uncertainties concerning the health effects of arsenic (see 62 Fed. Reg. at 42179, Col. 1). SDG&E supports this decision because it is important to base criteria upon sound science. Adoption of the criteria should be delayed until the referenced issues and uncertainties are resolved.

Comment: The draft California Toxics Rule (CTR) is clearly the product of substantial effort by USEPA staff, and we applaud this effort and its intent. On several issues of concern to public utilities, the CTR strikes a good balance between the need to promulgate standards and the need to base those standards on sound science. Examples include the use of dissolved concentrations rather than the total recoverable concentrations for metals, the deferral of human health criteria for arsenic until adequate information is available, and the revision of the human health criterion for mercury. We are also pleased with the CTR's guidance and flexibility, on mixing zones and dilution credits, total maximum daily loads (TMDLs), compliance schedules, and translators.

CROSS REFERENCES

Comment: EPA unscientifically rejects criteria for 16 dioxin-like chemicals that impair San Francisco Bay. The 16 dioxin compounds that are not controlled by EPA's proposed criteria cause 80% of dioxin-like toxicity in San Francisco Bay fish tests supporting the human health advisory noted above.(*20) Subtracting all 2,3,7,8-TCDD toxicity does not change these dioxin-like toxicity estimates enough to reverse the conclusions which support this advisory.(*20) (*16) Thus, these 16 compounds impair fishing uses in San Francisco Bay. A criterion which includes the 16 dioxins developed by the state was approved in EPA's prior technical review, and the discussion in EPA's proposal shows that EPA still believes this criterion is scientifically defensible. Therefore, EPA's rejection of a criterion it believes is scientifically sound renders EPA's refusal to include criteria needed to protect San Francisco Bay fishing from these 16 dioxin-like chemicals without any valid scientific support.

(*16) California Regional Water Quality Control Board, San Francisco Bay Region, 1995. Contaminant levels in fish tissue from San Francisco Bay. Final draft report. Excerpt including data from toxic pollutant analyses of fish tissue samples from S.F. Bay. December, 1994.

(*20) Comparison of dioxin-like toxicity equivalents in San Francisco Bay fish tissue: 2,3,7,8-TCDD v. seventeen 2,3,7,8-substituted dioxins and furans. Table using data from Attachment 16, and analysis by CBE.

Response to: CTR-002-006

A commenter suggests that the Agency not include dioxin (2,3,7,8-TCDD) in this rule, pending completion of its ongoing reassessment of risks associated with exposure to dioxin and related compounds. In a contrary view, other commenters suggest that the Agency promulgate criteria not only for dioxin, but for related compounds--to include toxicity equivalent factors (TEFs) for– polychlorinated dibenzo-p-dioxins, polychlorinated dibenzofurans and co-planar polychlorinated biphenyls (PCBs). TEFs evaluate these related compounds as equivalent concentrations of 2,3,7,8-TCDD and are used as a method for capturing the total dose associated with environmental exposure to mixtures of dioxin and dioxin-like compounds.

In response to the first comment, EPA disagrees. EPA still views dioxin as an extremely serious health threat and, therefore, does not wish to delay further establishment of an ambient water quality criterion for California subject to this rule.

In order to base its regulatory decisions on the best available science, EPA periodically updates its

scientific assessment of the risk associated with exposure to environmental toxicants. In September of 1991 EPA's Office of Research and Development (ORD) began such a reassessment on the toxicology and exposure science of dioxin and related compounds. The scope of this reassessment effort has been much broader than previous dioxin assessments. Included in the dioxin reassessment effort are the identification and characterization of: dioxin sources; dioxin environmental fate and transport; pathways of human exposure; levels of and trends in human exposure; full assessment of cancer, and non-cancer toxic effects; development of quantitative dose response relationships for all the effects; and the characterization of risks posed by dioxin exposure. Once completed after a final, upcoming peer review, the reassessment will serve as the principal scientific and technical basis for EPA's future dioxin risk management policies and programs.

When the reassessment began, the Administrator of EPA directed that Agency actions move forward without change in substance or timing until the reassessment is completed (Memorandum of William K. Reilly, September 11, 1991 "Dioxin Regulatory Program"). This direction has not changed. EPA continues to rely upon its 1985 assessment and the cancer slope factor it describes as the technical basis for policy and regulation; this is the assessment of dioxin in place as of September 11, 1991.

Consistent with this direction, EPA knows of no compelling reason not to include dioxin in the rule at this time. Instead, EPA believes it is an appropriate public health step to apply the current dioxin criteria in this rule and consider the merits of revising the criterion applicable in this rule (and to all other states covered by the National Toxic Rule) once the entire dioxin reassessment is complete and EPA revises its dioxin criteria. In the National Toxics Rule, EPA noted that a number of factors (as discussed below) may change but that the resulting criterion might remain the same. These concerns were reflected in EPA's response to comments in the National Toxics Rule. "It is too early in the process of scientific reassessment to support major changes in either the substance or timing of regulatory decisions related to dioxin." 57 Fed. Reg. 60884. EPA notes further that this approach, with respect to the National Toxics Rule, was upheld by the U.S. District Court for the District of Columbia in American Forest & Paper Assn, Inc. v. U.S. Environmental Protection Agency, No. 93-cv-0694 slip op. at 14-16 (D. D.C. 1996); 1996 U.S. Dist. LEXIS 13230. Based on information currently available to the Agency, the dioxin limit promulgated today for 2,3,7,8- tetraclorodibenzo[p]dioxin remains in the range of scientific defensibility.

EPA has provided a leadership role in the adoption and application of TEFs and is generally supportive of their use for risk assessment and risk management. However, the expansion of water quality criteria to include the full range of dioxin-like compounds is only one of many issues that needs to be addressed in revising water quality criteria. From an EPA perspective, the public is best served by having all these factors considered simultaneously. For this full review of the dioxin Water Quality Criteria to be well founded in science, it needs the benefit of a completed, peer reviewed, reassessment. Reexamining the cancer slope factor for 2,3,7,8- tetraclorodibenzo[p]dioxin and TEFs are among many issues important to future water quality criteria, but are not the only issues. The reassessment also includes coverage of reproductive, developmental, neurotoxic and other effects as well as fundamental questions as to the mode of action by which dioxin causes all of its effects. These will be considered in a thorough revision of water quality criteria. Interim adjustments based on only some parts of the toxicology or quantitative assessment would not support coherence in the scientific work or policy development that underlie Agency action. There are a number of outstanding issues that could result in modification of the water quality criteria, including: expanding the criteria to all dioxin-like compounds; adopting a new cancer slope factor; considering non-cancer effects as well as cancer effects; taking into account background levels and exposure; adjusting fish consumption patterns; adjusting bioconcentration and bioavailability factors; and adopting new TEF values. Some of these factors could lead to strengthening the water quality criteria while others might support relaxation. It is presently unknown what the net effect of all these factors may have on revised dioxin criteria. EPA continues to believe that waiting for the final

peer review reassessment to be completed so that all of these issues can be addressed simultaneously, is preferable to a sequence of incremental revision to the criteria based on only a few of these concerns. Thus, until EPA completes this reassessment, when EPA promulgates water quality criteria for a State, EPA will not use this approach.

For the reasons discussed above, the Agency is promulgating an ambient water quality standard only for 2,3,7,8-TCDD. This action is consistent with Section 303(c)(2)(B) and the National Toxics Rule (57 Federal Register 60863-60864, December 22, 1992) based on EPA's 1984 Ambient Water Quality Criteria Document for Dioxin. California, however, may adopt criteria for other related compounds.

Comment: Comments on the Proposed Dioxin Criteria

In the preamble, EPA states its support for California's use of Toxicity Equivalents (TEQ) in setting NPDES permit limits, yet proposes standards for only one type of dioxin. We have found that appropriate water quality protection requires consideration of all congeners because it is only through congener "fingerprints" that distinctions can be made between atmospheric deposition and wastewater sources. Most dioxins and furans are released to the environment through air emissions. In addition, EPA should also provide guidance for determining permit compliance for discharges dominated by higher chlorinated congeners given the slim data base that established the equivalent factors for these higher chlorinated congeners. Below are the reasons for these recommendations.

EPA is proposing standards for 2,3,7,8-tetrachlorinated dibenzo-p-dioxin (TCDD) that are consistent with the NTR and that are based on the 1984 criteria. The TEQ concept uses toxicity equivalency factors (TEF) to convert mixtures of polychlorinated dibenzo-p-dioxins and dibenzofurans (PCDD/PCDF) to equivalent concentrations of 2,3,7,8-TCDD.

EPA states in the preamble:

"...The concept of TEQ and the use of the I-TEFs/89, as outlined in EPA's 1989 Interim Procedures, provided valuable guidance in using the 2,3,7,8-TCDD water quality criteria in setting National Pollutant Discharge Elimination System (NPDES) water quality-based permit limits that are protective of human health for dioxin and dioxin-like compounds."

Discharge data from our region, which we have shared with EPA, show that applying this statement strictly would raise significant permit compliance issues for many wastewater point sources. Guidance

on an implementation strategy for dioxin is needed. We believe it is appropriate for EPA to provide this guidance because they have a broad multimedia understanding of the current state of knowledge about the major sources and fate of PCDD/PCDF.

Based on an extensive review of local and international scientific data, we have found that the major sources of dioxins to the environment are from emissions to air. However, the ultimate sink for PCDD/PCDF is the aquatic sediment. As a result, aquatic indicators such as fish tissue may show a problem regardless of the significance or insignificance of current wastewater point sources in that area.

In the San Francisco Bay area, we find that most of the PCDD/PCDF enters surface waters from storm water runoff. Another significant portion may come from direct deposition of PCDD/PCDF onto the bay surface from the ambient air. The sources to storm water are most likely from emissions to air and reservoir sources.

Considering this, control of the air emissions sources rather than controls through the NPDES permit program would appear to us to have the most impact on water quality. Of course, in certain areas where there is a significant point source such as paper and pulp mills, it may be prudent to control that source because of potential impacts on the local area.

In any case, because of the significance of air emission sources, EPA should provide an implementation strategy for regulating PCDD/PCDF using the TEQ approach.

On the issue of uncertainty of TEFs, we believe that, as part of the California Toxic Rule, EPA should provide guidance for determining permit compliance on samples dominated by hepta- and octa-CDDs and CDFs. We believe this is necessary because of the uncertainty of the TEF values for these congeners, and because of the dominance of these congeners in many of the discharge samples in our region.

According to EPA's 1989 Interim Procedures document, the data base for the TEFs for hepta- and octa-CDDs and CDFs are very slim. For octa-CDD and CDF specifically, EPA acknowledged in the document that the TEFs reflect the results of a single experiment. Permit violations triggered by TEFs that are based on a very slim data base concerns us. This concern is compounded by the fact that discharge and storm water sample data from our region show hepta- and octa-CDDs and CDFs account for 20 to 100% of the total TEQ of the samples.

Comment: p. 42178 -- 2,3,7,8-TCDD (Dioxin) Criteria We recommend that EPA not adopt criteria for dioxin at this time for the following reasons. First, we recommend that EPA is still completing the dioxin reassessment, and, similar to EPA's decision regarding the human health criteria for arsenic, we believe that EPA should defer adoption of the criteria at this time. Second, as pointed out elsewhere in these comments, we believe that there are fundamental problems in EPA's adopting criteria that are below detection limits and for which compliance costs cannot be properly determined. Third, use of dioxin has been banned, and therefore traditional control methods are unlikely to succeed in achieving meaningful reductions in dioxin levels in the ambient environment. Therefore, we urge EPA and the State to instead focus watershed management efforts on developing strategies for addressing dioxin issues (where dioxin is demonstrated to be causing water quality use impairment).

Comment: IV. EPA MUST LOWER THE PROPOSED 2,3,7,8 TCDD DIOXIN NUMBER IN ORDER TO ACCOUNT FOR THE ADDITIVE TOXICITY OF 16 OTHER DIOXIN CONGENERS

BayKeeper believes that the only appropriate water quality standard for dioxin is zero. That being said, the State of California's 1991 criteria for dioxin included all 17 dioxin compounds. EPA's rule purposes to establish a criteria for only one of those congeners - 2,3,7,8-TCDD. The State's 1991 rule applied toxicity equivalency factors ("TEFs") promoted but not promulgated by EPA in the proposed rule. The toxicity equivalency concept takes into account the additive toxicity of the congeners on each other and, as EPA appears to acknowledge, more likely protects human health for dioxin and dioxin-like compounds. Unfortunately, EPA once again defers to a non-existent state process to fill in the regulatory gap for the other 16 dioxin compounds. As is clear from the State of California's recently proposed implementation plan for EPA's proposed criteria, the State is not proposing to take EPA up on its offer to make the dioxin criteria truly protective by applying TEFs after the fact. Assuming that EPA insists on attempting to protect people from dioxin by only regulating one of the congeners, at a minimum, in order to account for the toxicity of 2,3,1,8-TCDD where a mixture of dioxins is present, EPA should reduce the proposed criteria of .014 pg/L to .0014 pg/L to account for additional toxicity resulting from the presence of other dioxins and consistent with the State's prior technical decision on dioxin.

Comment: 2,3,7,8-TCDD ("dioxin"). EPA has proposed a criterion for 2,3,7,8-TCDD ("dioxin') and is encouraging the state to implement the TEQ approach in implementing this criterion. WSPA does not agree with the TEQ approach entirely and strongly urges EPA and the state to wait until EPA and EPA's Science Advisory Board complete the re-evaluation of the health risk assessment of dioxin and its congeners. EPA may find that some congeners, especially the more highly substituted congeners which seem to be ubiquitous in the environment, are not as toxic as originally perceived. Until EPA's studies are complete, EPA and the state should regulate 2,3,7,8-TCDD based on the criteria set by EPA for this compound in the proposed rule.

Comment: On dioxin, despite proof that there are 17 dioxin compounds which harm the fishing public, EPA proposes a standard for only one of these compounds. EPA then says that it encourages the state to use the states previous scientifically correct standards for all 17 dioxins, instead of using the one EPA proposes, which deregulates 16 of the 17 most toxic chemicals known to science.

Our question here is, why does EPA think the state will have the courage to do the right thing about dioxin if EPA doesn't?

Comment: The toxicity equivalents notion is sort of held up as a good idea, and all states should go about doing that. It seems to me a simple step to say that the state has to do it. Just make those other 16 congeners --

And, of course, Baykeeper has signed on and there are a number of groups in the Bay Area that have signed on to the statewide notion of a zero dioxin standard anywhere possible. And I think that would be certainly the most practical place to put a zero discharge standard, would be in the standards themselves.

And to the extent there's other issues related to the particular permits, then we would obviously raise those at the time the permits came up. So we would propose a zero number for dioxin and all the congeners at this point.

Comment: 10. EPA has modified the PCB criteria from an approach where each aroclor has its own criteria to one where a single criterion applies to the sum of all aroclors. However, the new criterion does not represent the sum of the criteria for the aroclors. This, in effect, results in a much more stringent PCB criterion because an effluent previously could discharge several aroclors at concentrations which were not detrimental to biota but now those same concentrations add up to a sum which is greater than the new criterion. The 1995 Update document does not address why this change is made, and justification could not be located in the proposed rule. Such changes must be technically and scientifically defensible and necessary to protect and support designated uses. EPA should provide data and logic supporting the new approach and illustrate why it is now necessary to protect aquatic organisms.

Response to: CTR-037-010

The Agency agrees that the presentation of the aquatic life criteria for polychlorinated biphenyls (PCB) in the criteria matrix for this proposal differ from that in the NTR as amended; for this final rule, aquatic life criteria are expressed as the sum of aroclors (1242, 1254, 1221, 1232, 1248, 1260 and 1016, CAS numbers 53469219, 11097691, 11104282, 11141165, 12672296, 11096825 and 12674112, respectively) while for the NTR, as amended, the criteria limits are expressed for each of seven different aroclors. The Agency agrees that a criterion based on the sum of several aroclors may be more stringent than a criterion where each of several individual aroclors has a concentration limit. For example, a criterion of 0.014 ug/L applying to the sum of seven aroclors is more stringent than each of seven aroclors having a concentration limit of 0.014 ug/L.

The Agency does not agree that justification for a criterion based on the sum of aroclors could not be located in the proposed rule. Page 42168 of the Preamble states: "The presentation of the polychlorinated biphenyls (PCB) criteria in the criteria matrix for this proposal differ from that in the NTR, as amended: for this proposal, the criteria are expressed as a total of all aroclors, while for the NTR, as amended, the criteria are expressed for each aroclor." The aquatic life criteria proposed in the CTR were based on the criteria contained in the 1980 criteria document entitled, Ambient Water Quality Criteria for Polychlorinated Biphenyls, (EPA 440/5-80-068, October 1980) which was included in the Record for the proposed rule. This criteria document explains the derivation of aquatic life criteria based on total PCBs. Therefore, a criteria based on the sum of aroclors is comparable with the aquatic life criteria presented in the 1980 criteria document.

Comment: PROVISIONS SDG&E DOES NOT SUPPORT

As described in the following comments SDG&E does not support the following provisions:

PAHs criteria

EPA's proposed criteria for high molecular weight (HMW) carcinogenic PAHs (e.g., Benzo (a) Anthracene, Benzo (a) Pyrene, Benzo (b) Fluoranthene, Benzo (k) Fluoranthene, Chrysene, Dibenzo (a,h) Anthracene, Indeno (1,2,3-cd) Pyrene) used a number of assumptions which have made the resulting criteria overly conservative. Following is a discussion of these factors.

* PAHs are highly hydrophobic molecules and consequently bind to available suspended organic matter. Currently accepted methods for measuring concentrations of PAHs in water neglect the binding of such hydrophobic compounds to suspended organic matter(*1). The dissolved fraction (DOM) of this suspended material passes through a 0.45um filter and the organic extraction required for analysis of PAHs insures that both DOM-bound and free PAH will be reported. Since only the free PAH is bioavailable, this results in the proposed criteria being unnecessarily overprotective. The PAH criteria should account for the bio-availability of PAHs, as they do for the bio-availability of metals (e.g., dissolved criteria vs. total recoverable, translators, WERs).

* The simple use of octanol-water partition coefficients or fugacity modeling show that these HMW PAHs are only vanishingly soluble in seawater and to reach the proposed criteria values would have to originate from a large well-mixed source. For instance, assuming the HMW PAHs has a log octanol/carbon partition coefficient (log Koc) of 5.0, the sediment source would have to be 4.9 ppm in order to be the source for the proposed water quality criterion of 0.049 ppb. While there may be sites where this level has been reported for total PAHs, the highest values for a single HMW PAH reported at a very contaminated site was 2.3 ppb of benzo(a)pyrene(*2). Since the source of HMW PAHs in fish is unlikely to be the water column, the back-calculation of human health standards to water standards makes little sense.

* The fish consumption rate of 6.5 g/day used is not representative of fish consumption within the State of California, and overestimates exposure. This value is reported by the EPA to represent an estimate of average consumption of fish and shellfish from estuarine and fresh waters by the U.S. population(*3) . The draft EPA Exposure Factors Handbook (*4)(EFH) summarizes studies on the intake of fish and shellfish, and includes study results for Northern and Southern California from the National Marine Fisheries Service. While this data is compiled for fish from marine habitats, other data summarized in

Table 10-8 of the draft EFH suggests that the percentage of the population consuming and the mean daily fish intakes are higher for fish from marine habitats than for freshwater/estuarine habitats. The mean daily intake of marine finfish for anglers was 2.0 g/day for both Northern and Southern California, and the intake was 0.2 or 0.3 g/day on a per capita basis in the coastal population. The value of 2.0 g/day would be a more reasonable consumption rate and should be sufficiently health-protective of the more highly exposed sub-population of the state, because this intake is restricted to the angler population, which may reasonably be expected to consume their own catch and to represent a greater exposed population than the entire population of the state. The intake rate from this database is more up-to-date and is geographically representative. The criteria should be recalculated using the California fish intake rate.

* The use of a single, deterministic value of the BCF for each chemical is a gross oversimplification, and is likely to overestimate exposure. Some of the issues that should be considered in the selection of BCF values to use in the analysis are listed below:

* Most BCFs are reported for whole body samples, whereas the edible portion of the fish is typically only a fillet (muscle, skin, and adipose tissue). For example, in a study of the uptake and distribution benzo(a)pyrene in Northern Pike, less than 3% of the total accumulation of benzo(a)pyrene was located in the edible portion of the fish. The use of whole body BCFs in general overestimates the concentration of the chemical in the edible portion of the fish.(*5)

* BCFs have been shown to vary widely depending upon the fish species. Fish species with a higher content of lipids tend to bioconcentrate lipophilic substances to a greater degree than less oily, leaner fish from the same environment. In addition, fish species which lack or have a reduced capacity for metabolic elimination of a chemical tend to bioconcentrate chemicals to a greater degree. For example, the BCF for benzo(a)pyrene in snails is 82,000, while the BCF for benzo(a)pyrene in bluegill is 2,600.(*6) Creel studies should be utilized to select fish species caught and consumed by recreational fishers in California, and the appropriate BCFs selected to represent the regional fish populations ingested.

* Because of their low solubility and high affinity for organic carbon, PAHs in aquatic systems are primarily found sorbed to particles that are either settled to the bottom or are suspended in the water column.(*7) The sediments can be major sinks for PAHS. The concept of estimating concentrations in fish from water concentrations and BCF factors neglects the potentially very significant contribution of uptake from sediments into benthic organisms and subsequent ingestion by higher trophic levels.

* The presence of particulate organic material (POM) and dissolved organic material (DOM) may exhibit a significant effect on the BCF measured. For example, the BCF for benzo(a)pyrene in bluegills decreases from 2,600 to 220 in the presence of 20 mg/L DOM.(*8) Because the amount of organic materials in the waterbody may vary depending upon the freshwater or estuarine habitat, the BCFs should reflect the organic material in the freshwater and estuarine water bodies in California.

* Several studies by NOAA and others have shown that HMW PAHs do not bioaccumulate in fish tissue even under very polluted environmental conditions.(*9) This is because they either pass through the gut unchanged,(*10) or are extensively metabolized(*11) and excreted.(*12) Metabolism occurs in several tissues, but primarily in the liver and gut. Metabolism that occurs in the gut reduces the amount of PAH that is available for distribution within the fish flesh.

* There is a wide range of published BCFs for HMW PAHs. This is because a number of different methods and assumptions were used to deduce these values. Most laboratory studies derived BCFs

during short-term exposures to environmentally irrelevant high concentrations of PAHs, while field studies assumed that the only source of PAHs was the water column. In short-term high level exposures, the fish does not reach equilibrium and metabolic capacities are overwhelmed. The inability of fish to clear these PAHs results in apparently high BCFS. However, as discussed above, high levels of HMW PAHs do not occur even at very polluted sites.

* The use of BAF values in future evaluations is suggested in the proposed Water Quality Standards document. With regard to carcinogenic PAHs, extensive metabolism of the compounds by high-trophic-level consumers such as predatory fish has been demonstrated, therefore food chain biomagnification of these compounds does not appear to be significant, and the use of a BAF does not result in the conservatism that a BCF does.

* The EPA uses the oral slope factor for benzo(a)pyrene as the toxicity criteria for the other carcinogenic PAHs. While it is our understanding that the EPA does not have a national standard for assigning cancer potencies to different PAHs, both the EPA Region IX(*13) and the California EPA(*14) have policies which result in the assignment of toxicity equivalence factors to the carcinogenic PAHs. In general, the other carcinogenic PAHs are less potent than benzo(a)pyrene (i.e. the toxicity equivalence factors are less than one). Because the proposed Water Quality Standards are specific to California, the toxicity criteria used in the derivation should at a minimum reflect either current California EPA or EPA Region IX policies.

* The EPA should consider the use of probabilistic approaches to determine numeric water quality standards related to fish ingestion. The wide variability and relatively high uncertainty in the essential exposure parameters related to the intake rates, species of fish consumed, bioconcentration factors, and human sub-populations are ideally suited to a non-deterministic approach, and the expansion of studies which report distributional data should make a probabilistic approach feasible.

Response to: CTR-060-014

1. In response to the comment that EPA's proposed criteria for PAHs are overly conservative because they are not based on the freely dissolved fraction in water, EPA disagrees. While EPA agrees that the freely dissolved fraction of PAHs is the most bioavailable fraction for uptake by aquatic organisms, EPA believes that it would be premature to place in the final rule a criterion that is based on bioaccumulation factors normalized to the freely dissolved fraction because EPA has not yet completed peer review of its proposed national methodology for taking this approach. Until EPA completes the peer review of its national methodology for development of bioaccumulation factors, EPA believes it is most appropriate to base the criterion on the BCF, as is consistent with the NTR and EPA's current national recommended section 304(a) criteria. With respect to PAHs, EPA disagrees that its BCF of 30 necessarily results in an overly conservative criterion. Specifically, this BCF was derived from a study by Lu et al. (1977) and was measured in a model aquatic ecosystem environment containing multiple species at different trophic levels (e.g., algae, zooplankton, mosquito larvae, fish). Therefore, it is likely that some organic carbon was present in the study and that some sorption of the PAH compound (benzo-alpha-pyrene) onto dissolved and particulate carbon occurred thereby reducing the bioavailability of some portion of the PAH compound present. Further, since sufficient information is not presented in the Lu et al. study to estimate the freely dissolved fraction of the PAH compound, there is no basis for assuming that the bioavailability in the Lu et al. study was greater than waters in California generally.

EPA acknowledges that its revised national human health methodology would seek to develop water quality criteria for PAHs that are based on BAFs that consider the freely dissolved fraction in water (see 63 Fed. Reg. 43,756-43828; August 14, 1998, specifically pp. 43806-43823). However, this methodology has not been finalized and is currently undergoing external scientific peer review. EPA believes that

scientific peer review is essential to maintaining the scientific defensibility of its water quality criteria. In the aforementioned notice, EPA described its proposed methodology for appropriately determining bioaccumulation factors that are used to derive a criterion. As proposed, this would entail a two-step process: (1) calculation of a baseline BAF for organisms at each relevant trophic level from available field, laboratory, or model-derived bioaccumulation data, and (2) conversion of the trophic level-specific baseline BAFs to AWQC BAFs that reflect factors affecting bioavailability at the sites to which the AWQC is being applied. These factors include lipid content of consumed aquatic organisms and the organic carbon content (i.e., dissolved and particulate organic carbon) of waters applicable to the AWQC. In addition, EPA's proposed methodology includes guidance on selection of octanol-water partition coefficients (Kow), which are integral to several aspects of the methodology.

Although strong similarities exist between EPA's proposed national human health methodology (which includes the bioaccumulation methodology) and the 1995 methodology established under the Great Lakes Water Quality Initiative, all of the elements of EPA's proposed national bioaccumulation methodology require scientific peer review since it would be applied in a much broader scope than the GLWQI methodology (i.e., the national methodology applies to estuaries, lakes, streams, rivers throughout the United States whereas the GLWQI methodology applies just to waters of the Great Lakes region). In addition, the proposed national bioaccumulation methodology contains substantive changes since the 1995 publication of the GLWQI methodology (e.g., new guidance on selecting Kow values, revised estimates of food chain multipliers, additional guidance for the use of field data, revised default assumptions on lipid content of consumed aquatic organisms and particulate and dissolved organic carbon).

At the time of this rulemaking, EPA did not have sufficient time to adapt the GLWQI methodology in order to develop National or California-specific BAF estimates for the 304(a) criteria being promulgated, and also have these modifications peer reviewed. After the peer review process on the revised national methodology is complete, EPA plans to update its National 304(a) criteria on a periodic basis. As National 304(a) criteria are updated, EPA will evaluate the need to promulgate revisions to criteria in the CTR. Given that California is the only state with no numeric human health criterion in place for PAHs, and given that EPA has not completed a national methodology for developing BAFs on a freely dissolved basis, EPA believes it is most appropriate to promulgate the PAH criterion using the BCF that is consistent with the NTR and its most current national 304(a) recommendations.

2. In response to the comment that back calculation of human health criteria makes little sense because the source of PAHs in fish is not likely to be the water column, EPA disagrees that expressing human health criteria in the form of ambient water column concentrations is inappropriate for hydrophobic chemicals such as PAHs. For highly hydrophobic chemicals (i.e., log Kow > 6), EPA agrees that it is often the case that the concentrations in the water column are much lower than those in other environmental compartments such as sediment or food. EPA also acknowledges that the contribution of chemicals in food and sediment-based organisms to overall chemical uptake in higher trophic level organisms such as fish can be substantial, compared to the water column. However, EPA believes that expressing human health criteria in terms of concentrations in the water column concentrations is valid because environmental compartments in aquatic ecosystems (water, organisms, sediments) are all interconnected and therefore, concentrations of contaminants within these compartments are continuously being exchanged as a result of ongoing and competing chemical and biological partitioning processes. At equilibrium, contaminant concentrations within these environmental compartments are expected to be closely correlated, which is consistent with chemical equilibrium partitioning theory (i.e., higher water column concentrations would be correlated with higher sediment and prey concentrations). Thus, valid expressions of human health criteria can in theory be made for various environmental compartments (water, organisms, sediments). The Agency's choice of the water column for expressing

human health criteria largely reflects the need to use chemical criteria for determining acceptable chemical loadings to the water column and because more advanced implementation procedures are available for relating water column concentrations to chemical loadings, as compared to other compartments such as sediments and fish tissue.

3. In response to the comment concerning fish consumption, EPA disagrees with the comment regarding the consumption rate. For additional discussion of this issue, refer to the response to CTR-002-002a concerning fish consumption.

4. EPA disagrees with the comment that because lipid content in finfish is generally higher on a whole body basis compared to edible portions (e.g., fillet), the use of whole-body BCFs to calculate EPA's ambient water quality criteria significantly overestimates the concentration of the chemical in the edible portion of the fish and by implication is overly conservative. EPA disagrees with this comment because for lipophilic compounds such as PAHs, each BCF used in calculation of a human health ambient water quality criterion is first normalized to the lipid content of the tissue in which the residue was measured (45 FR 79346-79348). For example, BCFs determined from whole body residues are adjusted for the lipid content measured in the whole body, and BCFs determined from fish fillet residues are adjusted for the lipid content measured in the fish fillet. EPA performs this lipid normalization because it is widely recognized that accumulation of lipophilic chemicals is generally proportional to lipid content (Mackay 1982; Connolly and Pederson, 1988; Thomann, 1989) and this adjustment makes BCFs determined for different tissues and species comparable. Because of this proportionality with lipid content, steady-state BCFs for lipophilic compounds can be extrapolated from one tissue to another so long as they are expressed on a percent lipid basis. Once the average of the individual lipid normalized, BCFs are determined, this average, lipid normalized BCF is then adjusted to reflect the lipid content in the edible portions of aquatic organisms consumed by humans, which is 3.0% based on the EPA's 1980 Human Health Water Quality Criteria Methodology (45 FR 79318). In this way, the final BCF used to determine the human health water quality criterion reflects the chemical accumulation expected in the edible portions of consumed aquatic organisms. EPA further notes that for non-lipophilic compounds such as metals where lipid normalization does not apply, BCFs determined from only the edible portions are used in criteria calculations, per EPA's 1980 methodology.

5. In response to the comment that EPA's BCFs for PAHs are oversimplified and overly conservative because BCFs have been shown to vary widely depending on fish species and therefore, BCFs should only be used from organisms consumed by recreational fishers in California, EPA disagrees. EPA agrees that BCFs from specific organisms caught and consumed in California, if available and appropriately weighted by consumption data, would allow for derivation of BCFs that would be most tailored to the California situation. However, EPA believes that the use of BCFs in its 304(a) criteria are still appropriate to California because they were selected and derived to reflect accumulation in aquatic organisms consumed throughout the United States, including those consumed in California. While EPA agrees that BCFs can vary depending on the species due to a variety of factors (e.g., lipid content of the

organism, differences in chemical metabolism, bioavailability differences, duration of exposure), EPA has taken a number of steps in its determination of BCFs for its 304(a) criteria to limit this variability. For example, EPA in its 1980 criteria guidance recommends that individual BCFs be adjusted for lipid content and be based on steady-state conditions (typically > 28 days) in order to reduce variability in BCF estimates. Furthermore, in its calculation of human health criteria, the final BCF used is adjusted for the consumption-weighted lipid content based on the variety of aquatic organisms consumed throughout the United States. In its more recent Great Lakes Water Quality Initiative guidance (60 FR 15366) and in its proposed national human health criteria guidance (63 FR 43,756), EPA also recommends BAFs and BCFs also be adjusted based on the freely dissolved fraction of the contaminant in water and be determined separately for organisms of different trophic levels as further means for reducing variability. However, until EPA's national methodology for deriving human health water quality has undergone scientific peer review and is made final, the human health criteria for PAHs in the final CTR represent the most recent 304(a) criteria available and are based on the most current national human health criteria methodology. With respect to BCFs for PAHs, EPA used a bioconcentration factor of 30 for mosquito fish from Lu et al. (1977) which was measured from a 33-day exposure in a model aquatic ecosystem environment. EPA believes that this value is appropriate because it is believed to more closely approximate steady-state conditions compared to other, more variable BCF values which were based on much shorter exposure periods (e.g., 3-days) and because it accounts for the effects of metabolism which is known to be important for PAHs.

6. In response to the comment that the BCF neglects potential uptake from sediments for PAHs into benthic organisms and subsequent ingestion by higher organisms, EPA agrees that in general, standard laboratory-based BCFs involving water-only exposures ignore the potential uptake of contaminants from sediment-dwelling organisms (and other prey species). For some chemicals (e.g., high log Kow chemicals that are not readily metabolized), omission of exposure via the aquatic food web can underestimate exposure and bioaccumulation. For this and other reasons, EPA relies on bioaccumulation factors (BAFs), which incorporate multiple routes of exposure, for determining human health water quality criteria under the Great Lakes Water Quality Initiative Guidance (60 FR 15366). EPA is also in the process of adopting this general BAF approach in its proposed revisions to its 1980 National guidance for determining human health water quality criteria (63 FR 43,756). However, because the Great Lakes BAFs rely on a number of considerations and assumptions that are specific to the Great Lakes (i.e., lipid content of aquatic species consumed in the Great Lakes region, freely dissolved fraction in the Great Lakes, food chain multipliers specific to the Great Lakes ecosystem), they cannot be directly applied to national 304(a) criteria or other areas without adjustment and significant additional analyses to develop appropriate BAFs. As stated earlier, EPA is in the process of updating its national methodology which is undergoing scientific peer review and is developing national, default BAFs. Until such time as EPA revises its national methodology, the human health criteria for PAHs in the CTR represent the most recent 304(a) criteria available and are based on the most current national methodology.

With respect to EPA's PAH criteria, EPA used a bioconcentration factor of 30 for mosquito fish from Lu et al. (1977). This BCF was measured from a 33-day exposure period in a model aquatic ecosystem environment using a model food chain that included benthic organisms. Therefore, while the model ecosystem used by Lu et al (1977) may not completely replicate the exposure conditions of typical field situations, EPA believes that it does not ignore potential exposure via benthic organisms and disagrees with the comment.

7. In response to the comment that DOM (dissolved organic matter) may exhibit a significant effect on the BCF for PAHs, EPA agrees with the commenter that DOM (what EPA calls dissolved organic carbon or DOC) can influence the freely dissolved fraction of PAHs and other nonpolar organic chemicals. As stated above, EPA agrees that the freely dissolved fraction of PAHs is the most bioavailable fraction for

uptake by aquatic organisms. However, EPA believes that it would be premature to place in the final rule a criterion that is based on bioaccumulation factors normalized to the freely dissolved fraction in water because EPA has not yet completed peer review of its proposed national methodology for taking this approach. Until EPA completes the peer review of its national methodology for development of bioaccumulation factors, EPA believes it is most appropriate to base the criterion on the BCF, as is consistent with the NTR and EPA's current national recommended section 304(a) criteria.

Although EPA based its bioaccumulation factors (BAFs) on the freely dissolved fraction for the Great Lakes Water Quality Initiative (GLWQI) rulemaking, EPA did not have sufficient time to adapt the GLWQI methodology in order to develop National or California-specific BAF estimates for the human health criteria being promulgated, and also have these modifications peer reviewed. After the peer review process on the revised national methodology is complete, EPA plans to update its National 304(a) criteria on a periodic basis. As National 304(a) criteria are updated, EPA will evaluate the need to promulgate revisions to the CTR. Thus, given that California is the only state with no numeric human health criterion in place for PAHs, and given that EPA has not completed a national methodology for developing BAFs on a freely dissolved basis, EPA believes it is most appropriate to promulgate the PAH criterion using the BCF that is consistent with the NTR and its most current national 304(a) recommendations.

With respect to the BCF used to derive the PAH criteria, EPA's BCF was derived from a study by Lu et al. (1977) which was measured in a model aquatic ecosystem environment containing multiple species at different trophic levels (e.g., algae, zooplankton, mosquito larvae, fish). Therefore, it is likely that some organic carbon was present in the study and that some sorption of the PAH compound (benzo-alpha-pyrene) onto dissolved and particulate carbon occurred thereby reducing the bioavailability of some portion of the PAH compound present. Further, since sufficient information is not presented in the Lu et al. study to estimate the freely dissolved fraction of the PAH compound, EPA cannot determine the extent to which the freely dissolved fraction associated with the Lu et al. (1977) study would be systematically higher or lower than sites in California to which the criteria would apply.

8. In response to the comment EPA's PAH criteria are overly simplified and overestimates exposure because metabolism of PAHs and other factors indicate that some PAHs do not bioaccumulate extensively in fish, EPA disagrees. EPA agrees that some PAHs are known to metabolize rapidly in fish which results in much lower residues than would be predicted by the octanol-water coefficient (Kow). For this very reason, EPA chose not to rely on Kow-based estimates of bioconcentration for deriving the proposed human health water quality criteria for PAHs. Instead, EPA based the proposed criterion for PAHs on a bioconcentration factor of 30 determined for mosquito fish from Lu et al. (1977). This BCF was measured from a 33-day exposure in a model aquatic ecosystem environment and incorporates the effects of metabolism by organisms at various trophic levels. Thus, EPA believes that its BCF is appropriate for PAHs and is not overly conservative because it takes into account the effects of metabolism.

9. Another comment was made that EPA's BCF for PAH is oversimplified and overestimates exposure because: (1) a wide range of BCFs exists for high molecular weight PAHs, (2) different methods are used to determine BCFs, (3) BCFs are used from exposure durations that are too short, (4) use of field BCF studies only assumes that water is the exposure source, (5) BCF studies involve high exposure concentrations. While EPA agrees that BCFs can vary depending on the species due to a variety of factors (e.g., lipid content of organism, differences in chemical metabolism, bioavailability differences, duration of exposure), EPA has taken a number of steps in its determination of BCFs for its 304(a) criteria to limit this variability and disagrees with this comment. For example, EPA in its 1980 criteria guidance recommends that individual BCFs be adjusted for lipid content and be based on steady-state

conditions (typically > 28 days) in order to reduce variability in BCF estimates. Furthermore, in its calculation of human health criteria, the final BCF used is adjusted for the consumption-weighted lipid content based on the variety of aquatic organisms consumed throughout the United States. EPA also recommends that exposure concentrations be below levels that are cause overt toxicity to the test organisms. In its more recent Great Lakes Water Quality Initiative guidance (60 FR 15366) and in its proposed national human health criteria guidance (63 FR 43,756), EPA also recommends BCFs and bioaccumulation factors (BAFs) also be adjusted based on the freely dissolved fraction of the contaminant in water and be determined separately for organisms of different trophic levels as further means for reducing variability. However, until EPA's national methodology for deriving human health water quality has undergone scientific peer review and is made final, the human health criteria for PAHs in the CTR represent the most recent 304(a) criteria available and are based on the most current national human health criteria methodology. Therefore, EPA believes BCFs derived using its existing 1980 national methodology and BAFs resulting from its forthcoming revised national methodology are not oversimplified and do not result in overly conservative estimates of chemical accumulation.

With respect to BCFs for PAHs, EPA used a bioconcentration factor of 30 for mosquito fish from Lu et al. (1977) which was measured from a 33-day exposure period in a model aquatic ecosystem environment. This value was chosen for the BCF because it is believed to more closely approximate steady-state conditions compared to other, more variable BCF values which were based on much shorter exposure periods (e.g., 3-days) and accounts for the effects of metabolism which is known to be important for PAHs. Therefore, EPA disagrees that this BCF is oversimplified or results in an overestimation of PAH accumulation.

EPA disagrees that BCFs based on field data are inappropriate because they assume that chemical exposure result from only from water. On the contrary, such field-measured BCFs (now called BAFs) reflect uptake from multiple exposure routes (water, diet, sediment) but merely reference the accumulation to the water concentration. EPA believes that expressing human health criteria in terms of concentrations in the water column concentrations is valid because environmental compartments in aquatic ecosystems (water, organisms, sediments) are all interconnected and therefore, concentrations of contaminants within these compartments are continuously being exchanged as a result of ongoing and competing chemical and biological partitioning processes. At equilibrium, contaminant concentrations within these environmental compartments are expected to be closely correlated, which is consistent with chemical equilibrium partitioning theory (i.e., higher water column concentrations would be correlated with higher sediment and prey concentrations). Thus, valid expressions of human health criteria can in theory be made for various environmental compartments (water, organisms, sediments). The Agency's choice of the water column for expressing human health criteria largely reflects the need to use chemical criteria for determining acceptable chemical loadings to the water column and because more advanced implementation procedures are available for relating water column concentrations to chemical loadings, as compared to other compartments such as sediments and fish tissue.

10. Regarding the comment that BAFs should be used for further bioaccumulation evaluations in water quality criteria documents with particular reference to PAHs, EPA agrees. As discussed previously, EPA is in the process of revising its national human health methodology and has proposed a methodology that would develop water quality criteria for PAHs that are based on BAFs (see 63 Fed. Reg. 43,756-43828; August 14, 1998, specifically pp. 43806-43823). However, this methodology has not been finalized and is currently undergoing external scientific peer review. EPA believes that scientific peer review is essential to maintaining the scientific defensibility of its water quality criteria. When this methodology is made final, EPA will develop revised 304(a) criteria for chemicals, including PAHs, that are based on BAFs rather than BCFs. EPA notes that with respect to the BCF used in deriving the proposed PAH criteria, this BCF was similar to a BAF because it was measured in a model aquatic ecosystem

environment that contained organisms at different trophic levels.

11. The proposed PAH water quality standards for California are part of a Clean Water Act (CWA) Section 303promulgation that EPA has undertaken. For this promulgation, EPA utilizes published IRIS cancer slope factors and utilizes published guidance documents and adopted Agency policies. As such, the commenter is correct that EPA does not have an established policy on assigning cancer potencies based on TEFs to the various PAH chemicals. However, the State of California can endeavor to establish subsequent standards based on their own current policy. EPA would most likely approve such a decision during the Agency's triennial review of State standards, as long as the standard was scientifically defensible and was consistent with CWA requirements.

12. EPA agrees with the commenter that probabilistic approaches can be a viable option for addressing uncertainty and variability in the development of ambient human health water quality criteria, provided sufficient data are available from which to estimate statistical properties of input distributions (e.g., mean, standard deviation, type of distribution) and the methods are scientifically defensible. However, in many situations, insufficient data are available to estimate the necessary statistical properties of input distributions with sufficient confidence to provide meaningful results. Furthermore, it is highly unlikely that scientifically defensible input distributions could be used for all input parameters for all criteria in the CTR. It should be noted that EPA's criteria methodology does not preclude States and Tribes from using probabilistic approaches for criteria determinations, provided such approaches produce criteria which are scientifically defensible and achieve an appropriate level of protection. However, EPA does not consider the use of probabilistic modeling approach to be a prerequisite for deriving scientifically defensible criteria. EPA has demonstrated and continues to believe that scientifically defensible water quality criteria can be produced based on point estimates of toxicity and exposure parameters provided the estimates are based on reasonable and appropriate assumptions (i.e., worst case assumptions for all input parameters would probably not be reasonable because they would probably correspond to a highly unlikely or nonexistent risk scenario). EPA's criteria are not based on worst case assumptions but rather are based on assumptions that reflect different levels of conservatism depending on the input parameter. Together, these input parameters result in criteria that the Agency believes achieves an appropriate level of protection for its national 304(a) criteria and are appropriate for promulgation in California.

Comment: II. Use of New Scientific Information

The City acknowledges and supports EPA's update of several water quality criteria including those for mercury, cadmium and arsenic. While a number of criteria were updated to reflect current scientific information, there are a few notable exceptions.

The following briefly addresses the key updates and omissions that should be addressed in the final publication of this rule.

7. Adoption of More Stringent Requirements for Maximum Containment Levels ("MCLs") is Inappropriate

A number of the water quality-based criteria establish water ingestion-related requirements more stringent than tap water criteria. This leads to the anomalous result that ingestion of effluent is regulated more stringently than ingestion of tap water. An example of this problem is bromodichloromethane ("BDCM") and dibromochloromethane ("DBCM") which are two types of halomethanes formed by chlorination of effluents. EPA studies recognize that tap water contains higher levels of these constituents, but their presence is tolerated due to the beneficial effects of chlorine on killing bacteria. The CTR would regulate these pollutants in surface waters at one-tenth the level present in tap water.

EPA policies recognize that this is not a reasonable result and that application of the MCL should be considered protective in such instances (see, 62 Fed. Reg. 27709). Consistent with recent EPA action to delete the arsenic criteria from the CTR the Agency should delete the water ingestion-related requirements for BDCM and DBCM. Such action is even more appropriate for these pollutants as they are volatile and very shortlived in the environment. Thus, the discharge of these pollutants by publicly owned treatment works presents no actual threat of drinking water contamination.

Response to: CTR-020-018

EPA disagrees with commenter. EPA believes that discharges can meet both the requirements of the Safe Drinking Water Act (SDWA) and the Clean Water Act (CWA) after the CTR is promulgated. EPA believes that any final limits for THMs would be feasible to meet because it is unlikely that a discharger would receive criteria end-of-pipe limits due to the dilution in the receiving stream, as well as other factors taken into account, when translating a criterion into a water quality criteria-based effluent limit. EPA acknowledges that water quality criteria may be more stringent than drinking water MCLs and believes that this is appropriate (refer to response on this same issue in CTR-025-002a and

CTR-025-003a). Under the CWA, water quality criteria are required to protect the designated use, without respect to economic factors. Under the SDWA, EPA may take into account cost or availability of treatment technology in setting an MCL. As expressed by the commenter, the presence of the two trihalomethanes mentioned is a matter of balancing the potential for chemical risk associated with the formation of these chlorine byproducts and the beneficial effects of chlorine reducing microbial risk. Although EPA has stated that MCLs may be considered protective in the absence of water quality criteria, the Agency recommends the development of water quality criteria since the methodology specifically accounts for fish ingestion route exposure. Because water quality criteria take into account exposure to fish as well as water, they may be more stringent. Other factors that may also account for stringency differences are discussed in the response to CTR-025-002a. Concerning volatility, EPA does not disregard chemicals simply because they are volatile. Many chemicals may be somewhat volatile or short-lived, but may present health risks due to the frequency of discharge, biomagnification, or other factors.

Comment: Human health water quality criteria for a number of other priority pollutants are at levels significantly below the corresponding California SDWA MCL. While Metropolitan favors a margin of safety between human health-water quality criteria and the SDWA MCL, significant differences between these two regulatory requirements can create problems in the course of maintenance of drinking water facilities.

For example, water utilities need to periodically "de-water" their lines as part of routine maintenance. The de-watering of distribution lines transporting treating drinking water results in discharges containing trihalomethanes (THMs). The CTR proposes human health criteria for each of the four compounds comprising the THM classification. The total limit under the CTR for THMs as a group is 11 ug/L, sigficantly below the California SDWA MCL of 100 ug/L as well as the proposed level of 80 ug/L for Stage 1 of the Disinfection/Disinfectant By-Products Rule. Thus, the discharge of water that meets California SDWA standards could potentially violate CTR human health criteria if that water is discharged to a source of drinking water supply. Metropolitan requests that EPA establish CTR human health criteria for THMs consistent with the California SDWA MCLs for THMS.

Response to: CTR-025-003c

EPA acknowledges that water quality criteria may be more stringent than drinking water MCLs and believes that this is appropriate (refer to response on this same issue in CTR-025-002a and CTR-025-003a).

Comment: Due to the time constraints of the comment period, we have focused our review and comments primarily on those criteria that we anticipate may cause compliance issues for one or more of the Sanitation Districts' WRPs (see below). Based on our initial review of the proposed rule, the Sanitation Districts recommend that adoption of some of the criteria be deferred. As explained in the attached comments, we believe that there are significant scientific issues regarding the human health criteria for several trihalomethanes that call into question the accuracy and appropriateness of the proposed criteria. In addition, we reconunend that EPA defer adoption of those criteria that are below detection limits and that have not been demonstrated to be adversely affecting water quality or the attaimnent of designated uses on a water body-specific basis in California. In addition, we recommend that EPA not adopt criteria for effluent dependent waters, unless they have been adjusted to reflect the characteristics of this type of water body.

Trihalomethanes Human Health Criteria

EPA has proposed human health criteria for consumption of water and organisms for four of the Trihalomethanes (THMs): bromofom (4.3 ug/L), Chlorodibromomethane (0.41 ug/L), Chloroform (5.7 ug/L), and Dichlorobromomethane (0.56 ug/L). We have a number of concerns about these criteria and recommend that EPA defer the adoption of these criteria or consider utilizing either the current or proposed drinking water standards in lieu of the proposed criteria.

First we can find no basis for the Bioconcentration Factor (BCF) fisted in the CTR Administrative Record Matrix (ARM), or in any of EPA's supporting documentation for the CTF, The ARM lists the BCF for chloroform as 3.75; the other three compounds have been assigned the sarne BCF "based on chloroform." We have been unable to determine the origins of the 3.75 BCF. The Administrative Record Matrix refers back to the 1980 Water Quality Criteria Document (WQCD).(*4) On page C-39 of the WQCD, EPA notes that

"Approximately 1 percent of the chloroform exposure results from the consumption of aquatic organisms which exhibit an average bioconcentration potential of 3.75-fold. The remaining 99 percent of chloroform exposure results from drinking water."

No further reference is provided for the derivation of the 3.75 bioconcentration factor.

Second, we do not believe that the four THMs bioaccumulate in fish tissue, EPA has established a policy for setting hunan health criteria in the Great Lakes Initiative whereby chemicals with half-lives less than eight weeks in water columns, sediments or biota are not bioaccumulative chemicals of concern (BCCs). Literature on chloroform indicates that it is non-persistent in water, with a half-life of less than two

days.(*5) Based on this finding, chloroform should not be considered as a BCC. This conclusion is supported by other information in the literature which shows that the THMs do not bioaccumulate in fish.(*6)(*7)(*8) Thus, the BCF of 3.75 used by EPA in calculating criteria for these four THMs is not a documented nor reasonable assumption for calculating human health criteria.

Third, similar to the situation with arsenic, EPA has different human health values for drinking water and for ambient water. The current drinking water MCL for the THMs is 100 ug/L with a proposed MCL of 80 ug/L. The proposed MCL was recently endorsed by EPA's Microbial/Disinfection By-Products Federal Advisory Committee as part of an Agreement in Principle, and will form the basis for the 1998 Enhanced Surface Water Treatment Rule. We believe that the application of the CTR criteria is inappropriate and potentially wasteful of the status resources if it causes POTWs to invest in treatment merely for treatment's sake. Thus, we recommend that EPA defer the adoption of these criteria or consider utilizing either the existing or proposed MCL in setting the human health criteria for the THMs in the CTR.

Response to: CTR-059-008

EPA acknowledges that water quality criteria may be more stringent than drinking water MCLs and believes that this is appropriate (refer to responses on this same issue in CTR-025-002a and CTR-025-003a). See also response to CTR-020-018. Regarding detection limit issues, refer to the response on effluent-dependent waters in CTR-034-007 and CTR 036-009.

The commenter is incorrect regarding the lack of documentation on the BCF for chloroform. The basis of the value of 3.75 is explained in the very document that the commenter claims it is lacking from. Using a documented BCF of 6 and an average lipid content of 4.8 percent from bluegills, EPA used a lipid adjustment factor based on the weighted average lipid percentage of 3 for the same freshwater and estuarine species that represent the fish consumption rate of 6.5 gm/day. Refer to text in EPA 440/5-80-033, October 1980, pp. C-3 and C-4).

However, EPA has decided to reserve the numeric criteria for chloroform in the final rule. EPA is

revisiting the cancer risk assessment for chloroform (see section G.6. of the preamble).

Comment: While the draft regulations demonstrate clear progress on these and other issues, there remain some unresolved problems that could compromise our ability to serve our customers. We offer these comments in the hope of minimizing those potential impacts.

Disinfection By-Products

Sanitation utilities may not be able to meet the proposed criteria for trihalomethanes (chloroform, dichlorobromomethane, chlorodibromomethane), which appear to be more stringent than those adopted for drinking water standards. Some consideration should be given to dischargers who must, by law, disinfect their effluent discharges, as the most widely-used disinfection method (oxidation by chlorine) unavoidably produces trihalomethanes. In addition, chlorine is an integral treatment process additive for control of filamentous algae in our activated sludge process and for operational control of our tertiary filtration process -- we simply must use this chemical to optimize process performance.

The proposed criteria imply a potentially enormous investment in alternative disinfection methods, or equally-expensive post-disinfection removal using carbon adsorption or air-stripping towers. Our preliminary estimate is that compliance with the proposed criteria for trihalomethanes would cost our served communities over $650,000 per year. Furthermore, the benefits of these expenditures are unclear, since neither drinking water supplies nor consumptive uses such as fishing are important uses of the receiving,waters.

Response to: CTR-089-004

EPA acknowledges that water quality criteria may be more stringent than drinking water MCLs and believes that this is appropriate (refer to response on this same issue in CTR-025-002a and CTR-025-003a). See also response to CTR-020-018.

Comment: Trihalomethanes (THM) - The current California Department of Health services criterion for Total THMs, is 100ug/L to be reduced to 80 ug/L in 1998. Chloroform is the dominant THM in drinking water and is a disinfection byproduct and is typically found in drinking water in the range of 34-45 ug/l. The proposed value under the CTR is 5.7 ug/L, which is two orders of magnitude below the chronic toxicity criterion and one order of magnitude below the California DHS standard for drinking water promulgated under the auspices of the Safe Drinking Water Act. Such a restrictive criterion will inhibit municipal water supply agencies in operation and maintenance of their water supply system. EPA needs to explain the rationale for such a restrictive criterion for THM.

Response to: CTR-090-022

EPA acknowledges that water quality criteria may be more stringent than drinking water MCLs and believes that this is appropriate (refer to response on this same issue in CTR-025-002a and CTR-025-003a). See also response to CTR-020-018. However, EPA has decided to reserve the numeric criteria for chloroform in the final rule. EPA is revisiting the cancer risk assessment for chloroform (see section G.6. of the preamble).

Comment: 3) We do not agree with the use of the 10'-6 risk level proposed here. As is noted in the proposed rule, a significant uncertainty factor ranging from 10 to 10,000 is used to set human health criteria. We can understand the use of these factors but the public should understand that they may be paying to protect to the 10'-10 or one in ten billion risk level. We suggest that the risk level used be tied to the certainty of risk. For example, where uncertainty factors range from 1 - 10, use 10E-6; 11 - 100, 10E-5 101 - 10,000, 10E-4 risk level. Another option would be to promulgate a range from which the permit writer may choose depending on the site specific nature of the waters and the needs of the effected individuals. At a minimum the EPA should promulgate at a factor of 10E-5 and allow the regional boards to set more stringent criteria if warranted. We all need to keep in mind that lower limits mean higher costs and higher costs here mean fewer resources available elsewhere. Even with the best of intentions, we may be sacrificing hundreds in an attempt to save one. For example, an increase in sewer rates reduces the discretionary money normally used for the purchase of food and medical services with potentially significant impacts on the poor.

Response to: CTR-003-003

See also response to Comment CTR-058-001.

The comment author suggests that the rule provide variable risk levels dependent on the uncertainty factor used in calculating national criteria guidance. It is suggested that higher risk levels be allowed for parameters having criteria based on a higher uncertainty factor. This suggestion runs counter to EPA policy that greater protection be provided when uncertainty concerning the adequacy of protection is greatest.

This author also suggests giving individual permit writers the authority/responsibility to choose the risk level on a site specific basis for each permit. This approach, along with the above suggestion, would result in risk levels that vary both on a parameter specific basis and a site specific basis. This approach may result in selective inadequate protection for highly exposed populations and even for the general population. EPA would support, in this case, an approach that includes scientifically valid site-specific criteria.

If the State has a scientific basis, and wants to adopt more or less protective site-specific criteria, it is within the State's discretion to do so (See response to CTR-058-001), but this rule is a reasonable attempt to protect all of California's waters.

EPA cannot respond specifically to the author's assertion of higher costs for sewer ratepayers because it

is provided without supporting evidence. EPA's Economic Analysis indicates that a change in the risk level from 10-5 to 10-6 would cause only a negligible increase in compliance costs for the State as a whole based on a sample of California facilities (Economic Analysis of the California Toxics Rule, P. A-2). Due to limited resources, EPA was not able to estimate potential costs for every facility in the State. In any case, water quality criteria must be based on that which is necessary to protect human health and the environment and must be scientifically based. Under, the Clean Water Act, this requirement overrides consideration of economic impacts.

Comment: 6. Human health criteria for carcinogens should be adopted at a 10E-5 risk level. Based on the analyses performed by other Bay Area POT\ft, the District is concerned that organics monitoring of its effluent will identify human health criteria that cannot be achieved without dilution well beyond 1 0: 1 (e.g., aldrin, PAHS, heptachlor). At a 10E-6 risk level, the District would be forced to add activated carbon at a significant cost or possibly go to land disposal at an enormous cost. The benefits would be nil because the District is such a small contributor to the Bay and generally, according to the results of the Regional Monitoring Program, these criteria are not exceeded in the Bay.

Response to: CTR-005-007

EPA disagrees with this comment.

The comment author suggests that the rule should provide for a higher allowable risk level because monitoring indicates that current effluent concentration for certain pollutants exceed the levels provided at a risk level of 10-6 leading to enormous treatment/disposal costs. In the first place, the comment author has not provided specific data or evidence that shows any additional treatment will be needed. Secondly, EPA cannot justify reducingprotection to California's population across the State based on an assertion of a need for additional treatment and consequent added costs. Other federal and State processes such as site-specific criteria that lessen the need for pollutant removal and TMDLs that shift the need for pollutant load removal to other sources of that pollutant may be scientifically justified and could facilitate moving toward less costly treatment alternatives, should additional treatment be indicated; however, it is essential that beneficial uses remain fully protected.

In addition, the commentor notes that the criteria are not exceeded in the Bay. The State permit authority must show that the discharge of organics have reasonable potential to cause or contribute to an exceedence of water quality criteria in order to establish effluent limits. If no reasonable potential is established, the facility will not incur any costs for the control of organics.

E-01d

Comment: The City of Simi Valley discharges approximately 10 million gallons per day (mgd) of tertiarytreated wastewater (as well as municipal storm water) to the Arroyo Simi, an effluent dependent water body. Through much of the year, Arroyo Simi is dry several miles downstream from the City. The Arroyo Simi Characterization Report, completed by the City in 1995, concluded that the arroyo does not support a significant fishery, and observed only arroyo chub, mosquito fish and blunt-nosed minnow in the stream. Although designated as a potential municipal water supply in the Basin Plan, the arroyo waters are not used for municipal purposes. Effluent monitoring are limited, but available data indicate that the City's discharge may have a reasonable potential to exceed the proposed aquatic life criteria for several metals and the proposed human health criteria for several carcinogens.

Since Simi Valley is largely a residential community with supporting commercial development and little industry, and since the City already has an effective pretreatment program, it is unlikely that pollution prevention efforts would effectively reduce the problematic constituents. More likely, the City would be faced with end-of-pipe treatment controls such as lime precipitation and carbon adsorption to achieve the proposed criteria. The costs would undoubtedly be significant and the benefits relatively minor.

Under these circumstances, it appears reasonable to adopt criteria for Arroyo Simi, and similar effluent dependent waters, that are reasonably achievable without costly end-of-pipe controls and that reflect the actual use of the water (i.e., generally such waters are used for fishing or drinking). One way to address this issue, consistent with the requirements of the Clean Water Act, would be to adopt specific human health criteria for Arroyo Simi and other effluent dependent streams based on a cancer risk coefficient of 10E-5 or in some cases 10E-4. Based on the limited data collected by the City, risk levels of 10E-4 would have to be adopted for dioxins, aldrin, alpha-BHC and 4,4,-DDD (see Table 1). Risk levels of 10E-5 would be sufficient for chloroform and endoslfan 11 (Id.).

Response to: CTR-011-001a

EPA disagrees with this comment.

See also responses to CTR-058-001 and CTR-005-007.

When EPA promulgates a rule, it follows national policy and what it understands to be the policy of the state in selecting a risk level for the general population. (See response to comment CTR-058-001) EPA would not use a higher general risk level for specific pollutants unless it had data showing that consumption of those pollutants is less than the general consumption levels EPA uses along with the general risk level of 10-6.

The commenter suggests determining criteria by assessing what the condition of the effluent is, without assuming application of what it deems as costly controls, by applying a different risk level for various pollutants for the same waterbody. In other words, the commenter proposed that site specific human health criteria be adopted for their receiving water based on individual pollutant effluent data. Site specific criteria are the prerogative of the State and are generically recognized in this rule; however, effluent data cannot serve as sufficient justification for criteria.

The State could remove a use designation pursuant to its own regulations as long as it is not an existing use. Justification for the use removal or replacement would need to be developed as provided for in 40 CFR Part 131. This action would require a Use Attainability Analysis and would need to assure that full protection of existing uses and other designated beneficial uses of the waterbody is provided.

EPA cannot respond specifically to the commentor's assertion that it would incur costs for end-of-pipe costs for sewer ratepayers because it is provided without supporting data. EPA's Economic Analysis indicates that a change in the risk level from 10-5 to 10-6 would cause only a negligible increase in compliance costs for the State as a whole based on a sampling of facilities (Economic Analysis of the California Toxics Rule, P. A-2). Due to limited resources, EPA was not able to estimate potential costs for every facility in the State. In any case, water quality criteria must be based on that which is necessary to protect human health and the environment and must be scientifically based. Under, the Clean Water Act, this requirement overrides consideration of economic impacts.

Comment: Cancer Risk Level (FR p.42181, Preamble section E.3.f.)

The Agency requests comment on the adoption of a 10E-5 risk level for carcinogenic pollutants rather than a 10E-6 risk level. The Agency should be aware of an analysis conducted by the State Water Resources Control Board ("State Board") as part of the Functional Equivalent Document, or environmental impact review, for the Inland Surface Waters Plan in March, 1992. The analysis compared inland discharger's ability to attain objectives at both risk levels. Effluent data from 23 inland dischargers for the period of 1989 to 1991 were used. Thirty-nine constituents (mostly organic compounds) were examined. Although the State Board selected the 10E-6 level, differences in attainability were shown and described.

In the Agency's Economic Analysis of July, 1997 for this Rule, there was a comparison of costs between the two risk levels in Section 4. It is stated on p. 4-17 that there was a lack of data for organic pollutants and, for those facilities with data, most of these pollutants were found below detection limits. It is not certain, then, how many constituents were examined for the risk level economic analysis. Also, fewer dischargers were examined by the Agency than by the State Board in its previous studies. However, in

Section 10 (p. 10-2), it was concluded by the Agency that there were minimal cost differences between the two risk levels.

Obviously, the 10E-5 risk level would be more attainable and less costly than the 10E-6 risk level. It is probable, from our review so far, that the Agency has underestimated the cost differences. A more thorough cost/benefit analysis, i.e., a comparison done at a greater level of detail such as the State Board had done for attainability, is needed for the Agency's Rule before a risk level is suggested or adopted.

Response to: CTR-015-002

EPA disagrees with this comment.

See response to CTR-058-001.

In regard to the comment about the results of the economic analysis which compared the potential costs of a 10-5 and 10-6 risk level, EPA believes that its methodology is sound. EPA examined recent monitoring data for eachsample facility. The fact that some facilities have a lack of data or that many of the organic pollutants that were monitored were measured below the detection limit does not necessarily mean that these facilities would not be able to comply with WQBELs based on a 10-6 risk level Even if facilities expand monitoring efforts or if detection limits are improved, the commenter has provided no evidence that compliance costs would significantly increase. EPA included as many sample facilities it could to project statewide costs taking into account time and resource constraints.

Comment: It is with a sense of reluctance that Sunnyvale joins in CASA/Tri-TAC's adverse comments ont eh CTR and teh EA, and Sunnyvale does so in a spirit of constructive criticism and with an expectation that the Agency will make the necessary adjustments in its approach towards the CTR before the final rule is promulgated. In addition, in the same spirit and with the same expectation, Sunnyvale would like to make the following points on its own behalf:

2. Obligation to Assess Alternative Cancer Risk Levels for Human Health-Based Criteria. Sunnyvale is gravely concerned that EPA has used the wrong approach in proposing to establish human health criteria for organic pollutants, particularly those pollutants for which the proposed criteria are below the method level of detection ("MDL"). Sunnyvale recommends that EPA should thoroughly assess all of the potential impacts, including costs and benefits, of the 10E-4 and 10E-5 risk levels before proposing the

human health-based criteria. As pointed out in the EOA Letter, there is a significant potential for advancing technology to lower the MDL for many pollutants to the point where laboratory equipment is able to measure some or all of the organic compounds for which EPA is proposing to establish criteria at the new level. It is intuitively obvious that the costs of attaining criteria set at the 10E-6 level will be significantly greater than attainment of a 10E-5 or 10E-4 level, particularly where, as pointed out in the EOA Letter, the only available method of treatment is granular activated carbon. Sunnyvale is concerned that the EA does not adequately address the potential for these costs, and, consequently, does not take these potential costs into account in determining whether to exercise its flexibility in choosing whether to use a 10-4 , 10-5 or 10-6 cancer risk level as the basis for its CTR promulgation.

EPA is required by Executive Order 12866, the Regulatory Flexibility Act and the Unfunded Mandates Reform Act to identify and analyze alternatives to a proposed rule. We cannot understand, therefore, why EPA has done such a cursory analysis in the preamble to the CTR and the EA of the alternatives to the use of the most stringent (10E-6) risk level for establishing criteria for human health effects of pollutants, particularly organic pollutants. EPA cannot base its selection of the 10E-6 level based upon previous regulatory pronouncements by the State of California. Any new determination by the State will be subject to the analytical requirements of Section 13241 of the Porter-Cologne Act and by review by the Office of Administrative Law. Thus, it is not a foregone conclusion that the State will ultimately select the 10E-6 level. EPA has its own legal requirements to fulfill. Accordingly, we ask that EPA not promulgate the final human health criteria for the pollutants of concern unless and until it has adequately analyzed the costs and other implications of the various alternatives to the 10E-6 level.

In conclusion, we are entirely supportive of many of EPA's inovative approaches towards development of the CTR, particularly as regards the toxic metals. However, we believe that EPA has needlessly failed to comply with many of its legal obligations, particularly as regards the development of human health-based criteria on cancer risk levels of organic pollutants. We urge the Agency to reconsider its position in the matters covered by this letter (as amplified by the EOA Letter) and the CASA/Tri-TAC letter. Sunnyvale pledges its continued participation in place-based watershed management planning in the South Bay, its cooperation with the Agency in making a success of the WPI, and to an ongoing effort by the Agency and others to reach water quality goals in the South Bay. We thank you for the opportunity to comment on the proposed CTR.

Response to: CTR-021-005a

EPA disagrees with this comment.

See response to Comment CTR-058-001 and CTR-011-001a.

In regard to the comment about the results of the economic analysis which compared the potential costs of a 10-5 and 10-6 risk level, EPA believes that its methodology is sound. The fact that many of the organic pollutants that were monitored were measured below the detection limit does not necessarily mean that these facilities would not be able to comply with WQBELs based on a 10-6 risk level. Even if detection limits are improved, compliance could not be determined until the results of using the new monitoring method was completed.

Comment: [INDENT]- EPA should select human health criteria for carcinogens based on the 10E-5 or 10E-4 risk levels instead of the 10E-6 level. This approach would be consistent with other EPA regulatory actions such as the Great Lakes Initiative for which EPA used the 10E-5 risk level in setting the criteria, or the national drinking water program where maximum contaminant levels are commonly developed with a risk level of 10E-4 to 10E-5. Moreover, EPA should acknowledge that there is considerable uncertainty and variability in the risk assessment process. The criteria are calculated using a model that assumes low dose linearity. When using this kind of model, the calculation of risk to several significant figures at any given low dose gives the illusion of knowledge and precision that are not really there. Thus, the actual risk to the exposed population associated with a risk level of 10E-4 may be virtually indistinguishable from a risk level of 10E-6, yet the socioeconomic impacts associated with complying with criteria promulgated using the 10E-6 risk level can be significant. Thus, EPA should reconsider the risk level used in calculating criteria in the CTR and should select a lower risk level.

Response to: CTR-035-004

EPA disagrees with this comment.

See response to CTR-058-001.

The fact that maximum contaminant levels in the drinking water program are sometimes developed with a risk level in the range of 10-4 to 10-5 is not a factor in setting ambient water quality criteria. Under the Safe Drinking Water Act, MCLs are set taking best available technology into account, while under the Clean Water Act, water quality criteria are set solely based on human health or aquatic protection.

Comment: pp. 42175-42176 -- Reference Doses (RfDs) For non-carcinogenic human health criteria, EPA divides a "no observed effect" dose in animal studies by an uncertainty factor, which ranges from 10 to 10,000 based on various factors such as whether the data are being extrapolated from animals to humans. In addition, a modifying factor greater than 0 and less than 1O is applied to reflect the professional judgment of toxicologists. The use of such large uncertainty factors indicates that there is a large margin

of safety in the criteria, and some flexibility in the application of these factors. We recommend that EPA consider using this flexibility, for instance, to develop criteria appropriate to effluent dependent waters. In many cases, little or no fish consumption occurs and no direct use of the water for drinking water supplies may occur in effluent dependent waters; therefore the risk of human exposure is small, and it would be appropriate to use lower uncertainty and modifying factors in promulgating criteria for these water bodies.

Response to: CTR-035-021

EPA disagrees with this comment.

See response to CTR-058-001.

The comment author recommends that EPA develop criteria appropriate to effluent dependent waters. In the CTR, EPA has applied criteria on the basis of State adopted beneficial uses. As the State has not used a beneficial use category that distinguishes effluent dependent waters, there are no waters to assign a separate set of criteria. The CTR does not preclude the State from developing a special beneficial use category for effluent dependent waters should it choose that course of action. (See EPA Region 9's Interim Final "Guidance for Modifying Water Quality Standards and Protecting Effluent-Dependent Ecosystems", June 17, 1992, for guidance.)

Comment: p. 42181 -- Risk Factors for Carcinogens EPA has calculated the human health criteria for carcinogens in the proposed CTR using a 10E-6 risk level, but invites comment on whether the criteria for carcinogens should instead be calculated using a risk level of 10E-5. We recommend that EPA consider a range of risk levels between 10E-4 and 10E-6, which we understand to be consistent with EPA's policy of allowing States to use risk levels in the range of 10E-4 to 10E-6 when adopting criteria for carcinogenic priority pollutants in water quality standards (U.S., EPA, 1994b). We do not agree with EPA's proposition to adopt a 10E-6 risk level based upon previous regulatory decisions by the State. Any new determination by the State will be subject to the legal requirements of Section 13241 of the Porter-Cologne Act and by review by the Office of Administrative Law. Thus, it is not a foregone conclusion that the State will ultimately select the 10E-6 level. Moreover, EPA should acknowledge that there is considerable uncertainty and variability in the risk assessment process. The criteria are calculated using a model that assumes low dose linearity. When using this kind of model, the calculation of risk to several significant figures at any given low dose gives the illusion of knowledge and precision that are not really there. Thus, the actual risk to the exposed population associated with a risk level of 10E-4 may be virtually indistinguishable from a risk level of 10E-6, yet the socioeconomic impacts associated with complying with criteria promulgated using the 10E-6 risk level can be significant. EPA

should therefore revise its alternative analysis for the 10E-5 risk level evaluated for the cost analysis, and reassess its conclusions. We believe this re-analysis to be necessary for EPA to adequately comply with the requirements of Executive Order 12866, the Regulatory Flexibility Act and the Unfunded Mandates Reform Act to identify and analyze alternatives to a proposed rule.

Response to: CTR-035-027

EPA disagrees with this comment.

See response to CTR-058-001. In that response EPA explained that protection of the general population at the 10-6 risk level was necessary to assure that those segments of the California population that are more highly exposed are protected at a 10-4 risk level.

EPA is unable to respond to the generic comment that "...the actual risk to the exposed population associated with a risk level of 10E-4 may be virtually indistinguishable from a risk level of 10E-6,..." when using a linear cancer risk model. The commenter has provided no supporting evidence for this assertion.

Comment: RECOMMENDED MODIFICATIONS

To address our concerns, we recommend the following modifications which do not undermine the toxic pollutant control actions envisioned in EPA's economic analysis (e.g., BMPs for stormwater and source control). In fact, some of these recommendations would provide incentives for greater movement toward achieving the water quality criteria than would occur under the Rule as it is currently proposed.

II. Recommendation: Adopt human health criteria for PAHs at a 10 (-4) risk level and human health criteria for other carcinogens at risk levels that are generally achieved by municipal wastewater and stormwater dischargers.

* As previously stated, the Sacramento Stormwater Management Program would have to expend on the order of $260 million per year to treat stormwater, and this may not achieve the proposed criteria for PAHS, which is based on a 10 (-6) cancer risk level.

* Under the Unfunded Mandates Reform Act, EPA must adopt the least cost alternative for complying with the CWA, unless the Administrator explains in the final rule why the least cost alternative is not adopted. As indicated in the Preamble, risk levels of 10 (-5) and 10 (-4) are acceptable under the CWA.

* Therefore, pursuant to the spirit of the Unfunded Mandates Reform Act, EPA should adopt the PAH criteria at a 10 (-4) risk level. The same should be true for other carcinogens that present attainability problems for dischargers. Most carcinogenic constituents are not readily controllable through source control or BMPs and would generally require end-of-pipe controls to achieve significant reduction. The benefits associated with additional reduction of carcinogenic constituents are not expected to be measurable since, as acknowledged in the economic analysis,point sources are relatively minor sources of these constituents.

Response to: CTR-040-015b

See responses to CTR-058-001 and 011-001a.

Concerning comments CTR-043-006b and CTR-044-007a, the statements that neither Old Alamo Creek nor Tule Canal are "heavily fished" is not relevant to the health issue, i.e., are the people who do fish highly exposed because they are high consumers? The commentors have not provided sufficient information to evaluate either question.

The comment that the carcinogens that are asserted to be compliance problems for these two dischargers are not identified in EPA's economic analysis as a significant contributor to baseline cancer risks for recreational anglers consuming freshwater fish in California may merely reflect a lack of information on these pollutants in sample locations that were selected for the benefits analysis. The fact that no baseline risks were found for the purposes of the analysis does not mean that the risk from these pollutants do not exist anywhere in California or should not be prevented.

Comment: 6. EPA should adopt separate, site-specific human health criteria for Old Alamo Creek based on a 10 (-4) risk level. As previously indicated the City would have to construct costly end-of-pipe controls to comply with the human health criteria for several carcinogens. The subject criteria are based on a cancer risk level of 10 (-6). These controls would not produce a commensurate environmental benefit. At a 10 (-4) risk level, the City's discharge would not cause an in-stream exceedance of these criteria. The City does not believe Old Alamo Creek is heavily fished and therefore criteria based on a 10 (-4) risk level would likely provide greater protection than indicated by the risk level. The City notes that none of these carcinogens were identified in EPA's economic analysis as a significant contributor to baseline cancer risks for recreational anglers consuming freshwater fish in California (see Exhibit 8-9 in EPA's economic analysis).

Comment: We have reviewed the proposed CTR and offer the following comments:

6. EPA should adopt separate, site-specific human health criteria for Tule Canal based on a 10 (-4) risk level. Based on effluent sampling, the City would have to construct costly end-of-pipe controls to comply with criteria for aldrin (and perhaps other carcinogens) based on a 10 (-6) risk level. These controls would not produce a commensurate environmental benefit. At a 10 (-4) risk level, the City's discharge would not cause an in-stream exceedance of these criteria in Tule Canal. The City does not believe Tule Canal is heavily fished and therefore criteria based on a 10 (-4) risk level would likely provide greater protection than indicated by the risk level. The City notes that aldrin was not identified in EPA's economic analysis as a significant contributor to baseline cancer risks for recreational anglers consuming freshwater fish in California (see Exhibit 8-9 in EPA's economic analysis).

Response to: CTR-044-007a

See responses to CTR-058-001 and 011-001a.

Comment: With respect to other criteria proposed for adoption in the draft CTR, we recommend that USEPA:

1 . Adopt human health criteria for carcinogens which are based on the 10E-5 or 10E-4 risk levels instead of the 10E-6 level. (Based on all the conservative assumptions included in the calculation of the criteria, there is significant uncertainty in the numbers, which may translate to negligible risk in using the lower risk levels. This draft CTR should factor in this uncertainty into the risk assessment along with population exposure when calculating risk and appropriate human health criteria);

Comment: III. The Acceptable Risk Level Should be greater than 10E-6.

EPA has proposed that the criteria for carcinogens should be based on an acceptable risk level of 10E-6.

However, the Agency has also, at the request of the State of California, requested comment on an alternative risk level of 1OE-5. (62 Fed. Reg. at 42181). The 10E-5 figure is recognized and utilized by EPA in various Clean Water Act guidance documents as well as in other Agency programs: Moreover, in the most comprehensive development and implementation of water quality standards that the Agency has ever conducted - the Great Lakes Initiative (GLI) -EPA used this risk level in setting the criteria. Also, every State in Region 5 has followed the EPA policy and used 10E-5 as the acceptable risk level in setting water quality standards as part of their GLI rules. EPA should continue that policy in this rulemaking.

Response to: CTR-050-006

Comment: Human health criteria for carcinogens should be adopted at a 10 (-5) risk level at least for San Francisco Bay waters. BADA's attainability analyses shows that adoption of criteria for carcinogens based on a 10 (-6) risk level would result in significant costs without improving the present level of compliance in Bay waters. At a 10 (-6) risk level, two BADA agencies could be faced with adding carbon adsorption facilities at a total annual costs of $56 million per year (to achieve effluent limitations for aldrin, heptachlor and several PAHS). At a 10 (-5) risk level, carbon adsorption facilities would be unnecessary at these BADA agency plants. The cost savings would be significant, and the present high level of compliance would remain unchanged.

Comment: UPI requests the EPA use a Cancer Risk Level at 10E-5 (1 in 100,000) in the subject regulation.

The U.S. Environmental Protection Agency (EPA) and the State of California (State) have requested comment on the adoption of a 1OE-5 carcinogenic risk factor (page 42181) in lieu of the proposed 10E-6 factor. The EPA criteria documents for priority toxic pollutants do not recommend a specific carcinogenic risk factor, but rather a range of risk factors is recommended. The EPA is proposing a California rule that meets Clean Water Act (CWA) section 304(a) minimum. Since a 10E-5 carcinogenic risk factor meets CWA criteria as determined by the EPA, a 10E-5 carcinogenic risk factor is appropriate for the subject Section 131.38. The State should have the authority to use a 10E-5 carcinogenic level. The State needs the option of developing regulatory standards to protect the people and the environment in California in a manner which considers local conditions within the state.

For the above reasons, UPI requests the EPA promulgate a 10E-5 carcinogenic risk factor (1 in 100,000) in the subject regulation.

Comment: Third, regarding the criteria being proposed for adoption in the draft CTR, EBMUD recommends that EPA should:

* Select human health criteria for carcinogens based on the 10E-5 or more appropriate risk level instead of the 10E-6 level being proposed. Based upon the conservative risk assumptions included in the calculation of criteria, there is sufficient uncertainty in the numbers to permit the use of a less restrictive value than 10E-6. EBMUD believes that by using the "one in a million" risk assumption an undue attainability burden is being placed on dischargers to meet ultra-low water quality criteria for very little gain in risk reduction. EPA should factor the uncertainty of the numbers into the risk assessment along with the population exposure when calculating risk and appropriate human health criteria.

Comment: Risk Level

The EPA is strongly encouraged to consider the use of the 10E-5 carcinogenic human health risk

criterion as a baseline for all priority-pollutant criteria that can be adjusted as appropriate when conditions merit a change. The 10E-6 criterion, which itself already appears to serve as such a baseline, is too problematic for this purpose in view of the number of priority constituents which represent immediate compliance problems under the proposed Rule. The attached tables compare our chances for compliance with the proposed Rule under the two factors for our three facilities. We believe that the problems associated with the 10E-6 factor primarily reflect a difficulty with criteria compliance rather than an indication of environmental impact.

In addition, we believe that cost-benefit ratios of mitigation efforts based on a 10E-5 risk factor are considerably more justifiable than 10E-6 in view of the diminishing returns most POTWs would experience in terms of net environmental cost-benefit. For example, years of toxicity testing of Tillman effluent has not established any relationship between effluent lindane and/or DDT levels and aquatic survivability, yet further reduction of these pollutants below currently-observed levels does not justify the enormous required treatment costs. By comparison, the cost effectiveness of best-management practices for non-point sources is attractive, but the trade-off in terms of immediate benefit is a significant limitation- These observations imply that the 10E-5 risk factor should also be applicable on a constituent-specific basis, and we urge the EPA to consider this application as well.

Another factor to consider in setting the risk criterion involves pollutant source-controllability. For example, DDT is a banned pesticide that is ubiquitous in the environment and also a pass-through pollutant in conventional treatment processes what purpose does a 10E-6 factor serve when it cannot be controlled by either point or non-point sources? If treated, where and how are the wastes disposed? The provenance and ultimate fate of such pollutants should be considered as part of a more holistic approach to their control, and the establishment of overly-stringent risk criteria does not accomplish that.

Response to: CTR-057-005

EPA disagrees with this comment.

See response to CTR-058-001.

The comment author cites "years of toxicity testing of Tillman effluent" as evidence that effluent levels of lindane and/or DDT do not need to be further reduced . However, this comment overlooks the fact that these two pollutants are highly bioaccumulative, and standard toxicity tests, because of their short duration, do not account for most bioaccumulation. Thus, if anything, a 10-6 risk level is particularly appropriate for bioaccumulative pollutants.

EPA disagrees that a factor to consider in setting of risk criterion should involve pollutant source controllability. First, the commenter has provided no evidence supporting the assertion that either point or nonpoint sources cannot be controlled. EPA also disagrees that it should set criteria for pollutants that are difficult to control (which have been banned but remain persistent in the environment) at a higher risk level than other pollutants. The Clean Water Act requires that criteria be protective of designated uses. While EPA has discretion in setting risk levels appropriate to protect uses, EPA believes that it is appropriate to base the risk level on nationally appropriate risk levels and the risk level established by the State for the general population. (See the response to Comment CTR-058-001.) By doing so, EPA will be providing an acceptable measure of protection to all exposed subpopulations. If it is not feasible to attain a designated use due to human caused conditions or if sources of pollution prevent the attainment of the use and cannot be remedied, EPA regulations allow the State to remove the designated use if it is not an existing use. This approach allows for regulatory relief where attainment is infeasible while avoiding the lowering of water quality protection to people who live in areas where it may be feasible to

attain the criteria at a risk level of 10-6.

Comment: We appreciate the care that EPA has given to this proposal and especially the attempt to base the proposal on good science. Although there are significant improvements in the proposal, there are several issues of concern to WSPA. We are especially concerned that EPA has chosen to base the proposal on a human health risk level of 1x10E-6 while other environmental management programs administered by EPA or by California regulatory agencies have based decisions on risk levels of 1x10E-5 and above. EPA has not justified this overly cautious and potentially expensive approach. Our comments are included in the attachment to this letter.

1. Acceptable Risk Levels. WSPA opposes use of a 1x10E-6 risk level as a trigger level for regulatory action.

EPA has historically considered health risks above 1x10E-6 to be adequately protective of human health (see, e.g., 40 CFR 42176 in this rulemaking and review articles by Travis et al., Environ. Science Tech. 21(5): 415-420, 1987 and Rodricks et al., Toxicol. Pharmacol. 7: 307-320, 1987). Yet, "EPA is proposing criteria that protect at an incremental cancer risk level of one in a million (1x10E-6) for all priority toxic pollutants regulated as carcinogens" [62 FR 42181, subpart f]. EPA apparently bases this decision on what it believes to be the state's historical policy, although adequate justification for the target risk level selected is not provided.

EPA is overlooking an overwhelming consensus of state and national-level policy which indicates that, in reality a target risk level of 1x10E-6 is not commonly applied in developing regulatory levels. For example, in the most comprehensive rulemaking on development and implementation of water quality standards that EPA has ever conducted -- the Great Lakes Initiative -- EPA used a target risk level of 1x10E-5 in setting the criteria. Also, every state in Region V has followed EPA policy and used 1x10E-5 as the acceptable risk level in setting water quality standards as part of their GLI rules.

EPA's National Contingency Plan codifies 1x10E-4 to 1x10E-6 as the target acceptable risk range for evaluating hazardous waste sites under CERCLA. EPA has selected and promulgated a single risk level of 1x10E-5 in the Hazardous Waste Management System Toxicity Characteristics Revisions [55FR 11798-11863]. In so doing, EPA notes that "The chosen risk level of 10E-5 is at the midpoint of the reference risk range for carcinogens (10E-4 to 10E-6) generally used to evaluate CERCLA actions.". EPNs benzene waste NESHAPs used 10E-5 and drinking water MCLs are commonly associated with acceptable risk levels that exceed 1x10E-6. OSHA's recently proposed procedures for developing risk-based Permissible Exposure Limits (PELs) are based on acceptable risk levels of 1x10E-3 to 1x10E-4.

In California, state agencies commonly rely on target risk levels above 1x10E-6 for setting regulatory action levels. Cal-EPA, including the DTSC, the SWRCB and the RWQCBs routinely set cleanup levels for remediation projects based on a target risk of 1x10E-5 The air quality management districts charged with administering the California Air Toxics "Hot Spots" Program under AB2588 commonly rely on a 1x10E-5 target risk level for risk management purposes. California's proposed revision to the hazardous waste classification system is also similarly based on a 1x10E-5 risk level. California's Safe Drinking Water and Toxic Enforcement Act of 1986 (Proposition 65) established a no significant risk level of 1x10E-5 for evaluating potential exposures of the general population to carcinogenic chemicals.

Reliance on a single target risk level of 1x10E-6 for setting water quality criteria is now mostly an historical artifact. In reality, even when the Food and Drug Administration originally proposed that a 1x10E-6 target risk level be used to set safety standards in the 1970s, this level was clearly meant to be a de minimis level representing risks that are so small as to be of negligible concern. In the interest of responsible public policy, EPA's target risk level should reflect an enlightened understanding of the uncertainty and variability inherent in the risk assessment process gained since that time. In addition, given that the background cancer risk in the U.S. is now about 30%, EPA should recognize that a risk level of 0.30001, or for that matter 0.3001, is virtually indistinguishable from a risk level of 0.300001. By contrast, the socioeconomic impacts associated with the overly conservative reliance on a 1x10E-6 risk level could be staggering.

Response to: CTR-058-001

EPA disagrees with this comment.

EPA's section 304(a) criteria guidance documents for priority toxic pollutants that are based on carcinogenicity present concentrations for upper bound risk levels of 1 excess cancer per 100,000 people (10-5), per 1,000,000 people (10-6), and per 10,000,000 people (10-7). However, the criteria documents do not recommend a particular risk level as EPA policy. EPA uses a 10-6 risk level in establishing human health criteria guidance because it believes that a 10-6 risk level is an appropriate level of risk for the general population. This risk level is used by a majority of states and Tribes.

Subpopulations within a state may exist, such as subsistence anglers who as a result of greater exposure to a contaminant, are at greater risk than the assumed 70 kilogram person eating 6.5 grams per day of maximally contaminated fish and shellfish and drinking 2.0 liters per day of drinking water with pollutant levels meeting the water quality criteria.

When EPA promulgates criteria as regulations, EPA generally follows the policies of the affected state. In this case, California has articulated a policy choice of 10-6 for the general population. By establishing rules at the 10-6 risk level, EPA applies a risk management policy which ensures protection for all exposed population groups (Draft Water Quality Criteria Methodology: Human Health, EPA 822-Z-98-001,August 1998, Appendix II, page 72). EPA acknowledges that at any given risk level for the general population, those segments of the population that are more highly exposed face a higher relative risk. For example, if fish are contaminated at a level permitted by criteria derived on the basis of a risk level of 10-6, individuals consuming up to 10 times the assumed fish consumption rate would still be protected at a 10-5 risk level. Similarly individuals consuming 100 times the general population rate would be protected at a 10-4 risk level. EPA therefore believes that protection at the 10-6 risk level is a reasonable risk management decision protective of designated uses under the CWA. While outside the scope of this rule, EPA notes that states and Tribes, however, have the discretion to adopt water quality criteria that result in a higher risk level (e.g., 10-5). EPA expects to approve such criteria if the state or

Tribe has identified the most highly exposed subpopulation within the state or Tribe, demonstrates the chosen risk level is adequately protective of the most highly exposed subpopulation, and has completed all necessary public participation.

This demonstration has not happened in California. Further, the information that is available on highly exposed subpopulations in California supports the need to protect the general population at the 10-6 level. California has cited the Santa Monica Bay Seafood Consumption Study as providing the best available dataset for estimating consumption of sport fish and shellfish in California for either marine or freshwater sources (Chemicals in Fish Report No. 1: Consumption of Fish and Shellfish in California and the United States, Final Draft Report, July 1997). Consumption rates of 21g/day, 50 g/day,107 g/day, and 161 g/day for the median, mean, 90th, and 95th percentile rates, respectively, were determined from this study. Additional consumption of commercial species in the range of approximately 8 to 42 g/day would further increase those values. Clearly the consumption rates for the most highly exposed subpopulation within the State exceeds 10 times the 6.5 g/day rates used in the CTR. Therefore, use of a risk level of 10-5 to protect the general population would not be sufficient to protect the most highly exposed population in California at a 10-4 risk level. On the other hand, even the most highly exposed subpopulations cited in the California study do not have consumption rates approaching 100 times the 6.5 g/day rate used in the CTR. The use of the 10-6 risk level to protect median level consumers does not subject these subpopulations to risk levels as high as 10-4.

EPA believes it would be reasonable to conclude that carcinogens that bioaccumulate, particularly given the exposure of fishermen to such carcinogens, may justify site-specific criteria that result in more protective risk level than 10-6 for the average fish consumer. EPA has generally supported such decisions when adequate data are available. In this rulemaking, EPA has adopted a reasonable risk level to protect all of California's inland waters and enclosed bays and estuaries for consumption of fish and drinking water.

EPA believes its decision to establish a 10-6 risk level for the CTR is also consistent with EPA's policy in the NTR and GLI to select the risk level that reflect the policies or preferences of Clean Water Act programs in the affected states. CA adopted standards for priority toxic pollutants for its ocean waters in 1990 using a 10-6 risk level to protect human health (California Ocean Plan, 1990). In April 1991, and again in November 1992, CA adopted standards for its inland waters and enclosed bays and estuaries in its ISWP and EBEP using a 1x10-6 risk level. To be consistent with CA's WQS, EPA used a 10-6 risk level for CA in the NTR at 57 FR 60867/3. CA has continued using a 10-6 risk level to protect human health for its standards that were not withdrawn with the ISWP and EBEP. The most recent expression of risk level preference is contained in the Draft Functional Equivalent Document, Amendment of the Water Quality Control Plan for Ocean Waters of California, October 1998, where staff recommended maintaining a consistent risk level of 10-6 for the human health standards that they were proposing to revise. See also the discussion in responses to CTR-002-002a and CTR-002-005a.

The citation of programs that occasionally allow a risk level as high as 10-4 under specific circumstances does not prove to be inconsistent with protection of the general population at the 10-6 level recognizing that more highly exposed sub-populations such as ethnic or economically disadvantaged populations may face an excess risk level approaching 10-4.

There are several differences between the guidelines for the derivation of human health criteria contained in the Great Lakes Water Quality Guidance (the Guidance) and the California Toxics Rule (CTR) that make a 10-5 risk factor appropriate for the Guidance, but not for the CTR. These differences result in criteria developed using the 10-5 risk factor in the Guidance being at least as stringent as criteria derived under the CTR using a 10-6 risk factor. The relevant aspects of the Guidance include:

* targeting of sensitive subgroups of the population, such as people who routinely eat fish caught in the Great Lakes, in assessing risk (the CTR targets the population in general)

* use of fish consumption rates that are considerably higher (because of the targeted subgroup) than fish consumption rates for the CTR

* use of bioaccumulation factors rather than bioconcentration factors in estimating exposure, considerably increasing the dose of carcinogens to sensitive subgroups

* use of additivity of effects of mixtures of both carcinogenic and noncarcinogenic pollutants.

This combination of factors increase the calculated carcinogenic risk substantially under the Guidance (the combination would generally be more than one order of magnitude), making a lower overall risk factor acceptable. The Guidance risk factor provides, in fact, criteria with at least the same level of protection against carcinogens as criteria derived with a higher risk factor using the CTR. A lower risk factor for the CTR would not be appropriate absent concomitant changes in the derivation procedures that provide equivalent risk protection.

Remediation efforts and OSHA PELs were cited by the comment author as activities allowing risk levels higher than 10-6. These activities are site-specific and have far less impact beyond a very local area as contrasted to WQS which, in combination with existing California WQS providing protection of the general population at the 10-6 level, will provide consistent protection to the statewide population. [See the reference to HHM Notice above].

EPA disagrees that reliance on a 10-6 target risk level for setting water quality criteria is now mostly a historical artifact. The Food Quality Protection Act of 1996 (FQPA) amended the Federal Food, Drug, and Cosmetic Act to prohibit EPA from issuing tolerances for pesticide residues in or on food unless the agency determined that there is "reasonable certainty" that the residues will result in "no harm." The legislative history of FQPA indicated Congressional support for EPA's view that reasonable certainty of no harm would be met when a non-threshold risk is below a 10-6 level.

EPA believes that comparing the "background cancer risk in the U.S." (an aggregate risk combining the effect of all causes of cancer) with the excess cancer risk from a single toxic pollutant in water is not appropriate because they are not comparable measures. The comment author's argument does not lend support for raising the risk level specified in this rulemaking. The purpose of the CWA is to protect waters (in this case for the various human uses) irrespective of the cancer risk derived from other sources.

Finally, EPA is unable to respond to the author's assertion of "staggering" socioeconomic impacts because it is provided without supporting evidence (see response to CTR-005-007). EPA's Economic Analysis indicates that lowering the risk level from 10-5 to 10-6 would cause only a negligible increase in compliance costs (Economic Analysis of the California Toxics Rule, p. A-2). In any case, under the Clean Water Act, EPA must establish scientifically based criteria that protect designated uses. This requirement overrides any consideration of socioeconomic impacts. The Clean Water Act does allow consideration of socioeconomic impacts in decisions to remove a designated use which is not an existing use.

Comment: PROVISIONS SDG&E DOES NOT SUPPORT

As described in the following comments SDG&E does not support the following provisions:

* Health risk factor - The preamble to the rule (see 62 Fed. Reg. at 42,181, Col. 3) states that the cancer risk level used to calculate the criteria is 1 excess cancer case per 1,000,000 people. The State of California voters approved an initiative in 1986 "The Safe Drinking Water andToxic Enforcement Act of 1986" ("Prop. 65") to address concerns over exposures to toxic chemicals. Prop. 65 defines the "no significant risk" level as follows:

"For chemicals assessed in accordance with this section, the risk level which represents no significant risk shall be one which is calculated to result in one excess case of cancer in an exposed population of 100,000, assuming lifetime exposure at the level in question,...".(*15)

The criteria proposed in the rule should be recalculated to reflect a one excess case of cancer in an exposed population of 100,000 risk factor, which would be consistent with an existing risk factor which is acceptable to the voters in the State of California.

(*15) Subsection 12703 (b) at CCR Title 22, Division 2, Part 2, Subdivision 1, Chapter 3, Article 7.

Comment: The areas with which we find concerns and the requested changes include the following:

* With respect to the criteria proposed for adoption in the draft CTR, we believe EPA should select human health criteria for carcinogens based on the 10E-5 or 10E-4 risk levels instead of the 10E-6 level. Based on all the conservative assumptions embedded in the calculation of the criteria, there is significant uncertainty in the numbers, which may translate to negligible risk in using the lower risk levels. EPA should factor this uncertainty into the risk assessment along with population exposure when calculating risk and appropriate human health criteria.

Comment: The subject rule has a significant impact on our facility discharge and the citizens of the City. We therefore present the following comments for your consideration to re-open the comment period for this rule in order to facilitate a more complete review by public and in particular by those in the POTW community:

* Recommend USEPA use human health criteria for carcinogens based on the 10(*-5) or 10(*-4) instead of the 10(*-6) level. It is important to note that all conservative assumptions included in the calculation of the EPA proposed criteria there is a significant uncertainty in the numbers, which may translate to negligible risk in using the lower risk levels. EPA should factor in this uncertainty into the risk amount along with population exposure when calculating risk and appropriate human factor.

Comment: 2. The Cancer Potency Risk Factor Should Be 10E-5 EPA should not assume that 10E-6 is California's preferred risk level for estuarine and inland surface waters. The action adopting that risk level was invalidated by the courts specifically on the grounds that the SWRCB did not follow the required procedures of the Water Code section 13241. In fact, the State of California and the voters of California have made a clear policy statement about cancer risk factors when they enacted in 1986, the Safe Drinking Water and Toxic Enforcement Act, known as Proposition 65. This Proposition established significant restrictions on the use of toxicants based on a cancer risk level of 10E-5. This voter approved cancer risk is far more valid and should be the guide to the EPA for the criteria.

The use of the 10E-6 as a risk level for human health will cause some constituents to be to considered problem pollutants when in fact no problem exists based on site specific data and bioaccumulation data. This high level of risk compounds the very conservative assumptions and other safety factors already within the formula for the criteria.

We urge the EPA to revise the cancer risk level to 10-5. Until such time that a source of problem toxicants are better identified, interim CRFs of less than 10E-5 would be appropriate for some carcinogens (more discussion in the detailed comments)

Comment: We want to highlight our technical concern with one aspect of the Economic analysis in the text of this letter - EPA's proposal to protect at an incremental cancer risk level of one in one million (10E-6) for all priority toxic pollutants regulated as carcinogens. The CTR states that "EPA recommends

that states consider minimum risk levels in the range of 10E-4 to 10E-6 for carcinogenic priority pollutants to protect public health and welfare." The City supports EPA's policy of allowing States the flexibility to use a range of cancer risk levels in their derivation ofcriteria for carcinogenic priority pollutants, however the City believes that the EPA has the same obligation in promulgating the CTR. The City recommends that risk levels be determined dependent upon the degree of scientific uncertainty inherent with the appropriate criterion. Stringency of risk levels should be established based upon the degree of significance, that assumptions and uncertainties drive the criterion derivation process.

Comment: We would ask you to review scientific carcinogenic criteria with concern for special pathways that disclose how carcinogenics in aquatic runoff and wastewater interact with human health.

Presently the risk factor of 10 to the minus 6 is heaped on an already overly conservative criteria. The use of 10 to the minus 4 or 10 to the minus 5 have been incorporated by EPA in many other risk analysis plans that they've done, including the Safe Drinking Water Act and the Great Lakes Initiative,

Also in this area, greater study should be done to look at individual organic compounds to see what the cost/benefit ratio is and see if there is a way for removal of these specific organic compounds by source control or pollution prevention techniques.

Comment: MR. BEHJAN: Good afternoon. My name is John Behjan, B-e-h-j-a-n. My business address is 500 West Los Angeles Avenue, Simi Valley, California 93065.

Basically, I want to go over the CTR's proposed numerical objective for human health risk -- human health criteria which is based on human health risk assessment of 10(-6). That is basically for the cases that are consumable water for fish.

The previous speaker mentioned about waterways and this is where I'm coming from. We recommend EPA's consideration of another factor than the 10(-6). EPA does provide that, the flexibility. And this is a very appropriate application, perhaps in for -- because that would reduce the objectives more -- make them more difficult than for a lot of fish in Southern California who are discharging it into water.

Thank you.

Comment: I. TOXIC POLLUTANTS THREATEN PUBLIC HEALTH AND SAN FRANCISCO BAY.

Toxic pollution causes harm in San Francisco Bay. Species of bivalve shellfish, plankton and phytoplankton that are especially vulnerable to toxic trace elements such as copper are decimated in its southern reach though they thrive in comparable estuaries with less metals pollution.(*1) (*2) Mounting evidence suggests its sediment is toxic to some aquatic life.(*3) Extensive research strongly suggests that PCBs and PAHs released to the Bay negatively effect reproduction in starry flounder. (*4) Reproductive effects are also correlated with PCBs in Bay cormorant eggs, Bay harbor seals have PCBs levels twice those associated with immunotoxicity and a disease epidemic that decimated a European population of this species.(*5) Health advisories are in effect because dioxin, PCBS, mercury, chlordane, DDT, dieldrin, and selenium contaminate Bay food resources eaten by the public.(*6) (*7)

Public health threats from toxics in the food chain are of particular concern. A recent count found approximately 270,000 fishing licenses were issued to Bay Area residents. Surveys by CBESAFER!, the Save San Francisco Bay Association, and the Asian Pacific Environmental Network show that many people fish the Bay regularly to supplement their families' diet, that some people eat up to a maximum of a pound of fish per day, and that the majority of those who eat their catch regularly are people of color. [See attachment (*8)] A pound of fish per day is about 480 oz./month, sixty times the 8 oz./month "safety" cutoff for cancer and slow learning in the state's advisory.(*6)

In addition to these severe environmental health and justice problems, pollutant monitoring of the Bay is far from comprehensive, and undetected problems are likely. Indeed, EPA acknowledged that designated uses of the Bay are threatened or impaired by toxic pollutants when it named the Bay as a "toxic hot spot" under Section 304(l) of the Clean Water Act.(*9)

Response to: CTR-002-002a

See response to CTR-001-002.

EPA acknowledges the impacts of pollution in the San Francisco Bay. EPA believes that the intake rate of 6.5 grams/day is adequately protective of the general population of fish consumers over the course of a lifetime. The fish intake rate of 6.5 gm/day is from a national, 30-day survey - the National Purchase Diary (NPD), based on an empirical distribution, where 6.5 gm/day represents the average value for the general population. According to the NPD, which was based on over 25,000 individual respondents, 94 percent of the survey respondents reported that they ate fish. Therefore, EPA believes that 6.5 gm/day is an appropriate basis for characterizing the general population. EPA understands that fish intake patterns vary and that there are population groups that consume significantly greater amounts than the overall population.

For this regulation, the promulgated criteria were derived using a 10-6 risk level, which the Agency believes reflects an appropriate risk for the general population and ensures protection for all exposed population groups. EPA also considers that the goal is satisfied if the general population will be adequately protected by human health criteria when the criteria are met in ambient water. EPA acknowledges that at any given risk level for the general population, those segments of the population

that are more highly exposed face a higher relative risk. For example, if fish are contaminated at a level permitted by criteria derived on the basis of a risk level of 10-6, individuals consuming up to 10 times the assumed fish consumption rate would be protected at a 10-5 risk level. Similarly, individuals consuming up to 100 times the assumed rate would still be protected at a 10-4 risk level. Consistent with this, a criterion based on 6.5 gm/day at a risk level of 10-6 would protect those who consumed 650 gm/day at a 10-4 risk level.

EPA has advocated State and Tribal flexibility to develop criteria, on a site-specific basis, that provides additional protection appropriate for highly exposed populations. EPA has not found that such a demonstration has been made for specific waterbodies covered by the CTR that warrants a change or re-proposal of the CTR criteria at this time. EPA understands that highly exposed populations may be widely distributed geographically throughout a given State and Tribal area. Thus, if the State or Tribe determines that a highly exposed population would not be adequately protected by criteria based on the general population, EPA recommends that the State/Tribe adopt more stringent criteria. Furthermore, EPA recommends that States and Tribes ensure that the most highly exposed populations not exceed a risk level of 10-4.

It should also be understood when comparing the fish intake assumption of 6.5 grams/day used to develop these criteria with other studies, including the studies referenced by the commenter (such as the surveys by "CBESAFER!", the Save San Francisco Bay Association, etc.), that the 6.5 gm/day value reflects consumption of fresh/estuarine species only and does not include marine species. It is the fresh/estuarine species that apply to the development of water quality criteria for the waters covered under this rule. Specifically, the CTR's ambient water quality criteria are applicable to inland waters and estuaries. The CTR does not apply to ocean waters that are covered by California's Ocean Plan. The commenter needs to separate out marine species before any comparisons between studies can be appropriately made. EPA's water quality criteria program policy has historically been to evaluate fish intake from fresh and estuarine species only, based on knowledge of life-cycles of the species including relevant information from the National Marine Fisheries Service. The purpose is to include those species that are anticipated to be potentially exposed to pollutants in fresh and estuarine waterbodies, based on this life-cycle information [for further discussion on this policy, see the Ambient Water Quality Criteria Derivation Methodology Human Health Technical Support Document, Final Draft (EPA-822-B-98-005)].

EPA is developing a revised methodology for deriving water quality criteria to protect human health and is updating its recommendations for estimating fish consumption, including evaluating the most recent survey data (see draft revisions published August 14, 1998, Federal Register, Vol. 63, No. 157). EPA is currently reviewing public comments and is awaiting the results of a peer review on the draft methodology revisions. However, until the methodology is finalized, EPA believes that the current methodology is scientifically defensible.

Comment: C. Criteria for the pollutants of most concern do not provide equal protection for people of color and are not supportable by science.

EPA cannot show that its weaker proposed criteria will protect fishing and aquatic life from dioxin-like compounds, mercury, and copper. Further, EPA's proposal to allow greater health risks for subsistence fishers fails to provide equal protection under the law and is contrary to the President's Executive Order on Environmental Justice.

The proposed criteria provide unequal protection for people of color who fish for food. EPA admits in the proposal that: "There may be subpopulations within a state, such as subsistence anglers who as a result of greater exposure to a contaminant, are at greater risk than the hypothetical 70 kilogram person eating 6.5 grams per day of maximally contaminated fish.. ." Indeed, ample data show that some people exercise their fishing rights to "use" Bay waters by eating up to a pound (450 grams) per day of fish from San Francisco Bay, and most of them are people of color.(*8) EPA's discussion then goes on to admit that it is proposing to provide less protection for these subsistence anglers: "[I]ndividuals that ingest ten times more of a carcinogenic pollutant than is assumed in derivation of the criteria at a [one excess cancer in a million] risk level will be protected to a [one in 100,000] level, which EPA has historically considered to be adequately protective." However, people who eat a pound per day eat seventy times more, and pages 8- 11 and 8-12 of EPA's economic analysis admit people eat 16 times more, than the 6.5 grams (1/70th of a pound) of Bay fish per day assumed in EPA's criteria. EPA's own calculations show present cancer threats of nearly 1 in 1,000 for some Bay anglers at these higher consumption levels. Thus, EPA itself predicts that its proposal will result in lesser, inadequate protection for people of color who rely on Bay-caught fish for food.

(*8) Previously unpublished data from a 1993-4 survey of 500 anglers using South and Central San Francisco Bay by Conununities for a Better Environment-SAFER!; Save San Francisco Bay Association, 1995 (excerpt); West, 1992; West et al., 1992; Peterson et al., 1994; and USEPA, 1994. (excerpt of a draft report discussing and citing work by EPA, Wolfe and Walker (1987), Svensson (1991) and others. Includes analysis of the evidence.

Response to: CTR-002-005a

EPA believes that this rule is consistent with the terms of the Executive Order (E.O.) on Environmental Justice. EPA rejects the notion that the rule is, in any respect, discriminatory against persons or populations because of their race, color, or national origin. The final rule establishes criteria that are designed to ensure protection of the public, including highly exposed populations. While some groups and individuals, including some low income and minority persons and populations, may face a greater risk of adverse health effects than the general population due to their particular fish consumption patterns, EPA believes that these groups will nonetheless receive a level of public health protection within the range that EPA has long considered to be appropriate in its environmental programs (e.g., 10-4 to 10-6 incremental cancer risk). Obviously, as long as there is variability in fish consumption patterns among various segments of the population, it would be impossible for EPA to ensure that all groups would face identical risk from consuming fish. Therefore, EPA has sought to ensure that, after attainment of water quality criteria in ambient waters, no group is subject to increase cancer risks greater than the risk range that the EPA has long considered protective. EPA disagrees that individuals who consume up to a pound of fish per day would face a 10-3 cancer risk. Given that the basis of the criteria

are a 6.5 gm/day assumption at a 10-6 risk level, individuals who consume a pound of fish per day would be protected within the established acceptable range of 10-4 to 10-6, consistent throughout current EPA program office guidance and regulatory actions. See also the discussion in response to CTR-002-002a.

Comment: Dear Ms. Frankel,

The Natural Resources Defense Council strongly opposes the Region 9 EPA proposal to raise the allowable mercury criterion for continuous concentration in water from 0.012 parts per billion (ppb) to 0.770 ppb for aquatic life. This proposal is difficult to justify from the point of view of science and of public health. On behalf of our over 350,000 members nationwide and our over 55,000 California members, we are writing to register our opposition to the EPA proposed rule.

Mercury is a highly poisonous metal which results in toxicity to the brain and nervous system and toxicity to human reproduction. In addition, in sediments, mercury is bio-transformed into the even more toxic form, methyl mercury, which has resulted in some of the largest epidemics of neuro-developmental poisoning known to mankind. Methyl mercury bioaccumulates in the food chain and thereby results in greatly concentrated exposures to humans, because we eat off the top of the food chain. Underestimates of the toxicity and bioaccumulation of mercury have led to major mistakes in the past. The Minamata Bay disaster in Japan was caused by a failure to predict the potency of mercury and the extent of human exposure through fish. U.S. EPA's Draft Mercury Study Report to Congress documents that children of high-end fish consumers in the U.S. may be exposed to enough mercury to cause adverse neuro-developmental effects.

In this setting it is anomalous to relax the standards for mercury contamination in California water. Furthermore, the scientific reasoning behind the Region 9 EPA decision to relax the mercury standard 60-fold is fraught with errors. NRDC's major concerns with this approach are summarized below.

*Extrapolation for the Reference Dose (RfD) should start at a NOAEL, not at a level of 10% increased risk. *An additional 10-fold safety factor should be added in deriving the RfD to account for the vulnerability of fetuses, infants, and children. *The body weight in the calculation should be for a child, not an adult male. *The Fish consumption rates for those who do eat fish should be used instead of rates for the entire population including those who do not eat fish. *Average fish consumption quantities greatly understate the risk to those who eat a lot of fish. Instead, fish consumption for the top 5% of the population should be used. *Bioaccumulation is known to be 10 to 100 fold greater than the estimate used by EPA. *California's waters are already too polluted with mercury.

Use of Average Fish Consumption is not Health Protective

The assumption used by Region 9 EPA for fish consumption relies on the average fish and shellfish consumption in the entire general population, along with the average intake from each body of water. It is quite clear that fish consumption follows a highly skewed, or Poisson distribution in the population (see attachment from the U.S. EPA Draft Mercury Study Report to Congress, Appendix H, p. 20). Many people eat little or no fish, but a smaller, yet highly significant segment of the population eats a very large amount of fish. Surely EPA should strive just as hard to protect the health of those who eat fish frequently as it does to protect the health of those who do not eat fish.

In fact, this analysis adequately protects only those who eat little or no fish. The average whichwas used in the Region 9 EPA analysis appears to derive from the "per capita" data from the USDA Continuing Surveys of Food Intake by Individuals (CSF 11) from 1989-91 for males ages 15-44 years. (See attached tables from U.S. EPA Mercury, Report, Appendix H, pp. 8 & I 1). In fact, this average is highly influenced by those individuals who consume little or no fish. Non-fish-consumers, however, are not the population of interest for purposes of this analysis. Instead, if an average is to be used, it should be the average fish consumption rate for those people who do eat fish. This is substantially higher, at 53.7 g/day for males ages 15-44 years, and 41.4 g/day for females in the same age range. Furthermore, the average fish consumption will likely underestimate the fish consumption rate for the "high end" fish consumer by many orders of magnitude. For example, in the case of females ages 15-44 years, average fish consumption (among those who do eat fish) is 41.4 g/day, while fish consumption by the top 5% of the population of these women of childbearing age is about 112 g/day, or more than double the average consumption rate.

The implications of not adequately protecting the high fish consumer are not trivial. The population of California is nearly 30 million, of whom overall 31% would be expected to be fish consumers according to the CSF II survey. This represents over 9 million people who would be at disproportionate risk. The top 5% of that population consists of nearly half a million people in California who would be expected to eat fish at nearly 10-times greater quantity than the EPA calculations would predict. 10 times greater consumption would translate into roughly 10-times greater risk from the mercury in the fish. EPA is not adequately protecting this substantial portion of the California population from mercury hazards.

NRDC strongly urges Region 9 EPA to reassess the proposed standard for mercury. Recalculation of the reference dose to accommodate the known disproportionate impact of mercury on fetuses, infants, and children will require addition of at least another 10-fold safety factor. The starting point for RfD calculation should be a true NOAEL. The body weight calculation should use an average weight for a child. Fish consumption data should reflect the "high-end" consumer. Finally, the outdated and unsupportable bioaccumulation factor of 7300 should be discarded in favor of a BAF which is supported by the current science in California.

Response to: CTR-006-002b

Regarding the issues on mercury health effects, derivation of the RfD, and basis of the fish intake assumption (including discussion of the CSFII survey), see response to CTR-006-002a. For additonal discussion regarding the basis of the fish consumption rate, see the response to this issue in CTR-002-002a. Regarding the choice of body weight, see response to CTR-006-001a. Regarding the issues on bioaccumulation, see response to CTR-002-007b.

Comment: The Bay is already highly polluted, as is evidenced by the adverse impacts on beneficial uses, particularly fish consumption. The State's Bay Protection and Toxic Cleanup Program has identified numerous probable toxic hot spot locations in the San Francisco and Santa Monica Bays, and confirmed hot spots in San Diego Bay. As bad as San Francisco Bay water quality already is, EPA's Toxics Rule proposal will make current conditions seem pristine compared to what lays ahead if this proposal is enacted.

Response to: CTR-010-002

Regarding the site-specific contamination issues, see response to CTR-002-003.

Comment: Dear Ms. Frankel:

Eastern Municipal Water District ("District") provides potable and reclaimed water and sewer service to an area of 555 square miles in western Riverside County in Southern California. The District has five regional water reclamation facilities in Moreno Valley, Hemet/San Jacinto, Perris Valley, Temecula Valley and Sun City with a total available capacity of 49 million gallons per day. There are 77,000 fresh water customers and 122,000 sewer connections. The District has a National Pollutant Discharge Elimination System ("NPDES") permit to discharge effluent, which could be combined from all five facilities, to Temescal Creek in the Santa Ana River Basin.

Submitted herewith are comments from the District on the Proposed Rule referenced above, appearing in the August 5 Federal Register, also called the California Toxics Rule ("Rule") . Several District staff have participated in the State Water Quality Planning Process since 1990. It has been complicated and frustrating, especially in light of attempting to obtain NPDES permits while the state was developing plans. Generally, the District is pleased that your agency ("Agency") is bringing some closure to the

issue by promulgating criteria. We do have some recommendations and concerns, however, which we present for your consideration.

Human Health Criteria (FR p. 42178, Preamble section E.3.)

Regarding fish and shellfish consumption rates, which are an important factor in calculating these water quality criteria, the District supports the Agency's use of 6.5 grams/day. What is of concern is the Agency's statement, "EPA supports the State's use of any appropriate higher state-specific fish and shellfish consumption rates in its readoption of criteria in its statewide plans." The discussion centers on the adopted California Ocean Plan's use of 23 grams/day, which was based on a California Department of Health Services memorandum of 1989. It is important to note that this exposure value was based on ocean fish consumption, whereas the Agency's value is based on non-marine fish consumption.

If a high consumption rate is used, the water quality criterion is lower or more stringent. This would become an additional burden for inland dischargers such as our District. For inland waters, and for any developed inland surface water quality criteria, we would like the Agency to recognize that lower consumption rates could also be used. The following shows the mean consumption rates of fish which are representative of California freshwater fisheries. These rates were taken from the Agency's Exposure Factors Handbook of 1989.

Bluegills --O.089 grams/day Carp --O.016 grams/day Catfish --O.292 grams/day
Perch --O.062 grams/day Sunfish --O.020 grams/day Trout --O.294 grams/day

Generally, the District hopes that appropriate consumption rates are used and desires that site-specific studies be conducted before different rates are selected. We would like to summarize the Agency's own procedures for developing data upon which to base alternative consumption rates, from the Exposure Factors Handbook, 1989, p. 2-39:

1. Interview local recreational fishermen in the affected area and obtain actual consumption rates. Local surveys can provide the most accurate data for exposure assessment purposes.

2. Obtain productivity data for the area and divide total catch data by the number of recreational fishermen in the area.

3. Estimate what portion of fish consumed in the local area is caught in the local area. Apply the diet fraction to the 50th and 90th percentile consumption rates.

4. Develop exposure scenarios assuming a number of fish meals eaten in the area per year, applying a meal size in the range of 100 to 200 grams/meal.

The Agency should encourage the state to conduct, at a minimum, studies in the manner described above for the following situations: lakes and reservoirs, inland surface streams, effluent-dominated streams, and ephemeral and-intermittent streams.

Response to: CTR-015-001

EPA acknowledges the commenters support of the 6.5 gm/day fish intake assumption. EPA also generally agrees that the rate should be indicative of consumption of freshwater and estuarine species only (see additional discussion on the fish intake rate assumptions in response to CTR-002-002a). However, the commenter has expressed concern over the use of California's Ocean Plan fish consumption

rate as a potential "additional burden" for inland dischargers. The commenter appears to support this concern by providing six species-specific intake rates "representative of California freshwater fisheries." EPA believes that this comparison is not appropriate. First, the State of California has both an Inland Surface Waters Plan and an Enclosed Bays and Estuaries Plan that would be more relevant to inland dischargers. Second, the commenter has chosen only several species of fish from a much larger tabulated list in the original 1989 Exposure Factors Handbook (revised in 1995). The table presents consumption data from a study conducted approximately 20 years ago for fish consumers in the United States. EPA believes that this is not necessarily representative of California-specific consumption patterns. EPA has long supported the States' use of local site- or State-specific data over EPA's default values to better reflect the variability of local or regional consumption patterns, when adequate data are available. EPA has published guidance on how to conduct such surveys. The Agency's most recent document is Guidance for Conducting Fish and Wildlife Consumption Surveys (EPA-823-B-98-007).

Comment: 7. HUMAN HEALTH CRITERIA

As you are aware the Department of Fish and Game is the trustee for the natural resources of the State and, as such we are not in an appropriate position to address human health issues. However, we would like to take this opportunity to make EPA aware of our concerns in two areas. The first issue deals with one component of the formula that was used to derive the human health criteria. Obviously, the human health criteria takes into account fish consumption rates, as well as what portion of the fish is consumed. The CTR indicates that the consumption rate utilized was 6.5 grams per day of fish tissue. This consumption rate, at least for the portion of the population that are subsistence fishermen, appears to be very low. If the human health criteria is to be adequately protective, this consumption rate should be revisited and a new rate developed to better protect these fishermen. Our second comment deals with the proposal to base criteria on fish tissue as opposed to water concentration. The DFG does not have a position with respect to this approach except to point out that compliance monitoring for fish tissue criteria may impact resources. This approach would mean an increased number of fish being collected for monitoring purposes which may impact fish resources. It may also impact the DFG's fiscal resources since we regulate scientific collection activity under which fish monitoring would fall.

Response to: CTR-026-007a

Regarding the fish consumption rate, see the response to this issue in CTR-002-002a. Regarding the comments on collecting fish for compliance monitoring and its impact on the Department of Fish and Game's (DFG) resources, the commenter has misunderstood EPA's reference to elevated fish tissue levels. The CTR criteria values are for ambient water quality criteria - that is, the numerical values represent water concentrations. EPA does not intend to add, through the CTR, the collection of fish for

monitoring purposes. Therefore, the DFG should not expect to have any additional workload for collecting or analyzing fish, nor should the DFG anticipate any loss to fisheries resources as a result of the CTR.

Comment: The Center for Marine Conservation (CMC) is a nationwide, nonprofit advocacy group dedicated to the conservation and enhancement of coastal and ocean life and resources. CMC submits these comments on behalf of its 16,000 members in California and over 120,000 members nationwide.

CMC applauds EPA's efforts to bring California into compliance with the Clean Water Act 303(c)(2)(B). Implementing numeric criteria that will protect the beneficial uses of California's waters is of great importance to the health of coastal and marine ecosystems, and so to CMC and its members. The reliance in many areas of the state on narrative criteria threatens the health of most of the state's waters, thereby impacting both human health and the health of the state's economy that relies on clean water.

While CMC strongly supports the swift adoption of an Enclosed Bays and Estuaries Plan and an Inland Surface Waters Plan that contain numeric criteria for toxic pollutants, CMC also is concerned that many of the specific criteria contained in the proposed rule are weaker than those contained in published guidance. CMC also believes that the proposed rule can better protect certain subpopulations from harm caused by consumption of contaminated fish and shellfish. Finally, CMC is concerned that the economic analysis of the proposed rule over-emphasizes costs and under-reports the many benefits of improving water. quality throughout the state. These three points are reviewed below.

Fish Consumption Figures Should Be Recalculated to Protect Exposed Subpopulations Adequately

For purposes of establishing human health criteria, the proposed rule assumes the consumption of 6.5 grams of fish and shellfish per day by an average adult with a body weight of 70 kilograms.(*7) These two figures should be adjusted to better protect subpopulations exposed to contaminated fish and shellfish, particularly mercury contaminated fish and shellfish.

First, the 6.5 grams per day figure simply averages fish consumption over all of the population without accounting for the fact that much of the population either does not eat fish at all or relies on fish for much of their daily diet. A simple average thus underprotects much of the more significantly exposed population. Moreover, this figure is inconsistent with the Ocean Plan's estimate of 23 grams of fish and shellfish ingested per day. At a minimum, the analysis should be revised to use this more conservative figure.

Second, the use of a 70-kilogram man significantly underprotects children and pregnant women, who are most at risk from eating fish and shellfish contaminated with toxics. The proposed rule justifies this figure by claiming that "[p]ersons of smaller body weight are expected to ingest less ... so the dose per kilogram of body weight is generally expected to be roughly comparable." In fact, growing children and pregnant women often eat as much or more than many 70-kilogram adults, and so the calculated "safe" dose will be far too high for their body size. We urge EPA to base the human health criteria on a child 's weight in order to better protect this most vulnerable group of people.

(*7) Id. at 42176.

Response to: CTR-029-003

Regarding the protectiveness of the proposed criteria, see response to CTR-029-002a. With respect to EPA's estimation of costs and benefits, see response to CTR-029-004a.

EPA disagrees with the commenter that the fish consumption rate is based on "the fact that much of the population does not eat fish" - the opposite is true (see discussion on this same issue in the response to CTR-002-002a). Also, the commenter has advocated the use of 23 gm/day from the State of California's Ocean Plan estimate. This Plan, which is the State's undertaking, and the fish intake estimate is based on consumption relevant to marine species of fish and is, therefore, not an appropriate comparison to the estimate of 6.5 gm/day, which is based on fresh/estuarine species only. EPA acknowledges that there are population groups who consume greater amounts of fish than the overall population. However, EPA believes that its assumption of 6.5 gm/day is adequately protective. These issues are discussed in the response to CTR-002-002a. Regarding the body weight assumption, EPA believes that 70 kg is an appropriate body weight because it represents a reasonable measurement for adults and most of the criteria are based on chronic health effects [i.e., Reference Doses (RfDs) based on exposure over the course of a lifetime] for which the adult population is most appropriate. EPA acknowledges that where the RfD is based on health effects in children, the exposure parameters, including the body weight assumption, should be adjusted for a child. Such assumptions may be used on a chemical-by-chemical basis in calculating criteria. However, for this rule EPA believes it has made appropriate assumptions with the chemicals being regulated. For a specific discussion on this issue related to the mercury criterion, see the response to CTR-006-001a.

Comment: p. 42176 & 42178 - Fish Consumption Rates In general, we support EPA's use of a fish consumption rate of 6.5 g/day in the CTR criteria. However, it may be more accurate to develop rates based on freshwater fish/shellfish consumption and marine/estuarine fish/shellfish consumption. While

EPA says on p. 42176 that the State may want to develop site-specific criteria where warranted, the Preamble also states on p. 42178 that EPA "supports the State's use of any appropriate higher state-specific fish and shellfish consumption rates in its readoption of criteria in its statewide plans." (emphasis added) We believe that the latter statement should be consistent with the previous statement, and that site-specific criteria should be developed using local fish and shellfish consumption rates where warranted, regardless of whether they are higher or lower than the national average consumption rate. For instance, in recalculating human health criteria for effluent dependent waters where fish consumption is a designated use, EPA or the State should consider using 1.72 g/day (see 62 Fed. Reg. 42179). We believe that this freshwater consumption rate may even be high, based on the following mean consumption rates of fish that are representative of California's freshwater fisheries (U.S. EPA, 1990b):

Bluegills 0.089 grams/day Carp 0.016 grams/day Catfish 0.292 grams/day Perch 0.062 grams/day Sunfish 0.020 grams/day Trout 0.294 grams/day

Response to: CTR-035-022

EPA disagrees that the two referenced statements regarding criteria development and fish intake rates are inconsistent. If a State determined, based on adequate data, that its population did in fact consume less fish than EPA's default value, EPA would support the State's use of that value. However, the commenter has presented values from only several species of fish from a much larger tabulated list in the original 1989 Exposure Factors Handbook (revised in 1995) and suggested that they are appropriate for a site-specific criterion. EPA disagrees with this rationale. The table actually presents consumption data from a study conducted for fish consumers in the United States. EPA believes that this is not necessarily representative of California-specific consumption patterns. The point of allowing such flexibility with site-specific criteria is that data are available for that particular site, which the commenter has not demonstrated. Further, EPA disagrees that the use of 1.72 gm/day would protect the general population of California. See additional discussion on protecting the general population in response to CTR-002-002a.

Comment: On behalf of San Francisco BayKeeper, its Stockton-based DeltaKeeper project, San Diego BayKeeper and Santa Monica BayKeeper (hereinafter "BayKeepeer"), I am submitting these comments for consideration in finalizing EPA's proposed rule establishing water quality criteria for priority toxic pollutants for the waters of the State of California. The need for numeric criteria for priority toxic pollutants was identified by Congress ten years ago when, in October, 1987, it enacted amendments to the Clean Water Act mandating that States issue such criteria by not later than October 18, 1990. The State of California adopted a portion of the mandated criteria in April, 1991, which, in large part, EPA approved. However, even that partial compliance was thwarted by the Sacramento Superior Court's

overly broad decision vacating the State's decision based solely on a flawed economic analysis purportedly required by State law.

Now, seven years later, although appreciative of the complexity of the task required by Congress, BayKeeper is deeply concerned that EPA's proposed rule to cure the State's violation will undermine permit limits promulgated throughout the Bay area and other regions, allowing more pollution to be discharged to San Francisco Bay and other state waters in violation of the State and EPA's antidegradation policies. BayKeeper also is very concerned that EPA is promulgating criteria for mercury, dioxin and 13 other pollutants which are based on drastic underestimates of the quantity of fish consumed by recreational and subsistence anglers throughout the State of California. BayKeeper also believes that at this late date, the proposal to allow compliance schedules which could delay for up to ten years compliance with permit effluent limitations based upon the proposed criteria is inappropriate given the already seven year delay suffered by California's aquatic ecosystems and the people who depend upon the health of those systems for food and recreation.

II. MANY RECREATIONAL AND SUBSISTENCE ANGLERS EAT MORE THAN 6.5 GRAMS OF FISH PER DAY.

According to EPA's "Economic Analysis of the Proposed California Water Quality Toxics Rule," (July 1997), anglers throughout the State who eat on average 107.1 grams/day of fish from California's waters (about 10% of the people fishing), after the proposed rule is enacted, will still be confronted with a lifetime cancer risk of from 6.65 x 10E-4 to 9.26 x 10E-4. Economic Analysis at 8-15. That correlates

roughly to a 1000 times greater chance of those anglers getting cancer than the 1 x E10-6 risk established by the State or an increased cancer risk of approximately I cancer death per 1,000 people. 107 grams is about a quarter of a pound. Surveys in the San Francisco Bay area have found that many anglers eat up to a pound (450 grams) per day of fish, increasing the risk even beyond that documented in the Economic Analysis. There is no reason to assume that subsistence anglers throughout the State are not consuming fish at a similar rate. In calculating criteria for mercury, dioxin, PCBs and other contaminants, EPA "assumes" a consumption rate of 6.5 grams per day. That number purports to be "equivalent to the average per-capita consumption rate of all (contaminated and non-contaminated) freshwater and estuarine fish and shellfish for the U.S. population." 62 Fed. Reg. at 42176. Congress' directive that the "solution to pollution is not dilution" should apply even more forcefully to human health impacts. EPA should not be allowed to dilute the health effects of fish consumption in California by averaging it into the fish consumption rates of the entire country nor should EPA dilute the effects of contaminated fish on those people who choose or need to use the Nation's waters more than others -- recreational and subsistence anglers -- by lumping their consumption rates in with the general populations.

Despite the fact that EPA has acknowledged in its Economic Analysis that it is well-documented that a significant subpopulation of people eat considerable amounts of fish, the proposed rule chooses to ignore this fact, couching it as a mere possibility which the State should address if it chooses to. See 62 Fed. Reg. 42176 ("[t]here may ... be circumstances where site specific numeric criteria are more stringent than the statewide criteria are necessary to adequately protect highly exposed subpopulations [like subsistence anglers'). Of course, the whole rationale for EPA to be issuing the proposed rule is inaction by the State of California. The notion that certain critical determinations involving direct human health impacts should be left to a crippled process is arbitrary and does not accomplish what Congress set out to do in establishing Section 303(c)(2)(B) back in 1987.

Perhaps the greatest irony of EPA's methodology in selecting a consumption rate is apparent if one considers that, as our waters become more and more deteriorated from toxic contaminants and people become more and more aware of that contamination, they are likely to eat less and less fish, driving down the national fish consumption average and, under EPA's way of calculating, allowing more pollution to be discharged. EPA must set a consumption level that protects the most sensitive users and renders California's waters truly "fishable" not "fishable if you want torisk getting cancer."

Response to: CTR-039-004

EPA believes its estimate of consumption level for the general population is reasonable and its selection of risk level for the general population affords adequate protection for all populations. For water quality criteria established in the CTR, individuals consuming 107.1 gm/day would be protected at approximately a 10^{-5} risk level and that individuals consuming up to a pound a day would still be protected at a 10^{-4} level. For a more detailed discussion on this same issue see the response to CTR-002-002a.

EPA acknowledges that the commenter drew its lifetime cancer risk estimates for people who eat an average of 107.1 gm/day of fish of 6.7×10^{-4} to 9.3×10^{-4} from the benefits portion of EPA's Economic Analysis (EA). However, the post rule cancer risk estimates in EPA's EA were calculated conservatively and are likely overstated for two reasons.

First, the benefits portion of the EA only accounts for risk reduction that occurs from reducing point source discharges. Thus, the post rule risk estimate in the EA is only a partial accounting of the potential reductions in fish contamination that will eventually result from implementation of the CTR. The reason for this is that EPA only accounted for costs of the rule to NPDES dischargers. In order to fairly compare costs with benefits, the benefits only included estimates of risk reductions that would take place due to increased controls on NPDES dischargers. However, in actuality, the standards established in the CTR apply to the waterbodies (i.e., inland

surface waters and enclosed bays and estuaries). As controls on other sources are implemented, perhaps as a matter of state law, (*e.g.*, remediation of contaminated sediments; best management practices to control non point sources and runoff from agricultural land), EPA expects that in the future the CTR criteria will be attained in the waterbodies and concentrations of pollutants in fish tissue will decline further.

Second, the baseline and post-regulatory risk estimate in the benefits portion of the EA was calculated by adding together all of the individual excess lifetime cancer risks for all of the chemicals identified in fish tissue data collected throughout the State. This assumes that an individual is eating fish contaminated with all of the chemicals identified in the study. To the extent that not all fish contain all contaminants at the assumed concentrations, both baseline and post-regulatory cancer risk estimates in the EA may be overstated. While this approach is appropriate for analytical purposes in the economic analysis' benefits assessment, agency scientists who establish ambient water quality criteria do not believe that the science demonstrates that individual risks can simply be added together for purposes of criteria development.

The commenter, in its discussion, also states that the consumption rate accounts for both contaminated and non-contaminated fresh/estuarine fish and shellfish. Although there are many circumstances relevant to fish consumption and contamination patterns, in an effort to be protective of populations that do consume most or all of their fish from a given water body, the equation to derive criteria does not subtract any of the consumption rate - that is, there is no discounting for non-contamination. This assumption helps to ensure that people can safely consume fish from waters designated for fishing and to derive allowable levels of toxics that are adequately protective of human health under the Clean Water Act.

EPA believes that its criteria are adequately protective. States have the flexibility to be more protective if they believe it is appropriate. However, with this rule, EPA is only promulgating criteria. That is, antidegradation policies are not affected by this action. Regulated entities must still comply with existing State antidegradation policies and procedures. Also, compliance schedules are a fact-specific, facility-specific determination. All stakeholders will have an opportunity to review the facts and comment on the appropriateness of a compliance schedule for any given situation as part of the public noticing of the draft NPDES permit. With respect to the comments regarding the length of the compliance schedule, see response to comment CTR-002-010b.

Comment: PROVISIONS SDG&E DOES NOT SUPPORT

As described in the following comments SDG&E does not support the following provisions:

* The fish consumption rate of 6.5 g/day used is not representative of fish consumption within the State of California, and overestimates exposure. This value is reported by the EPA to represent an estimate of average consumption of fish and shellfish from estuarine and fresh waters by the U.S. population(*3) . The draft EPA

Exposure Factors Handbook (*4)(EFH) summarizes studies on the intake of fish and shellfish, and includes study results for Northern and Southern California from the National Marine Fisheries Service. While this data is compiled for fish from marine habitats, other data summarized in Table 10-8 of the draft EFH suggests that the percentage of the population consuming and the mean daily fish intakes are higher for fish from marine habitats than for freshwater/estuarine habitats. The mean daily intake of marine finfish for anglers was 2.0 g/day for both Northern and Southern California, and the intake was 0.2 or 0.3 g/day on a per capita basis in the coastal population. The value of 2.0 g/day would be a more reasonable consumption rate and should be sufficiently health-protective of the more highly exposed sub-population of the state, because this intake is restricted to the angler population, which may reasonably be expected to consume their own catch and to represent a greater exposed population than the entire population of the state. The intake rate from this database is more up-to-date and is geographically representative. The criteria should be recalculated using the California fish intake rate.

General human health criteria issues

* Fish consumption rate - See the above discussion for PAHs regarding the over estimation of fish consumption rates used in the human health criteria.

(*3) U.S. EPA, 1989. Assessing Human Health Risks from Chemically Contaminated Fish and Shellfish. Office of Water Regulations and Standards. EPA-503/8-89-002.

(*4)U.S. EPA, 1996. Exposure Factors Handbook. EPA/600/P-95/002Ba. Office of Research and Development.

Response to: CTR-060-015

EPA disagrees with the commenter. EPA believes that the 6.5 grams/day fish intake estimate is adequately protective of the general population of fish consumers over the course of a lifetime and is appropriate for this rule. The commenter suggests that EPA use an intake value based on marine finfish consumption of 2.0 gm/day. However, it is the fresh/estuarine species of finfish and shellfish that apply to the development of water quality criteria for the waters covered under this rule. Specifically, EPA's ambient water quality criteria are applicable to inland waters and estuaries. Further, EPA is aware of other studies that indicate higher consumption rates than suggested by the commenter. For further discussion on the basis of EPA's estimate, refer to the response for CTR-002-002a.

Comment: HUMAN HEALTH CRITERIA

EHC is very concerned about the use of 6.5 grams per day of fish tissue as a basis upon which to derive human health criteria. This is not adequate to protect the many thousands of subsistence fishers of California coastal waters. We trust EPA is not in the business of protecting "most of the people, most of the time" as is the indicated goal for marine organisms elsewhere in the CTR (see comments below).

We refer you to a study conducted by the Save San Francisco Bay Association that concluded that fishers of San Francisco Bay consumed 81grams per day in the week prior to the survey with consumption rates as high as 450 grams/day... This element of the CTR must be recalculated at a higher rate of consumption and with a healthy safety margin to accommodate for synergistic and cumulative effects. Further, the Save San Francisco study showed that heads and skin were frequently consumed, the health criteria must reflect these actual eating patterns and practices as well and reflect the cultural diversity of users of the Bays. Since many subsistence fishers are people of color, adoption of this rule could violate the President's Order on Environmental Justice b exposing these populations to increased and undue environmental health risks.

Response to: CTR-065-003a

EPA acknowledges that there are population groups that consume greater amounts of fish than the overall population. However, EPA believes that the intake rate of 6.5 grams/day is adequately protective of the general population of fish consumers over the course of a lifetime. EPA has reviewed the materials submitted by the commenter from the Save San Francisco Bay Association and, as is discussed in CTR-002-002a, the commenter needs to separate out those species defined as marine from the referenced tables (e.g., shark, ray, cod, halibut, mackerel, marine salmon) in order to appropriately compare fish intake rates that are relevant to the development of the CTR criteria. Other issues on the fish consumption rate are also discussed in the response to CTR-002-002a. Regarding the comment on the President's Executive Order on Environmental Justice, see the response to CTR-002-005a.

Comment: In regard to the numeric water quality standards criteria for California surface water, they have been revealed by environmental groups to be insufficiently protective and environmentally unjust. The proposed new rules assume fish ingestion of 6.5 grams per day. In reality, consumption of fish in some communities can be as high as 1 pound per day. This level of consumption is especially likely among subsistence fishers.

Please prevent toxic pollution in California's bays by making more protective standards that consider all toxic pollutants and consider the fish consumption habits of subsistence anglers.

Comment: I am writing to urge you to more stringent - and more protective - water quality standards for California surface water. The proposed standards are too weak and discriminatory in their effects.

Lastly, the proposed standards are discriminatory in their effects in that they assume consumption of only 6.5 grams of fish per day per person. Many poorer communties catch and eat fish for subsistence - as much as a pound per day per person (more than sixty what the EPA estimates!) placing them at greater risk. The standards should be set to protect everybody, including those who happen to be poor and/or eat a significant amount of fish.

Please set the standards to protect us all and move us closer to the goals of the Clean Water Act, that our waters be safely fishable and swimmable.

Comment: I am writing to urge you to work towards the prevention of toxic pollution in the bavs of California. It is evident that more protectiive standards are needed to protect those who fish and those who consume the

fish. Not to do so would be completely irresponsible. Turning a deaf ear to the situation or bending to pressure from business interests would, I suggest, also be immoral.

Comment: First, the 6.5 grams per day must be out in left field. Your staff must have divided the total consumption by the population. It ignored that some people do not eat fish, some eat very little and others eat fish regularly. Subsistence fishers are the obvious case in point, but what about so many of us who have eschewed red meat for a contemporary healthy diet of fish and fowl. We eat about I/3 LB three times a week. This comes to about 61 grams a day, almost an order of magnitude larger than you baseline case.

Response to: CTR-099-002

EPA acknowledges that there are population groups that consume greater amounts of fish than the overall population. However, EPA believes that the intake rate of 6.5 grams/day is adequately protective of the general population of fish consumers over the course of a lifetime. For a more detailed discussion on this issue, see response to CTR-002-002a.

Comment: California EPA should not be satisfied that our state's water quality standards are adequate if they only protect the segment of the population that does not have regular or frequent contact with the water or aquatic organisms. Water quality standards should ensure that the state's waterways are pure enough to protect that segment of the population that includes subsistence fish consumers.

Since the Clean Water Act has the goal of making our Nation's waterways "fishable and "swimable", any water quality standards that do not protect the health of that segment of the population that consumes more fish than the prescribed 6.5 grams per day is simply flawed.

Comment: It has been proven that unacceptable amounts of such toxins as mercury, cioxin and 13 other pollutants are in our state's surface waters. In establishing standards for these toxins, proposed new rules assume fish consumption at 6.5 grams per day. But in certain communities where subsistence anglers eat fish more often, it can amount to one pound daily. Even at 1/4 pound daily, the proposed standards would mean a cancer risk 1000 times higher than current state law states as "acceptable".

We should address the consumption habits of subsistence fishers, as well as the average fish consumer from the general public.

Thank you for your immediate attention to the above.

Response to: CTR-104-001

EPA disagrees with the commenter that persons consuming a quarter pound of fish per day would experience a cancer risk 1,000 times higher than the basis of the CTR. EPA believes that individuals consuming this amount would be protected at approximately a 10-5 risk level and that idividuals consuming up to a pound a day would still be protected at a 10-4 risk level. For a more detailed discussion on this issue, see response to CTR-002-002a.

Comment: The new water quality standards the EPA is proposing for California surface waters disturbs me greatly. There are several problems with the proposed rules. First in establishing standards for mercury, dioxin, PCBs, and other contaminants, the proposed new rules assume fish consumption at 6.5 grams per day yet consumption of fish in certain communities can be as high as one pound per day, over 60 times more than estimated by the EPA. Please don't underestimate fish consumption by people of different races and cultures.

Please prevent the toxic pollution of California waters by creating more protective standards that consider all toxic pollutants and all consumers of fish. Thank you.

Response to: CTR-109-001a

Comment: For mercury, certainly I would concur with the previous comments, that the number should be -- that is appropriate is accumulation factors.

Now the bioconcentration factor, in deference to this state's consumption rates that have been determined are appropriate for California, I think using the average consumption rate for everyone in the country, by definition, lops off about half of the population. It seems to me that it doesn't account for those users of the bay who are the high consumption -- high fish-consumption users, which obviously there's a number of them, and that's not reflected in that average at all.

So I think that those bioaccumulation factors are important to the mercury number base data that we have for the bay for all the reasons stated earlier, and similarly for dioxin. It seems as if EPA would like to back away on that, the criteria that is listed.

Comment: I already mentioned average consumption rate, but 6.5 grams is just not realistic. I have people out fishing every day at -- my office is on the end of a pier in San Francisco, and every day there are at least five or six people fishing off that pier, the same people every day, and some of them are great at it. They throw that line in and get six or seven fish every day, and I'm sure they're eating them.

I can't actually communicate with them very well -- one of them, I can. And people who eat a lot of fish, consuming fish regularly from the bay, 6.5 is really not a realistic number to protect the most sensitive part of the population.

And EPA is doing air rules related to asthma, geared for the most sensitive part of the population, but you get to the water rules and we're looking at very little -- the average for the whole country, even including Montana or Idaho, where -- I don't even know whether fish consumption goes down in the middle of the country, but I have to imagine that in the coastal states it's much higher.

So the average has nothing to do with the most sensitive population. so that should be taken into account. That would adjust some numbers pretty drastically.

Comment: Proposed Application of Saltwater and Freshwater Criteria

In the proposed California Toxics Rule, EPA is proposing to use the definitions in 40 CFR 131.38(c)(3) to determine when saltwater and freshwater criteria should apply to water bodies. The proposal is to use the lower of the freshwater and saltwater criteria when salinities are between less than 1 ppt 95% of the time and greater than 10 ppt 95% of the time. In the 1995 Basin Plan amendments, the Regional Board included a different application procedure. Like EPA, the Regional Board uses the lower of the freshwater and saltwater objectives for estuarine waters, but defines estuarine water as having salinities between less than 5 ppt 75% of the time and greater than 5 ppt 75% of the time, or "tidally influenced fresh waters that support estuarine beneficial uses." The Regional Board elected to use a combination of biological indicators (estuarine beneficial uses) and salinity measurements to define estuarine areas because of the difficulty of accurately depicting estuarine zones using salinity measurements without extensive data spanning channel depth and width, and variability with tides, seasons, and riverine flows.

The Regional Board's definition of how salt and freshwater objectives/ standards will be applied in estuarine waters was part of the 1995 Basin Plan amendments (p. 4-13, first column--attached). Those amendments have been formally approved by all of the appropriate state agencies and have been submitted to EPA for final approval.

We recommend that EPA add a provision to the proposed rulemaking that indicates the primary decision for whether waters are classified as estuarine should be based on the presence of estuarine organisms for any significant period of time and the secondary decision based on salinity measurements. In addition, we request that EPA specifically exclude the proposed federal definition of estuarine waters for implementation of federally promulgated standards within the San Francisco Bay Region (or formally approve the 1995 Basin Plan amendments and indicate that Basin Plan provisions take precedence over provisions in this proposed rule).

Comment: pp. 42183-42184 -- Applicability of Freshwater or Saltwater Aquatic Life Criteria in Estuarine Environments The proposed regulation includes a provision for estuarine waters where the salinity is between 1 and 10 parts per thousand, whereby the more stringent of the freshwater and saltwater criteria would apply unless EPA approves the application of the freshwater or saltwater criteria based on a biological assessment. We challenge the basis for the following rationale put forth in the Preamble: "In the brackish water transition zones of estuaries, there generally will be a mix of freshwater and saltwater species. Generally, therefore, it is reasonable for the more stringent of the freshwater or saltwater criteria to apply." We find this conclusion to be questionable; it is equally possible that the saltwater or freshwater species that occur in brackish environments may be more tolerant rather than more sensitive. We recommend that EPA include these procedures for determining appropriate criteria for those instances where salinity is between 1 and 1O parts per thousand as guidance in the Preamble, rather than placing them in the rule itself.

Comment: 10. EPA should allow permit authorities flexibility in establishing saltwater criteria where the salinity is between 1 and 10 parts per thousand. The proposed rule states that for these salinities the more restrictive of the salt and freshwater criteria should apply. This is unnecessary and has the effect of preempting the permit authority's flexibility to apply the most appropriate criteria in any given circumstance. In preempting the permit authority's flexibility, it conflicts with numerous statements in the Preamble and the economic analysis, which point to the considerable flexibility the State has in implementing the criteria.

Comment: 3. Freshwater/saltwater. WSPA supports giving permit writers and other regulators flexibility when selecting the appropriate criteria when waters may not be clearly salty or clearly fresh.

EPA proposes to require using the more stringent of freshwater or saltwater criteria when the receiving water is neither >10 ppt salinity 95% of the time (i.e., clearly salty) nor <1 ppt salinity 95% of the time (i.e., clearly fresh). This approach is needlessly inflexible. Permit writers and others should be allowed to judge which criterion is appropriate.

For example, there may be many cases when the freshwater criterion is lower, but the receiving water is salty enough that no freshwater aquatic life could survive. Thus, a freshwater criterion to protect species that are not there is invalid, inappropriate, and potentially wasteful of the state's resources if it causes point sources to invest in treatment merely for treatment's sake. Conversely, a saltwater criterion might be the lower value in a receiving water which is never salty enough to support marine life. A similar argument applies.

Lastly, it will probably be common to find receiving waters which may support both marine and freshwater organisms and in such cases the permit writer would use the more restrictive criterion. Each receiving water should be evaluated based on the facts and the permit writer should be allowed to exercise their professional judgment.

EPA trusts permit writers to select different criteria based on seasonal concerns. There is no reason not

to allow them to select the appropriate criteria I in the'case of ambiguous salinity as well.

Comment: Applicability of Freshwater/Saltwater Criteria in Estuarine Environments

We disagree with EPA's proposal in the Preamble to apply the more stringent of the freshwater and saltwater criteria when waters are in an intermediate salinity range or when salinity fluctuates diurnally due to tidal action. We believe a more valid approach is for the State to approve the choice of criteria based on a biological assessment. There may be many cases when the freshwater criterion is lower, but the receiving water is salty enough so that no freshwater aquatic life could survive there. Under this scenario, the application of a freshwater criterion to protect species that are not present is inappropriate and a waste of resources should it trigger the need for additional control efforts. A similar argument applies in cases where a saltwater criterion is used for a receiving water which is never salty enough to support marine life. Each receiving water should be evaluated based on the facts and the permit writer should be allowed to exercise his professional judgment in selecting the appropriate criteria and establishing water quality-based effluent limits. We recommend that EPA delete this provision from the Preamble, and if necessary develop guidance on determining appropriate criteria for those instances where salinity is between 1 and 10 parts per thousand.

Comment: Proposed California Toxic Rule

The Metropolitan Water District of Southern California (Metropolitan) appreciates this opportunity to comment on the U.S. Environmental Protection Agency's (U.S.EPA) proposed California Toxics Rule(CTR). Metropolitan, through its 27 member agencies, supplies nearly 60% of the drinking water used by approximately 16 million people living in the six-county region of Southern California. Our sources of supply are surface waters from Northern California and the Colorado River.

The water quality criteria proposed in the CTR are of critical importance to Metropolitan and other drinking water suppliers. These criteria create the basis for source water protection activities which are the first line of defense for ensuring a safe drinking water supply. Further, the criteria help protect aquatic species, including the unique aquatic resources of the Bay-Delta. The health of the Bay-Delta ecosystem and waters tributary to the Delta is linked to the amount of water available for export and thus directly affects water supply reliability of the exporting water agencies such as Metropolitan. Lastly, the CTR criteria affect the ability of water suppliers to operate and maintain their facilities.

Metropolitan recognizes that the CTR is only required to address the Clean Water Act's "priority pollutants". We note, however, that many of the drinking water contaminants regulated under the Federal and/or California Safe Drinking Water Acts (SDWA) are not among the priority pollutants. Table I lists the drinking water chemical constituents regulated under the California SDWA which are not priority pollutants. (The California SDWA regulates a broader set of contaminants than the Federal SDWA and provides the appropriate regulatory comparison since the CTR pertains solely to California.) Drinking water beneficial, uses cannot be fully protected without water quality criteria for all California SDWA regulated contaminants. Metropolitan requests that U.S. EPA consider including human health criteria for the contaminants listed in Table I as part of the CTR.

Response to: CTR-025-001a

The scope of today's rule is to establish numeric criteria to bring California into compliance with CWA Section 303(c)(2)(B). Section 303(c)(2)(B) requires adoption of numeric criteria for priority toxic pollutants contained in CWA Section 307(a) for which EPA has issued Section 304(a) criteria guidance the discharge or presence of which could reasonably be expected to interfere with the designated uses of state waters. The promulgation of pollutants that are not identified as priority toxic pollutants (i.e, those pollutants that are not contained in the CWA Section 307(a) list) are outside of the scope of today's rule.

While EPA agrees that there may be other pollutants that adversely impact environmental protection,

EPA notes that states do have the authority to develop and adopt criteria for pollutants that are not contained on the 307(a) list in order to protect the designated uses of their waters. The Water Quality Standards Regulation (see 40 CFR 131) requires all states, including California, to adopt criteria that provide sufficient coverage to protect the designated uses of their waters. Furthermore, where a state has not adopted sufficient coverage of numeric criteria to protect the designated uses, the state may utilize its narrative criteria to derive criteria for pollutants to supplement the numeric criteria.

CROSS REFERENCES C-17a

Comment: For California SDWA regulated contaminants which are also priority pollutants, the human health water quality criteria proposed under the CTR and existing California SDWA primary Maximum Contaminant Levels (MCLs) are not always consistent. While CTR criteria apply to source waters and drinking water MCLs apply to finished drinking water, Metropolitan urges that U.S. EPA ensure greater consistency between these regulatory levels.

Table 2 identifies the priority pollutants which have California SDWA primary MCLs and for which the CTR either does not establish any human health criteria or the CTR human health criteria exceed the California SDWA primary MCL. Metropolitan requests that U.S. EPA set the CTR human health criteria for the contaminants in Table 2 at levels not to exceed the California SDWA MCL.

Response to: CTR-025-002b

When multiple criteria apply to a waterbody, the most stringent criterion governs. For instances where California has adopted an MCL as a water quality standard that is more stringent than criteria contained in the final CTR, the MCL would provide the basis for protecting the drinking water use.

CROSS REFERENCES C-17a
C-12a

Comment: Human health water quality criteria for a number of other priority pollutants are at levels significantly below the corresponding California SDWA MCL. While Metropolitan favors a margin of safety between human health-water quality criteria and the SDWA MCL, significant differences between these two regulatory requirements can create problems in the course of maintenance of drinking water facilities.

For example, water utilities need to periodically "de-water" their lines as part of routine maintenance. The de-watering of distribution lines transporting treating drinking water results in discharges containing trihalomethanes (THMs). The CTR proposes human health criteria for each of the four compounds comprising the THM classification. The total limit under the CTR for THMs as a group is 11 ug/L, significantly below the California SDWA MCL of 100 ug/L as well as the proposed level of 80 ug/L for Stage 1 of the Disinfection/Disinfectant By-Products Rule. Thus, the discharge of water that meets California SDWA standards could potentially violate CTR human health criteria if that water is discharged to a source of drinking water supply. Metropolitan requests that EPA establish CTR human health criteria for THMs consistent with the California SDWA MCLs for THMS.

Comment: The proposed CTR freshwater aquatic life criteria for copper are also problematical for many drinking water suppliers. Copper algaecides are a necessary element of algal control strategies for drinking water reservoirs and conveyances. Even with a comprehensive reservoir management program based on immunological principles, copper algaecides need to be part of the algal control arsenal. Algal growth, if uncontrolled, can lead to unacceptable levels of trihalomethanes (THMS) in treated water supplies, among other impacts.

The CTR proposes freshwater aquatic life criteria for copper which could severely hamper the ability of drinking water suppliers to use copper algaecides. The dosage of these algaecides which is effective for controlling algal growth could lead to periodic exceedances of the copper freshwater criteria. Yet, use of copper algaecides is sometimes necessary to protect drinking water beneficial uses, and there is currently no economically feasible alternative available. Drinking water suppliers have the difficult task of meeting conflicting requirements to protect drinking water beneficial uses while ensuring that aquatic life criteria for copper are met.

Response to: CTR-025-004b

See responses to CTR-020-018 and CTR-025-002a.

EPA believes that discharges can meet both the requirements of the Safe Drinking Water Act (SDWA) and the Clean Water Act (CWA) after the CTR is promulgated. EPA believes that any final limits for copper would be feasible to meet because it is unlikely that a discharger would receive criteria end-of-pipe limits due to the dilution available in the receiving stream, as well as other factors taken into account, when translating a criterion into a water quality criteria-based effluent limit. EPA acknowledges that controlling trihalomethanes is important, but does not believe it is incompatible with protecting aquatic life in the stream. EPA is including the freshwater copper criteria in today's rule to ensure adequate protection of aquatic organisms in California. EPA also notes that there are some flexibilities and regulatory relief mechanisms that California may exercise to assist dischargers in meeting their permit limits for the criteria included in today's rule. (See preamble discussion on E.O. 12866).

Comment: Some of the concerns noted above could be addressed through the implementation provisions of the CTR. As you know, the State Water Resources Control Board has just made available for public review the Proposed Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California (Proposed ISWP/EBEP Policy), the implementing document for the CTR. Because of the length of the document (several hundred pages) and the fact that it has only recently become available, there has been insufficient time for thorough review. Yet, this document is crucial to understanding the practical impact of the CTR.

Metropolitan strongly requests that U.S. EPA extend the comment period on the CTR to December 10, 1997, the end of the comment period for the Proposed ISWP/EBEP Policy. This would allow drinking water suppliers and others affected by the CTR to evaluate the CTR in the context of its implementation. Without workable implementation provisions, the operational and economic impacts on drinking water suppliers could be significant and may need to be taken into account in the CTR. If the comment period is not extended, we ask that U.S. EPA fully consider the impacts of the freshwater aquatic life criteria on the operation and maintenance activities of drinking water suppliers and the effect on water reclamation activities and to modify the CTR, as necessary, so that these activities can continue to be undertaken in an economically feasible manner.

The CTR forms the backbone of the water quality regulatory process and Metropolitan urges U.S. EPA to review the proposed criteria in light of regulatory requirements of the California/Federal SDWA and the operating and maintenance requirements of drinking water suppliers. If you have any questions regarding Metropolitan's comments, please feel free to call Marcia Torobin of my staff at (213) 217-7830.

Comment: Additional Comments

Presented below are some specific comments on statements made in the proposed CTR Federal Register.

Page 42160, third column, near the bottom, municipal stormwater dischargers should be added to the list of NPDES dischargers who have an interest in this rule. If anything, they probably will be affected more than any other entity.

Page 42161, third column, first paragraph, states,

"Numeric criteria for toxic pollutants allow the State and EPA to evaluate the adequacy of existing and potential control measures to protect aquatic ecosystems and human health. Numeric criteria also provide a more precise basis for deriving water quality-based effluent limitations in National Pollutant Discharge Elimination System (NPDES) permits to control toxic pollutant discharges."

That statement is somewhat unreliable and misleading.

While it is bureaucratically simpler for regulatory agencies to numerically compare concentrations found in an effluent or in ambient waters with a chemical concentration-based water quality criterion, the claim made in the quoted statement is not necessarily true. In fact, rarely is the exceedance of numeric criteria a reliable basis for assessing the impacts of constituents on human health or the environment. While it may be more precise, it can be highly inaccurate. This is one of the areas that needs to be corrected by the US EPA where biological effects-based approaches are used, rather than chemical-based approaches for regulating such impacts as aquatic life toxicity for potentially toxic constituents.

Response to: CTR-061-005b

EPA agrees that storm water dischargers may be affected by this rule. EPA does not agree that application of numeric criteria, after adjustment by the site-specific water-effect ratio provided by the rule, would rarely be reliable. Also see response to CTR-020-006.

In addition, EPA believes that for the regulated community, the chemical-specific approach offers the advantage of allowing the permittee to focus immediately on a single contaminant for the purposes of designing effluent treatment. In contrast, whole effluent toxicity often leads to a facility conducting fairly extensive investigations to identify the cause of adverse effects on the tested organisms and to

develop an effective approach to reducing the effects.

Comment: Page 42162, third column, last paragraph, states,

"The forward to that guidance noted EPA's two-fold water quality based approach to controlling toxic pollutants: chemical specific numeric criteria and biological testing in whole effluent or ambient waters to comply with narrative 'no toxics in toxic amounts' standards. "

That statement was published in 1983 in the US EPA Water Quality Standards Handbook. While the significant technical deficiencies of this two-fold approach have been known now for over 15 years, the Agency has still not addressed the over-regulation that occurs from trying to use chemical concentration-based criteria to regulate biological impacts associated with aquatic life toxicity and excessive bioaccumulation of hazardous chemicals in aquatic life tissue.

Response to: CTR-061-008

EPA does not agree. EPA believes that the rule's provision for site-specific adjustments to criteria addresses the problem of unnecessarily stringent chemical criteria. See response to CTR-061-005b. With respect to bioaccumulative chemical risks, EPA believes that the best way to monitor bioaccumulative chemicals is to measure the concentration in the portions or tissues of aquatic biota that are consumed by humans and wildlife.

Comment: Page 42163, first column, last paragraph, states,

"Congress was frustrated that states were not using the numerous CWA section 304(a) criteria guidance that EPA had and was continuing to develop, to assist states in controlling the discharge of priority toxic pollutants. "

The reason the states were not adopting those criteria was that the criteria as implemented tend to over-regulate. The criteria do not properly consider how chemical constituents impact beneficial uses. The US EPA's adjustments of the criteria do not properly incorporate the aqueous environmental chemistry of the constituents in developing site-specific criteria. Basically, there is still a significant problem with how the US EPA developed criteria relative to how they are implemented at the state and local level. I was involved as a US EPA invited peer-reviewer of the criteria development approach, as well as several criterion documents that became part of the "Gold Book" criteria. I am, therefore, familiar with this topic area and know that it was never the intent of those who helped develop those criteria to have them mechanically implemented, as is being done today, into discharge limits. This leads to significant over-regulation and significant waste of public and private funds in construction of unnecessary treatment works beyond those that would be needed to protect the designated beneficial uses of a waterbody.

One of the fundamental problems that exist today is the US EPA's Independent Applicability Policy. That Policy was adopted without public review in the early 1990s. It establishes that chemical-specific criteria must be met, even if appropriately conducted biological assessments of toxicity, bioaccumulation, etc. show that the chemical-specific criteria are technically invalid for the particular situation of concern. This is a fundamentally flawed approach that should be terminated. This issue has been discussed in a paper, "Independent Applicability of Chemical and Biological Criteria/standards and Effluent Toxicity Testing" (Lee and Jones-Lee, 1995). While the US EPA criteria and standards group in Washington, D.C. has indicated that it is proposing to change the Independent Applicability Policy, the proposed changes as discussed thus far are not adequate to eliminate the fundamentally technically flawed aspects. The purpose of water quality criteria and standards is to protect designated beneficial uses, which for aquatic life means to prevent toxicity as might be measured by the kinds of tests that were used to establish the criteria. It is inappropriate to require achieving chemical-specific criteria as they currently exist, in waters in which there is no toxicity; that Independent Applicability Policy is obviously fundamentally flawed and should not be perpetuated.

Response to: CTR-061-009

EPA does not agree that the criteria, when adjusted for site-specific factors as provided by the rule, do not properly consider how chemical constituents impact beneficial uses. In setting criteria, EPA considers the scientific evidence of the toxicity of a pollutant. EPA stands behind the judgements made in its derivation of the criteria, and believes these judgements are reasonable.

The independent application policy is outside the scope of this rule. Nevertheless, independent application means that in stream biological monitoring and ambient or effluent toxicity testing can be used in a scientifically sound procedure for site-specific modification of the chemical criteria, but may not be used as a rationale simply to suspend implementation of the criteria.

Comment: Page 42168, first column, first paragraph, states,

"EPA's guidelines are designed to derive criteria that protect aquatic communities by protecting most of the species and their uses most of the time, but not necessarily all of the species all of the time (1985 Guidelines, page 1). EPA 's 1985 Guidelines attempt to provide a reasonable and adequate amount of protection with only a small possibility of substantial overprotection or underprotection. "

While the statement is appropriate for under-protection for the regulated chemicals, it is inappropriate for over-protection. Many of the water quality criteria tend to grossly over-protect based on the way they are implemented. This applies even to metals implemented as salt species.

Response to: CTR-061-010

EPA does not believe that the rule's provisions tend to grossly over-protect. The rule includes some provisions to modify criteria concentrations, averaging periods, and allowable exceedance frequencies to avoid either over- or under-protection.

Comment: Page 42168, first column, first paragraph, the statement, "The approach EPA is using is believed to be as well balanced as possible, given the state of the science." is inappropriate. The US EPA has still not graduated to the level of science that was present as part of the National Academies of Science and Engineering "Blue Book" "Water Quality Criteria" which focused on directly measuring toxicity of chemicals rather than trying to estimate toxicity through chemical-specific criteria.

Response to: CTR-061-011

EPA stands behind its technical assumptions made in the derivation of its criteria, and believes the resulting criteria are reasonable. EPA believes the calculation of water quality criteria for aquatic life based on toxicity data for aquatic species is appropriate. Congress further endorsed this approach in the 1987 amendments that added section 303(c)(2)(B) to the CWA.

EPA does not believe that chemical-specific criteria are inconsistent with the 1972 Blue Book approach. The Blue Book recommended numerous chemical-specific criteria, where available toxicity data were sufficient to support them.

Comment: Thank you for the opportunity to comment on the proposed California Toxics Rule. The City's comments are related to five main concepts:

1. The numerical standards are ambiguous or incomplete to address the variety of operating conditions under which discharges to waters of the United State occur.

Specifically, the City submits the following comments:

A. California's receiving waters have a very wide diversity of hydraulic and environmental conditions. The numerical standards do not take into account the wide range of rainfall patterns, storm durations, irrigation flows and power generation flows that are the current aquatic habitat. California's rivers are highly regulated, highly managed. The proposed regulations neither address this variety, nor provide a means by which numerical standards can be readily developed to address such variety.

B. The California Toxic Rule presents new water quality standards for the State of California. This rule presents water quality standards for all water bodies within the state. Water quality standards as presented in this rule would apply to all environmental conditions (dry and wet weather). During wet weather, conditions in the receiving streams can be extremely variable due to the quality and quantity of stormwater. Treatment plants generally have hydraulic capacity to process twice the average dry weather flow received. Water quality standards were developed based on dry weather conditions. Therefore, numerical water quality standards should not need to be achieved during storm events. If water quality standards need to be achieved during storm conditions, it is suggested that new standards be developed to account for the changes in environmental conditions.

Response to: CTR-096-001b

The criteria specified in the rule are adequate across California because they are designed to apply under all environmental conditions. EPA does not agree that its criteria concentrations were based on dry-weather conditions. Most of concentrations are based on laboratory toxicity tests. EPA agrees that its numerical exceedance frequency and design flow specifications are based on dry-weather conditions. Nevertheless, the rule provides for alternative development of averaging periods and exceedance frequencies, thereby allowing the extension of their applicability to wet-weather conditions. In addition, the Rule provides for site-specific modifications of criteria concentrations, to account for a site's water

quality characteristics.

The criteria specified in the rule are adequate across California because they are designed to apply under all environmental conditions. Comment: I. TOXIC POLLUTANTS THREATEN PUBLIC HEALTH AND SAN FRANCISCO BAY.

Toxic pollution causes harm in San Francisco Bay. Species of bivalve shellfish, plankton and phytoplankton that are especially vulnerable to toxic trace elements such as copper are decimated in its southern reach though they thrive in comparable estuaries with less metals pollution. (*1) (*2) Mounting evidence suggests its sediment is toxic to some aquatic life.(*3) Extensive research strongly suggests that PCBs and PAHs released to the Bay negatively effect reproduction in starry flounder. (*4) Reproductive effects are also correlated with PCBs in Bay cormorant eggs, Bay harbor seals have PCBs levels twice those associated with immunotoxicity and a disease epidemic that decimated a European population of this species.(*5) Health advisories are in effect because dioxin, PCBS, mercury, chlordane, DDT, dieldrin, and selenium contaminate Bay food resources eaten by the public (*6) (*7)

Public health threats from toxics in the food chain are of particular concern. A recent count found approximately 270,000 fishing licenses were issued to Bay Area residents. Surveys by CBESAFER!, the Save San Francisco Bay Association, and the Asian Pacific Environmental Network show that many people fish the Bay regularly to supplement their families' diet, that some people eat up to a maximum of a pound of fish per day, and that the majority of those who eat their catch regularly are people of color. [See attachment (*8)] A pound of fish per day is about 480 oz./month, sixty times the 8 oz./month "safety" cutoff for cancer and slow learning in the state's advisory.(*6)

In addition to these severe environmental health and justice problems, pollutant monitoring of the Bay is far from comprehensive, and undetected problems are likely. Indeed, EPA acknowledged that designated uses of the Bay are threatened or impaired by toxic pollutants when it named the Bay as a "toxic hot spot" under Section 304(l) of the Clean Water Act.(*9)

Comment: B. The criteria do not control pollution that harms fishing, and aquatic life.

Adoption of EPA's proposed criteria values will result in less control of toxic pollutants that exceed state criteria values in large parts of San Francisco Bay. Examples of this problem are shown in tables 3 through 6 for mercury, copper, nickel and PAH measured in 1995 at monitoring stations shown on a map of San Francisco Bay (Figure 1). The EPA-proposed criteria would allow:

- mercury violations triggered by state criteria values through much of the northern reach of the Bay. EPA-proposed criteria trigger violations only at the Petaluma river mouth and in South Bay. Bay-wide, 8 of 15 state criteria-triggered violations (53%) are allowed by EPA criteria.

- copper violations triggered by state criteria (4.9 ug/L total) throughout the northern reach of the Bay. EPA'S 3.1 ug/L dissolved value triggers violations only in the Petaluma river and in' South Bay. Bay-wide, 15 of 25 state-triggered violations (60%) are allowed by EPA criteria,

- nickel violations triggered by state criteria throughout most of the northern and southern reaches of the Bay. EPA's 8.2 ug/L dissolved value triggers violations at the Petaluma river mouth and one South Bay slough. Bay-wide, 20 of the 22 water quality standards violations (91 %) triggered by the 7.1 ug/L criterion are allowed by EPA criteria.

- PAH violations triggered by state criteria at Coyote Creek and the Petaluma River mouth, EPA-proposed criteria trigger 4 violations for benzo(a)pyrene and indeno(1,2,3-cd)pyrene while state criteria trigger 40 violations for these compounds and 6 other PAHS.

Though EPA criteria do not control mercury except at the Petaluma River and in South Bay, a state human health advisory cites mercury contamination,(*6) and demonstrates that mercury restricts fishing uses Bay-wide. A severe threat and possible harm to aquatic life of the Bay's entire southern reach is evidenced by reduced abundance of all species known to be most vulnerable to copper toxicity, while these same species thrive in otherwise similar estuaries with less copper and nickel pollution.(*1) (*2) EPA criteria do not control copper and nickel in most of this area. Nor do EPA criteria control PAHs which -- with PCBs -- cause toxic effects in starry flounder in Central Bay.(*4)

Further, EPA'S proposed criteria include no criteria for 16 dioxin compounds that are included in the state dioxin criterion for TCDD equivalents.(*10) (*21) These 16 compounds are 6 dibenzo-paradioxins chlorinated in the 2,3,7, and 8 positions (except for 2,3,7,8-TCDD which is included in the EPA criterion), and 10 dibenzofurans chlorinated in the 2,3,7 and 8 positions. Under the state criteria, these 16 compounds and 2,3,7,8-TCDD are assigned toxicity equivalence factors as discussed in the proposed rule. Under the state criterion all these compounds are limited: if only 2,3,7,8-TCDD is present it cannot exceed 0.014 pg/L; if only OCDD is present it cannot exceed 14 pg/L; and if a mixture of dioxins is present the sum of their toxicities cannot exceed 0.014 pg/L. By failing to use toxicity equivalents and then failing to propose separate criteria for these 16 compounds, EPA is essentially deregulating 16 of the most toxic chemicals known to science even though these dioxins harm fishing uses, as shown by the health advisory discussed above. (*6)

The EPA criteria do not control toxics that threaten and harm the Bay, fishing and public health.

Comment: For California SDWA regulated contaminants which are also priority pollutants, the human health water quality criteria proposed under the CTR and existing California SDWA primary Maximum Contaminant Levels (MCLs) are not always consistent. While CTR criteria apply to source waters and drinking water MCLs apply to finished drinking water, Metropolitan urges that U.S. EPA ensure greater consistency between these regulatory levels.

Table 2 identifies the priority pollutants which have California SDWA primary MCLs and for which the CTR either does not establish any human health criteria or the CTR human health criteria exceed the California SDWA primary MCL. Metropolitan requests that U.S. EPA set the CTR human health criteria for the contaminants in Table 2 at levels not to exceed the California SDWA MCL.

Response to: CTR-025-002a

With respect to the issue of pollutants where the MCL is more stringent than the CTR criterion, EPA has determined that the CTR criteria are appropriate. As background, the Agency agrees with the commenter that the SDWA Maximum Contaminant Levels (MCLs) and the ambient water quality criteria are not always consistent. There are several reasons why this may be the case. First, while water quality criteria are health-based values only, MCLs take into account availability of treatment technologies and associated costs, and the availability of analytical methods. Second, the methodologies between the two programs differ in numerous ways, including the way that carcinogens are handled, the selection of the risk level, the approach to accounting for exposure, and the fact that water quality criteria specifically account for fish exposure. Third, there are differences associated with the fact that the information that each criterion is based on at the time of development also varies. That is, criteria developed at different times for the same chemical may be based on different exposure data and/or toxicity studies. The MCLs also apply to the chemical concentration in public water supply distributed tap water, whereas water quality criteria are used to develop State standards which are then used with water transport models to derive permit limits for point source discharges. For a more detailed discussion on the reasons for differences between these two methodologies, refer to the Notice of Draft Revisions to the Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health (Federal Register, Vol. 63, No. 157, August 14, 1998). See also 63 FR 36742, 36775-36777 (July 7, 1998).

The Agency believes that for a given pollutant, the drinking water component of a water quality criterion should be consistent with the Maximum Contaminant Level Goal (MCLG) and is working to foster greater consistency between these two programs. Specifically, the Agency is currently revising the water quality criteria human health methodology, referenced above. Once finalized, EPA will revisit the methodology for deriving MCLGs, again, with a focus toward greater consistency.

The following policy is that recommended in the draft EPA methodology revisions when either water quality criteria have not been established or when the water quality criteria exceed MCL values. Although the use of MCLs is acceptable in the absence of 304(a) criteria, EPA is recommending that MCLs only be used when they are numerically the same as the MCLG and only when the sole concern is the protection of public water supply sources and not the protection of the CWA section 101(a) goal regarding fish consumption (e.g., where the chemically toxic form in water is not the form found in fish tissue and, therefore, fish ingestion exposure is not an issue of concern). Where consideration of available treatment technology, costs, or availability of analytical methodologies has resulted in MCLs that are less protective than MCLGs or water quality criteria, States and Tribes should consider using MCLGs and/or the health-based water quality criteria to protect water uses. Where fish consumption is an existing or potential activity, States and Tribes should ensure that their adopted human health criteria adequately address this exposure route. When fish consumption is a use, EPA recommends development of water quality criteria due to the fact that fish consumption and bioaccumulation are explicitly addressed. In all cases, water quality criteria should be set to ensure that all routes of exposure have been considered. EPA believes if water monitored at existing drinking water intakes has concentrations at or below MCLGs, then the water could be considered to meet a designated use under the CWA as a drinking water supply. In situations where a 304(a)criterion was less protective than an MCL, it is permissible to use the MCL as the criterion for segments designated as drinking water supplies. For carcinogens where the MCLG is equal to zero, States are encouraged to base water quality criteria at the drinking water intake on an acceptable cancer risk level (i.e., a level within the range of 10-4 to 10-6), to promote pollution prevention and anti-degradation.

The commenter has provided a short list indicating where some of the proposed CTR human health criteria are less stringent than the California MCLs. In some cases, the listed MCL has been developed by the State of California only - that is, there is no EPA national SDWA MCL (e.g., 1,3-dichloropropene, nickel). In some cases, California's MCL is more stringent than EPA's national SDWA MCL (e.g.,

benzene, vinyl chloride). However, where MCLs are more stringent than the CTR criteria, EPA has chosen not to revise the CTR number to make it the same as the MCL because the CTR criteria are adequate to protect the designated use.

As stated above, EPA is in the process of revising its water quality criteria human health methodology. EPA is currently reviewing public comments and is awaiting the results of a peer review on the published draft revisions. Again, as part of this effort, EPA intends to foster greater consistency between its drinking water and surface water programs, where appropriate.

Comment: Human health water quality criteria for a number of other priority pollutants are at levels significantly below the corresponding California SDWA MCL. While Metropolitan favors a margin of safety between human health-water quality criteria and the SDWA MCL, significant differences between these two regulatory requirements can create problems in the course of maintenance of drinking water facilities.

For example, water utilities need to periodically "de-water" their lines as part of routine maintenance. The de-watering of distribution lines transporting treating drinking water results in discharges containing trihalomethanes (THMs). The CTR proposes human health criteria for each of the four compounds comprising the THM classification. The total limit under the CTR for THMs as a group is 11 ug/L, significantly below the California SDWA MCL of 100 ug/L as well as the proposed level of 80 ug/L for Stage 1 of the Disinfection/Disinfectant By-Products Rule. Thus, the discharge of water that meets California SDWA standards could potentially violate CTR human health criteria if that water is discharged to a source of drinking water supply. Metropolitan requests that EPA establish CTR human health criteria for THMs consistent with the California SDWA MCLs for THMS.

Response to: CTR-025-003a

In general, EPA believes it is appropriate that water quality criteria are at levels below MCLs in consideration of the Agency's goals of pollution prevention. That is, ambient waters should not be contaminated to a level where the burden of achieving health objectives is shifted away from those responsible for pollutant discharges and placed on downstream users to bear the costs of upgraded or supplemental water treatment. However, there are numerous reasons why a water quality criterion may not be the same as an MCL. This is discussed in the response to CTR-025-002a.

Regarding the issue of the proposed human health criteria for trihalomethanes (THMs), the commenter has made an inappropriate comparison between the values in the CTR and the Stage I

Disinfection/Disinfectant By-Product (DDBP) Rule. The commenter has attempted to add the separate values proposed in the CTR for each individual THM and compare that total to the DDBP value, which represents total THMs. These values cannot be compared directly because the basis for their derivation is significantly different. The THM values in the CTR are based on four separate cancer potency factor values (i.e., q1* values) and a chosen acceptable cancer risk level (specifically, a 10-6 risk level), which were then both used in the water quality criteria equation (which includes factors for body weight, water ingestion, fish consumption, and bioconcentration) to derive the individual criteria values. The DDBP Rule that determined the MCL for total THMs - a composite value for all four THMs combined - was based on a weight-of-evidence approach that considered the available toxicological data, known epidemiological information on the incidence of disease associated with chlorinated drinking water (i.e., morbidity rates), information on the relative proportions and uncertainties in the composition of total THMs (including regional and seasonal variation, as well as other variables and their uncertainties) and technological feasibility. The MCLs were the output of an extensive "regulatory negotiation" between EPA and stakeholders. The approach used in the DDBP Rule is vastly different from the ambient water quality criteria calculations used for the CTR. Additionally, the water quality criteria derivations are health-based values only, whereas the MCLs include consideration of economic and feasibility issues, as was the case with the DDBP regulatory negotiation.

Regarding the commenter's concern for the periodic "dewatering" of utility lines, refer to the response to CTR-020-018.

Comment: 3 . TOXICITY DATABASE USED TO DEVELOP CRITERIA

The CTR indicates that the criteria being proposed are based upon a review of the most recent literature and toxicity data bases. The DFG is concerned that the databases utilized by EPA may not be as comprehensive as they could be with respect to inclusion of toxicity studies on a wide variety indigenous species found in State waters. Furthermore, data included in such databases such as EPA's AQUIRE have been found, in some instances, to be less than acceptable. Obviously we would like to see the criteria based on the most recent and scientifically sound toxicity data available. The DFG believes that it would be beneficial to describe in more detail the literature and databases utilized by EPA in development of the proposed criteria.

Also a discussion on appropriate and acceptable methodologies for data collection needs to be provided. It is not only important that the databases utilized by EPA be as comprehensive as possible, with respect to the inclusion of toxicity studies on a wide variety of indigenous species found in State waters. It is also important to know how the data was developed so that it won't be misinterpreted. For example, DFG would prefer using data that was derived from sampling whole organisms rather than edible filets if

we were looking at bioaccumulation, biomagnification, or other types of food chain issues. Most predators don't limit their diet to only the edible portions of a prey organism. Sampling only the edible portions of an organism could lead to faulty conclusions.

Finally, with regards to the development of chronic toxicity standards or criteria based on a straight percentage of the determined acute toxicity level, we would like to participate in any process that attempts to establish chronic levels in that manner.

Response to: CTR-026-003b

Regarding the comment on comprehensive evaluation of toxicity data, refer to the response to CTR-026-003a. Regarding the comment on sampling, edible portions are relevant when deriving human health criteria. Therefore, the practice of sampling edible filets is appropriate. The commenter's statement on the use of whole organisms because "most predators don't limit their diet to only the edible portions of a prey organism" is not relevant because the aquatic life criteria derivation process does not rely on the use of BCFs.

Comment: 7. HUMAN HEALTH CRITERIA

As you are aware the Department of Fish and Game is the trustee for the natural resources of the State and, as such we are not in an appropriate position to address human health issues. However, we would like to take this opportunity to make EPA aware of our concerns in two areas. The first issue deals with one component of the formula that was used to derive the human health criteria. Obviously, the human health criteria takes into account fish consumption rates, as well as what portion of the fish is consumed. The CTR indicates that the consumption rate utilized was 6.5 grams per day of fish tissue. This consumption rate, at least for the portion of the population that are subsistence fishermen, appears to be very low. If the human health criteria is to be adequately protective, this consumption rate should be revisited and a new rate developed to better protect these fishermen. Our second comment deals with the proposal to base criteria on fish tissue as opposed to water concentration. The DFG does not have a position with respect to this approach except to point out that compliance monitoring for fish tissue criteria may impact resources. This approach would mean an increased number of fish being collected for monitoring purposes which may impact fish resources. It may also impact the DFG's fiscal resources since we regulate scientific collection activity under which fish monitoring would fall.

Response to: CTR-026-007b

Regarding the issue of fish consumption, refer to the response to CTR-002-002a on this same issue.

Regarding the issue of basing the criteria on fish tissue versus water column concentrations, refer to the response to CTR-020-004b on this same issue.

Comment: The Center for Marine Conservation (CMC) is a nationwide, nonprofit advocacy group dedicated to the conservation and enhancement of coastal and ocean life and resources. CMC submits these comments on behalf of its 16,000 members in California and over 120,000 members nationwide.

CMC applauds EPA's efforts to bring California into compliance with the Clean Water Act 303(c)(2)(B). Implementing numeric criteria that will protect the beneficial uses of California's waters is of great importance to the health of coastal and marine ecosystems, and so to CMC and its members. The reliance in many areas of the state on narrative criteria threatens the health of most of the state's waters, thereby impacting both human health and the health of the state's economy that relies on clean water.

While CMC strongly supports the swift adoption of an Enclosed Bays and Estuaries Plan and an Inland Surface Waters Plan that contain numeric criteria for toxic pollutants, CMC also is concerned that many of the specific criteria contained in the proposed rule are weaker than those contained in published guidance. CMC also believes that the proposed rule can better protect certain subpopulations from harm caused by consumption of contaminated fish and shellfish. Finally, CMC is concerned that the economic analysis of the proposed rule over-emphasizes costs and under-reports the many benefits of improving water. quality throughout the state. These three points are reviewed below.

In Light of Significant Threats to Water Quality, the Proposed Rule Should Contain the Most Stringent Criteria That Are Scientifically Defensible

Many of the criteria in the proposed rule are weaker than criteria in current published guidance. The proposed rule summarily states that the difference between the proposed, weaker criteria and the published guidance documents is "insignificant"(*4); however, in light of the current contamination problems in California's waters today, any move backwards, particularly when spread out over the state, must be viewed as significant.

Any weakening of the criteria should be subject to close scrutiny and the most rigorous analysis, which the proposed rule itself does not do. Among other things, the criteria in the proposed rule may be under protective because additive and synergistic effects were not considered; and because the effects on

wildlife, which can be particularly significant for bioaccumulative chemicals, were ignored.(*5) In addition, the proposed rule contains dissolved rather than total recoverable metals criteria, despite the fact that EPA acknowledges that total recoverable metals criteria are "scientifically defensible" and that they are more protective than dissolved metals criteria because they consider "sediment, food-chain effects and other fate-related issues," rather than simply water column impacts.(*6)

Clean Water Act section 303(c)(2)(B) mandates the development of numeric criteria that will "support such designated uses [that are adopted by the State]." The statistics available on the health of the state's waters indicates that their use already is significantly threatened or impaired by toxics. The strongest. criteria supportable by science are necessary to reverse this trend and begin to restore the state's waters.

(*4) 62 Fed. Reg. 42159, 42168 (Aug. 5, 1997).

(*5) Id. at 42168.

(*6) Id. at 42172.

Response to: CTR-029-002a

Regarding the evaluation and protectiveness of the proposed criteria, the commenter states that many of the criteria in the proposed rule "are weaker than those contained in published guidance." However, EPA has updated its national criteria guidance from that previously published. The values proposed in the CTR are a part of that update and, therefore, there is now consistency with all criteria values [see 63 FR 68353-68364 (December 10, 1998)]. Regarding the issue of fish consumption, refer to the response to CTR-002-002a on this same issue.

Comment: 2. Since the preamble implies that CTR criteria may be applied in NPDES permits for municipal storm water dischargers as numeric effluent limitations, the proposed rule is flawed with regard to: a) setting attainable, scientifically valid criteria in a manner consistent with state and federal regulatory approaches; b) assessing the potential economic impact on the public served by municipal storm water dischargers; c) assessing environmental impacts pursuant to the National Environmental Policy Act and the Endangered Species Act; and d) providing for the coordinated review and evaluation of the proposed CTR in conjunction with the proposed State Implementation Plan. y

I

Comment: If the proposed rule is carefully and sufficiently modified to affirm a commitment by EPA to effect only its Congressional authorization as established by CWA section 402(p), then EPA's failure to assess municipal storm water dischargers" ability to attain the proposed standards and associated economic and environmental impacts may be set aside at this time. However, if EPA persists in maintaining the CTR as drafted in this regard, the ambiguities presented in the preamble demand serious consideration and analyses as follows.

a. Many of the criteria are not attainable or scientifically valid with regard to municipal stormwater dischargers, nor is the proposed approach consistent with an appropriate delegation of authority to the State.

ii. Scientific Defensibility of Standards

Municipal storm water discharges require a uniquely different scientific as well as regulatory approach. The episodic nature of storm flow events; the huge variances in flow volume, rate, timing, concentrations, and loads; the variability in receiving waters; and organism tolerance for and recovery f rom episodic exposure need to be taken into account in developing standards.

In a July 1992 memorandum addressing a Combined Sewer Overflow/Wet Weather workshop, Tudor Davies, Director of EPA's Office of Science and Technology wrote: "Changes being considered in the aquatic criteria development methodology to enhance the scientific defensibility of the criteria would be applicable to both constant and to wet weather discharges. One such change undergoing consideration is a change in the duration and frequency of exposure assumptions to make criterion more toxicologically realistic.

EPA has begun this work and is apparently nearing completion. With EPA's own Science and Technology office recognizing the inadequacy of the current approach to setting criteria relative to wet weather discharges, it must be concluded any attempt to apply the CTR criteria to municipal stormwater system discharges is ill-founded and likely inconsistent with the CWA.

Comment: 3. EPA has deleted data from several databases without indicating the reason for the deletions. This introduces the same problem as that described in #2 above, and results in variability in how water quality criteria are developed. Additionally, stakeholders need to know why data is deleted so that these decision criteria can be used in the development of defensible site-specific criteria. EPA should provide their reasoning for deleting data that was once believed acceptable so that this same reasoning can be used to update current criteria and to develop new sound criteria.

Comment: Organics

In proposing criteria for toxic organic compounds, we urge the EPA to include considerations of net environmental benefit. We see a potential for stringent pollutant limits as a means of influencing

replacements in the service area by other, equally toxic constituents. We have seen this occur to varying extent for chromium, selenium, zinc and molybdenum, and feel that similar instances involving trace organics can occur as well. We support the EPA's intention to evaluate receiving-water background concentrations and provide credit as appropriate.

Response to: CTR-057-007

"Net environmental benefit" is not an appropriate concept for establishing ambient water quality criteria. Ambient water quality criteria, as articulated in CWA Section 304, are supposed to characterize "all identifiable effects" from individual pollutants. See response to CTR-042-007a (Category C-21; Legal Issues). Ambient water quality criteria define the maximum pollutant concentrations allowable in order to maintain a specific designated use. The concept of "net environmental benefit" can be incorporated into other aspects of water quality standards if a State or Tribe so chooses. Designated uses, variances, and antidegradation all allow for the balancing of water quality goals with community priorities. For example, a community may choose to downgrade the designated use for a waterbody to address exceedances of specific chemical criteria because remediation of contaminated sediments (in this case, the source of loading to the water column) through dredging would cause more harm to the biological community through habitat destruction although the chemical concentrations for individual pollutants would decrease as a result. The CTR does not affect California's flexibility with respect to designated uses, variances, and antidegradation.

Comment: PROPOSED RULE ALLOWS SIGNIFICANT AND UNACCEPTABLE INCREASES IN TOXIC POLLUTANT CONCENTRATIONS IN BAYS AND ESTUARIES

Our initial review indicates that the proposed criteria for a number of toxic constituents are unacceptably high and will allow more pollution of bays and estuaries by several orders of magnitude. If adopted as proposed, the CTR will allow a 900% increase of dioxin, 140% increase of PCBS, 325% increase of mercury, 2760% increase of zinc, 23,000% increase of lead, and a stunning 430 million % increase for total PAH, some of the most problematic pollutants in San Diego Bay. The CTR only improves (i.e. strengthens) criteria for only 3 of 64 pollutants. This does not square with new studies that show reasons for concern about the synergistic and long-term effects of exposures to these toxic pollutants. In sum, the CTR proposes weaker criteria for 58% of the pollutants and no change for 37% of the criteria. This kind of action will not bring us closer to our goal of cleaner water containing healthier organisms in the future.

Comment: There are many features of the proposed rule which we strongly endorse, specifically:

* the use of the latest IRIS values for human health criteria, it is essential that the criteria be based on the latest scientific and environmental information;

* recognition that the dissolved fraction of metals, rather than the total recoverable, better reflect the aquatic toxicity of metals;

* recognition that for certain metals (e.g. copper and zinc) ambient water chemistry is critical in determining toxicity thereby endorsing the Water Effects Ratio;

* recognition and strong endorsement of the multi-tiered mixing zones for acute, chronic and human health effects; and

* recognition of interim limits and compliance schedules as appropriate implementation strategies,

Response to: CTR-090-002a

EPA agrees with the comment and its endorsement of the rule.

Comment: Human health criteria - p 42175 - Human Health Criteria - These criteria are based on a hypothetical series of events. Each link in the series must be present for the presumed risk to occur at the levels used to set the criteria. The links assumed to be present in the criteria include: (1) Non-degradation in the receiving water - Some regulated pollutants (various PAHs) rapidly break down in receiving waters.

(2) Continued presence in the receiving water at the level of discharge or at the calculated dilution level - Implementation plans and policies give no dilution credit or use very conservative dilution assumptions. As implemented in California, none of the dilution equations take into account far-field effect-, nor the time-averaging effects which in reality typically reduce concentrations to far below those assumed in the risk assessment. The result is as if we assumed that the human endpoint on the risk assessment only ate fish which lived within a few feet of the outfall.

(3) Bioaccumulation in fish or other higher organisms; non-degradation in these organisms - The bioaccumulation assumptions are based on the worst case bioaccumulation encountered in the scientific literature rather than the bioaccumulation actually taking place in commercial species in the waters in question- Not infrequently, tissue samples from food species indicate that less Bioaccumulation is taking place. Another complicating factor is that bioaccumulation factors are derived from steady-state conditions, whereas municipal discharges of chlorinated hydrocarbon carcinogens are usually episodic. Use of steady-state derived water concentration to tissue concentration relationships is especially problematic for wet-weather discharges, as these have durations measured in hours to days, whereas bioconcentration in mature (i.e. legal sized) fish occurs over weeks to months.

(4) Pervasive contamination - Ongoing consumption by humans of contaminated fish (or shellfish) with the level of contamination.

(5) Necessary safety factors - Assumed carcinogenicity or toxicity to humans at 10 or 100 times the frequency experienced by test animals. These safety factors are necessary but their overall effect is to significantly decrease the likely impact of the pollutant (i.e., shift a 10E-6 risk to 10E-7 or 10E-8). EPA's Cancer potency factors are based on an upper bound, i.e. 95 % percentile estimate of the slope.

(6) Non-threshold effects - Carcinogenicity is assumed to have no threshold mechanisms, i.e., there is no low level below which the human body can safely detoxify the carcinogen.

While the use of this chain of events and these assumptions are necessary to identify potential problems, the cumulative uncertainty creates too speculative a result to use for decisions regarding significant expenditures for remedial projects. Better sources of risk information are available, specifically, tissue samples from the organisms presumed to be carrying the risk to humans. What we propose is a three step process prior to controls being mandated for dischargers:

1. numerical criteria to identify potential risks. 2. site specific tissue samples of edible species to identify actual bioaccumulation (as has been done in San Francisco Bay with PCBs and other chemicals). 3. source assessment to determine if prospective controls on point sources provide meaningful reductions.

This approach is within EPA's mandate to set criteria and implement a permit program which meets the goals of the CWA.

San Francisco proposes that the designation of an appropriate level(s) be left to the state in its implementation documents.

Response to: CTR-090-019

EPA disagrees with the commenter that "... bioaccumulation assumptions are based on the worst case bioaccumulation encounter in the scientific literature ...". EPA has and will continue to use the best available science in the selection of the bioaccumulation data for the development of ambient water quality criteria. In the process of selecting bioaccumulation data, all published data are carefully evaluated and bioaccumulation factors are determined using all possible methods. The bioaccumulation data selected in this process for use in the development of water quality criteria represents the best synthesis and consensus of all available scientific information. The commenter also states that "... tissue samples from food species indicate that less bioaccumulation is taking place." However, no supporting information was provided nor were citations from the scientific literature provided. EPA disagrees with the commenter. EPA has and will continue to use the best available science in the selection of the bioaccumulation data for the development of ambient water quality criteria. The commenter further suggests that bioaccumulation factors developed using long term average concentrations in fish and the water are inappropriate for developing ambient water quality criteria for persistent bioaccumulative chemicals. EPA disagrees with the commenter. For human health, EPA uses lifetime consumption rates in setting acceptable doses/exposures for bioaccumulative chemicals and to be consistent with the dose/exposure basis, bioaccumulation factors must be developed using long term average concentrations as well. Regarding the commenter's statements on the chemical degradation of various PAHs, refer to the response to CTR-060-014.

Regarding the commenter's statements on risk assumptions, EPA uses risk methods consistent with published risk assessment guidelines that are available in both EPA reports and peer reviewed literature [e.g., Guidelines for Mutagenicity Assessment (Federal Register, Vol. 51, September 24, 1986), Final Guidelines for Developmental Toxicity Risk Assessment (Federal Register, Vol. 56, December 5, 1991), Integrated Risk Information System (IRIS) - On-line]. EPA acknowledges the commenter's proposed three-step process. When EPA promulgates criteria, it uses CWA Section 304(a) criteria guidance. EPA does not perform site-specific risk assessments; the Agency relies on protective assessments that apply to the nation as a whole. This is consistent with EPA's approach to the National Toxics Rule (NTR), of which this CTR is a part. A State or Tribe has the flexibility to utilize site-specific data when available in its assessments and decision-making process.

Comment: In regard to the numeric water quality standards criteria for California surface water, they have been revealed by environmental groups to be insufficiently protective and environmentally unjust. The proposed new rules assume fish ingestion of 6.5 grams per day. In reality, consumption of fish in some communities can be as high as 1 pound per day. This level of consumption is especially likely among subsistence fishers.

Please prevent toxic pollution in California's bays by making more protective standards that consider all toxic pollutants and consider the fish consumption habits of subsistence anglers.

Comment: I am writing to urge you to more stringent - and more protective - water quality standards for California surface water. The proposed standards are too weak and discriminatory in their effects.

Lastly, the proposed standards are discriminatory in their effects in that they assume consumption of only 6.5 grams of fish per day per person. Many poorer communities catch and eat fish for subsistence - as much as a pound per day per person (more than sixty what the EPA estimates!) placing them at greater risk. The standards should be set to protect everybody, including those who happen to be poor and/or eat a significant amount of fish.

Please set the standards to protect us all and move us closer to the goals of the Clean Water Act, that our waters be safely fishable and swimmable.

Response to: CTR-097-001a

Comment: I have recently been reading about some proposed new quality standards for pollutants of California surface waters. I feel very concerned about these proposed standards, as they appear to be more lenient toward pollutants than the existing regulations. I believe very strongly that our surface water is of serious concern to the millions of Californians who use this water every day. In particular, to children and elderly who are more vulnerable to toxins. There is growing evidence that water pollutants lead to cancer and other serious illnesses. I urge you to create more protective standards for our water. The people of this country are being exposed to potentially serious harm by toxicities in our water supply and I hope that more stringent standards can and will be implemented.

Thank you for allowing me to express my concern.

Comment: MS. PLA: My name is Michelle Pla. I'm with the Public Utilities Commission, City and County of San Francisco.

I made the comment on my card that I also said that I would try to be constructive, and so I'm going to follow my mentor here, Phil Bobel, and say that there are some things in this rule that we're very pleased to see.

We're very pleased to see use of the latest scientific information, particularly the use of latest IRIS, I-R-I-S, numbers-for human health. We're very pleased that you're using dissolved versus total recoverable form for the metals.

We're very pleased to see recognition of the water effects ratios. We're pleased to see recognition for a multi-tiered mixing zone for acute and chronic human health effects and hope that the state pays particular attention to that.

We do have a problem with the way you've described compliance schedules and hope to be working strictly by the state on that as well. We think that the five-year system is fairly shortsighted, and -we can't even do FMDSLs in five years.

Response to: CTRH-001-024e

EPA acknowledges the commenter's support for the aspects of the rule mentioned in the comment. With respect to compliance schedules, see response to CTR-002-010b (Category G-02; Compliance Schedules).

Comment: B. The criteria do not control pollution that harms fishing, and aquatic life.

Adoption of EPA's proposed criteria values will result in less control of toxic pollutants that exceed state criteria values in large parts of San Francisco Bay. Examples of this problem are shown in tables 3 through 6 for mercury, copper, nickel and PAH measured in 1995 at monitoring stations shown on a map of San Francisco Bay (Figure 1). The EPA-proposed criteria would allow:

- mercury violations triggered by state criteria values through much of the northern reach of the Bay. EPA-proposed criteria trigger violations only at the Petaluma river mouth and in South Bay). Bay-wide, 8 of 15 state criteria-triggered violations (53%) are allowed by EPA criteria.

- copper violations triggered by state criteria (4.9 ug/L total) throughout the northern reach of the Bay. EPA'S 3.1 ug/L dissolved value triggers violations only in the Petaluma river and in' South Bay. Bay-wide, 15 of 25 state-triggered violations (60%) are allowed by EPA criteria,

- nickel violations triggered by state criteria throughout most of the northern and southernreaches of the Bay. EPA's 8.2 ug/L dissolved value triggers violations at the Petaluma river mouth and one South Bay slough. Bay-wide, 20 of the 22 water quality standards violations (91%) triggered by the 7.1 ug/L criterion are allowed by EPA criteria,

- PAH violations triggered by state criteria at Coyote Creek and the Petaluma River mouth, EPA-proposed criteria trigger 4 violations for benzo(a)pyrene and indeno(1,2,3-cd)pyrene while state criteria trigger 40 violations for these compounds and 6 other PAHS.

Though EPA criteria do not control mercury except at the Petaluma River and in South Bay, a state human health advisory cites mercury contamination,(*6) and demonstrates that mercury restricts fishing uses Bay-wide. A severe threat and possible harm to aquatic life of the Bay's entire southern reach is evidenced by reduced abundance of all species known to be most vulnerable to copper toxicity, while these same species thrive in otherwise similar estuaries with less copper and nickel pollution.(*1) (*2) EPA criteria do not control copper and nickel in most of this area. Nor do EPA criteria control PAHs which -- with PCBs -- cause toxic effects in starry flounder in Central Bay.(*4)

Further, EPA'S proposed criteria include no criteria for 16 dioxin compounds that are included in the state dioxin criterion for TCDD equivalents.(*10) (*21) These 16 compounds are 6 dibenzo-paradioxins chlorinated in the 2,3,7, and 8 positions (except for 2,3,7,8-TCDD which is included in the EPA criterion), and 10 dibenzofurans chlorinated in the 2,3,7 and 8 positions. Under the state criteria, these 16

compounds and 2,3,7,8-TCDD are assigned toxicity equivalence factors as discussed in the proposed rule. Under the state criterion all these compounds are limited: if only 2,3,7,8-TCDD is present it cannot exceed 0.014 pg/L; if only OCDD is present it cannot exceed 14 pg/L; and if a mixture of dioxins is present the sum of their toxicities cannot exceed 0.014 pg/L. By failing to use toxicity equivalents and then failing to propose separate criteria for these 16 compounds, EPA is essentially deregulating 16 of the most toxic chemicals known to science even though these dioxins harm fishing uses, as shown by the health advisory discussed above. (*6)

The EPA criteria do not control toxics that threaten and harm the Bay, fishing and public health.

Response to: CTR-002-004b

EPA disagrees with the comment. EPA sets its criteria values at concentrations that will protect aquatic life or human health, based on the evaluation of the toxicity of the pollutants. Aquatic life criteria are expected to protect at least 95 percent of all genera, based on prediction from measured toxicological values. EPA's approach is a longstanding policy; EPA has used this approach to deriving aquatic life criteria since 1980. Criteria concentrations are not selected either to match existing concentrations in particular California waterbodies, or match criteria concentrations previously used by the state.

EPA does not believe that the information provided by the comment can be used reasonably to evaluate whether criteria concentrations protect aquatic life uses. Whether EPA's criteria are higher or lower than criteria previously used by the state are not germane to whether EPA's criteria protect aquatic life uses.

The observations that certain aquatic taxa are impaired in South Bay cannot validly be interpreted to indicate whether EPA's criteria are or are not protective. The cause or causes of impairment in South Bay are in fact not known. The concentrations of many contaminants are correlated with each other and with other occurrence of other stresses. Because of the presence of so many confounding factors, the information on South Bay cannot be used to derive criteria or to judge their validity.

EPA did not derive its criteria concentrations by considering whether the existing concentrations in

particular California waterbodies would or would not attain criteria concentrations. Rather EPA derived its criteria from toxicity data indicating that concentrations that are necessary to protect aquatic life. The comment offers no definitive toxicological or ecological evidence that the criteria are not protective.

The preamble discusses why the only dioxin compound included in the rule is 2,3,7,8-TCDD, which is the only dioxin compound that is a priority pollutant.

Comment: 2. PARTIAL PROTECTION BY THE PROPOSED AQUATIC LIFE CRITERIA (FRESHWATER OR SALTWATER)

On page 42168, the proposed rule includes the following language: "EPA's guidelines are designed to derive criteria that protect aquatic communities by protecting most of the species and their uses most of the time." The CTR goes on to state that this approach results in only a "small possibility" of substantial overprotection or underprotection. Obviously, it is underprotection that is of concern to the DFG. The DFG has very serious concerns that criteria are being proposed that protect "most" of the species "most" of the time. We are aware of the protocols that require a minimum of eight specified families be used to develop criteria and that it may be difficult to determine criteria that are one hundred percent protective; however, this does not preclude the real possibility that certain designated uses and aquatic organisms will not be maintained, and or protected, as a result of the proposed criteria. The DFG is also concerned that criteria and protocols developed for specific constituents do not take into account the additive or synergistic effects that contaminant combination may have on aquatic organisms. Another factor that needs to be considered is bioaccumulation, as well as the effect this may have on organisms at higher trophic levels.

As trustee of all the fish and wildlife resources in the State, it is our agency's responsibility to ensure appropriate protection of all fish and wildlife resources, not just "most", and this includes adequate water quality standards. Due to our concerns and the very real possibility of underprotection to aquatic organisms and designated uses, the DFG believes that it may be appropriate to derive the criteria as proposed, and subsequently develop some additional safety factors for inclusion. It is our understanding that this approach was used in the formulation of water quality objectives for protection of aquatic organisms in the California Ocean Plan. In the short term, the safety factor could possibly be realized by the development of a comprehensive biological monitoring program to determine whether the proposed criteria are indeed fully protective.

Response to: CTR-026-002a

EPA disagrees with the comment. EPA believes that incorporating the type of safety factor requested in

the comment would be arbitrary and would be difficult to defend scientifically. In particular EPA does not believe such a safety factor could be defended as being necessary for the protection of aquatic life. The commenter provides no data demonstrating that the criteria do not protect aquatic life.

The phrase "most of the species...most of the time" generally means a high percentage of species, a very high percentage of time. Aquatic life criteria are expected to protect at least 95 percent of all genera, based on prediction from measured toxicological values. In most streams, the duration and frequency goals result in attainment of criteria more than 99 percent of time. Past application of aquatic life criteria indicate that this level of protection will protect all aquatic life uses of a waterbody. Considering the variability of natural stresses on all species in a waterbody, EPA can find no basis in data or analysis for a concern that its goals for criteria concentrations and attainment time would not protect aquatic life uses. Because EPA's aquatic life criteria are derived using an appropriately conservative methodology, there is no need to develop the safety factors suggested by the comment.

See response to CTR-026-002b for discussion of the additive or synergistic concerns.

Comment: 3 . TOXICITY DATABASE USED TO DEVELOP CRITERIA

The CTR indicates that the criteria being proposed are based upon a review of the most recent literature and toxicity data bases. The DFG is concerned that the databases utilized by EPA may not be as comprehensive as they could be with respect to inclusion of toxicity studies on a wide variety indigenous species found in State waters. Furthermore, data included in such databases such as EPA's AQUIRE have been found, in some instances, to be less than acceptable. Obviously we would like to see the criteria based on the most recent and scientifically sound toxicity data available. The DFG believes that it would be beneficial to describe in more detail the literature and databases utilized by EPA in development of the proposed criteria.

Also a discussion on appropriate and acceptable methodologies for data collection needs to be provided. It is not only important that the databases utilized by EPA be as comprehensive as possible, with respect to the inclusion of toxicity studies on a wide variety of indigenous species found in State waters. It is also important to know how the data was developed so that it won't be misinterpreted. For example, DFG would prefer using data that was derived from sampling whole organisms rather than edible filets if we were looking at bioaccumulation, biomagnification, or other types of food chain issues. Most predators don't limit their diet to only the edible portions of a prey organism. Sampling only the edible portions of an organism could lead to faulty conclusions.

Finally, with regards to the development of chronic toxicity standards or criteria based on a straight

percentage of the determined acute toxicity level, we would like to participate in any process that attempts to establish chronic levels in that manner.

Response to: CTR-026-003a

The derivation of each aquatic life criteria concentration is explained in detail in the criteria documents and in the 1995 update document, all of which were publicly available. This information was not repeated in the preamble of the proposed rule.

EPA does not agree with the comment about the comprehensiveness of the toxicity database. At the time the criterion document for each pollutant was developed, a comprehensive search of the literature was performed. The comment has offered no literature citations that EPA missed. Regarding the comment on the database AQUIRE, this database was never intended to include only the data that EPA would use for criteria development. EPA agrees that for purposes of developing criteria, some of the data in AQUIRE is "less than acceptable." However, EPA would not and has not used such data in development of the rule's criteria.

Bioaccumulation factors developed from data on edible portions of aquatic organisms have been used in criteria designed to prevent the edible portions of fish or shellfish from exceeding FDA action levels, and to prevent human health risks.

EPA encourages the commenter to participate in State adoption of water quality objectives, which after approval, would supersede these federal criteria.

Comment: The Center for Marine Conservation (CMC) is a nationwide, nonprofit advocacy group dedicated to the conservation and enhancement of coastal and ocean life and resources. CMC submits these comments on behalf of its 16,000 members in California and over 120,000 members nationwide.

CMC applauds EPA's efforts to bring California into compliance with the Clean Water Act 303(c)(2)(B). Implementing numeric criteria that will protect the beneficial uses of California's waters is of great importance to the health of coastal and marine ecosystems, and so to CMC and its members. The reliance in many areas of the state on narrative criteria threatens the health of most of the state's waters, thereby impacting both human health and the health of the state's economy that relies on clean water.

While CMC strongly supports the swift adoption of an Enclosed Bays and Estuaries Plan and an Inland Surface Waters Plan that contain numeric criteria for toxic pollutants, CMC also is concerned that many of the specific criteria contained in the proposed rule are weaker than those contained in published

guidance. CMC also believes that the proposed rule can better protect certain subpopulations from harm caused by consumption of contaminated fish and shellfish. Finally, CMC is concerned that the economic analysis of the proposed rule over-emphasizes costs and under-reports the many benefits of improving water. quality throughout the state. These three points are reviewed below.

In Light of Significant Threats to Water Quality, the Proposed Rule Should Contain the Most Stringent Criteria That Are Scientifically Defensible

Many of the criteria in the proposed rule are weaker than criteria in current published guidance. The proposed rule summarily states that the difference between the proposed, weaker criteria and the published guidance documents is "insignificant"(*4); however, in light of the current contamination problems in California's waters today, any move backwards, particularly when spread out over the state, must be viewed as significant.

Any weakening of the criteria should be subject to close scrutiny and the most rigorous analysis, which the proposed rule itself does not do. Among other things, the criteria in the proposed rule may be underprotective because additive and synergistic effects were not considered; and because the effects on wildlife, which can be particularly significant for bioaccumulative chemicals, were ignored.(*5) In addition, the proposed rule contains dissolved rather than total recoverable metals criteria, despite the fact that EPA acknowledges that total recoverable metals criteria are "scientifically defensible" and that they are more protective than dissolved metals criteria because they consider "sediment, food-chain effects and other fate-related issues," rather than simply water column impacts.(*6)

Clean Water Act section 303(c)(2)(B) mandates the development of numeric criteria that will "support such designated uses [that are adopted by the State]." The statistics available on the health of the state's waters indicates that their use already is significantly threatened or impaired by toxics. The strongest criteria supportable by science are necessary to reverse this trend and begin to restore the state's waters.

(*4) 62 Fed. Reg. 42159, 42168 (Aug. 5, 1997).
(*5) Id. at 42168.
(*6) Id. at 42172.

Response to: CTR-029-002b

EPA disagrees with the comment, with respect to incorporation of weaker criteria. EPA incorporated its latest criteria values into the proposed and final rule. EPA believes that these criteria are fully protective, and are the most scientifically defensible available at this time. The commenter offers no evidence that these criteria are not protective.

EPA disagrees with the assertion that "EPA acknowledges that total recoverable metals criteria...consider sediment, food-chain effects and other fate-related issues." The preamble to the proposed rule (62 FR 42172) has no such acknowledgment. Total recoverable metals criteria do not consider sediment, food-chain, or fate. Rather, EPA has acknowledged that a state may consider such factors in risk management decisions affecting water quality programs and standards. See also response to CTR-26-004.

See response to CTR-026-002b regarding additive or synergistic issues.

Comment: 2. Since the preamble implies that CTR criteria may be applied in NPDES permits for municipal storm water dischargers as numeric effluent limitations, the proposed rule is flawed with regard to: a) setting attainable, scientifically valid criteria in a manner consistent with state and federal regulatory approaches; b) assessing the potential economic impact on the public served by municipal storm water dischargers; c) assessing environmental impacts pursuant to the National Environmental Policy Act and the Endangered Species Act; and d) providing for the coordinated review and evaluation of the proposed CTR in conjunction with the proposed State Implementation Plan.

Response to: CTR-031-002c

EPA disagrees with item a). The commenter offers no evidence to support this alleged flaw.

Comment: If the proposed rule is carefully and sufficiently modified to affirm a commitment by EPA to effect only its Congressional authorization as established by CWA section 402(p), then EPA's failure to assess municipal storm water dischargers" ability to attain the proposed standards and associated economic and environmental impacts may be set aside at this time. However, if EPA persists in maintaining the CTR as drafted in this regard, the ambiguities presented in the preamble demand serious consideration and analyses as follows.

a. Many of the criteria are not attainable or scientifically valid with regard to municipal stormwater dischargers, nor is the proposed approach consistent with an appropriate delegation of authority to the State.

ii. Scientific Defensibility of Standards

Municipal storm water discharges require a uniquely different scientific as well as regulatory approach.

The episodic nature of storm flow events; the huge variances in flow volume, rate, timing, concentrations, and loads; the variability in receiving waters; and organism tolerance for and recovery from episodic exposure need to be taken into account in developing standards.

In a July 1992 memorandum addressing a Combined Sewer Overflow/Wet Weather workshop, Tudor Davies, Director of EPA's Office of Science and Technology wrote: "Changes being considered in the aquatic criteria development methodology to enhance the scientific defensibility of the criteria would be applicable to both constant and to wet weather discharges. One such change undergoing consideration is a change in the duration and frequency of exposure assumptions to make criterion more toxicologically realistic.

EPA has begun this work and is apparently nearing completion. With EPA's own Science and Technology office recognizing the inadequacy of the current approach to setting criteria relative to wet weather discharges, it must be concluded any attempt to apply the CTR criteria to municipal stormwater system discharges is ill-founded and likely inconsistent with the CWA.

Response to: CTR-031-004b

EPA agrees that the specified numeric criteria concentrations, chronic averaging period, and allowable frequency may not be completely appropriate for every possible application of each criterion. For this reason, the proposed and final rules incorporate provisions for the Water-Effect Ratio for modifying the criteria concentrations for site-water conditions. The final rule also incorporates a provision that the State of California, with EPA approval, after public notice and comment, may use alternative, scientifically defensible, averaging periods and allowable frequencies. When the numeric values are coupled with these provisions, EPA believes that the rule provides criteria that are fully applicable to all types of discharges, including storm water where appropriate.

Comment: 2. EPA has used its 1985 Guidelines to develop the criteria designed to protect aquatic life and its uses proposed in this rule. However, EPA has used new decision criteria in this rule that are not part of the 1985 Guidelines or any addendum of the Guidelines. Examples include the use of test results where measured concentrations were reported rather than for tests where concentrations were not reported, regardless of whether the test was flow through; and the use of the lowest SMAV or SMCV as the GMAV or GMCV when SMAVs or SMCVs varied by more than a factor of five within a genus. EPA should not be "making the rules up as they go" and should be amending the Guidelines as changes are necessary. Changes to the methods used to develop criteria must be made public in an organized fashion to facilitate consistent development of criteria across the country. EPA may find that if these new decision criteria were applied to all criteria that they too would change. Changes to the Guidelines

without formal documentation introduces too much variability into the water quality criteria program and does not insure that all regulatory agencies will acknowledge and implement the changes. EPA should follow the Guidelines that they have developed until new methods are available.

Response to: CTR-037-002

EPA agrees that the derivation of some of the criteria for the rule used certain decision criteria that were not part of the 1985 Guidelines. These included a preference for results from flow-through tests with measured concentrations, and setting the GMAV at the lowest SMAV where SMAVs differ by more than a factor of five. These decision criteria are used in the derivation of the GLI criteria, although they are also not part of the GLI Guidelines (40 CFR 132). EPA believes that the preference for flow-through measured tests is reasonable because the toxicant exposure has greater certainty in such tests. Provided that experimental variability had little to do with accounting for observed differences in SMAVs, then setting the GMAV equal to the lowest SMAV might likewise be reasonable, if the intent were to protect all tested species within the genus in such situations. These changes do not constitute changes to the national Guidelines. EPA believes that it is not bound by the 1985 Guidelines where there is a reasonable scientific basis for deviating from the Guidelines.

Comment: 3. EPA has deleted data from several databases without indicating the reason for the deletions. This introduces the same problem as that described in #2 above, and results in variability in how water quality criteria are developed. Additionally, stakeholders need to know why data is deleted so that these decision criteria can be used in the development of defensible site-specific criteria. EPA should provide their reasoning for deleting data that was once believed acceptable so that this same reasoning can be used to update current criteria and to develop new sound criteria.

Response to: CTR-037-003a

EPA disagrees. The commenter did not identify particular data that were at issue. EPA believes that the derivation of criteria was fully explained in the 1995 Updates and in the original criteria documents, both of which were included in the public record for the proposed rule.

Comment: PROPOSED RULE ALLOWS SIGNIFICANT AND UNACCEPTABLE INCREASES IN TOXIC POLLUTANT CONCENTRATIONS IN BAYS AND ESTUARIES

Our initial review indicates that the proposed criteria for a number of toxic constituents are unacceptably high and will allow more pollution of bays and estuaries by several orders of magnitude. If adopted as proposed, the CTR will allow a 900% increase of dioxin, 140% increase of PCBS, 325% increase of mercury, 2760% increase of zinc, 23,000% increase of lead, and a stunning 430 million % increase for total PAH, some of the most problematic pollutants in San Diego Bay. The CTR only improves (i.e. strengthens) criteria for only 3 of 64 pollutants. This does not square with new studies that show reasons for concern about the synergistic and long-term effects of exposures to these toxic pollutants. In sum, the CTR proposes weaker criteria for 58% of the pollutants and no change for 37% of the criteria. This kind of action will not bring us closer to our goal of cleaner water containing healthier organisms in the future.

Response to: CTR-065-002c

EPA disagrees. EPA did not derive its criteria concentrations with the intent of matching existing concentrations in particular California waterbodies. EPA derived its criteria based on toxicity data indicating concentrations that are necessary to protect aquatic life. In most waterbodies having impairment of aquatic life, there are particular pollutants or other factors that are causing a stress. The concentrations of all other contaminants not causing stress are below their criteria. The comment's observation that existing concentrations are below the criteria in some waterbodies does not provide a reasonable basis for setting or judging a criterion intended to be necessary for the protection of aquatic life.

Comment: EHC DOES NOT SUPPORT THE "MOST OF THE SPECIES, MOST OF THE TIME" TEST

EHC is VERY concerned about the EPA.proposing criteria to protect "most of the species and their uses most of the time". This is tantamount to condoning and facilitating marine life destruction through regulation. It is a terrible policy and should be abandoned. We are allowing polluting industries and dischargers. to bombard our marine resources with pollutants that result in multiple chemical exposures

of which we know very little of the, cumulative and synergistic effects.

Further, what is the EPA's definition of "most"? Is it 99.99%, 75% or 51%? Will estuarine environments survive standards that could be argued need only protect half of the organisms? This is completely unacceptable. EPA promulgated standards should be protective of all the living creatures 'in and' near the waters of the state. If we err, let us err on the side of protection. Although there is much that is unknown about impacts of multiple pollutants on marine organisms, one thing is for sure: once the damage is done it is hard to undo. One look at DDT- and PCB contamination in California waters should serve as an adequate reminder.

Discharging known, toxic pollutants into the marine environment is not a right, it is a privilege. The privilege should be granted only when the discharge does not harm the marine environment. Instead of trying to closely walk the ever unknowable line of exact protection, EPA should propose standards that assure complete protection so that bays, oceans, and inland waters containing all of their species, all of the time can be passed to the next generation.

Comment: This letter is to comment on the water quality standards for California surface water. It is my stronly held opinion that the proposed standards do not meet the minimum legal requirements of protecting health, let alone other aspects of the environment. The numbers should be adjusted to lower MAC's by roughly an order of magnitude.

Response to: CTR-099-001b

EPA disagrees. EPA believes that is the criteria are fully protective of designated aquatic life uses. The commenter offers no evidence that the criteria are not protective.

EPA agrees that with the comment that a criterion that would protect only half of all the aquatic organisms would be unacceptable. However, EPA finds no evidence, within the comment or elsewhere, indicating that its criteria yield so little protection.

EPA criteria are derived such that they would be expected to protect at least 95 percent of the genera, based on prediction from measured toxicological values, a very high percentage (usually more than 99 percent) of the time. This very high level of protection is sufficient to protect aquatic life uses.

Comment: p. 42177 --New Human Health Criteria Methodology Please clarify when the new human health criteria methodology will be available, when EPA will be promulgating revised criteria as a result of the new methodology, and how those will be incorporated into the CTR and ultimately into permits. Will the criteria being adopted in this rule automatically be updated, or will EPA update them through subsequent rulemakings? If it is EPA's intent to modify the criteria in the CTR without undertaking a full rulemaking process, then those changes must be analyzed now, including an analysis of the costs and benefits of the different criteria. Also, please clarify whether, if specific criteria are changed within 5 years of adoption of the CTR, it is EPA's intent that compliance schedules already placed into permits would be extended if necessary to meet lower criteria?

Response to: CTR-035-023

Any changes to the CTR as a result of the new human health criteria methodology would be done through rulemaking to stay, withdraw, or amend the CTR. The draft revisions to the methodology for deriving ambient water quality criteria for the protection of human health were published in the Federal Register on August 14, 1998. A 120-day public comment period closed on December 14, 1998. The draft methodology revisions are available at the U.S. EPA National Center for Environmental Publications and Information (NCEPI), 11029 Kenwood Road, Cincinnati, OH 45242 or (513) 489-8190. They also may be downloaded from the EPA Office of Science and Technology's internet site (http://www.epa.gov/OST/humanhealth).

The most recent Federal action establishes the Agency's current water quality criteria. To date, the most recent Federal recalculation of 304(a) criteria occurred in the CTR. These 22 CTR criteria, plus the previously published 78 criteria, are the Agency's recommended human health criteria. As such, they will continue to be used as the basis for Agency decisions, both regulatory and nonregulatory, until EPA revises and reissues chemical-specific criteria. For example, EPA intends to use these criteria: (1) as guidance to States and Tribes for use in establishing water quality standards; (2) as the basis for EPA promulgation of water quality standards; (3) in establishing NPDES water quality-based permit limits, where the criteria have been adopted by a State or Tribe or promulgated by EPA; and (4) for all other purposes of Section 304(a) criteria under the Act.

EPA views the criteria program as constantly evolving. When the AWQC Methodology Revisions are final, any chemical-specific 304(a) criteria published using the revised methodology will be considered the Agency's most current recommended 304(a) criteria. EPA notes revisions of existing 304(a) criteria prior to the finalization of the revised methodology may be undertaken and are not precluded. Until such time as EPA re-evaluates a chemical, subjects the criteria to appropriate peer review, and subsequently

publishes revised chemical-specific 304(a) criteria, the existing recommended 304(a) criteria remain in effect.

States and Tribes have three options when adopting water quality criteria for which EPA has published 304(a) criteria. They can establish numerical values based on 304(a) criteria, 304(a) criteria modified to reflect site specific conditions, or other scientifically defensible methods. When States or Tribes revise their water quality criteria to correct deficiencies identified in a Federal promulgation, EPA will assess the scientific defensibility of the criteria in terms of the Agency's most recent recommended water quality criteria. Once new or revised 304(a) criteria are published by EPA, the Agency expects States and Tribes to adopt new or revised water quality criteria into their water quality standards consistent with the three options discussed above. EPA emphasizes it will be reviewing State and Tribal water quality standards to assess the need for new or revised water quality criteria. EPA believes five years from the date of publication of new or revised 304(a) criteria is a reasonable time frame by which States and Tribes should take action. This period is intended to accommodate those States and Tribes which have begun a triennial review and wish to complete the actions they have underway, deferring initiating adoption of new or revised water quality criteria until the next triennial review.

Comment: p. 42172 -- Acute/Chronic Saltwater Conversion Factors for Metals We question the validity of the assumption that acute saltwater conversion factors for metals can be substituted for chronic. EPA should further explain and document the basis for substituting acute saltwater conversion factors for chronic saltwater conversion factors.

Response to: CTR-035-017

Because EPA's previous criteria guidance had been expressed as total recoverable metal rather than dissolved, EPA developed conversion factors that account for the possible presence of particulate metal in the laboratory toxicity tests used to develop the total recoverable criteria. EPA has used the best data available to it for estimating the percentage of dissolved metal in the toxicity test waters which support the derivation of its criteria. The commenter provides no evidence that the application of saltwater acute conversion factors to saltwater chronic criteria is inappropriate. Nor does the commenter offer an alternative solution. EPA believes its assumptions regarding chronic conversion factors are reasonable; EPA believes that using dissolved metals criteria for water quality standards better approximates the bioavailable metals in the water column and better approximates metals toxicity than do criteria based on total recoverable metal. Based on the close similarity between the measured conversion factors for freshwater acute and chronic toxicity tests, and absent any other information to the contrary, it is reasonable to expect that saltwater acute and chronic conversion factors would be similar to each other.

Comment: Calculation of Final Residual Values Based on FDA Action Levels

The Regional Board agrees with EPA's assessment that it is inappropriate to use FDA Action Levels to develop criteria intended to be protective of aquatic life; at the same time, we question the appropriateness of using Action Levels as the basis for criteria intended to be protective of human health. In 1991, Board staff reviewed all historical Federal Register documents pertaining to the Action Levels dating back to the early '60s. In that review, we found that the majority of Action Levels FDA was using in 1991 were derived from studies conducted by pesticide manufacturers in the '60s. These studies characterized the expected residual level of pesticides in meat and poultry following application of pesticides on grain according to manufacturer's specifications. The implicit presumption on FDA's part was that the marginal health risks posed by pesticide residues were negligible compared to the benefits associated with pesticide-aided food production. We sincerely hope that the FDA has revised its methodology for deriving Action Levels since 1991, but do not believe that a predetermined percentage of food on the market is an acceptable factor to include in the derivation of environmentally protective criteria. Based on our findings, we encourage EPA not to use any Action Level until it has passed a level of technical review comparable to other risk-based federal environmental criteria.

Response to: CTR-016-006

None of EPA's Section 304(a) human health criteria, including the criteria that are being promulgated in today's rulemaking, are derived using FDA action levels.

Comment: Proposed California Toxic Rule

The Metropolitan Water District of Southern California (Metropolitan) appreciates this opportunity to comment on the U.S. Environmental Protection Agency's (U.S.EPA) proposed California Toxics Rule(CTR). Metropolitan, through its 27 member agencies, supplies nearly 60% of the drinking water used by approximately 16 million people living in the six-county region of Southern California. Our sources of supply are surface waters from Northern California and the Colorado River.

The water quality criteria proposed in the CTR are of critical importance to Metropolitan and other drinking water suppliers. These criteria create the basis for source water protection activities which are the first line of defense for ensuring a safe drinking water supply. Further, the criteria help protect aquatic species, including the unique aquatic resources of the Bay-Delta. The health of the Bay-Delta ecosystem and waters tributary to the Delta is linked to the amount of water available for export and thus directly affects water supply reliability of the exporting water agencies such as Metropolitan. Lastly, the CTR criteria affect the ability of water suppliers to operate and maintain their facilities.

Metropolitan recognizes that the CTR is only required to address the Clean Water Act's "priority pollutants". We note, however, that many of the drinking water contaminants regulated under the Federal and/or California Safe Drinking Water Acts (SDWA) are not among the priority pollutants. Table 1 lists the drinking water chemical constituents regulated under the California SDWA which are not priority pollutants. (The California SDWA regulates a broader set of contaminants than the Federal SDWA and provides the appropriate regulatory comparison since the CTR pertains solely to California.) Drinking water beneficial, uses cannot be fully protected without water quality criteria for all California SDWA regulated contaminants. Metropolitan requests that U.S. EPA consider including human health criteria for the contaminants listed in Table 1 as part of the CTR.

Response to: CTR-025-001b

The scope of today's rule is to establish numeric criteria to bring California into compliance with CWA Section 303(c)(2)(B). Section 303(c)(2)(B) requires adoption of numeric criteria for priority toxic pollutants contained in CWA Section 307(a) for which EPA has issued Section 304(a) criteria guidance the discharge or presence of which could reasonably be expected to interfere with the designated uses of state waters. The promulgation of pollutants that are not identified as priority toxic pollutants (i.e, those pollutants that are not contained in the CWA Section 307(a) list) are outside of the scope of today's rule.

Comment: 8. ADDITIONAL CRITERIA

The proposed rule would establish freshwater aquatic organism acute criteria for 24 constituents, freshwater aquatic organism chronic criteria for 28 constituents, saltwater aquatic organism acute criteria for 23 constituents, and saltwater aquatic organism chronic criteria for 27 constituents. The DFG agrees that establishment of criteria for these constituents will go a long way towards protecting fish and wildlife resources. However, we also believe that criteria for additional constituents would further strengthen the proposed rule. To this end, the DFG recommends that acute and chronic toxicity criteria be established for chlorine and ammonia. As a starting point, the EPA 1986 Gold Book has fresh and saltwater criteria guidance developed for both constituents. With respect to acute and chronic toxicity, the CTR should develop criteria similar to that which exists in the California Ocean Plan. From an overall toxicity standpoint, setting acute and chronic criteria would better address the additive or synergistic effects that individual constituent criteria fail to take into account.

Response to: CTR-026-008

The scope of today's rule is to establish numeric criteria to bring California into compliance with CWA Section 303(c)(2)(B). Section 303(c)(2)(B) requires adoption of numeric criteria for priority toxic pollutants contained in CWA Section 307(a) for which EPA has issued Section 304(a) criteria guidance and where those pollutants could reasonably be expected to interfere with the designated uses of state waters. Neither ammonia nor chlorine are identified as priority toxic pollutants in CWA Section 307(a) and are thus outside of the scope of today's rule. This is consistent with EPA's action in the National Toxics Rule 57 FR 60848 (Dec 22, 1992). See p. 60852, col. 2; 60856-60859.

EPA, however, recognizes the detrimental impacts of ammonia, chlorine, and other toxins on aquatic ecosystems, and encourages states, including California, to adopt criteria for these and other pollutants so that the designated uses of state waters can be fully protected (the CWA and Water Quality Standards Regulation requires states to adopt water quality standards, which includes water quality criteria, sufficient to protect the designated uses of their waters). States may also use their narrative criteria to prevent toxic effects caused by pollutants, such as ammonia and chlorine, in instances where a state does not have numeric criteria in place or to supplement their numeric criteria.

Comment: MTBE. WSPA supports EPA's decision not to set criteria based on secondary or organo-leptic considerations and to remain focused on setting criteria to protect human health and aquatic life.

Given the controversy surrounding use of MTBE, particularly in California, WSPA supports an open, objective and comprehensive scientific discussion of the issues and possible solutions. In fact, WSPA is supporting (with EPA and API) a detailed study of ambient aquatic toxicity data on MTBE in surface waters, with a goal to agree on appropriate water quality criteria to protect aquatic life. It is appropriate to allow this study to run its course, at which time EPA and the states can examine the data and set criteria based on sound science.

Other stakeholders may raise concerns about the carcinogenicity of MTBE. However, EPA (the agency charged with deciding whether MTBE is a carcinogen) has not taken an official position on this issue. The data which suggest that it might be (e.g., Belpoggi et al.) provide, at best, only weak evidence and are highly controversial from a methodological standpoint. It is imperative that EPA carefully review the evidence and decide the matter in an appropriate forum. Certainly, this rulemaking is not the appropriate forum.

In the interim, water quality officials are already well-empowered to address concerns of taste and odor when needed. Establishing an MTBE criterion in this rulemaking will not enhance protection of drinking water supplies.

Response to: CTR-058-009

The scope of today's rule is to establish numeric criteria to bring California into compliance with CWA Section 303(c)(2)(B). Section 303(c)(2)(B) requires adoption of numeric criteria for priority toxic pollutants contained in CWA Section 307(a) for which EPA has issued Section 304(a) criteria guidance and the discharge or presence of which could reasonably be expected to interfere with the designated uses of state waters. MTBE is not identified as a priority toxic pollutant in CWA Section 307(a) and is thus outside of the scope of today's rule. Additionally, EPA acknowledges the support for the Agency in not promulgating criteria that are based on organoleptic considerations. This is consistent with the NTR. See 57 FR 60873.

Comment: Page 42162, second column, near the top, does not provide a reliable discussion about how the Priority Pollutant list was developed. It was a court-ordered consent decree that was not internally peer-reviewed by the US EPA, or reviewed by the technical community or the public concerned with these issues. The Priority Pollutant list as promulgated and implemented has proven to be a significant detriment to proper water pollution control efforts in the US since it focuses resources on a number of chemicals that have limited significance to public health and the environment and allows regulatory agencies, dischargers, etc. to ignore the vast arena of hazardous or detrimental chemicals that exist in various types of wastes and point and non-point source stormwater runoff that can and, in some instances, do cause real water quality impacts.

Response to: CTR-061-006

EPA believes that the derivation of the Section 307(a) priority toxic pollutant list is outside of the scope of today's rule. Additionally, EPA disagrees that the current Section 307(a) list of priority toxic pollutants is a detriment to water pollution control. The Agency believes that the establishment of criteria for priority toxics pollutants represents significant progress in controlling the discharge of toxins to the nation's waters and will result in many improvements in protecting water resources and in achieving the fishable/swimmable goals of the Clean Water Act. EPA maintains that the control of toxic pollutants in ambient waters is fundamental in a number of Clean Water Act programs, including permitting programs, protection of contaminant levels in fish and shellfish, improvements in marine, coastal, and inland surface water quality, contamination of sediments, pollution prevention, and in ecological protection.

While EPA agrees that there may be other chemicals that adversely impact environmental protection, EPA notes that states do have the authority to develop and adopt criteria for pollutants that are not contained on the 307(a) list in order to protect the designated uses of their waters. The Water Quality Standards Regulation (see 40 CFR 131) requires all states, including California, to adopt criteria that will provide sufficient coverage to protect the designated uses of their waters. Furthermore, where a state has not adopted sufficient coverage of numeric criteria to protect the designated uses, the state may utilize its narrative criteria to derive criteria for pollutants to supplement the numeric criteria.

Comment: TOXICITY TESTING

EHC strongly supports inclusion of acute and chronic toxicity tests. However, it is very important that

chlorine and ammonia be added to the list of constituents.

Response to: CTR-065-006b

The scope of today's rule is to establish numeric criteria to bring California into compliance with CWA Section 303(c)(2)(B). Section 303(c)(2)(B) requires adoption of numeric criteria for priority toxic pollutants contained in CWA Section 307(a) for which EPA has issued Section 304(a) criteria guidance and where those pollutants could reasonably be expected to interfere with the designated uses of state waters. Neither ammonia nor chlorine are identified as priority toxic pollutants in CWA Section 307(a) and are thus outside of the scope of today's rule. This is consistent with EPA's action in the National Toxics Rule 57 FR 60848 (Dec 22, 1992). See p. 60852, col. 2; 60856-60859.

EPA, however, recognizes the detrimental impacts of ammonia, chlorine, and other toxins on aquatic ecosystems, and encourages states, including California, to adopt criteria for these and other pollutants so that the designated uses of state waters can be fully protected (the CWA and Water Quality Standards Regulation requires states to adopt water quality standards, which includes water quality criteria, sufficient to protect the designated uses of their waters). States may also use their narrative criteria to prevent toxic effects caused by pollutants, such as ammonia and chlorine, in instances where a state does not have numeric criteria in place or to supplement their numeric criteria.

Comment: Major Concerns About the Proposed Criteria and Rule

1. The Proposal is Based on Poor Data and Will Not Result in Better Water Quality for California. We stated that our own attainability analysis and that of BADA show that San Francisco,) will be impacted by this rule. Unfortunately, due to the short time for review, the poor quality of data and basis for statements and assumptions in the proposal and the problem with detection limits we cannot specifically say what will be the cost to Sari Francisco. One analysis tell us it could be $2.3 million per year annualized costs and another analysis tells us it could be much more. We strongly recommend major revision to the proposal and the economic analysis before final promulgation for the following reasons:

The criteria includes many toxicants which are not known to cause problems in the waters; many are banned substances. On the other hand, substances which are known to be problems and which are being released in large amounts are not included in the proposed criteria;

Response to: CTR-090-005

EPA believes that the derivation of the Section 307(a) priority toxic pollutant list is outside of the scope

of today's rule. Furthermore, EPA disagrees that the criteria promulgated in today's rule are not to known to cause problems in ambient waters. See response to CTR-061-006. The criteria are based on laboratory studies showing harm to human health or aquatic life. Further, because permit limits are incorporated into NPDES permits only for constituents having a reasonable potential to exceed water quality standards, a discharger does not receive a limit in its permit unless the discharge contains the pollutant. Thus existence of criteria does not translate into unnecessary permit limits.

Comment: Outdated priority pollutant list - p 42162. B. Statutory and Regulatory Background (paragraphs 3,4) - As noted in the preamble, the 1978 priority pollutant list has not been updated since January 1981. This has several important implications for this rule-making:

1. The absence of criteria for significant toxicants - Chemical usage changes over time. New chemical intermediates and products are continually being developed and brought to market. Pesticides, in particular, have a relatively short commercial existence. Of the approximately eighteen pesticides and metabolites on the priority pollutant list, all but two are now banned or significantly restricted. Newer, or otherwise non-listed, pesticides are not covered by the CTR even though there is evidence of their presence in surface waters and adverse impacts. The Pollutant Policy Document (SWRCB, May 1990 final draft) noted that the San Joaquin drains an agricultural area which may receive as much as 23 million kilograms of pesticides annually. In the river, it noted that, "Consistently detected are 2,4-D, atrazine, simazine, dacthal and diazinon." Yet this proposed rule contains criteria for none of these pesticides. Of particular importance is diazinon. Approximately 2,000,000 pounds are sold annually in California with about half going to agriculture and half to residential users. Monitoring by Alameda County has tied it to toxicity in some county creeks. Diazinon appears in all of Palo Alto's creeks at levels that -may be of concern (Fish and Game recommends 80 ppt to protect aquatic life and Palo Alto has detected it at up to 400 ppt.).

Although this pesticide is subject to hydrolysis and eventually breaks down, the process may take four to six months. More significantly, the U.S. Geological Survey has tracked pulses of this pesticide down the San Joaquin and Sacramento and into San Francisco Bay. During the USGS study, water samples from the San Joaquin were toxic for 12 consecutive days to the water flee, Ceriodaphia dubia. (USGS, Water Fact Sheet, Diazinon Concentrations in the Sacramento and San Joaquin Rivers and San Francisco Bay, California, February 1993, K. Kuivila, 1993). The USGS report noted that other pesticides (chlorpyrifos, methidathion, and carbaryl) were also routinely detected in the samples and may have contributed to the toxicity. These other pesticides also do not have EPA criteria.

The Central Valley Regional Water Quality Control Board has detected diazinon, chlorpyrifos, fonofos, and carbaryl at concentrations toxic to Ceriodaphnia. In fact, the principal conclusion of their two and

half year study was that a 43 mile stretch of the San Joaquin River was toxic to Ceriodaphnia about half the time (Insecticide Concentrations and Invertebrate Bioassay Mortality in Agricultural Return Water from the San Joaquin Basin, CVRWQCB, December 1995). Other chemicals, methyl tertiary butyl ether (WBE), for example, a fuel additive, and related compounds are now showing up in California drinking water supply reservoirs and appear to be persistent

These unregulated toxicants are may be a significant water quality problem in California surface waters yet EPA has not found it appropriate to issue criteria for them. The excuse for inaction for all of these constituents cannot be that they have only recently appeared or have not been evaluated. Although MTBE is relatively new, in 1973, the National Academy of Sciences issued a guideline for diazinon of 9 ppt for the protection of aquatic life. More recently the California Department of Pesticide Regulation proposed quantitative response limits (QRLS) for diazinon, chlorpyrifos, and methidathion.

The CALFED program is proposing to spend a billion dollars over the next 20 years for water course and riparian habitat enhancements in the Delta. This effort will be undermined unless steps are taken to reduce toxicity from agricultural drainage.

The Clean Water Act in Section 303(c)(4) allows the Administrator to issue a standard in any case where it is necessary to meet the requirements of the Act. If there ever was an obvious, overwhelming need for standards, this is it. EPA needs to work with the State and agricultural interests to develop effective programs to control the release of pesticides to the inland surface waters and Bays and Estuaries of California

Comment: 2. Criteria for no longer relevant toxicants - Listing chemicals which no longer have relevance to water quality is not as serious as omitting chemicals which are important. Listing irrelevant toxicants does, however, waste resources since these chemicals are routinely placed in NPDES permits with both effluent limits and mandated monitoring regardless of whether they have ever been detected. The result is permits with impressive lists of priority pollutants which give the false impression that they are comprehensive and therefore protective of the receiving waters.

For each chemical included in this rule-making EPA should demonstrate that the chemical is present either in effluents or receiving waters at concentrations which cause or have the reasonable Potential to cause, or contribute to an excursion above any criteria published by EPA under Section 304. The

adoption of irrelevant criteria is not "necessary to support such, designated uses," 303(c)(2)(B), and therefore can be omitted.

The information on which toxicants are present should be readily available since EPA receives the NPDES monitoring reports and state water quality assessments. By limiting the rule-making to real constituents of concern, we can - begin to focus on those toxic chemicals which are damaging the biota or threatening human health.

Comment: In regard to the numeric water quality standards criteria for California surface water, they have been revealed by environmental groups to be insufficiently protective and environmentally unjust. The proposed new rules assume fish ingestion of 6.5 grams per day. In reality, consumption of fish in some communities can be as high as 1 pound per day. This level of consumption is especially likely among subsistence fishers.

Please prevent toxic pollution in California's bays by making more protective standards that consider all toxic pollutants and consider the fish consumption habits of subsistence anglers.

Comment: The new water quality standards the EPA is proposing for California surface waters disturbs me greatly. There are several problems with the proposed rules. First, in establishing standards for mercury, dioxin, PCBs, and other contaminants, the proposed new rules assume fish consumption at 6.5 grams per day yet consumption of fish in certain communities can be as high as one pound per day, over 60 times more than estimated by the EPA. Please don't underestimate fish consumption by people of different races and cultures.

Please prevent the toxic pollution of California waters by creating more protective standards that consider all toxic pollutants and all consumers of fish. Thank you.

Comment: C. Criteria for the pollutants of most concern do not provide equal protection for people of color and are not supportable by science.

EPA cannot show that its weaker proposed criteria will protect fishing and aquatic life from dioxin-like compounds, mercury, and copper. Further, EPA's proposal to allow greater health risks for subsistence fishers fails to provide equal protection under the law and is contrary to the President's Executive Order on Environmental Justice.

The proposed criteria provide unequal protection for people of color who fish for food. EPA admits in the proposal that: "There may be subpopulations within a state, such as subsistence anglers who as a result of greater exposure to a contaminant, are at greater risk than the hypothetical 70 kilogram person eating 6.5 grams per day of maximally contaminated fish.. ." Indeed, ample data show that some people exercise their fishing rights to "use" Bay waters byeating up to a pound (450 grams) per day of fish from San Francisco Bay, and most of them are people of color.(*8) EPA's discussion then goes on to admit that it is proposing to provide less protection for these subsistence anglers: "[I]ndividuals that ingest ten times more of a carcinogenic pollutant than is assumed in derivation of the criteria at a [one excess cancer in a million] risk level will be protected to a [one in 100,000] level, which EPA has historically considered to be adequately protective." However, people who eat a pound per day eat seventy times more, and pages 8- 11 and 8-12 of EPA's economic analysis admit people eat 16 times more, than the 6.5 grams (1/70th of a pound) of Bay fish per day assumed in EPA's criteria. EPA's own calculations show present cancer threats of nearly 1 in 1,000 for some Bay anglers at these higher consumption levels. Thus, EPA itself predicts that its proposal will result in lesser, inadequate protection for people of color who rely on Bay-caught fish for food.

(*8) Previously unpublished data from a 1993-4 survey of 500 anglers using South and Central San Francisco Bay by Communities for a Better Environment-SAFER!; Save San Francisco Bay Association, 1995 (excerpt); West, 1992; West et al., 1992; Peterson et al., 1994; and USEPA, 1994.(excerpt of a draft report discussing and citing work by EPA, Wolfe and Walker (1987), Svensson (1991) and others. Comment: D. EPA's proposals fail to meet federal laws and regulations.

Proposed criteria would revise water quality standards contrary to law and regulations. Pursuant to 40 CFR section 131.22(c) revised water quality criteria must protect existing uses under 40 CFR section 131.12 (a)(1), and shall support the most sensitive designated use of Bay waters based on sound scientific rationale, under 40 CFR section 131.11(a)(1). However, EPA criteria for pollutants shown in Table 2 above do not meet these tests, as shown by sections II A, B, and C of these comments.

Inappropriate rejection of scientifically sound criteria for 16 dioxin compounds accumulation, and mercury and copper field data results in criteria which allow pollutant levels shown to threaten or harm aquatic life and the fishing public. Human health criteria do not protect people who eat up to a pound of Bay fish per day because EPA assumes people eat only 6.5 grams of these fish per day. In this crucial analysis, protecting the most sensitive use must mean protecting people who eat as much as a pound of fish per day (seventy times more than 6.5 grams), and more often than not are people of color fishing for food as well as recreation.(*8) The criteria do not protect designated uses of Bay waters for fishing and propagation of aquatic life- based on sound science.

Even if EPA argues that some of the pollutants for which it proposes weaker criteria attain levels necessary to achieve water quality standards and protect fishing, aquatic life and wildlife, under 40 CFR 131.12(a)(2) EPA cannot allow water quality to be degraded because this is not "necessary to accommodate important economic or social development." At EPA's request, CBE has supplied evidence showing that long-term economic benefits to the manufacturing base resulted from pollution prevention measures driven by the implementation of state criteria more stringent than EPA's proposal with zero dilution effluent limits. The economy of this area, Silicon Valley, grew substantially at the same time and this growth was led by the industries involved in this effort. Although we are concerned that EPA seems to have arbitrarily rejected evidence that the most "stringent" criteria implementation resulted in economic benefit rather than cost, we trust EPA will agree there is no evidence that weakening these criteria is needed for economic or social reasons.

Response to: CTR-002-009

EPA disagrees with this comment. The CTR criteria are based on sound science and are protective of the most sensitive uses of waters in California, in compliance with 40 CFR 131.11(a)(1) and 131.22(c). The criteria are based on the uses which the State itself has designated: the CTR does not adopt or modify any use designations. The scientific bases for the CTR criteria are set forth in The California Toxics Rule Administrative Record Matrix.

As to some of the CTR criteria which this commenter claims will allow increases in pollution of San Francisco Bay, this commenter's concerns are no longer applicable. EPA's decision to not promulgate final CTR criteria for those waters where there are EPA-approved San Francisco Basin Plan criteria in effect addresses those CTR criteria which this commenter compares unfavorably to existing Bay Basin Plan criteria. (See response to CTR-016-001.)

As to those CTR criteria which the commenter compares unfavorably with ISWP and EBEP criteria, see response to CTR-002-003.

The commenter's implication that adoption of the CTR violates anti-degradation provisions in EPA's regulations is misplaced. In the first place, it is not appropriate to compare CTR criteria with California's ISWP and EBEP criteria for purposes of determining whether degradation of water quality may result from adoption of the CTR. The California criteria do not exist for purposes of making such a comparison, since the ISWP and EBEP were rescinded in 1994. Secondly, the adoption of criteria sufficient to protect designated uses is not an action which in and of itself results in any change in water quality. The implementation of such criteria may raise anti-degradation issues in specific instances in the future, but this rulemaking does not.

With respect to the commenter's concern about certain people eating more fish than 6.5 grams/day, see response to CTR-002-005a (Category C-14; Fish and Water Consumption).

Comment: 5. The proposed rule is inconsistent with applicable Federal law and regulations. In proposing a single set of criteria for all estuaries, the rule is inconsistent with the Clean Water Act and EPA's water quality standards regulations. The Clean Water Act requires that water quality standards be established taking into consideration their use and value for public water supplies, propagation of fish and wildlife, recreational purposes, and also taking into consideration their use and value for navigation (See CWA section 303(c)(2)(A)). Consistent with this, EPA regulations require that water quality standards be based on identification of where toxic pollutants may be adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern. For those identified waters, states must adopt criteria for such toxic pollutants applicable to sufficient to protect the designated use"(See 40 CFR 131.1 1 (a)(2)).

Clearly the intent of both the Act and EPA regulations is that water quality standards be tailored to the characteristics of the waters in question. In failing to properly evaluate the rule's economic impacts and in failing to adequately consider regulatory alternatives, the rule is inconsistent with Presidential Executive Order 12866 and the Unfunded Mandates Reform Act. In failing to properly consider the impacts on small entities, the rule is inconsistent with the Regulatory Flexibility Act.

Response to: CTR-005-006a

See responses to CTR-036-005, CTR 035-012a, and CTR 005-007a.

With respect to EPA's compliance with E.O. 12866, the Unfunded Mandates Reform Act, and the Regulatory Flexibility Act, see the preamble to the final rule, EPA's economic analysis conducted pursuant to the order, and the record for the rule. EPA notes that the water quality criteria only have an impact when the permit authority finds that a discharge has the reasonable potential to violate water quality standards. EPA based its economic analysis on two scenarios, a high end scenario and a low end scenario. The high end established baseline concentrations as being equal to existing permit limits, whether or not the pollutant was detected in the effluent. This provides and upper bound because most facilities typically discharge below their permit limit. The low end scenario is based on actual data about what pollutants are present in the effluent and the actual concentrations of the dischargers in the effluent.

Comment: 7. Separate, scientifically defensible, reasonably achievable aquatic life criteria for copper should be adopted for San Pablo Bay in the vicinity of the District's discharge, or alternatively EPA should state in the Preamble that the Regional Board should: (1) allow a dilution credit for the District based on modeling studies; and (2) apply metals translator determined based on EPA procedures from the results of the Regional Monitoring Program. To comply with the Clean Water Act and EPA regulations, EPA should consider specific water bodies. To fulfill the spirit of Presidential Executive Order 12866 and the requirements of the Unfunded Mandates Reform Act and the Regulatory Flexibility Act, EPA should evaluate regulatory alternatives based on an analysis of costs and benefits. Based on the analysis of costs and benefits performed by the District (see Attachment 1), EPA should either adopt the criteria that is currently achieved, or alternatively specify implementation criteria that will allow the current discharge to continue. The District has performed dilution studies (see Attachment 2) and performed reasonable potential analyses using dilution and metals translators (see Attachments 3 and 4). These show that with the use of these implementation provisions, the proposed criteria can be achieved in-stream. Without EPA specifying that dilution studies and metals translators should be utilized in the District's case, it is possible that the CTR could impose enormous costs on the District (and the small entities it serves) without providing any environmental benefit. In that case, the CTR would be

inconsistent with the Clean Water Act, EPA regulations, Presidential Executive Order 12866, the Unfunded Mandates Reform Act and the Regulatory Flexibility Act.

Comment: 3. The District requests that in the Final CTR, a provision be placed in the rule that grants a waiver to the water quality criteria or that the approach is shifted to a risk based approach where an agency or responsible party engages in cleanup or remediation activities.

Response to: CTR-007-004

EPA disagrees with this comment. The CTR does not include implementation provisions because this rule's intent is to implement section 303(c)(2)(B) of the CWA for California. EPA believes that implementation of these provisions is appropriately left to the state. To the extent that this commenter is proposing implementation provisions that are consistent with CWA requirements, such provisions may be considered by the State for inclusion in its implementation plan. 40 CFR 131.11. See also response to CTR 042-007a. Further, designation of uses is primarily left to the states. In this rule, EPA is simply establishing criteria necessary to protect the designated uses. Use designation may consider economics. If a state wishes to designate a use that is not a CWA section 101(a) use, the state must conduct a use attainability analysis to determine that the use is not attainable.

Comment: EPA's proposal also does not comply with the federal Clean Water Act and is certain to stir up

a hornet's nest of protest if moved forward. The proposals also restrict the ability of the public and concerned agencies from involvement in ensuring standards are complied with. U.S. environmental policy is often hamstrung by the short-term, corporate bottom line influence to the detriment of the vast majority. Ultimately such short-sightedness will result in not only a continued worsening quality of life for the general public, but also in a loss of economic competiveness to those industries and countries able to profit from pollution prevention.

Though the mission of the U.S. EPA is to protect the environment, the California Toxics Rule harms the environment. The proposed criteria should be revised before being adopted. We would welcome the opportunity to discuss these issues with you, along with other concerned parties. We would also appreciate a response to this letter.

Response to: CTR-010-003

EPA disagrees with this comment.

First, concerning the ability of the public and concerned agencies to be involved in ensuring that standards are complied with, EPA reaffirms that the CTR is an adoption of criteria, and it does not include implementation provisions. The State is responsible for the application of CTR criteria to point and non-point sources. The State is currently developing a plan for implementation of the CTR criteria, following its own public participation requirements (Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California, September 11, 1997). Furthermore, as the State applies CTR criteria in specific actions that it will take in the future, such as issuing discharge permits, the public can pursue applicable participation opportunities as they arise. The commenter has not explained how the rule will impair the ability of the public and concerned agencies to ensure standards are complied with.

Secondly, EPA cannot respond specifically to the comment regarding the influence of "the short-term, corporate bottom line" on federal environmental policy, as there is no support for this conclusory statement. Although Executive Order 12866 and the Unfunded Mandates Reform Act require EPA to estimate the costs of certain rules (rules deemed "significant under the E.O., and rules that require "Federal mandates" that may result in expenditures in excess of 100 million/year under UMRA, the E.O. and UMRA do not override applicable law. Under the CWA, economics or cost benefit analysis is not a basis for adopting water quality criteria. See CWA section 303(c), 40 CFR 131.11. See response to CTR-042-007a. For a discussion of the Regulatory Flexibility Act, see the preamble to the final rule. The CTR fully complies with all of these requirements.

Comment: 1. General Comments

A. Applicability of the Rule is Overly Broad

The CTR applies the various water quality criteria to "all waters of the United States" regardless of the actual aquatic life or beneficial uses present. EPA specifically disclaimed any need to individually assess hydrologic unit needs as mandated by the Porter-Cologne Act and the court decision overturning the Inland Surface Waters Plan ("ISWP"). In effect, this means that the CTR will be applied in an overly broad manner, particularly with respect to storm water discharges, as the criteria designed for high quality wann and cold water fisheries will be applied to storm water ditches which the Agency may classify as intermittent streams pursuant to the Regional Water Quality Control Board's (the "Regional Board") "tributary policy" (i.e., tributaries are presumed to contain the same uses as designated main streams). Such water bodies are dry other than during precipitation events and cannot maintain sensitive aquatic life uses. These water bodies have not been classified for specific use protection, and approved Basin Plans allow consideration of site-specific factors in determining actual use protection needs.

EPA's Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and their Uses (1985) ("National Guidelines") specify that criteria must be applied in the manner in which they were derived to provide reasonable and appropriate protection. Federal water quality regulations (40 CFR Part 131) also specify that water quality criteria must be necessary to protect the beneficial uses. Thus, EPA lacks authority to establish water quality criteria that are more restrictive than necessary to ensure that actual uses will be protected. The Agency's attempt to apply stringent water quality criteria to water bodies that either have no reasonable likelihood of maintaining sensitive aquatic life or have not been classified by the state to protect such uses is arbitrary and capricious. In addition, application of stringent human health ingestion-based and fish tissue criteria to receiving waters that lack a potable water supply use or that cannot support a game fishery is clearly not consistent with the National Guidelines and is unnecessarily restrictive. Similarly, pursuant to the Porter-Cologne Act and applicable case law, EPA may not enact requirements that would otherwise be unlawful under California law.

As the Porter-Cologne Act would not allow such action (i.e., overly broad use designations) on the part of the State's Water Quality Control Boards, EPA needs to restrict the application of the CTR to circumstances where the water quality criteria are reasonably applicable. Thus, the proposed criteria for aquatic life should only be applied to perennial streams and not to intermittent watercourses that primarily exist during rainfall events. Human health criteria that include a water ingestion component should only be applied to water bodies that have a demonstrated capability to provide potable water, and application of the criteria should be at the water intake (which would allow for loss of pollutant in the environment and documented pollutant reduction achieved by the water treatment facility). Applying the ingestion-based criteria at appropriate water intake points will help to avoid the assumption that surface waters are consumed without treatment, as such an assumption is not lawful under the Safe Drinking Water Act.

Response to: CTR-020-002

EPA disagrees with this comment. EPA must adopt criteria in accordance with the requirements of the CWA. As a federal agency, EPA is not subject to the requirements of the Porter-Cologne Act, which is State law, nor to the State court decision which overturned the ISWP and EBEP.

Regarding the failure to individually assess the needs of hydrologic units, such an undertaking would amount to adoption of site-specific criteria. It is beyond the scope of the CTR to adopt site-specific

criteria for individual pollutants and/or water bodies, based on localized information and data. As explained in the preamble to the proposed CTR, and further discussed in the response to CTR-003-006, et al., EPA will work with the State to approve acceptable State-adopted criteria (including site-specific criteria) and to stay the CTR where such State criteria are in effect.

EPA further disagrees that the CTR criteria will be applied "in an overly broad manner," based on EPA'sfailure to consider the actual uses of specific water bodies. The CTR does not modify or adopt any uses for any waters. Rather, the CTR adopts criteria for waters of the United States in California to protect aquatic life and human health uses already designated by the State. It is not arbitrary or capricious for EPA to rely on uses designated by the State in accordance with its own laws. Commenters may seek to have the State modify or eliminate uses for particular water bodies; however, EPA cautions that the State is subject to the requirements of 40 CFR 131.10 if it undertakes to do so.

Finally, EPA disagrees that it lacks authority "to establish water quality criteria that are more restrictive than necessary to ensure that actual uses will be protected." (Emphasis added.) The term "actual uses" is an undefined term, but the commenter clearly uses it to describe uses that differ from designated uses. EPA has the authority as well as the legal obligation to adopt criteria which protect the designated uses, however, even if such uses require a greater level of protection than existing uses. 40 CFR 131.5(a)(2); 131.6(c); 131.11(a). If an existing use (as defined in CWA regulations) is less sensitive than the designated use, then the appropriate initial response is not to adopt less stringent criteria to protect the less sensitive use. That would not be allowed unless the designated use itself had been modified. The State may undertake to modify designated uses, including, in some instances, downgrading some uses, in accordance with 40 CFR 131.10, but no such action has been taken which would affect the adoption of the final CTR.

Comment: If the proposed rule is carefully and sufficiently modified to affirm a commitment by EPA to effect only its Congressional authorization as established by CWA section 402(p), then EPA's failure to assess municipal storm water dischargers" ability to attain the proposed standards and associated economic and environmental impacts may be set aside at this time. However, if EPA persists in maintaining the CTR as drafted in this regard, the ambiguities presented in the preamble demand serious consideration and analyses as follows.

a. Many of the criteria are not attainable or scientifically valid with regard to municipal storm water dischargers, nor is the proposed approach consistent with an appropriate delegation of authority to the State.

i. Attainability of Standards

The statutory premise of the CWA is to provide water quality for protection and propagation of aquatic life, wildlife, and recreation wherever attainable. The CWA therefore establishes a reality test in that objectives must be attainable.

The proposed CTR criteria can not be attained by municipal storm water dischargers. The District treats through detention and retention all but 1% of its urban runoff on an annual average basis. Nonetheless, its urban runoff discharges, after detention, would exceed proposed dissolved copper, lead, and zinc criteria. Concentrations would need to be reduced by 67%-95% to meet the proposed chronic criteria. No storm water best management practices, including conventional end-of-pipe storm water treatment facilities (i.e., detention systems), are believed to be able to achieve these levels of reductions for these constituents.

Response to: CTR-031-003a

EPA disagrees with this comment. There is no authority for revising the proposed CTR criteria based on the considerations cited in this comment. Water quality criteria adopted pursuant to CWA section 303 must be based on sound science and must protect the designated uses of the water bodies to which they apply. 40 CFR 131.11. There is no provision for EPA to consider the attainability or the scientific validity of the criteria with regard to specific dischargers or class of dischargers in adopting ambient water quality criteria in the CTR. Attainability issues may be considered in accordance with CWA section 303 in designating or modifying uses for those water bodies; however, the CTR does not undertake to modify or adopt any uses for waters in California. Scientific validity of criteria is based on ambient conditions, not on dischargers. The scientific bases for the CTR criteria are set forth in The California Toxics Rule Administrative Record Matrix.

In raising the question of storm water dischargers' ability to attain CTR standards, this comment apparently relies on language in CWA section 402(p) which requires storm water dischargers to reduce pollutants only to the maximum extent practicable (MEP). MEP, however, is a point source permitting standard; it does not apply to the adoption of ambient water quality criteria. Moreover, EPA has interpreted the MEP standard as applying only to technology-based permit requirements. It does not affect the requirement of CWA section 301(b)(1)(C) that CWA permits include limitations necessary to meet water quality standards. Memorandum from E. Donald Elliot, Assistant Administrator and General Counsel, to Nancy J. Marvel, Region 9, dated January 9. 1991.

Comment: * SCAP recommends that EPA defer adoption of criteria contained in the draft CTR which are typically below detection limits. While we understand EPA's rationale for setting criteria that may

not be detectable based on EPA's determination of the criteria needed to adequately protect aquatic life and human health, we believe that EPA has not fulfilled its duties under the Clean Water Act, Unfunded Mandates Act, and E.O. 12866. In accordance with federal water quality standards regulations, EPA is required to review water quality data and information on discharges to specific water bodies where toxic pollutants may be adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern and must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use (see 40 CFR section 131.11). Thus, if the pollutant has not been detected, there is no basis for determining whether the chemical is adversely affecting water quality or the attainment of designated uses.

Further, EPA cannot make an accurate determination of the costs and benefits of promulgating CTR criteria for those criteria that are below detection levels. It is quite likely that detection limits for some substances will improve in the near future, and dischargers previously projecting full attainment will no longer be able to comply. For instance, a SCAP member agency was issued an NPDES permit in the early 1990s containing effluent limits for a number of toxic pollutants. In this agency's case, lindane was not being detected at the time of permit issuance (and the detection level was higher than the permit limit). Yet, in the following years, the detection level dropped and this agency began to experience exceedences of the permit limit. Lindane cannot be readily controlled at the source by normal industrial waste source control methods because it is in widespread use by consumers. Therefore, the only reliable option for the POTW to come into compliance may be to add end-of-pipe treatment, a very expensive proposition. This scenario is likely to happen again with many of the criteria being proposed in the CTR. The potential compliance costs could be high, yet the Economic Analysis for the draft CTR could not estimate such costs. For all of the above reasons, EPA should defer adoption of these criteria until they can be detected and EPA can more fully determine the potential economic impacts of promulgation of the CTR. Instead, we recommend that a watershed approach be used to address these pollutants (see below).

Response to: CTR-034-010b

EPA disagrees with the commenter that it should defer promulgating water quality criteria below detection limits or that such promulgation is in any way inconsistent with the CWA, UMRA, or E.O. 12866. EPA's water quality standards regulation at 40 CFR 131.11 requires that criteria be adopted by the States at concentrations necessary to protect the designated use. Given this requirement, consideration of analytical detectibility is not an appropriate factor to consider when calculating water quality criteria to protect designated uses since they are not related to actual environmental impacts. As EPA stated in the preamble to the National Toxics Rule, 57 FR 60876, col. 1, this has been the Agency's longstanding position. See also 57 FR 60870. EPA's criteria are based on scientific information about a pollutant's toxic effects, without regard to analytical methods or techniques. The criteria are based on the concentrations that either cause toxic effects to aquatic life or to human health. EPA's criteria development methods for aquatic life are generally based on laboratory analyses with sensitive aquatic life. The results from these tests are analyzed by mathematical procedures outlined in EPA's criteria guidelines. EPA's human health criteria are developed from protocols generally using toxicity studies on laboratory animals such as mice and rats. Thus, because the criteria are based on data showing toxic effects, EPA does not believe that the analytical detection limit should determine the basis for the criteria.

The water quality standards established in this rule are not self implementing; they will be applied by the State in developing total maximum daily loads, wasteload allocations to point sources, (which may be used to develop NPDES permit limits) and load allocations to nonpoint sources. The sensitivity of analytical methods is relevant for determining compliance with water-quality based permit limits. The permit authority, here the State of California, establishes the analytical methodology to be used for

determining compliance with the permit limit. EPA has issued guidance on how constituents with water quality criteria below the sensitivity of official analytical methods (i.e., those listed in 40 CFR Part 136) are established in permits. See Strategy for the Regulation of Discharges of PHDDs and PHDFs from Pulp and Paper Mills to Waters of the United States, memorandum from the Assistant Administrator for Water to the Regional Water Management Division Directors and NPDES State Directors, May 21, 1990. This guidance presents a model for addressing toxic pollutants which have criteria recommendations less than current detection limits and it is applicable to other criteria as well. The guidance explains that standard analytical methods may be used for determining compliance with permit limits but not for establishing water quality criteria or permit limits. Also, EPA's Great Lakes Guidance Procedure 8 specifies that where the water quality-based effluent limit is lower than the pollutant's quantification level, the quantification level is the method for determining compliance with the limit. This approach is mandated by the CWA, which requires that permit contain WQBELs as necessary to achieve standards. (CWA section 301). Neither EPA nor the States are authorized to set WQBELs at higher levels simply because of technical difficulties in measuring compliance. See NRDC. v. EPA, 859 F.2d 156, 208 (D.C. Cir. 1988)("Congress did not intend to tie compliance with water quality-based effluent limitations to the capabilities of any given level of technology."] It should also be noted that by the time criteria are converted into permit limitations after calculating total maximum daily loads, waste load allocations and load allocations, the actual permit limit may be in the range of standard analytical methods cited by EPA in 40 CFR Part 136.

EPA also establishes water quality criteria for many chemicals of concern because they biomagnify in the tissue and organs of fish (e.g., mercury and PCBs) to levels that can adversely effect aquatic life, wildlife and human health. Fish tissue information can be used to determine if the water body is attaining water quality standards even when the water quality criteria and instream pollutant concentrations are below detectable levels. For chemicals that are not highly bioaccumulative but have criteria below detectable levels, fate and transport (mass balance) models can be used to predict instream pollutant concentrations and attainment of water quality criteria and designated uses. This information with other field observed data showing stress or adverse effects on the biological community serve as an earlier warning to the public that water quality is being degraded and steps must be taken if the designated use for the water body is to be protected and maintained.

The decision to maintain a designated use or to downgrade the water body to a lower use designation is a place-based decision that must rest solely in the hands of the local community, elected officials and other stakeholders that use the water resource affected by such decisions. Therefore, the importance of adopting statewide numeric water quality criteria to protect designated uses (e.g., fishable, swimmable) is not predicated on costs or benefits but on the public's "right-to-know" and participate in decision-making affecting their water resources. Congress understood this and in CWA sections 303 and 304 preserved the public's right-to-know about the condition and safety of the waters they use for food, drinking, recreation and commerce. See responses to CTR-036-005 and CTR-O42-007a.

With respect to EPA's compliance with UMRA and E.O. 12866, see the preamble to the final rule andEPA's Regulatory Impact Analysis conducted for the rule. Although analytical detection limits may improve in the future, EPA has reasonably estimated the costs of the rule in the regulatory impact analysis based on the best available data about how permit limits might change under the final rule. EPA evaluated the costs of attaining permit limits derived from CTR criteria but maintains that the costs associated with attaining effluent limits that are less than detectable levels are speculative and EPA's methods may tend to overstate costs. Nevertheless, EPA estimated costs under a high scenario using assumptions about how much pollutant reduction would be required even when it had "no" effluent data indicating the presence of the pollutant in the discharge or that the control strategy was actually necessary.

EPA's estimates of costs include control technology costs for pollutant reduction that would be required to reduce pollutant levels to the MDL as well as pollutant minimization programs to reduce the pollutant level to below the MDL. EPA's estimates reflect the goal of reducing all potential sources of the pollutant necessary to maintain the final effluent quality discharged to the receiving water to a level at or below the permit limit. The costs for pollutant minimization programs include both capital and O&M costs to find sources and implement reduction control strategies. EPA estimated these costs both for direct municipal and industrial dischargers as well as for indirect discharges to publicly owned treatment works (POTWs). Thus, EPA accounted for all anticipated costs to the extent feasible, even in situations were potential "hidden" pollutant loads may exist below detectable levels.

The issue of potential hidden loads raised by commenters on the CTR is not new. In 1994, EPA evaluated a sample of nine POTWs in the Great Lakes Basin using super-clean and high-resolution analytical methods (many of which were experimental) to determine whether, in fact, there was a substantial hidden pollutant load of bioaccumulative chemicals of concern (BCC). This study was undertaken because the regulated community in the basin raised concerns regarding the potential presence of mercury and other BCCs just below current Part 136 methods and the associated costs to remove these potential hidden loads. EPA assumed BCCs to be ubiquitous in the Great Lakes Basin at major POTWs because of the historical widespread use of these chemicals and well documented problems in the basin. Therefore, EPA concentrated its sampling efforts on POTWs which have less control of the potential sources of BCCs being discharged to their collection system than industrial dischargers.

In this study, EPA found the infrequent presence of BCCs (38 detections in 477 observations, approximately 8%) in POTW effluents. Of BCC's detected, mercury was detected at each of the POTWs (either as total mercury or methyl mercury). The concentrations of mercury found in POTW effluents were above EPA's most stringent ambient water quality criterion for the Great Lakes Basin in five of the nine samples taken. Where effluent concentrations exceeded the ambient criterion, however, they did so by small amounts, indicating that pollutant minimization programs (PMPs) would more than likely control mercury discharges to the levels required to comply with permit limits. The results of the study, when extrapolated to the universe of 316 POTWs in the Great Lakes Basin, indicates that the median concentration of mercury in all effluents is 0.99 ppt, the 75th percentile is 5.14 ppt, and the 95th percentile is 55.0 ppt.

These results indicate substantial compliance with permit limits significantly more stringent than those expected from CTR-based criteria and would not indicate substantial additional costs if the facilities were required to demonstrate compliance through analytical methods with lower MDLs. Furthermore, the study demonstrates that hidden pollutant loads do not exist at the levels once thought even for highly contaminated areas. This information is important when evaluating the economic analysis for the CTR because it indicates that the estimated costs at the high end of the cost range for the CTR, which accounts for controlling hidden pollutant loads were no effluent data exists may never materialize should analytical methods improve in the future.

EPA has also identified a number of locations where pollutant minimization programs have either been highly effective in reducing pollutant loads or have been implemented but have had inadequate time to determine results. For example, the Inland Empire Utilities Agency, serving the Chino Basin with three POTWs, has successfully reduced lindane in its effluents to permit limits through education of health authorities and pet service providers on effective alternatives to lindane-based products for lice and flea control. A similar program is being implemented at a facility in Arizona. The Western Lake Superior Sanitary District's (WLSSD) efforts to reduce mercury levels in their effluent include diverting

incinerator scrubber water; implementing external source identification studies and subsequent control programs at a pulp and paper mill, dental facilities, and medical facilities and laboratories; and conducting extensive public education and outreach, including mercury collection under a bounty program. As of 1996, WLSSD had successfully reduced mercury concentrations at their waste water treatment plant by more than 74% from 1990 dry sludge levels (from 4.50 ppm to 1.15 ppm) and by more than 97% from 1990 effluent levels (from 0.58 ppb to 0.015 ppb). The following are some additional examples of pollution prevention activities undertaken by facilities in the State of California:

* Replaced a sewer running through an arsenic-contaminated Superfund site (City of Palo Alto, California Regional Water Quality Control Plant).

* Allowed diversion of residential graywater containing mercury for use as on-site irrigation (City of Palo Alto, California Regional Water Quality Control Plant).

* Developed BMPs with medical facilities/offices about the use of mercury, handling of mercury-containing wastes, management of mercury-containing reagents, prevention and response for mercury spills, nonmercury analytical methodologies, and nonmercury-containing equipment (City of Palo Alto, California Regional Water Quality Control Plant).

* Educated pharmacists on mercury-containing products (City of Palo Alto, California Regional Water Quality Control Plant).

* Developed BMPs addressing mercury-containing equipment and reagent handling in laboratories (City of Palo Alto, California Regional Water Quality Control Plant).

* Published and distributed a BMP booklet to local pottery studios, schools, and art supply stores (City of Palo Alto, California Regional Water Quality Control Plant).

* Reduced the local discharge limit for nickel (applicable primarily to metal finishers) (City of Palo Alto, California Regional Water Quality Control Plant).

* Educated photo processors and medical and dental offices processing x-rays on silver use and disposal (City of Palo Alto, California Regional Water Quality Control Plant).

As a final point, EPA does not wish to delay or defer any further having ambient criteria for toxics as required under section 303(c)(2)(B) of the CWA. California is the only state in the nation without such numeric limits and it is important in order to meet the requirements of the CWA to bring California into compliance with the CWA by promulgation of this rule.

Comment: 1. Comments on Proposed Rule A. General Comments p. 42166-67 --Legal Basis

EPA argues that:

EPA does not believe that it is necessary to support the criteria proposed today on a pollutant-specific, water body-by-water-body basis. For EPA to undertake an effort to conduct research and studies of each stream segment or water body across the State of California to demonstrate that for each toxic pollutant for which EPA has issued CWA section 304(a) criteria guidance there is a 'discharge or presence' of that pollutant which could reasonably 'be expected to interfere with' the designated use would impose an enormous administrative burden and would be contrary to the statutory directive for swift action manifested by the 1987 addition of section 303(c)(2)(B) to the CWA.

Contrary to EPA's argument, we believe that the requirement in Section 303 of the CWA that States adopt water quality standards where there is a discharge or presence of toxic pollutants in the affected waters which could reasonably expected to interfere with designated uses, applies to EPA. EPA's claim that such a review would impose an "enormous administrative burden" is not compelling, since States, in their adoption of water quality standards, must perform this pollutant specific review of each stream segment under the express terms of Section 303(c)(2)(B). EPA's own regulations require that, in promulgating water quality standards for a State, EPA is subject to "the same policies, procedures, analyses, and public participation requirements established for States in these regulations" (40 CFR section 131.22). The regulations require States to "review water quality data and information on discharges to specific water bodies where toxic pollutants may be adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern and must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use"(40 CFR section 131.11)(emphasis added). Thus, the regulations regarding the adoption of water quality standards do not suggest that States adopt uniform water quality standards for every water body merely because there may be a large amount of work required to determine the appropriate water quality standards for each water body. We especially believe this issue to be pertinent to pollutants for which the proposed CTR criteria are below detection levels. We therefore recommend that EPA defer the adoption of criteria for constituents which are below detection limits until such time as data are available demonstrating that particular toxic pollutants are being discharged to specific water bodies at levels to warrant concern. The pollutants in this category include the following: aldrin, alpha-BHC, beta-BHC, chlordane, 4,4'-DDD, 4,4'-DDT, 4,4'-DDE, dieldrin, 2,3,7,8-TCDD (dioxin), endosulfan I, endosulfan II, endrin, endrin aldehyde, heptachlor, heptachlor epoxide, toxaphene, PCB-1016, PCB-1221, PCB-1232, PCB-1242, PCB-1248, PCB-1254, PCB-1260, hexachlorobenzene, n-nitrosodi-n-propylamine, pentachlorophenol, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoroanthene, benzo(k)fluoroanthene, chaysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene. EPA, upon determining that promulgation of a 303(c)(2)(B) criterion is necessary, should promulgate the criterion on a water body-specific basis. Also, EPA would need to conduct an economic impact analysis at that time. Finally, as with the CTR, EPA must pursue adoption of these criteria through a rulemaking process, allowing opportunities for public review and comment in accordance with the Clean Water Act and Administrative Procedures Act.

Response to: CTR-035-012a

EPA disagrees with the commenter. See response to CTR-036-005. In addition to the response outlined above, the commenter cites EPA regulations at 40 CFR 131.11 and 131.22 arguing that the regulation

constrains how EPA may implement CWA section 303(c)(2)(B) . The regulation cited by the commenter with respect to toxics control, 131.11, however, was part of the 1983 water quality standards regulations (48 Fed. Reg. 51400, Nov. 8, 1983), which preceded by several years enactment of CWA section 303(c)(2)(B) as part of the 1987 Amendments to the CWA. EPA did not amend the regulations after enactment of section 303(c)(2)(B), but instead issued guidance interpreting how the provision couldbe implemented by states consistently with the statute. Availability of the guidance was published in the Federal Register at 54 Fed. Reg. 346 (Jan. 5, 1989) and discussed at length in the preamble to the final National Toxics Rule at 57 Fed. Reg. 60848, 60853 (Dec. 22, 1992). In this guidance, EPA stated that states could implement CWA section 303(c)(2)(B) in three different ways, as specified by its 1989 Program Guidance for Implementing Section 303(c)(2)(B):

Option 1. Adopt statewide numeric criteria in State Water Quality Standards for all section 307(a) toxic pollutants for which EPA has developed criteria guidance, regardless of whether the pollutants are known to be present.

Option 2. Adopt chemical-specific numeric criteria for priority toxic pollutants that are the subject of EPA section 304(a) criteria guidance, where the State determines based on available information that the pollutants are present or discharged and can reasonably be expected to interfere with designated uses.

Option 3.Adopt a procedure to be applied to a narrative water quality standard provision prohibiting toxicity in the receiving waters. Such procedures would be used by the State in calculating derived numeric criteria which must be used for all purposes under section 303(c) of the CWA.

In this rule, EPA has adopted the first approach. In addition, EPA has gathered information on the presence of toxic pollutants in the waters of the State to the extent possible, but does not believe it is necessary to demonstrate impairment of the water before applying ambient criteria to the water for the reasons stated in See response to CTR-036-005. However, because EPA has chosen an approach consistent to the guidance it gave the states, EPA has applied the same requirement of scientific defensibility it would require of states, and because EPA has allowed for public comment on the rule, EPA has applied the same policies, procedure, analyses and public participation requirements it established for States in Part 131.

Finally, with respect to detection levels, see responses to CTR-034-010b; CTR-005-009; CTR011-002; CTR-013-004; CTR-020-020; CTR-021-005b; CTR-027-004; CTR-030-009; CTR033-003a; CTR-034-010a; CTR-035-005; CTR-035-012b.

Comment: Authority for EPA to Adopt Statewide Criteria

Contrary to what EPA asserts, it cannot promulgate statewide water quality criteria for priority toxic pollutants without considering whether the discharge or presence of such pollutants will interfere with the specific designated uses of those California waters that are covered by the criteria. Under Section 303(c)(4)(B) of the CWA, EPA is permitted to "promptly prepare and publish proposed regulations setting forth a revised or new water quality standard for the navigable waters involved in any case where [EPA] determines that a revised or new standard is necessary to meet the requirements of [the CWA]." 33 U.S.C. section 1313(c)(4)B). However, a water quality standard consists of both "the designated uses of the navigable waters involved" and the "water quality criteria for such waters based upon such uses." 33 U.S.C. section 1313(c)(2)(A).

Here, EPA has proposed water quality criteria for California waters, not water quality standards. More importantly, EPA has failed to develop such criteria "based upon" the designated uses of these waters. EPA has not determined whether these criteria pollutants are present in all California waters. EPA attempts to argue that there is evidence in the record indicating the presence of priority toxic pollutants throughout the waters of the States, yet EPA admits that the evidence is "not necessarily complete (62 Fed. Reg. 42160, 72167) nor has EPA determined whether the discharge or presence of these pollutants "could reasonably be expected to interfere with" the designated uses of such waters, as is required under CWA Section 303(c)(2)(B). See 33 U.S.C. section 1313(c)(2)(B).

EPA argues that it would be an "enormous administrative burden" for it to determine on a "water body-by-water body basis" whether the discharge or presence of the priority toxic pollutants could reasonably be expected to interfere with the designated use of affected waters. [62 Fed. Reg. 42160, 42166]. EPA further asserts that interpreting Sections 303(c)(2)(B) and (c)(4) to require it to perform "such a cumbersome pollutant specific effort on each stream bed" in California would render Section 303(c) meaningless [Id. at 42167]. Finally, EPA claims that based on the statutory language, purpose and legislative history of Section 303(c), it is empowered to act swiftly and promptly when it determines that new or revised standards are necessary to comply with the CWA, and thus it may disregard the strictures of CWA Section 303(c)(2)(B). Id.

Unfortunately, these arguments ignore the plain meaning of Section 303(c). EPA must (1) promulgate water quality standards, not water quality criteria, when it determines that such standards are necessary to meet the requirements of the CWA, and (2) develop these water quality standards taking into account the designated uses of the waters to which such standards are being applied. 33 U.S.C. sections 1313(c)(2), (4).

Moreover, the call to prompt action contained in section 3043(c)(4) cannot be read in a way that transforms the remaining provisions of Section 303(c) into mere surplusage. Despite EPA's assertion that the "numerous deadlines" imposed by Section 303(c) require it to ignore the demands of Section 303(c)(2)(B), there in fact is no specific time frame within which EPA must promulgate a new or revised water quality standard when it acts pursuant to section 303(c)(4). Thus, the requirements that EPA act "promptly" govern the manner, not the time frame, in which it must act.

Nor can the legislative history of Section 303(c) be used to ignore the express language and plain meaning of section 303(c)(2)(B). When a statute is plain and unambiguous on its face there is no need to look to legislative history as a guide to its meaning [Tennessee Valley Authority v. Hill, 437 U.S. 153 (1978)]. The requirement of Section 303(c)(2)(B) to determine whether the "discharge or presence" of priority toxic pollutants "could reasonably be expected to interfere with" the designated uses of affected waters is not ambiguous, even juxtaposed with the requirement that EPA act "promptly". Congress may

have wanted EPA to act promptly, but it equally wanted EPA to act within the constraints of Section 303(c).

In short, Congress's supposed quest for swift action is not enough to ignore the plain language of Section 303(c). Legislative history may be considered where the plain meaning of statute produces an absurd result, but it may not be considered where it merely produces a "cumbersome" one.

Response to: CTR-036-005

EPA disagrees with the comment. EPA interprets section 303(c)(4)(B) to give EPA authority to act if the State fails to act by promulgate ambient water quality criteria pursuant to section 303(c)(2)(B) for water bodies with either human health or aquatic life uses designated by the state for pollutants for which EPA has issued national section 304(a) recommended criteria guidance. As EPA has reiterated throughout the rulemaking record, EPA's strong preference would have been for the state to take the lead in promulgating these criteria. Pursuant to section 303(c)(4)(B), the State's failure to take such action after its standards were invalidated in state court constitutes a failure to meet the requirements of the Act under CWA section 303(c)(2)(B). Further, EPA is acting consistent with its authority because as explained below, the criteria in the rule are ambient criteria that define attainment of the designated uses, and they will result in additional controls on dischargers only where necessary to protect the designated uses.

EPA disagrees with the comment that it has somehow violated the CWA by promulgating water quality criteria instead of "water quality standards." EPA's regulations explain that there are three components to water quality standards, designated uses; water quality criteria to protect those uses, and an antidegradation policy. See 40 CFR Part 131.6. In the rule, EPA is promulgating one component of water quality standards because this is what the state has failed to do. The CWA's reference to water quality standards, a broader authority encompassing designated uses, criteria to protect those uses and an antidegradation policy, does not preclude EPA from issuing one component of standards, water quality criteria.

EPA disagrees that it has failed to develop such criteria "based upon" the designated uses of such waters. The criteria in the rule are based on protection of human health (either through ingestion of drinking water or drinking water and organisms) or aquatic life (saltwater or freshwater) which relate directly to the uses designated by the State of California for the waterbody. The State has designated the waters covered by this rule for a number of uses related to recreation, drinking water and aquatic life. The State always retains the discretion to change the designated uses of the State, as long as it meets the criteria set forth in 40 CFR 131.10. These criteria define what is necessary to protect the designated use. In essence, EPA's interpretation of section 303(c)(2)(B) of the CWA means that if the discharge or presence of the pollutant exceeds the criteria values, the discharge or presence of the pollutant would interfere with the designated uses of the waterbody.

As these are ambient criteria, they do not in and of themselves require control of a discharge. The ambient criteria are implemented in two ways -- to point sources through NPDES permits for direct dischargers (that may be based on wasteload allocations in impaired waters) or pretreatment standards for indirect discharges (both of which are enforceable limits) and through load allocations for non-point sources (which are not enforceable under the Clean Water Act, but which represent the portion of a receiving waters receiving capacity attributable to a non-point source that would attain applicable water quality standards). Under the NPDES regulations, the ambient criteria promulgated in the rule are applied in NPDES permits as effluent limitation control only if the uncontrolled discharge of a particular pollutant has a "reasonable potential" to exceed applicable water quality criteria. EPA defines

"reasonable potential" in its regulations as where a discharge is projected or calculated to cause an excursion above a water quality standard based on a number of factors including, as a minimum, the four factors listed in 40 CFR 122.44(d)(1)(ii). Absent that determination, the criteria in and of themselves have no impact. Thus, EPA's promulgation of criteria for all water bodies in California that currently have no numeric criteria for toxic pollutants criteria for protecting the designated use ensures a safety net that does not impose any needless burden or costs on any dischargers. (EPA made this point in describing its guidance implementing section 303(c)(2)(B), 57 Fed. Reg. 60853 col. 1 (Dec. 22, 1992)). If EPA were to interpret section 303(c)(2)(B) to compel it to prove conclusively that all of the priority pollutants are present in all California waters, this would impose a huge resource burden on EPA with no substantive benefit in terms of environmental protection. In fact, if EPA were not to have perfect information upon which to base a determination that current discharges are impairing designated uses, EPA might overlook a waterbody that needs criteria as a basis for controlling discharges. In essence, establishment of these ambient criteria is necessary to establish the benchmark against which the permit authority can make the reasonable potential determination. The commenter's argument that EPA needs to do a more site specific evaluation of whether the discharge of the pollutant "could reasonably interfere" ignores that criteria are not only used to remediate where there is impairment but to prevent it from happening in the first place.

The comment further criticizes EPA's interpretation of the statutory language calling for the states to act within three years of the Act (which was enacted in 1987) coupled with that language in CWA section 303(c)(4) stating that EPA is to act "promptly" does not support EPA's approach to cover all waterbodies. EPA, however, believes that the time frames envisioned by Congress, to put in place ambient criteria for toxic pollutants where EPA had issued recommend criteria under section 304(a) of the CWA for those pollutants, are reasonably considered when interpreting what Congress intended EPA to do. Congress, by linking section 303(c)(2)(B) to the triennial review period, gave states a chance to comply with section 303(c)(2)(B) on their own. To interpret the combination of subsections (c)(2)(B) and (c)(4) as requiring monitoring and analysis to demonstrate impairment before establishing ambient standards would be counter to Congress' goal of putting in place the ambient standards as the foundation for toxics control. Another reason EPA believes that its approach is appropriate is that section 303 establishes a regime whereby EPA's role is one of overseer of the national program, with states taking the primary role for standards. The State of California is better positioned to make local site-specific determinations than is EPA and EPA believes that it is more appropriate to issue state-wide criteria and then to allow the State if it so chooses to establish and submit for approval water quality standards that are based on site-specific considerations. Finally the reference in section 303(c)(2)(B) to section 304(a) criteria suggests that section 304(a) serve as "default" criteria, that once EPA had issued its national section 304(a) criteria recommendations, states were to adopt numeric criteria for those pollutants based on the 304(a) criteria, unless they had other scientifically defensible criteria. Here, California is the only state without such numeric criteria. EPA also notes that this rule follows the approach EPA took nationally in promulgating the National Toxics Rule for states that had failed to comply with CWA section 303(c)(2)(B). 57 Fed. Reg. (Dec. 22, 1992). EPA incorporates the rationale for EPA's action used in the NTR as expressed in the preamble into this final rule.

As the Supreme Court has stated, if a statute is silent or ambiguous on a specific question, a reviewing court must defer to any reasonable construction of that statute by the administering agency. Chevron, U.S.A. v. NRDC, 467 U.S. 837, 843 (1984). Under Chevron, a reviewing court must determine "whether the agency's answer [to the ambiguous question] is based on a permissible construction of the statute." Id. The agency's construction need not be the one the court itself would adopt or the one the court feels would best implement congressional policy. It need only be a reasonable construction of the statutory question at issue. Id. At 844-45. Here, to recognize Congress' desire for timely establishment of numeric criteria for toxics and recognizing that these criteria do not have a regulatory impact unless

reasonable potential for exceeding the criteria is found in a permit-specific context, EPA believes that its approach to implementing section 303(c)(2)(B) is a reasonable construction of the statute.

Comment: 5. The proposed rule is inconsistent with applicable Federal law and regulations. In proposing a single set of criteria for all estuaries, the rule is inconsistent with the Clean Water Act and EPA's water quality standards regulations. The Clean Water Act requires that water quality standards be established taking into consideration their use and value for public water supplies, propagation of fish and wildlife, and recreational purposes (see CWA section 303(c)(2)(A)). Consistent with this, EPA regulations require that water quality standards be based on identification of "specific water bodies where toxic pollutants may be adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern..." For those identified waters, "states must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use" (See 40 CFR 131.11(a)(2)). Clearly the intent of both the Clean Water Act and EPA regulations is that water quality standards be tailored to the characteristics of the waters in question. In failing to properly evaluate the rule's economic impacts and in failing to adequately consider regulatory alternatives, the rule is inconsistent with Presidential Executive Order 12866 and the Unfunded Mandates Reform Act. Moreover, in failing to properly consider the impacts on small entities, such as the District and the small communities it serves, the rule is inconsistent with the Regulatory Flexibility Act.

Response to: CTR-038-006a

EPA disagrees with the comment. See responses to CTR-035-012a and CTR-036-005. For a discussion of how the rule complies with the E.O. 12866, the Unfunded Mandates Reform Act and the Regulatory Flexibility Act, see the preamble to the final rule.

Comment: MAJOR CONCERNS

We do, however, have fundamental concerns with the Rule as it is presently proposed and its supporting economic analysis. We believe the Rule can be modified in a manner that will be responsive to our concerns while at the same time being consistent with applicable Federal law and regulations. Our major concerns are presented here and are followed by our recommended modifications.

III. Concern: The proposed Rule violates applicable Federal law and regulations

* In proposing a single set of criteria for all fresh waters, the Rule is inconsistent with the CWA and EPA's water quality standard regulations because it has not been determined that these criteria are necessary to avoid interference with designated uses (See Attachment B). The CWA requires that standards be established taking into consideration their use and value, and EPA regulations require consideration of specific water bodies where toxics may be adversely affecting water quality or uses.

Response to: CTR-040-011

EPA disagrees with the comment. See responses to CTR-035-012a and CTR-036-005.

Comment: RECOMMENDED MODIFICATIONS

To address our concerns, we recommend the following modifications which do not undermine the toxic pollutant control actions envisioned in EPA's economic analysis (e.g., BMPs for stormwater and source control). In fact, some of these recommendations would provide incentives for greater movement toward achieving the water quality criteria than would occur under the Rule as it is currently proposed.

III. Recommendation: Adopt separate, scientifically defensible, reasonably achievable aquatic life criteria for effluent-dominated/effluent-dependent streams.

Available discharge data for effluent-dominated streams in Sacramento indicate that a number of the proposed criteria are not presently being achieved and cannot be achieved with implementation of BMPs or other reasonable controls (See Attachment A). This is also true for many municipal stormwater programs in California.

* The application of the proposed statewide criteria to effluent-dominated waters would force the Sacramento Stormwater Management Program, and other stormwater programs, to remove these discharges, essentially drying up the waters for most of the year. The costs would be significant and the

benefits assessed in EPA's economic analysis (enhanced fishing, passive benefits, and reduced cancer risk) would be zero. The removal of these discharges would likely be detrimental rather than beneficial. The effluent-dependent aquatic and riparian habitat, which previously supported aquatic life and wildlife, would no longer exist.

* Effluent-dominated and effluent-dependent water bodies, which are common in California, require separate and distinct water quality criteria. Such a move is common sense and would be in accordance with the spirit (if not the letter) of Presidential Executive Order 12866 and the Unfunded Mandates Reform Act.

* Additionally, the CWA requires that water quality standards be established taking into consideration their use and value for public water supplies, propagation of fish and wildlife, recreational purposes, and also taking into consideration their use and value for navigation (See CWA section 303(c)(2)(A)). Consistent with this statutory mandate, EPA regulations require that water quality standards be based on identification of specific water bodies where toxic pollutants may be adversely affecting water quality or the attainment of the designated water use, or where the levels of toxic pollutants are at a level to warrant concern and must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use. Clearly the intent of both the CWA and EPA regulations is that water quality standards be tailored to the characteristics of the waters in question, rather than based on the "one-size-fits-all" approach used in the proposed Rule. This is not the cumbersome task suggested by the Preamble, at least with respect to developing criteria appropriate for effluent-dependent waters. But, even if it were a cumbersome task, the difficulty of complying with the law is not an excuse for noncompliance.

* EPA could fulfill its obligation under the CWA and EPA regulations with respect to effluent-dominated waters simply by proposing criteria for these waters that are generally achievable by present stormwater discharges. Then, using the more stringent statewide criteria as a tracer, control measures and BMPs could be implemented to reduce the discharge of problematic pollutants to the MEP.

Response to: CTR-040-016b

EPA disagrees with this comment. Adoption of aquatic life criteria for effluent-dominated and effluent-dependent waters, based on local information and data, is beyond the scope of the CTR. EPA supports State adoption of such site-specific criteria, however, and intends to stay the CTR after approving any such State-adopted criteria (see response to CTR-003-006, et al.), but EPA cannot undertake to adopt such criteria itself. Even if EPA were to include site-specific criteria in the CTR, such criteria could not be based on considerations as to whether or not they were "reasonably achievable" by dischargers, as proposed in this comment. Water quality criteria must be based on sound scientific rationale and must protect designated uses. Their attainability is not a basis for selecting appropriate criteria. 40 CFR 131.11(a).

The costs (reasonableness) of attainability, which cannot justify adopting criteria that do not protect uses already designated, may be taken into consideration in the designation or modification of uses for individual waterbodies. 40 CFR 131.10. For this reason, EPA believes that this commenter's concerns are misplaced. The suggestion that EPA adopt "separate and distinct water quality criteria" for effluent-dominated and effluent-dependent waters, "tailored to the characteristics of the waters in question," and "reasonably achievable" by dischargers, could be best addressed, initially, through adoption or modification of designated uses. This is also beyond the scope of the CTR, the purpose of which is to adopt numeric toxic pollutant criteria for those waters in California, with designated uses already in place, where there are currently no criteria for these pollutants in effect. The CTR does not

undertake to designate any uses for waters in California or modify any uses already designated by the State.

Also, See responses to CTR-035-012a and CTR-036-005. For a discussion of how the rule complies with the E.O. 12866, the Unfunded Mandates Reform Act and the Regulatory Flexibility Act, see the preamble to the final rule.

Comment: 1. The California Toxics Rule is inconsistent with the Clean Water Act and EPA's water quality standards regulations.

a. EPA Failed to Adopt Criteria on a Case-by-Case, Pollutant-by-Pollutant Basis.

Section 303 of the Clean Water Act (CWA) requires that whenever a State adopts water quality standards, it "shall adopt criteria for all toxic pollutants listed pursuant to section 1317(a)(1) of this title for which criteria have been published under section 1314(a) of this title, the discharge or presence of which in the affected waters could reasonably be expected to interfere with those designated uses adopted by the State, as necessary to support such designated uses." 33 U.S.C. section 1313(c)(2)(B). In other words, criteria only need to be developed where there is a "discharge or presence" of toxic pollutants in the affected waters, which could reasonably be expected to interfere with those designated uses" adopted by the State.(*1) Thus, a water body and pollutant specific determination must be made before criteria are adopted as part of a water quality standard.

In its Preamble to the CTR, EPA stated that:

EPA does not believe that it is necessary to support the criteria proposed today on a pollutant specific, water body-by-water-body basis. For EPA to undertake an effort to conduct research and studies of each stream segment or water body across the State of California to demonstrate that for each toxic pollutant for which EPA has issued CWA 304(a) criteria guidance there is a "discharge or presence" of that pollutant which could reasonably "be expected to interfere with" the designated use would impose an enormous administrative burden and would be contrary to the statutory directive for swift action manifested by the 1987 addition of section 303(c)(2)(B) of the CWA. 62 Fed. Reg. 42166.

...Thus, to interpret CWA section 303(c)(2)(B) and (c)(4) to require such a cumbersome pollutant specific effort on each stream segment would essentially render section 303(c)(2)(B) meaningless. The provision and its legislative background indicate that the Administrator's determination to invoke her

303(c)(4)(B) authority can be met by a generic finding of inaction by the State without the need to develop pollutant specific data for individual stream segments.

This determination is supported by information in the rulemaking record showing the discharge or presence of priority toxic pollutants throughout the State. While this data is not necessarily complete, it constitutes a strong record supporting the need for numeric criteria for priority toxic pollutants with section 304(a) criteria guidance where the State does not have numeric criteria. 62 Fed. Reg. 42167.

Thus, EPA basically states that it is not necessary for it to make the statutorily-required findings of "discharge or presence" or reasonable expectation of interference with designated uses because it would be a great administrative burden and because swift action is required.

EPA supports its contention that swift action is required by citing the statutory framework and purpose of section 303, and the CWA's legislative history. "In adding section 303(c)(2)(B) to the CWA, Congress understood the existing requirements in section 303(c)(1) for triennial water quality standards review and submissions and in section 303(c)(4)(B) for promulgation. CWA section 303(c) includes numerous deadlines and section 303(c)(4) directs the Administrator to 'act promptly' where the Administrator determines that a revised or new standard is necessary to meet the requirements of the Act. Congress, by linking section 303(c)(2)(B) to the section 303(c)(1) three-year review period, gave States a last chance to correct this deficiency on their own. The legislative history of the provision demonstrates that chief Senate sponsors, including Senators Stafford, Chaffee and others wanted the provision to eliminate State and EPA delays and force quick action." 62 Fed. Reg. 42,167. Thus, EPA rests its entire argument regarding the need for swift action on the existence of the word "promptly" in the section of the statute related to the Administrator's duty to promulgate standards in the absence of approved State standards. It is unclear how EPA can argue that it has acted "promptly" thus far to adopt these new standards since it has been over three years since the State standards were overturned. Arguably, the additional extra time it would have taken to make the statutorily required findings would not have been substantial, and would probably result in less impact on dischargers.

EPA's other argument that such a "cumbersome pollutant specific effort on each stream segment" would "impose an enormous administrative burden" is not compelling. States, in their adoption of water quality standards, must perform this "cumbersome pollutant specific effort on each stream segment" under the express terms of section 303 (c)(2)(B). Therefore, it logically follows that EPA, in promulgating the standards for California, stands in the State's shoes and should be subject to the same requirements imposed upon the State. (*2) Furthermore, EPA's reasoning that it is not required to do something merely because it is "cumbersome" may be subject to a legal challenge that such a determination is "arbitrary and capricious" under the Administrative Procedures Act (5 U-S.C. section 701 et seq.).

(*1) See also 4O C.F.R. part 131.11 (a)(2) ("States must review water quality data and information on discharges to identify specific water bodies where toxic pollutants may be, adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern and must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use.")

(*2) See accord 40 C.F.R. 131.24(c) regarding EPA promulgation of water quality standards ("In promulgating water quality standards, the Administrator is subject to the same policies, procedures, analyses, and public participation requirement established for States. . .").

Comment: 7. The CTR may violate the Administrative Procedures Act, the and Executive Order (E.O.) Unfunded Mandates Reform Act No. 12866.

In the Preamble to the CTR, EPA repeatedly claims that the CTR will not result in expenditures of more than $100 million per year and, therefore, the statutory requirements of the UMRA and E.O. 12866 are not triggered.(*1) Caltrans' annual costs alone and only in Los Angeles will exceed the $100 million annual figure, even assuming the lowest level of treatment. Therefore, EPA's cost assumptions are challengeable as being arbitrary and capricious and in violation of the Administrative Procedures Act.(*2)

Request: Caltrans requests that EPA reconsider its cost estimates based on the comments received during the public comment period.

Caltrans would like to thank EPA for the opportunity to provide comments on this proposed regulation. It is hoped that EPA will consider and address Caltrans' comments in the final version of the CTR. Should you have any questions concerning our comments on the CTR, please feel free to address these questions to Marcia Arrant at (916) 657-5381.

(*1) See CTR, 62 Fed. Reg. at 42,188, and at 42,191 ("EPA has determined that this rule does not contain a federal mandate that may result in expenditures by State, local and tribal governments, in the aggregate, or by the private sector, of $100 million or more in any one year.")
(*2) See American Iron and Steel Institute v. EPA, 1997 WL 297251 (D.C. Cir., 1497)(the court found that EPA had arbitrarily failed to adequately address cost-justification for its elimination of mixing zones. EPA had estimated the total cost of elimination mixing zones for bioaccumulative chemicals of concern (BCCS) from all dischargers to the Great Lakes at $200,000, without even acknowledging a comment estimating the cost to one town for removal of mercury from its sewage discharge would be approximately $300,000).

Response to: CTR-042-007a

For a discussion of how the rule complies with the E.O. 12866, the Unfunded Mandates Reform Act, see the preamble to the final rule, and EPA's economic analysis for the final rule. For an evaluation of Caltrans' analysis of costs associated with storm water discharges, see response to CTR-040-004 (Category J; Stormwater Economics).

The commenter cited the decision reviewing EPA's Great Lakes' Initiative with respect to eliminating mixing zones for bioaccumulative pollutants of concern. EPA views this decision as remanding the matter to the agency for a failure to respond adequately to a comment as required under the Administrative Procedure Act. The decision did not address or reverse EPA's longstanding interpretation of the CWA that its ambient based water quality criteria must be set at levels necessary to protect the designated use (either aquatic life or human health, or both). The elimination of the mixing zone in the GLI was not a water quality criterion. It was a specific requirement that would have imposed criteria as end-of-pipe effluent limitations for bioaccumulative pollutants where feasible. EPA's current regulations at 40 CFR.131.11 state that criteria must be based on sound scientific rationale and must containsufficient parameters to protect the designated use. Further, such criteria shall be based on EPA's section 304(a) criteria recommendations, EPA's 304(a) criteria recommendations modified to reflect site-specific conditions, or other scientifically defensible methods. From the outset of the water quality standards program, EPA has explained that while economic factors may be considered in designating uses, scientific and technical factors must justify criteria to meet those uses. 44 Fed. Reg. 25,223, -24, 25 (April 30, 1979). When criteria cannot be attained due to economic factors, the state may consider whether a change or "downgrade" the use designation for the waterbody would be appropriate. Id. at 25,224. See. e.g., Mississippi Comm. on Natural Resources v. Costle, 625 F.2d 1269, 1277 (5th Cir. 1980), where the Court addressed whether EPA's action disapproving the state's water quality criterion for dissolved oxygen was arbitrary and capricious because EPA failed to consider economic factors. In affirming EPA's disapproval, the Court stated that

Nevertheless, we are convinced that EPA's construction is correct. See E.I. du Pont de Nemours & Co. v. Train, 430 U.S. 112, at 134-35. Congress itself separated use and criteria and stated that 'the water quality criteria for such waters [shall be] based on such uses. 33 U.S.C. Section 1313(c)(2)(1976). The statute requires EPA to develop criteria 'reflecting the latest scientific knowledge." Id. Section 1314(a)(1)(emphasis added). "The interpretation that criteria were based exclusively on scientific data predates the 1972 amendments. Water Quality Criteria vii (1968). Furthermore, when Congress wanted economics to be considered, it explicitly required it. See Sections 1311(b)(2)(A), 1312(b), 1314(b)(1976).

EPA reiterated this interpretation of the CWA and its implementing regulations in discussing section 304(a) recommended criteria guidance stating that they "are based solely on data and scientific judgments on the relationship between pollutant concentrations and environmental and human health effects" and "do not reflect consideration of economic impacts or the technological feasibility of meeting the chemical concentrations in ambient water." 63 FR 36,742, 36,762 col. 3 (July 7, 1998).

Comment: 5. The proposed rule is inconsistent with applicable Federal law and regulations.

In proposing a single set of criteria for all estuaries, the rule is inconsistent with the Clean Water Act and EPA's water quality standards regulations. The Clean Water Act requires that water quality standards be established taking into consideration their use and value for public water supplies, propagation of fish and wildlife, recreational purposes (see CWA section 303(c)(2)(A)). Consistent with this, EPA regulations require that water quality standards be based on identification of "specific water bodies where toxic pollutants may be adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern..." For those identified waters,"states must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use"(See 40 CFR 131.1 I (a)(2)). Clearly the intent of both the Act and EPA regulations is that water quality standards be tailored to the characteristics of the waters in question. In failing to properly evaluate the rule's economic impacts and in failing to adequately consider regulatory alternatives, the rule is inconsistent with Presidential Executive Order 12866 and the Unfunded Mandates Reform Act. Moreover, in failing to properly consider the impacts on small entities, the rule is inconsistent with the Regulatory Flexibility Act.

Comment: LEGAL ANALYSIS OF THE PROPOSED CALIFORNIA TOXICS RULE

1. The California Toxics Rule is inconsistent with the Clean Water Act and EPA's water quality standards regulations.

a. EPA Failed to Adopt Criteria on a Case-by-Case, Pollutant-by-Pollutant Basis.

Section 303 of the Clem Water Act (CWA) requires that whenever a State adopts water quality standards, it "shall adopt criteria for all toxic pollutants listed pursuant to section 1317(a)(1) of this title for which criteria have been published under section 1314(a) of this title, the discharge or presence of which in the affected waters could reasonably be expected to interfere with those designated uses adopted by the State, as necessary to support such designated uses." 33 U.S.C. section 1313(c)(2)(B). In other words, criteria only need to be developed where there is a "discharge or presence" of toxic pollutants in the affected waters, which could "reasonably be expected to interfere with those designated uses" adopted by the State.(*1) Thus, a water body and pollutant specific determination must be made before criteria are adopted as part of a water quality standard.

In its Preamble to the CTR, EPA stated that:

EPA does-not believe that it is necessary to support the criteria proposed today on a pollutant specific, water body-by-water-body basis. For EPA to undertake an effort to conduct research and studies of each stream segment or water body across the State of California to demonstrate that for each toxic pollutant for which EPA has issued CWA 304(a) criteria guidance there is a "discharge or presence" of that pollutant which could reasonably "be expected to interfere with" the designated use would impose an enormous administrative burden and would be contrary to the statutory directive for swift action manifested by the 1987 addition of section 303(c)(2)(B) of the CWA. 62 Fed. Reg. 42166.

Thus, to interpret CWA section 303(c)(2)(B) and (c)(4) to require such a cumbersome pollutant specific effort on each stream segment would essentially render section 303(c)(2)(B) meaningless. The provision and its legislative background indicate that the Administrator's determination to invoke her 303(c)(4)(B) authority can be met by a generic finding of inaction by the State without the need to develop pollutant specific data for individual stream segments. This determination is supported by information in the rulemaking record showing the discharge or presence of priority toxic pollutants throughout the State. While this data is not necessarily complete, it constitutes a strong record supporting the need for numeric criteria for priority toxic pollutants with section 304(a) criteria guidance where the State does not have numeric criteria. 62 Fed. Reg. 42167.

Thus, EPA basically states that it is not necessary for it to make the statutorily-required findings of "discharge or presence" or reasonable expectation of interference with designated uses because it would be a great administrative burden and because swift action is required.

EPA supports its contention that swift action is required by citing the statutory framework and purpose of section 303, and the CWA's legislative history. "In adding section 303(c)(2)(B) to the CWA, Congress understood the existing requirements in section 303(c)(1) for triennial water quality standards review and submissions and in section 303(c)(4)(B) for promulgation. CWA section 303(c) includes numerous deadlines and section 303(c)(4) directs the Administrator to act promptly where the Administrator determines that a revised or new standard is necessary to meet the requirements of the Act. Congress, by linking section 303(c)(2)(B) to the section 303(c)(1) three-year review period, gave States a last chance to correct this deficiency on their own. The legislative history of the provision demonstrates that chief Senate sponsors, including Senators Stafford, Chaffee and others wanted the provision to eliminate State and EPA delays and force quick action." 62 Fed. Reg. 42,167. Thus, EPA rests its entire argument regarding the need for swift action on the existence of the word "promptly" in the section of the statute related to the Administrator's duty to promulgate standards in the absence of approved State standards. It is unclear how EPA can argue that it has acted "promptly" thus far to adopt these new standards since it has been over three years since the State standards were overturned. Arguably, the additional extra time it would have taken to make the statutorily required findings would not have been substantial, and would probably result in less impact on dischargers.

EPA's other argument that such a "cumbersome pollutant specific effort on each stream segment" would "impose an enormous administrative burden" is not compelling. States, in their adoption of water quality standards, must perform this "cumbersome pollutant specific effort on each stream segment" under the express terms of section 303 (c)(2)(B). Therefore, it logically follows that EPA, in promulgating the standards for California, stands in the State's shoes and should be subject to the same requirements imposed upon the State. (*2) Furthermore, EPA's reasoning that it is not required to do something merely because it is "cumbersome" may be subject to a legal challenge that such a determination is "arbitrary and capricious" under the Administrative Procedures Act (5 U.S.C. section 701 et seq.).

(*1) See also 4O C.F.R. section 131.11 (a)(2) ("States must review water quality data and information on discharges to identify specific water bodies where toxic pollutants may be, adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern and must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use.")

(*2) See accord 40 C.F.R. 131.241(c) regarding EPA promulgation of water quality standards ("In promulgating water quality standards, the Administrator is subject to the same policies, procedures, analyses, and public participation requirement established for States. . .").

Comment: On behalf of the American Petroleum Institute (API), we are submitting the following comments on U.S. EPA's proposal to establish water quality criteria for toxic pollutants for the State of California (62 Fed. Reg. at 42160, Aug. 5, 1997). API is a national trade association representing 300 companies with operations in all facets of the petroleum industry

(exploration, production, refining, and marketing. API has member companies in California as well as member companies in the Midwestern states currently implementing the Great Lakes Initiative. API member companies have experience with many of aspects of the proposed rule which are quite similar to the Great Lakes Initiative.

Many of API's members own and operate facilities in the State of California that discharge wastewater pursuant to NPDES permits. Those facilities will likely be issued new permit limits based on the criteria set forth in the EPA rule, once that rule is issued in final form. Therefore, API has a strong interest in the EPA proposal. Based on its review, API believes that the proposal has substantial legal flaws. Those flaws are described below.

1. EPA is Not Authorized to Impose the Proposed Criteria on a State-wide Basis.

EPA has proposed to impose the new criteria on all-waters in the State of California. EPA claims that it has the authority to impose state-wide criteria because the State's water quality control plans, which contain water quality criteria, have been invalidated by a court. Therefore, according to EPA, the State has not met its obligations under section 303(c)(2)(B) of the Clean Water Act, which requires the State to issue water quality criteria for toxics, "the discharge or presence of which in the affected waters could reasonably be expected to interfere with those designated uses adopted by the State, as necessary to support such designated uses." Because the State has not taken that action, EPA claims that it must promulgate standards for the State, under section 303(c)(4)(B) of the Act, which requires EPA to act when it determines that "a revised or new standard is necessary to meet the requirements of the Act." (62 Fed. Reg. at 42165).

EPA's position that it may impose state-wide criteria is squarely inconsistent with the plain language and intent of the Clean Water Act. First, Section 303(c)(2)(b) requires that the state must establish criteria for toxics, the discharge or presence of which in the affected waters could reasonably be expected to interfere with those designated uses adopted by the state as necessary to support such designated uses by requiring that criteria be established for certain toxics, i.e., those which interfere with the designated uses of specified waters, i.e., affected waters, it is clear that Congress intended that criteria be set on a

pollutant specific and stream-specific basis, not according to state geographic boundaries. Uses are designated for particular water bodies. Thus, EPA's position that it need not make any specific findings at all nullifies the clear statutory language of section 303(c)(2)(b) and violates a cardinal principle of statutory construction that each and every word of a provision be given effect.

Response to: CTR-050-001

See responses to CTR-035-012a and CTR-036-005. Further, EPA's interpretation does give effect to each word in CWA section 303(c)(2)(B) because the phrase "discharge or presence of which in the affected waters could reasonably be expect to interfere with those designated uses adopted by the State, as necessary to support such designated uses" reasonably could be interpreted to mean that if the pollutant were discharged, it could interfere with the designated uses. As explained in the above cited comment responses, this is a reasonable interpretation of the CWA given the time frames set forth by Congress and given the practical reality that no water quality based effluent limit must be included in a particular permit unless the State makes a "reasonable potential" determination for a given discharge.

Comment: On behalf of the American Petroleum Institute (API), we are submitting the following comments on U.S. EPA's proposal to establish water quality criteria for toxic pollutants for the State of California (62 Fed. Reg. at 42160, Aug. 5, 1997). API is a national trade association representing 300 companies with operations in all facets of the petroleum industry

(exploration, production, refining, and marketing. API has member companies in California as well as member companies in the Midwestern states currently implementing the Great Lakes Initiative. API member companies have experience with many of aspects of the proposed rule which are quite similar to the Great Lakes Initiative.

Many of API's members own and operate facilities in the State of California that discharge wastewater pursuant to NPDES permits. Those facilities will likely be issued new permit limits based on the criteria set forth in the EPA rule, once that rule is issued in final form. Therefore, API has a strong interest in the EPA proposal. Based on its review, API believes that the proposal has substantial legal flaws. Those flaws are described below.

Second, EPA concedes that it has not made the factual findings to support state-wide application of the proposed standards, i.e., that a particular standard for a particular pollutant on a particular stream is "necessary to meet the requirements of the Act." (62 Fed. Reg. at 42166-42167) In fact, EPA states that its data concerning "discharge or presence" of toxics is "not necessarily complete." (62 Fed. Reg. at 42167) Perhaps, it is this acknowledged lack of supporting data that compels EPA to ignore the language

of section 303(c)(2)(b), which so plainly contradicts the concept of a state-wide applicability of toxic criteria.

Comment: On behalf of the American Petroleum Institute (API), we are submitting the following comments on U.S. EPA's proposal to establish water quality criteria for toxic pollutants for the State of California (62 Fed. Reg. at 42160, Aug. 5, 1997). API is a national trade association representing 300 companies with operations in all facets of the petroleum industry

(exploration, production, refining, and marketing. API has member companies in California as well as member companies in the Midwestern states currently implementing the Great Lakes Initiative. API member companies have experience with many of aspects of the proposed rule which are quite similar to the Great Lakes Initiative.

Many of API's members own and operate facilities in the State of California that discharge wastewater pursuant to NPDES permits. Those facilities will likely be issued new permit limits based on the criteria set forth in the EPA rule, once that rule is issued in final form. Therefore, API has a strong interest in the EPA proposal. Based on its review, API believes that the proposal has substantial legal flaws. Those flaws are described below.

Third, EPA's claim that it does not have to make pollutant and stream-specific determinations because Congress wanted it to take "quick action" (62 Fed. Reg. at 42167), is not supported by the pertinent statutory provisions which contain no deadlines at all. Section 303(c)(4)(B) merely directs the Agency to act to promptly" and has no explicit connection to section 303(c)(2)(B), which contains the State's obligations to issue criteria for toxicities.

If Congress had wanted to establish a connection between the two statutory provisions, and authorize EPA to take "quick action" to issue state-wide criteria if the State has not acted, Congress could easily have inserted appropriate language in either section 303(c)(2)(B), section 303(c)(4)(B), or both. Congress did not insert such language. Thus, Congress did not authorize the Agency to make an "end run" around the explicit provisions of the statute by issuing state-wide criteria without stream-specific or pollutant-specific findings that such criteria are necessary.

Comment: On behalf of the American Petroleum Institute (API), we are submitting the following comments on U.S. EPA's proposal to establish water quality criteria for toxic pollutants for the State of California (62 Fed. Reg. at 42160, Aug. 5, 1997). API is a national trade association representing 300 companies with operations in all facets of the petroleum industry

(exploration, production, refining, and marketing. API has member companies in California as well as member companies in the Midwestern states currently implementing the Great Lakes Initiative. API member companies have experience with many of aspects of the proposed rule which are quite similar to the Great Lakes Initiative.

Many of API's members own and operate facilities in the State of California that discharge wastewater pursuant to NPDES permits. Those facilities will likely be issued new permit limits based on the criteria set forth in the EPA rule, once that rule is issued in final form. Therefore, API has a strong interest in the EPA proposal. Based on its review, API believes that the proposal has substantial legal flaws. Those flaws are described below.

Finally, EPA imposition of state-wide standards is not "necessary to meet the requirements of the Act," as required by Section 303(c)(4)(B). In discussing the potential economic impacts of the proposal, EPA points out that if it did not issue a rule, the State could use its narrative water quality criteria to impose permit limits for toxicities. (62 Fed. Reg. at 42187) EPA fails to recognize that if the state were allowed to use its criteria in this manner, there would be no need for EPA to usurp state authority and federally impose statewide criteria.

For the reasons cited above, EPA's action to propose toxic criteria in the State of California is without legal authority and should be withdrawn.

Response to: CTR-050-004

See responses to CTR-035-012a and CTR-036-005. EPA is promulgating numeric criteria here even though the state could use its narrative to develop water quality based effluent limits in order to meet the requirements of CWA section 303(c)(2)(B). Section 303(c)(2)(B) of the CWA was enacted in 1987 in response to Congress' impatience with the progress in implementation of water quality controls for toxic pollutants for which EPA has national section 304(a) recommended criteria guidance. In enacting section 303(c)(2)(B), Congress required states to adopt numeric criteria. In light of California's failure to have such criteria, EPA's promulgation is implementing Congressional intent.

Comment: IV. EPA Has Not Complied With Applicable Regulatory Review Requirements. There are several significant statutes and executive orders that require EPA to undertake analyses of the costs and benefits of its regulations, and to submit the regulations and analyses to other governmental bodies, including the Office of Management and Budget (OMB) and Congress. Those authorities include the Regulatory Flexibility Act, the Small Business Regulatory Enforcement and Fairness Act (SBREFA), the Unfunded Mandates Reform Act, the Congressional Review Act, and Executive Order 12866 (Regulatory Planning and Review). EPA apparently believes that it does not need to comply with any of those requirements for this rulemaking. (62 Fed. Reg. at 42188-42191). API believes that EPA is required to meet those obligations for the proposed criteria, and that the Agency's rationale for avoiding this responsibility has no legal basis.

EPA supports its decision not to comply with the regulatory review statutes by stating that the proposed criteria "by themselves, do not directly impose economic impacts." (62 Fed. Reg. at 42188). EPA admits that when those criteria are combined with the designated uses that have been adopted by the State, and implemented in permit limits, "there may be a cost to some dischargers." (62 Fed. Reg. at 42188) could be substantial; the Agency itself estimates that the compliance cost could be between $15 and $87 million per year.(62 Fed. Reg. at 42189). (That does not include indirect costs to the economy, which would surely put this rule above the $100 million impact threshold specified in several of the regulatory review statutes listed above.) EPA cannot ignore those costs by creating its own interpretation of those statutes in which only "direct" impacts need be considered. There is no support in the statutory language or legislative history for such a reading, and EPA has cited no such support in its Federal Register notice.

There is another problem with EPA's rationale for avoiding regulatory review: if EPA were right that "indirect" impacts do not trigger those reviews, the impacts of this rulemaking are not really "indirect." Those impacts emerge clearly once the proposed criteria are combined with the State's designated uses. Those designations have already been established, so there is nothing uncertain or indefinite about that aspect of the water quality standards. Then, once the standards are completed, the State must implement those standards through permit limits. While there are some decisions that the State must make in determining the proper permit limits, which can influence the size of the compliance costs, EPA can readily determine a range of possible costs. In fact, the Agency has already done so, resulting in the $15 - $87 million cost range discussed above. While those costs may not be fixed with certainty, they are certainly "direct economic impacts". Therefore, even if the Agency were correct in looking at only "direct" impacts, this rulemaking poses such impacts, and EPA must comply with the statutory requirements to conduct and submit cost and benefit analyses of its proposed criteria.

V. CONCLUSION

As explained above, EPA's proposal to issue water quality criteria for toxicities in the State of California suffers from serious legal flaws. API urges the Agency to reconsider its intended course of action in light of the issues raised in these and other public comments. If you have any questions regarding these comments, or would like any additional information, please call Theresa Pugh at 202/682-8036.

Response to: CTR-050-007a

EPA disagrees with the comment. EPA has explained its compliance with E.0. 12866, the Regulatory Flexibility Act (as amended), and the Unfunded Mandates Reform Act in the preamble to the final rule.

With respect to the Regulatory Flexibility Act (RFA), and as stated in the preamble to the proposed and final rules, the RFA requires agencies to assess the economic impact of a rule only on small entities that are subject to the requirements of the rule. Today's rule does not impose any impacts on small entities.

The Regulatory Flexibility Act generally requires federal agencies to prepare a regulatory flexibility analysis (RFA) that describes the impact of a rule on small entities (small businesses, small organizations and small governmental jurisdictions) whenever an agency promulgates a final rule under section 553 of the Administrative Procedure Act, 5 U.S.C. Section 553. 5 U.S.C. Section 604. Under section 605(b) of the Regulatory Flexibility Act, however, if the head of an agency certifies that a rule will not have a significant economic impact on a substantial number of small entities, the statute does not require the agency to prepare an RFA. Pursuant to section 605(b), the Administrator is today certifying that this rule will not have a significant economic impact on a substantial number of small entities for the reasons explained below. Consequently, EPA has not prepared an RFA.

The RFA requires analysis of the economic impact of a rule only on the small entities subject to the rules' requirements. See United States Distribution Companies v. FERC, 88 F.3d 1105, 1170 (D.C. Cir. 1996). ("[N]o [regulatory flexibility] analysis is necessary when an agency determines that the rule will not have a significant economic impact on a substantial number of small entities that are subject to the requirements of the rule," United Distribution at 1170, quoting Mid-Tex Elec. Co-op v. FERC, 773 F.2d 327, 342 (D.C. Cir. 1985) (emphasis added by United Distribution court).) Thus, the RFA requires that any regulatory flexibility analysis prepared for a final rule must include estimates of "the number of small entities to which a rule will apply." 5 U.S.C. Section 604(a)(3). The analysis must also include a description of the recordkeeping, reporting and compliance requirements of the rule, including an estimate of the classes of small entities "which will be subject to the requirements." 5 U.S.C. Section 604(a)(4). In light of these provisions, courts have consistently interpreted the RFA to impose no obligation on an agency to conduct a small entity impact analysis on entities it does not regulate. Motor & Equip. Mfrs. Ass'n v. Nichols, 142 F.3d 449, 467 & n.18 (D.C. Cir. 1998).

The U.S. Court of Appeals for the District of Columbia Circuit recently reaffirmed its conclusion that the RFA does not require an agency to prepare an assessment of the economic impact of a rule on small entities that are not directly affected by a rule. American Trucking Association, Inc. v. U.S. Environmental Protection Agency, (D.C. Cir. 1999). In that case, the court determined that EPA was not required to prepare a regulatory flexibility analysis of the economic impact of a rule on small entities when it promulgated air quality standards under the Clean Air Act. There, EPA had certified that the rule would not have a significant impact on small entities because the air standard did not directly impose requirements on small entities and consequently they were not subject to the rule. Under the Clean Air Act, states regulate small entities through state implementation plans that they are required to develop under the Act. States have broad discretion in determining how to achieve compliance with the standards and may choose to avoid imposing any of the burden of complying with the standards on small entities.

The CTR presents a situation very similar to that described in the American Trucking case. It establishes no requirements that are directly applicable to small entities, and so the agency is not required to conduct a regulatory flexibility analysis under the RFA. (See United States Distribution Companies v. FERC, 88 F.3d 1105, 1170 (D.C. Cir. 1996). The Agency is therefore certifying that today's rule will not have a significant economic impact on a substantial number of small entities, within the meaning of the RFA.

Under the CWA water quality standards program, states must adopt water quality standards for their waters that must be submitted to EPA for approval. If the Agency disapproves a state standard and the state does not adopt appropriate revisions to address EPA's disapproval, EPA must promulgate standards consistent with the statutory requirements. EPA has authority to promulgate criteria or standards in any case where the Administrator determines that a revised or new standard is necessary to meet the requirements of the Act. These state standards (or EPA-promulgated standards) are implemented through various water quality control programs including the National Pollutant Discharge Elimination System (NPDES) program that limits discharges to navigable waters except in compliance with an EPA permit or permit issued under an approved state program. The CWA requires that all NPDES permits must include any limits on discharges that are necessary to meet state water quality standards.

Thus, under the CWA, EPA's promulgation of water quality criteria or standards establishes standards that the state, in turn, implements through the NPDES permit process. The state has considerable discretion in deciding how to meet the water quality standards and in developing discharge limits as needed to meet the standards. In circumstances where there is more than one discharger to a water body that is subject to water quality standards or criteria, a state also has discretion in deciding on the appropriate limits for the different dischargers. While the state's implementation of federally-promulgated water quality criteria or standards may result indirectly in new or revised discharge limits for small entities, the criteria or standards themselves do not apply to any discharger, including small entities.

EPA recognizes that it has undertaken an economic analysis pursuant to E.O. 12866 for this rule. This analysis, however, makes numerous assumptions and does not necessarily predict how the state will implement the criteria. Thus, the economic analysis represents EPA's best estimate of the implementation costs of the rule given the broad flexibility the state has in implementing the criteria.

The CTR, as explained above, does not itself establish any requirements that are applicable to small entities. As a result of EPA's action here, the State of California will need to ensure that permits it issues comply with the water quality standards established by the criteria in today's rule. In so doing, the State will have a number of discretionary choices associated with permit writing. While California's implementation of today's rule may ultimately result in some new or revised permit conditions for some dischargers, including small entities, EPA's action today does not impose any of these as yet unknown requirements on small entities.

Although the statute does not require EPA to prepare a regulatory flexibility analysis when it promulgates water quality criteria which will establish water quality standards for California, EPA has prepared an assessment of potential economic impact. This evaluation focuses on State and local implementation procedures related to the NPDES permit program. This evaluation is included in a document entitled, Implementation Analysis of Ambient Water Quality Criteria for Priority Toxic Pollutants in California which is part of the administrative record for this rulemaking. This document looks at the many implementation procedures of the NPDES permit program that the State implements to control pollutants from point source discharges. The procedures discussed in the document include: methods to calculate water quality-based effluent limits; mixing zones; site-specific translators for

metals criteria; compliance schedules; effluent trading; water-effect ratios; variances; designated use reclassification; and site-specific criteria. Each of these implementation procedures may have an effect on how water quality standards, based on the criteria in today's rule, will impact NPDES permit holders. Many of these procedures will lessen impacts on regulated entities.

The document also looks at implementation procedures used in the pretreatment program to control pollutant discharges from dischargers that do not discharge directly but introduce pollutants to publicly owned treatment works (POTWs). These dischargers include retail, commercial, and small industrial facilities that discharge to publicly owned treatment works (POTWs). Local entities have significant flexibility to implement their pretreatment programs. These procedures include: methods to calculate local limits (allocation of pollutants); methods of pollution prevention for various specific sources; pretreatment pollutant trading; methods of low cost pollutant reductions; technical assistance to move toward or achieve zero-discharge; cost accounting to drive down levels of discharges; and a few of the regulatory relief options discussed in the direct discharger section, e.g., compliance schedules.

The discussion illustrates the significant amount of flexibility available to the State and local agencies when implementing the NPDES permit program and pretreatment program and emphasizes that appropriate use of the available implementation tools can greatly affect the impact to many direct and indirect dischargers.

EPA recognizes that it has undertaken an economic analysis pursuant to E.O. 12866 for this rule. This analysis, however, makes numerous assumptions and does not necessarily predict how the state will implement the criteria. Thus, the economic analysis represents EPA's best estimate of the costs of the rule given the broad flexibility the state has in implementing the criteria.

Comment: C. RECOMMENDATIONS FOR MODIFICATIONS TO THE CTR AND EA

EPA should revise the proposed rule and economics analysis such that they are consistent with applicable Federal law and regulations. In proposing a single set of criteria for all estuaries, the rule is inconsistent with the Clean Water Act and EPA's water quality standards regulations. In failing to properly evaluate the rule's economic impacts and in failing to adequately consider alternative criteria for San Francisco Bay Area waters, the rule is inconsistent with Presidential Executive Order 12866 and the Unfunded Mandates Reform Act. In failing to properly consider the impacts on small entities, the rule is inconsistent with the Regulatory Flexibility Act. Specific citations for these inconsistencies are contained in comments from BADA and CASA/Tri-TAC.

Comment: LEGAL ANALYSIS OF THE PROPOSED CALIFORNIA TOXICS RULE

1. The California Toxics Rule is inconsistent with the Clean Water Act and EPA's water quality standards regulations.

a. EPA Failed to Adopt Criteria on a Case-by-Case, Pollutant-by-Pollutant Basis.

Section 303 of the Clem Water Act (CWA) requires that whenever a State adopts water quality standards, it "shall adopt criteria for all toxic pollutants listed pursuant to section 1317(a)(1) of this title for which criteria have been published under section 1314(a) of this title, the discharge or presence of which in the affected waters could reasonably be expected to interfere with those designated uses adopted by the State, as necessary to support such designated uses." 33 U.S.C. section 1313(c)(2)(B). In other words, criteria only need to be developed where there is a "discharge or presence" of toxic pollutants in the affected waters, which could "reasonably be expected to interfere with those designated uses" adopted by the State.(*1) Thus, a water body and pollutant specific determination must be made before criteria are adopted as part of a water quality standard.

In its Preamble to the CTR, EPA stated that:

EPA does-not believe that it is necessary to support the criteria proposed today on a pollutant specific, water body-by-water-body basis. For EPA to undertake an effort to conduct research and studies of each stream segment or water body across the State of California to demonstrate that for each toxic pollutant for which EPA has issued CWA 304(a) criteria guidance there is a "discharge or presence" of that pollutant which could reasonably "be expected to interfere with" the designated use would impose an enormous administrative burden and would be contrary to the statutory directive for swift action manifested by the 1987 addition of section 303(c)(2)(B) of the CWA. 62 Fed. Reg. 42166.

Thus, to interpret CWA section 303(c)(2)(B) and (c)(4) to require such a cumbersome pollutant specific effort on each stream segment would essentially render section 303(c)(2)(B) meaningless. The provision and its legislative background indicate that the Administrator's determination to invoke her 303(c)(4)(B) authority can be met by a generic finding of inaction by the State without the need to develop pollutant specific data for individual stream segments. This determination is supported by information in the rulemaking record showing the discharge or presence of priority toxic pollutants throughout the State. While this data is not necessarily complete, it constitutes a strong record supporting the need for numeric criteria for priority toxic pollutants with section 304(a) criteria guidance where the State does not have numeric criteria. 62 Fed. Reg. 42167.

Thus, EPA basically states that it is not necessary for it to make the statutorily-required findings of "discharge or presence" or reasonable expectation of interference with designated uses because it would be a great administrative burden and because swift action is required.

EPA supports its contention that swift action is required by citing the statutory framework and purpose of section 303, and the CWA's legislative history. "In adding section 303(c)(2)(B) to the CWA, Congress understood the existing requirements in section 303(c)(1) for triennial water quality standards review and submissions and in section 303(c)(4)(B) for promulgation. CWA section 303(c) includes numerous deadlines and section 303(c)(4) directs the Administrator to act promptly where the Administrator determines that a revised or new standard is necessary to meet the requirements of the Act. Congress, by linking section 303(c)(2)(B) to the section 303(c)(1) three-year review period, gave States a last chance to correct this deficiency on their own. The legislative history of the provision demonstrates that chief Senate sponsors, including Senators Stafford, Chaffee and others wanted the provision to eliminate State and EPA delays and force quick action." 62 Fed. Reg. 42,167. Thus, EPA rests its entire argument regarding the need for swift action on the existence of the word "promptly" in the section of the statute related to the Administrator's duty to promulgate standards in the absence of approved State standards. It is unclear how EPA can argue that it has acted "promptly" thus far to adopt these new standards since it has been over three years since the State standards were overturned. Arguably, the additional extra time it would have taken to make the statutorily required findings would not have been substantial, and would

probably result in less impact on dischargers.

EPA's other argument that such a "cumbersome pollutant specific effort on each stream segment" would "impose an enormous administrative burden" is not compelling. States, in their adoption of water quality standards, must perform this "cumbersome pollutant specific effort on each stream segment" under the express terms of section 303 (c)(2)(B). Therefore, it logically follows that EPA, in promulgating the standards for California, stands in the State's shoes and should be subject to the same requirements imposed upon the State. (*2) Furthermore, EPA's reasoning that it is not required to do something merely because it is "cumbersome" may be subject to a legal challenge that such a determination is "arbitrary and capricious" under the Administrative Procedures Act (5 U.S.C. section 701 et seq.).

(*1) See also 4O C.F.R. section 131.11 (a)(2) ("States must review water quality data and information on discharges to identify specific water bodies where toxic pollutants may be, adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern and must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use.")
(*2) See accord 40 C.F.R. 131.241(c) regarding EPA promulgation of water quality standards ("In promulgating water quality standards, the Administrator is subject to the same policies, procedures, analyses, and public participation requirement established for States. . .").

Comment: Waste Load Allocation (WLA) is a flawed concept and UPI requests the EPA promulgate conditions for exemption as part of the requirement for compliance with such allocations.

The implementation of CWA Section 303(c)(2)(B) as discussed beginning on page 42184 causes numerous obstacles, both financial and technological, to facilities such as UPI. Our facility will be subject to water quality-based effluent limitations (WQBELs). Therefore, total maximum daily loads (TMDL) and WLAs will be utilized as future discharge permit criteria.

State Task Force recommendations also recognize that the TMDL process can be significantly labor and data intensive. UPI concurs that the TMDL process is significantly labor and data intensive. During the five year period from 1989 through 1993 UPI spent close to a million dollars ($1,000,000) on the studies of point source wasteload performance at its facility. The study was initiated to verify the efficacy of our

waste water treatment system in removing chemical process constituents that were added to the water from the river (Delta) during use of the water as process water. Chain-of-custody and laboratory results for this study were documented in our required monthly self monitoring reports to the RWQCB.

The above study of efficacy of wastewater treatment prior to discharge is summarized in the following attached tables which show averages for three month periods over five full years.

Table 9. Summary of Discharge 001 Gross Mass Loading, lb/day Table 10. Summary of Discharge 001 Net Mass Loading, lb/day Table 11. Summary of Discharge 001 Net Concentrations, ug/l

Each table is shown in two sections. Section A shows the tabulation of results for cadmium (Cd), total chromium (Cr, total), hexavalent chromium (CrE+6), copper (Cu), total iron (Fe, total), dissolved iron (Fe, dissolved), lead (Pb), nickel (Ni) and zinc (Zn). Section B shows the tabulation of results for arsenic (As), mercury (Hg), selenium (Se), silver (Ag), tin (Sn), cyanide, phenolics, polyaromatic hydrocarbons (PAHs), naphthalene, and tetrachloroethylene. All analyses were done using approved standard procedures to determine the total concentration of each chemical. All results that were reported at minimum detection level (MDL) are included in the averages at one half of the reported MDL.

The attached tables illustrate the following: The gross lb/day discharge loadings (Table 9) show certain trends of improvement, eg, CrE+6, for which the process sources had been controlled. Note that since completion of the study compliance samples for CrE+6 during the most recent two year period have been reported at less than MDL. Other decreases, such as shown for Cd, Hg and Pb, are the result of improved analytical test procedures.

The net discharge lb/day loadings (Table 10) and net discharge ug/l concentrations (Table 11) show many results that are at or below zero discharge for many constituents. Other net discharge ug/l concentrations are significantly below the applicable MDLs, which also indicates that the net concentration is essentially zero. This indicates that chemical control for most chemicals is essentially 100% complete and that no process constituents are contained in the permitted discharge, except as noted below.

Exceptions to the above are Cr, Sn, and phenolics for which the net results are significantly above zero.

The above study shows the substantial effort and expenditure that was required to verify performance with respect to chemicals of concern (COCs) for a specific source category (and for several additional chemicals that were added to the COC list). The list of COCs is being expanded to 126 in the proposed regulations, more than six times as large a list as was evaluated in our performance study.

While the use of the Waste Load Allocation (WLA) principle may sound good, it is only good if properly administered. Two criterion should be considered to make the use of WLAs practicable and administratively feasible for both the agencies and the dischargers.:

* The COCs applicable to WLA discharge compliance should be identified by the Administrator for each source category, per Title 33, Section 1316(b)(1).

* Each NPDES Permit Applicant shall analyze and report on chemical listed on the standard permit application every five years to verify which if any discharge chemicals are subject to WLA discharge compliances.

For the above reasons, UPI requests the EPA add the following to the end of Section 131.38(e)(1) of part

131 of Title 40:

"New and existing point source dischargers shall be considered to be in compliance with such WQBELs except for (i) any WQBEL constituent that is identified for the source category pursuant to Section 1316(b)(1) of Title 33, or (ii) any WQBEL constituent which may cause an increase in the receiving water due to such discharge as determined from information contained in the standard required permit application."

Comment: HUMAN HEALTH CRITERIA

EHC is very concerned about the use of 6.5 grams per day of fish tissue as a basis upon which to derive human health criteria. This is not adequate to protect the many thousands of subsistence fishers of California coastal waters. We trust EPA is not in the business of protecting "most of the people, most of the time" as is the indicated goal for marine organisms elsewhere in the CTR (see comments below).

We refer you to a study conducted by the Save San Francisco Bay Association that concluded that fishers of San Francisco Bay consumed 81grams per day in the week prior to the survey with consumption rates as high as 450 grams/day... This element of the CTR must be recalculated at a higher rate of consumption and with a healthy safety margin to accommodate for synergistic and cumulative effects. Further, the Save San Francisco study showed that heads and skin were frequently consumed, the health criteria must reflect these actual eating patterns and practices as well and reflect the cultural diversity of users of the Bays. Since many subsistence fishers are people of color, adoption of this rule could violate the President's Order on Environmental Justice b exposing these populations to increased and undue environmental health risks.

Response to: CTR-065-003b

Comment: In regard to the numeric water quality standards criteria for California surface water, they have been revealed by environmental groups to be insufficiently protective and environmentally unjust. The proposed new rules assume fish ingestion of 6.5 grams per day. In reality, consumption of fish in some communities can be as high as 1 pound per day. This level of consumption is especially likely among subsistence fishers.

Please prevent toxic pollution in California's bays by making more protective standards that consider all toxic pollutants and consider the fish consumption habits of subsistence anglers.

Comment: Finally, the timing must be strictly political, since 17 years of delay is unconscionable. Since you advisors must have found it difficult to understand the scientific literature, may I recommend a scientifically accurate book that is accessible to the non-scientist that may explain the dangers and the need for bold action by the EPA. It is Living Downstream - An Ecologist Looks at Cancer and the Environment by Sandra Steingraber, Addison Wesley, NY, 1997.

Response to: CTR-099-004

EPA disagrees with this comment. EPA began work on the CTR in 1994, and only after the State rescinded its ISWP and EBEP. The complexities of this rulemaking have prolonged the CTR process, but EPA is pleased to now be issuing final water quality criteria for toxic pollutants in the State of California.

Comment: The maximum levels proposed for mercury, dioxin, and thirteen other pollutants have been identified by respected environmental advocacy groups as (1) insufficiently protective, and (2) environmentally unjust, potentially increasing the cancer risks for subsistence fishers, who are, in large part, people of color.

The standards must be established at a level that makes California waters truly "fishable," and not just "fishable if you don't object to cancer."

Thank you for your consideration.

Comment: MR. KARRAS: I'm Greg Karras, K-A-R-R-A-S. I'm with Communities for a Better Environment; I'm a senior scientist.

CBE is a multiracial environmental health and justice organization with 20,000 California members, most of them in the Bay Area. We work with communities imperiled by urban pollution. I represent people who depend upon the environmental health of San Francisco Bay, including people who fish the bay for food.

CBE has worked to clean up the bay for years. We helped EPA establish the first National Estuary Conference and served on the management committee of the San Francisco Estuary Project and signed its consensus plan to protect and restore the bay. We participated in the development of every numeric toxins standard promulgated for the bay, with the possible exception of one adopted by EPA for selenium

in 1992.

We used these standards to leverage toxic prevention that cut toxics of the bay by tons, while netting economic benefits to the manufacturing base and jobs at more than a hundred Bay Area industrial plants. We submitted these data for your work on this proposed rule and we've done a preliminary analysis of the proposal that resulted.

It looks to us as a preliminary matter that EPA's proposed rule today could reverse a decade of environmental policy progress in San Francisco Bay and represent the biggest step backward ever taken for the bay's toxics policies in 25 years under the Clean Water Act. This conclusion is alarming, and this conclusion is surprising.

We hope to find out that we're wrong about that preliminary conclusion. Accordingly, before we make a final judgment, which I understand we need to make by next Friday to submit written comments, I ask that you give CBE and our members, which are the public, important information by answering now or as soon as possible some of our most pressing questions.

On environmental justice, EPA says in its preamble to the proposal that it is EPA's intention to calculate cancer criteria in a way that will provide less protection from cancer for people who rely on locally caught fish for food than it does the average person.

EPA then goes on to say this might still provide adequate protection. However, low-income people of color who fish San Francisco Bay for food are eating up to 60 times more contaminated fish than the state health advisory says is quote, unquote, safe.

And I also note that in Exhibit 8A of your economic analysis, EPA, you say that the hazard from peaks in the mercury and from dioxin in fish consumed in San Francisco Bay exceeds what you consider to be a significant level.

So our first question is simply is EPA proposing to provide the poor --

I should mention, we know from surveys done by several entities in the bay that the vast majority of people who fish the bay and use it for food, rely on it for food, most of them are low-income people and we can determine for sure that the majority are people of color.

So the question is, is EPA proposing to provide poor people and people of color unequal protection under the law?

Comment: Finally, this is a daytime hearing. I think the record will show that the vast majority of people who attended this hearing are environmental professionals, and the vast majority of those are people who represent regulated interests and the discharge interests.

The people who are most directly impacted in terms of their health, their livelihood, their ability to work when they're sick, their ability to raise children who don't have slow learning, their rights to fish a clean bay, are not here.

My final question --

And I think it's obvious why many of them are not here. Many of these folks are lower-income people of color, immigrant people, people who are working people, who have the kinds of jobs where it's very difficult for them to ask the boss for time off to attend a hearing of EPA to address fish contamination held at 1:00 p.m. on a Wednesday in the middle of the week.

Will EPA hold a public hearing in the evening on a fishing pier on San Francisco Bay before your proposal is adopted?

Those conclude my questions.

I, again, am serious about getting answers to these now, today, in this hearing or as soon as possible, so that we could make sure that we are as correct as possible in our comments which we will be submitting into the record in writing.

Thank you.

Response to: CTRH-001-017

EPA was unable to hold a public hearing in the evening on the rule. EPA operates during normal business hours. Nevertheless, EPA's intent here is not discriminatory, but rather an administrative necessity in terms of its own staffing, and support mechanisms for its operations. As always, people may submit written comments to EPA if they cannot attend a public hearing.

Comment: Because the California Toxics Rule uses the same approach as the UAA in setting water quality objectives for cadmium and copper, SARDA strongly supports the CTR objectives for those metals. We also agree with EPA's written statements acknowledging the binding character of organic carbon and the role it plays in rendering heavy metals non-toxic. We enthusiastically endorse the agency's decision to include Water Effects Ratio as a formal factor to be considered when formulating water quality objectives. It will do much to adjust national criteria to local conditions.

Comment: 4. DISSOLVED V.S. TOTAL RECOVERABLE METALS CRITERIA

The proposed CTR promulgates the metals criteria as dissolved concentrations instead of the historic use of total recoverable concentrations. The DFG has argued against the use of dissolved concentrations as we believe that they do not rally protect aquatic resources. Chemical constituents of natural waters

affect the biota as essential nutrients and as potential toxicants. These interactions are directly dependent on the chemical speciation of the constituents. While it is generally recognized that only the free concentrations of metals are the toxic component, most laboratories do not have the capability to determine the speciation of the metal. Use of only the dissolved fraction to determine criteria promotes the theory that metals adsorbed to sediments or suspended solids are not biologically available. Additionally, not all species of metal which are detected in the dissolved fraction are biologically available.

Metal complexes in natural waters can be classified into three groups: ion pairs, inorganic complexes, and organic complexes. Complex formation is a reversible reaction of two dissolved species to form a third specie. Free metal ions in solutions are really aquo complexes, the water itself is a ligand that binds metals, and every complexation reaction in water is effectively aligand-exchange reaction. The reaction of a metal with a ligand can be of an electrostatic or covalent nature or both. Speciation tells the fate of metals in the environment (mineral, redox, or bioavailable).

Particulate material is chemically defined as that material retained on a 0.2 u filter. The dissolved fraction is that portion smaller than 5 rim in size, and the colloidal fraction is between 5.0 um and 0.2 um in size. The EPA definition of particulate material is that material retained on a 0.45 um filter. Therefore, inorganic and organic complexed material will be contained in the dissolved fraction. A large portion of the dissolved nickel in south San Francisco Bay is organically complexed (not bioavailable) and remains in the water column for longer than the resident time of the water mass. Currently, most laboratories that will be affected by the proposed change from total recoverable concentrations will not be able to speciate out the free ions from the inorganic ligands and determine the true toxic concentrations of the metal. For example, at a 10E-9 concentration, free copper becomes toxic to aquatic organisms. A single laboratory using the same analytical method, but different analytical conditions, can have different detection windows which provide different speciation information.

Metals retained in the particulate fraction are available to aquatic organisms during the chemical processes of desorption from suspended particles, resuspension via wind mixing and tidal currents, and interstitial-water transport, In addition, the biological processes of ingestion of sediment or suspended solids (e.g., filter feeders, zooplankton, etc.), direct contact transport, and bioaccumulation through the food chain, provide organisms bioavailable metals which are currently retained in the particulate fraction. Average concentrations of particulates are 0.01 ppm in the deep ocean, 10-400 ppm in San Francisco Bay, 50,000 ppm in turbid estuaries, and up to 80 percent in riverine systems. Metals bound to humic acids (freshwater systems) readily dissociate and do not bind for any length of time. In San Francisco Bay, the various forms of selenium are not in equilibrium (surface sediment, water column) and the routes of exposure are additive.

Since the measurement of metals as total recoverable includes that portion associated with sediments or suspended solids, it provides a more accurate (although conservative) descriptor of metal availability in its toxic form. As previously discussed, metals associated with the particulate fraction are available to aquatic organisms through biological and chemical mechanisms. It is now known that metals associated with particulates do not remain permanently associated with the sediments, but rather are transformed into the free ions and become bioavailable. Therefore, the DFG urge the establishment of metal criteria as a total recoverable measurement, at least for the purpose of developing statewide numeric criteria for priority toxic pollutants.

Response to: CTR-026-004

EPA disagrees with the commenter. EPA believes that the scientific evidence indicates that

particulate-bound metals do not contribute toxicity when suspended in the water column, and do not increase in bioavailability if or when settled into sediment. Consequently, EPA believes that to incorporate total recoverable metal criteria into the rule would be an ineffective use of federal, state, and local resources EPA notes that two expert workshops, one in Annapolis in 1993 (58 FR 32131, June 8, 1993) and one in Pensacola in 1996 (Bergman, H.L. and E.J. Dorward-King (eds.), Reassessment of Metals Criteria for Aquatic Life Protection. SETAC Press. Pensacola, FL.. 1997) were held to discuss this issue. Both workshops recommended that EPA express its criteria as dissolved metal. EPA has found the expert workshop recommendations, with their supporting rationale, to be persuasive.

EPA does not believe that the factual material cited in the comment supports the contention that criteria should be expressed as total recoverable. The information provided in the comment merely indicates that metals exist in both dissolved and particulate forms, and that one can conceive of some potential exposure routes involving particulate metals. However, none of the information provided by the comment suggests that particulate potential exposure routes are in fact actually significant when compared to dissolved metals exposure. Consequently, EPA does not believe that any of the information presented in the comment counterbalances the information provided by the above mentioned workshops, supporting use of dissolved metals criteria.

EPA nevertheless agrees with the comment that not all dissolved metal is bioavailable. For this reason, EPA included the Water-Effect-Ratio (WER) in the equation for criteria in the rule to account for varying site-specific toxicity.

Comment: PROVISIONS OF THE PROPOSED RULE WE SUPPORT

Not withstanding the above comments, we believe there are certain elements of the proposed rule with respect to establishing water quality standards that we can support:

* Metal criteria expressed in the dissolved fraction rather than expressed in the total recoverable fraction.

* Metal criteria that are developed as a function of the water-effect-ratio (WER).

* The current proposed human health criterion for mercury.

* The current preamble language regarding metal translators and mixing zones.

We believe the above provisions provide a more acceptable, scientific approach to the water quality-based pollution control approach. We recommend these provisions of the current rule remain as proposed.

Comment: The Center for Marine Conservation (CMC) is a nationwide, nonprofit advocacy group dedicated to the conservation and enhancement of coastal and ocean life and resources. CMC submits these comments on behalf of its 16,000 members in California and over 120,000 members nationwide.

CMC applauds EPA's efforts to bring California into compliance with the Clean Water Act 303(c)(2)(B). Implementing numeric criteria that will protect the beneficial uses of California's waters is of great importance to the health of coastal and marine ecosystems, and so to CMC and its members. The reliance in many areas of the state on narrative criteria threatens the health of most of the state's waters, thereby impacting both human health and the health of the state's economy that relies on clean water.

While CMC strongly supports the swift adoption of an Enclosed Bays and Estuaries Plan and an Inland Surface Waters Plan that contain numeric criteria for toxic pollutants, CMC also is concerned that many of the specific criteria contained in the proposed rule are weaker than those contained in published guidance. CMC also believes that the proposed rule can better protect certain subpopulations from harm caused by consumption of contaminated fish and shellfish. Finally, CMC is concerned that the economic analysis of the proposed rule over-emphasizes costs and under-reports the many benefits of improving water. quality throughout the state. These three points are reviewed below.

In Light of Significant Threats to Water Quality, the Proposed Rule Should Contain the Most Stringent Criteria That Are Scientifically Defensible

Many of the criteria in the proposed rule are weaker than criteria in current published guidance. The proposed rule summarily states that the difference between the proposed, weaker criteria and the

published guidance documents is "insignificant"(*4); however, in light of the current contamination problems in California's waters today, any move backwards, particularly when spread out over the state, must be viewed as significant.

Any weakening of the criteria should be subject to close scrutiny and the most rigorous analysis, which the proposed rule itself does not do. Among other things, the criteria in the proposed rule may be under protective because additive and synergistic effects were not considered; and because the effects on wildlife, which can be particularly significant for bioaccumulative chemicals, were ignored.(*5) In addition, the proposed rule contains dissolved rather than total recoverable metals criteria, despite the fact that EPA acknowledges that total recoverable metals criteria are "scientifically defensible" and that they are more protective than dissolved metals criteria because they consider "sediment, food-chain effects and other fate-related issues," rather than simply water column impacts.(*6)

Clean Water Act section 303(c)(2)(B) mandates the development of numeric criteria that will "support such designated uses [that are adopted by the State]." The statistics available on the health of the state's waters indicates that their use already is significantly threatened or impaired by toxics. The strongest criteria supportable by science are necessary to reverse this trend and begin to restore the state's waters.

Comment: Regulatory Flexibility and Relief

The District supports EPA's use of "sound science" and current data in developing the proposed criteria in the California Toxics Rule (CTR). The District strongly supports language in the Preamble that references and endorses recommendations of the State Task Forces including use in permitting of:

* reasonable potential analyses * dissolved metals criteria * translators * water effects ratios * site specific objectives * innovative TMDL processes such as effluent trading * performance based interim limits * chronic and acute mixing zones, and * compliance schedules in NPDES permits.

Comment: Second, we commend EPA for its inclusion in the CTR of several innovative and flexible regulatory approaches, such as metals criteria expressed as dissolved rather than total recoverable concentrations, and the revised human health criterion for mercury. In addition, in light of the issues surrounding the human health criteria for arsenic we support EPA's decision not to promulgate human health criteria at this time. With respect to implementation issues discussed in the Preamble, we support EPA's policies and guidance regarding the application of mixing zones and dilution credits. the use of interim permit limits while Total Maximum Daily Loads (TMDLs) and other special studies are being performed, and EPA's guidance to Regional Water Quality Control Boards (RWQCBs) that they may use any of the methods described in EPA's guidance document on the use of translators. We also support EPA's proposal to create a rebuttable presumption for Water Effects Ratios (WERs), allowing the RWQCBs and SWRCB to develop site-specific WERs that can be approved by EPA during the NPDES permit approval process. We believe that this approach will help facilitate the development of appropriate site-specific adjustments for metals criteria.

Comment: pp. 42171-42173 -- Dissolved Metals Criteria We support EPA's policy regarding the expression of criteria for metals as the dissolved fraction, rather than as total recoverable metals. We believe that the dissolved fraction more closely approximates the fraction that is bioavailable, and that metals criteria expressed as total recoverable are usually overprotective. We request that EPA include guidance to the State in the Preamble such that, if the State wishes to adopt metals criteria in the total recoverable form, the State must demonstrate, for the particular water bodies, why the total recoverable form is necessary to protect the aquatic resources.

Comment: I . APPLYING DISSOLVED METALS CRITERIA AS PROPOSED VIOLATES THE ANTIDEGRADATION POLICY FOR SAN FRANCISCO BAY AND OTHER WATERS OF THE STATE

The practical effect of EPA's decision to rely on dissolved metals criteria is to allow higher levels of total recoverable metals to be discharged from point sources into San Francisco Bay as well as other waters of the State. Since 1991, many permits in the Bay area and else where have been issued applying the State Water Resources Control Board's technically-based and EPA approved numeric criteria for numerous toxic pollutants. For at least three years, permits throughout the State were required to be issued using the duly-promulgated criteria established by the State Water Resources Control Board ("SWRCB"). After the Sacramento court vacated the criteria on economic grounds, numerous permitting decisions were made by local regional boards and their staffs applying the previously applicable standards using

their best professional judgement ("BPJ") in order to assure the protection of beneficial uses. Each of the permitting decisions based directly or deferentially on the SWRCB's criteria would be more stringent than permits for the same parameters authorized by EPA's proposed rule where a discharger opts to follow the Water Effects Ratio protocol for translating the criteria into a permit limit. BayKeeper would not anticipate that many, if any, dischargers will opt for the default WER of 1.0. Thus, for many regulated dischargers, EPA's proposal will lead to major increases in the total metals they are allowed to discharge into the Bay and other waters of the State. This massive increase in the total pollution proposed to be allowed to be discharged into the Bay and other State waters is completely inconsistent with the State's and EPA's antidegradation policies mandating that existing water quality be maintained and protected. As the State's policy sets forth:

Whenever the existing quality of water is better than the quality established in policies as of the date on which such policies become effective, such existing high quality will be maintained until it has been demonstrated to the State that any change will be consistent with maximum benefit to the people of the State, will not unreasonably affect present and anticipated beneficial use of such water and will not result in water quality less than that prescribed in the policies.

SWRCB Resolution No. 68-16. Under the federal version of the policy:

[w]here the quality of the waters exceed levels necessary to support propagation of fish, shellfish, and wildlife and recreation in and on the water, that quality shall be maintained and protected unless the State finds, after full satisfaction of the intergovernmental coordination and public participation provisions of the State's continuing planning process, that allowing lower water quality is necessary to accommodate important economic or social development.

40 C.F.R. 131.12(a)(2). The antidegradation policies apply both to permit decisions as well as decisions establishing water quality standards. See, e.g., In The Matter of the Petition of Remmon C. Fay, SWRCB Order No. WQ 86-17 (Nov. 20, 1986). In the case of EPA's proposed rule, throughout California the rule, if adopted, will allow more pollution to be discharged than is currently allowed by permits validly issued to numerous dischargers throughout the State without any consideration of the policies, including the intergovernmental coordination and public participation requirements, required by the antidegradation policies.

Of course, in addition to that procedural problem, BayKeeper is opposed to the proposed reliance on dissolved numbers, especially in the Bay area, because it will in fact allow more pollution to be discharged into the State's waters than is currently allowed today and likely will prove detrimental to beneficial uses. See Comments of Communities For A Better Environment. BayKeeper also is very concerned about the burdens and uncertainty placed on the public by the need for translators in order to apply the dissolved criteria in permit limits that must be based on total recoverable numbers. As noted above, BayKeeper does not anticipate that many dischargers will opt for EPA's proposed WER default of 1.0 BayKeeper views this proposal as an invitation for dischargers to prepare site-specific limitations based on their own studies which will frustrate the public' s ability to participate effectively in the formulation of effluent limits. Further, the proposal will present a moving target for the public to understand and will burden the resources of regional board staff to a degree that may undermine the quality of those site by site determinations.

Response to: CTR-039-003a

EPA does not agree that the criteria adopted by the rule in any way violate antidegradation policies. State and federal antidegradation requirements must still be met. EPA believes that the commenter may

have confused antidegradation concerns with anti-backsliding concerns. Anti-backsliding is a permit issue, not a water quality standards regulatory issue.

EPA also does not agree that use of dissolved metals will prove detrimental to beneficial uses. The commenter provides no evidence to support its assertion, and EPA is not aware of such evidence. EPA acknowledges that the complexity of metals criteria application, which stems from the problem that the same concentration of a metal yields different toxicity in different waters, makes it more difficult for non-experts to understand and participate in the formulation of effluent limits. However, EPA believes that incorporation of the dissolved provision and the water-effect ratio provision is necessary for defense of the scientific validity of most of the metals criteria.

Comment: The District's comments on the proposed CTR are as follows:

1. Items Generally Supported by the District

The District supports a number of the provisions of the proposed rule. That support, however, varies from strong in some cases to a level of grave reservations in other cases. First, the District strongly supports the use of dissolved metals criteria rather than the use of total recoverable metals criteria. The continued use of the dissolved metals approach is a prime example of making a good recommendation based not only on the most recent sound scientific data, but also on the results of both intense national public input and court decisions.

Response to: CTR-041-002

Comment: 2. Additional Strong Reasons to Maintain use of Dissolved Metals and Mercury Criteria

The District also has significant economic reasons to support the use of dissolved metals and the updated mercury criteria. Previous District studies have shown that adoption of metal criterion as total recoverable would cost the District more than $50 million a year while reducing metal loads in the Sacramento River by several percent. Likewise, if old mercury criteria were adopted it would cost the District over $100 million a year while reducing mercury loads in the Sacramento River by several percent.

Response to: CTR-041-007b

EPA acknowledges the commenter's support.

Comment: 6. The CTR should maintain many of the proposed provisions relating to metals criteria.

Caltrans supports the EPA's decision to include metals criteria expressed as dissolved instead of total recoverable; the development of metals criteria as a function of the Water Effect Ratio (WER); the current proposed human health criterion for mercury; and the use of metals translators and mixing zones. Caltrans is of the opinion that these provisions reflect a more sound scientific approach to regulating metals.

Request: Caltrans requests that the provisions described in the preceding paragraph be maintained in the final draft of the CTR.

Response to: CTR-042-006

EPA agrees with the comment and has maintained the provisions.

Comment: We have reviewed the proposed CTR and offer the following comments:

2. The following provisions of the rule are supported:

(1) adoption of metals criteria as dissolved concentrations;

(2) expression of the metals criteria as a function of the water-effect ratio;

(3) adoption of the proposed new human health criteria for mercury; and

(4) the Preamble discussions regarding metals translators, mixing zones, and interim permit limits.

Were the old human health criterion for mercury (0.012 ug/ l) to be adopted, the City would have to remove its discharge from Tule Canal and go to land disposal. The capital cost to do this would be $22.1 million and the total present worth cost would be $23.1 million (see Exhibit B, Required Capital

improvements and Costs for Beryllium and Mercury). This would translate to an annual cost of $3.1 million per year (at 7% over 10 years) and would require that monthly sewer service charges be increased by more than 100%.

Response to: CTR-044-003a

EPA acknowledges the commenter's support.

Comment: BADA supports adoption of the metals criteria as dissolved concentrations and the expression of the criteria as a function of the water-effect ratio. These changes place the metals criteria on a firmer scientific base than the old State Plans. Moreover, previous BADA studies have shown that adoption of the copper criterion as total recoverable could cost Bay Area POTWs several billion dollars while reducing copper loads to the Bay by only several percent (see Attachment 1). Further, building the water-effect ratio into the criteria will lessen the administrative burden on all parties when it becomes necessary to pursue the development of such a ratio. For these reasons, it would not be in the public interest nor consistent with Presidential Order 12866 or the Unfunded Mandates Reform Act to adopt the metals criteria as total recoverable concentrations or to require approval of a site-specific objective whenever a water-effect ratio is developed.

Response to: CTR-054-002a

EPA acknowledges the commenter's support for the use of dissolved metals criteria.

Comment: Metals

We support the EPA's intention to adopt metals criteria that are based on dissolved, rather than total recoverable, fractions in the water column. This provision clears up an issue that seemed straight forward but intractable only a few years ago. This provision will also allow the State to make decisions regarding the use of dissolved or total recoverable on a waterbody-specific basis, which we view as appropriate. The City also supports the proposed Rule with respect to applications of the water effect ratio and metal-translator provision (metal-specific partitioning), even though we do not see an immediate application of the latter with respect to our facilities.

Comment: 2. Dissolved Criteria for Metals. WSPA supports the use of metals criteria based on the dissolved species.

EPA has reviewed the science in this area carefully over the past several years and rightly concluded that dissolved species best reflect the bioavailability of heavy metals in the aquatic environment. That is, metals species which are not available or reactive to aquatic life should not be regulated as toxics. This proposed rule is consistent with EPA's thorough review of this issue.

WSPA believes that EPA will follow this approach in assessing whether waters of the state meet water quality standards based on these criteria. That is, the waters should be judged based on the presence of dissolved or bioavailable metals, not total metals.

Comment: [INDENT]USE OF DISSOLVED CONCENTRATIONS OF METALS WILL UNDERESTIMATE IMPACTS

EHC does not support the use of dissolved concentrations for metals criteria as it will lead to significant underestimation of levels of contamination. Metals in sediments can be bioavailable or could become bioavailable in the future. EHC recommends the use of total recoverable metals as the appropriate basis for metals.

Response to: CTR-065-005

EPA does not agree. See response to CTR-026-004. EPA does not know of any scientific evidence that indicates that metals loading at the criteria levels would eventually or ultimately yield sediment contamination problems. In addition, EPA does not believe that use of total recoverable metals criteria is an effective or appropriate method for protecting sediments from contamination. Instead of basing metals criteria on total recoverable measurements, EPA is proceeding with the development of Equilibrium Partitioning Sediment Guidelines (ESGs) in order to protect sediments, the contamination of which would generally be related to elevated historical loads rather than to the loads allowed after implementation of this rule. EPA has not found the use of total metal concentrations in sediment to be useful or reliable for expressing ESGs. Rather, EPA has used a measure of the sediment's metal enrichment compared against its metal binding (or detoxifying) capacity. EPA's ESGs ensure that there will not be bioavailable metals by determining that the total extractable metal does not exceed total acid

sulfide concentration in the sediment. The ESGs protect against chronic toxicity to benthic organisms from metals in sediment, and can include effects from exposure through pore water and exposure from ingesting sediment.

Comment: * The proposed metals limits appear to conflict with our current NPDES permit. This will raise questions of our ability to meet the less stringent standards proposed in the CTR. We assume that these new criteria are more scientifically based than four years ago when we negotiated our NPDES permit. Added treatment will surely be required for the four areas of concern we see in the CTR.

Response to: CTR-066-019

EPA acknowledges the concerns about whether the Sanitation District can attain the criteria without added treatment; however, the commenter does not provide EPA with any evidence to support its contentions.

Comment: * OVSD supports EPA's proposed adoption of criteria for metals expressed as the dissolved fraction rather than as total recoverable metals. OVSD recommends that EPA provide guidance to the State in the Preamble to the CTR stating that the State should also use the dissolved form for metals unless it has been demonstrated that the total recoverable form is necessary to protect aquatic resources in a particular water body. This is extremely important because OVSD's current NPDES permit specifies limits for total recoverable metals.

Response to: CTR-067-002

See response to CTR-034-008. Note also that permit limits, per 40 CFR 122.45, must still be expressed in terms of total recoverable metal. When derived from a receiving-water dissolved criterion, total recoverable permit limits are calculated by accounting for the fraction of effluent metal that is or becomes dissolved after discharge.

Comment: Dissolved Criteria for Metals

We support the approach that waters should be judged based on the presence of dissolved or bioavailable metals, not total metals, and therefore agree with EPA's conclusion that metals species which are not available or reactive to aquatic life should not be regulated as toxics. We support the use of this approach in assessing whether waters of the state meet water quality standards based on these dissolved species criteria.

Thank you for your consideration of our comments. We look forward to working with EPA and the state in conjunction with the implementation phase of the California Toxics Rule to ensure a well balanced,

feasible and scientifically sound water quality program.

Response to: CTR-077-003

Comment: The draft California Toxics Rule (CTR) is clearly the product of substantial effort by USEPA staff, and we applaud this effort and its intent. On several issues of concern to public utilities, the CTR strikes a good balance between the need to promulgate standards and the need to base those standards on sound science. Examples include the use of dissolved concentrations rather than the total recoverable concentrations for metals, the deferral of human health criteria for arsenic until adequate information is available, and the revision of the human health criterion for mercury. We are also pleased with the CTR's guidance and flexibility, on mixing zones and dilution credits, total maximum daily loads (TMDLs), compliance schedules, and translators.

Comment: There are many features of the proposed rule which we strongly endorse, specifically:

* the use of the latest IRIS values for human health criteria, it is essential that the criteria be based on the latest scientific and environmental information;

* recognition that the dissolved fraction of metals, rather than the total recoverable, better reflect the aquatic toxicity of metals;

* recognition that for certain metals (e.g. copper and zinc) ambient water chemistry is critical in determining toxicity thereby endorsing the Water Effects Ratio;

* recognition and strong endorsement of the multi-tiered mixing zones for acute, chronic and human health effects; and

* recognition of interim limits and compliance schedules as appropriate implementation strategies,

Comment: Dissolved Metals Criteria

The City supports the promulgation of dissolved concentration criteria for priority pollutant metals. Dissolved metal more closely approximates the bioavailable fraction, and thus toxicity, of metal in the water column than does total recoverable metal. The City believes there may be specific instances whereby risk management decisions (sediment resuspension, bioconcentration, food web issues) could result in scientifically defensible criteria based upon the total recoverable fraction. The City recommends, that any such decision be established with relevant data, sound science, peer review, and involve active public participation.

Response to: CTR-092-002

EPA agrees with the comment.

Comment: Particularly in regards to the Bay Area, we are concerned with the EPA's reliance on dissolved numbers, on using a dissolved number for the criteria, and believe that total recoverable would be a more appropriate standard to use.

Total recoverable as proposed, from our initial review, it seems to us that we're going to end up with a lot of existing dischargers that will in fact be allowed to discharge more into the bay, where most, or at least first blush looking at it, most of the metals detected in the bay are present in the dissolved stage, probably attached to sediment, which are a large amount of what's in the bay. It seems that these sediments will disattach themselves and then become dissolved some day.

It seems to me this doesn't take a look at the whole picture, and that is basically carving it off. And it seems to me that the process that led to that wasn't one that was available to all of us to discuss.

It was driven by a case in D.C. and some policy decisions made in Washington, D.C., where here all the permits, of course, are total recoverable units. All of the standards to date that have -- that exist or have been proposed are total recoverable.

Comment: 1. It is the District's understanding that where sediments exceed the CTR's water quality criteria, the sediment could not be put to a beneficial use after dredging. If this is indeed the case, the District would request that some allowance be given to allow dredged sediments to be put to beneficial use.

Response to: CTR-007-002

The purpose of this rule is to establish numeric criteria for those navigable waters in California that do not have water quality criteria for priority toxic pollutants in place and for which EPA has issued section 304 (a) criteria guidance. Specific implementation procedures regarding the disposal and application of dredged sediments are beyond the scope of the rule. The final CTR does not impact California's ability to designate specific uses, including sub-category of uses that allow for disposal of dredged sediments (e.g., artificial wetlands).

Furthermore, EPA notes that through the state 401 certification process, California would determine whether or not disposal of sediments in a particular instance is consistent with the ambient criteria established in the CTR. In addition, any existing State guidelines for approving beneficial reuse of dredged sediments remain in effect.

Comment: A substantial portion of the membership of the Coalition represent the maritime industry which consists of the six public port authorities and one private port, several vessel carriers, dredging contractor companies, maritime trade unions, shippers, and pilots. The industry is dependent on a safe and navigable waterway system maintained by regular dredging so essential to sustain the Bay as an

international center for trade and commerce.

Dredging applicants must apply for permit approval to dredge and dispose of channel sediment from the federal and state dredging regulatory agencies and are required to evaluate the dredged material to be disposed using a suite of chemical, physical and biological tests. The tests we conduct are very expensive. Due to the high cost, uncertainty and inconclusivity of the test results, essential navigation dredging is often delayed at tremendous expense to the Bay public at large.

Numeric Standards for Pollutants as Applied to Dredged Sediment Physical and Chemical Tests

Our primary concern is what effect will the new water quality standards have on the number of and cost for the sediment physical and chemical tests required for dredging permit approval. Will the Toxics Rule standards alter the current protocol contained in jointly signed Public Notice 93-2 entitled, "Testing Guidelines for Dredged Material Disposal at San Francisco Bay Sites"? We have asked the Sediment Management Unit of EPA and the Dredging Regulatory Unit at the S. F. Bay Regional Water Quality Control Board for an assessment of the effect of the Toxics Rule on the current dredging protocol, and we are waiting for a response from them.

We acknowledge that it is the combined results from all tests for dredging (chemical, physical, and biological) which comprise the overall evaluation of potential sediment toxicity and hence acceptability for discharge at unrestricted or restricted disposal sites. In fact the Testing Guidelines indicate that it is the bioassay responses, as indicators of potential toxicity, that will determine the effect of a proposed discharge of dredged material on the receiving aquatic ecosystem, and that the chemistry standards will not be used as pass/fail standards. However, the Guidelines state in the Response to Comments section that, "however, depending on the contaminants of concern and other factors, elevated chemistry could independently indicate the need for more that the routine Tier II testing..." Thus if the water quality standards become more restrictive, then dredging applicants may have to spend more money to conduct more tests.

Further, we are uncertain as to the environmental relevancy of potential lower water quality standards as they may be applied to dredging discharges because there are often false-positive test results between the chemical and biological tests.

Response to: CTR-077-001

See response to CTR-007-002.

The final CTR does not trigger any additional testing of dredged material. The results of any existing testing requirements may be compared to criteria contained in the CTR, but the CTR itself does not address when sediments need to be tested or specify what constituents need to be tested for.

Even under the 404 guidelines, failing WQC does not in itself trigger any additional testing requirements. The process of evaluating dredged material for proposed open water disposal first involves bulk sediment chemistry analysis (required under 404 guidelines for several purposes) and comparison to any applicable numeric criteria (assuming 100% solubility). To evaluate whether or not narrative criteria (e.g., "no toxics in toxic amounts") are met, the elutriate is subjected to standard bioassays (following allowable dilution) regardless of whether or not there are applicable numeric criteria. In the rare instance that the chemistry is projected to exceed a numeric criterion and an elutriate bioassay is passed, additional elutriate chemistry may be required to confirm the numeric criterion failure. But the need for additional chemical evaluation is independent of the criteria used to compare the results. EPA believes there is no

reason to expect more frequent false positives when comparing elutriate chemistry results to CTR criteria than the criteria previously adopted by California.

Furthermore, EPA notes that through the state 401 certification process, California would determine whether or not disposal of sediments in a particular instance is consistent with the ambient criteria established in the CTR. In addition, any existing State guidelines for approving beneficial reuse of dredged sediments remain in effect.

Comment: MR. McGRATH: Good afternoon. My name is Jim McGrath, Environmental Manager for the Port of Oakland. I'm going to testify about a fairly narrow application of the CTR, one not considered and one I think you need to.

The Port of Oakland has built a facility for removal of dredge material from the marine environment. At completion of dredging of about 1 million cubic yards of contaminated sediment, it's pumped into that facility and dried.

The facility has been constructed as a series of ponds, which physically settle the material but do not provide for treatment. The removals in that facility have ranged about 99.98 percent removal or a little better, depending on how it's being operated.

I think the bottom line for it is the permits in terms of the CTR. The standards that were used for discharge from this facility were those of the basin regional board at the time -- in effect at the time. This rule is dangerous due to the limits contained in the CTR, and the nature of the CTR would prevent that operation.

Our discharge limit is 20 parts per million. The CTR would lower that to 3.1 parts per billion. That cannot be met settling fine grain dredge material, clean or dirty, without treatment.

Thus the application of this rule might prevent not only the Galbraith operation, which is intended to and is effectively removing material presently from the marine environment, but could also prevent beneficial use of dredge material that involved a return discharge to the bay. That includes such projects by the Environmental Protection Agency as Sonoma Baylands, already built, and other projects under consideration.

Now, how does that come about? I think the problem is that the rule has been developed under a conceptual mode of input-output. Stuff comes into the bay; it goes out of the bay.

The real world and the real physics is a little more complicated than that. This gets stored in sediment. We dredge -- we in the maritime industry dredge a small amount of what is stored by the dynamic of the contaminant movement in the water column to the sediment bed and back again. That's substantially more complicated than that. Worse than that, the blinders have been put on by the input-output concept, and the thinking is one of a steady state of input-output.

And the rule doesn't contemplate transient impact due to cleanups of some sort and we're particularly concerned about -- that sediment cleanups and resource enhancement don't fit into the conceptual model used to come up with this rule.

So that's the problem. There is -- there are many different ways to deal with that problem. The waiver or variance process could be expanded to allow special consideration of cleanups or resource enhancement projects. You could apply the risk based on overall project management. I'm sure there are opportunities beyond that.

I want to propose a hypothetical problem in the rule: that a literal application would require for sediment cleanups, physical treatment. Under the Clean Water Act, the standard on dredge material is practicability, and you've got two different regulatory approaches.

If you're talking about cleanup of the sediment in the marine environment, feasibility is an element. And I can tell you from experience, very little contaminated sediment will be dredged if physical treatment rather than settling is going to be required.

Comment: I'm Ellen Johnck, director of the Bay Planning Coalition, a San Francisco Bay planning coalition organization, a membership organization of about 200 members that reflect the maritime industry, shoreline business and industry, several small and large property owners, recreational use and local governments and many counties and cities.

I am here today because I want EPA to understand the far-reaching effect of this particular California Toxics Rule on the broad range of recreational, commercial and environmental uses and users here in the estuary.

One of the major things that we have seen with this California Toxics Rule is that it affects our

international commerce and our trade, which is totally dependent on the navigation channel. We have to dredge about 4 to 5 million cubic yards of material each year from the channel in order to support the Bay's trade and economy.

What this rule will affect will be our terrific program that was initiated in the last several years to try to expand the reuse of dredge material for environmentalpurposes.

In corroborating Mr. McGrath's statements for the Port of Oakland, we discovered that our whole program to restore wetlands of the bay with dredge material actually will not be able to happen because of discharge limits, because the standard could not be met.

And we frankly think that the Environmental Protection Agency needs to look at the whole numeric criteria and how it was devised. It really is not as scientific as that could be, as we look at interaction with the Bay and the properties of the metals attached to it as sediment, therefore, making these metals not necessarily available and having an environmental effect.

So I think my point, number one, is that this -- and I really don't think EPA wants to deter the environment reuse of dredge material -- it will be exceeding the numeric criteria particularly for copper and will deter the environmental reuse of dredge material.

Comment: II. THE EPA PROPOSALS WILL NOT PROTECT FISHING AND OTHER USES OF SAN FRANCISCO BAY WATERS OR PROVIDE EQUAL PROTECTION FOR PEOPLE OF COLOR.

A. The criteria allow more pollution than prior technically-based criteria.

The proposed criteria would replace criteria found to be scientifically sound by the State Water Resources Control Board staff, adopted by the state, and approved by EPA, for San Francisco Bay in the 1991 California Bays and Estuaries Plan,(*10) the 1986 San Francisco Bay Basin Plan,(*11) and the Basin Plan amendment adopting the 1992 Site Specific Copper Objective for San Francisco Bay.(*12) Table I compares the lowest concentration criteria for the 64 toxic pollutants identified by the San Francisco Estuary Project as "pollutants of concern" for the Bay.(*13) The EPA criteria proposal:

*weakens environmental health protection for 37 of these 64 toxic pollutants (58%). It allows greater ambient water concentrations for 30 pollutants, includes new extremely liberal criteria for 4 of the 64 pollutants, and fails to replace previous state criteria for 3 pollutants,

*makes no change for 24 of these 64 pollutants (37%). It includes equivalent criteria for 6 pollutants, and includes no criteria for 18 pollutants which had no state-adopted criteria.

*improves criteria for only 3 of the 64 pollutants (5%). It includes new restrictive criteria for 2 pollutants, and proposes a criterion allowing 200,000 instead of 300,000 ug/L toluene.

The magnitude of increased pollutant concentrations allowed in Bay waters by EPA'S proposal is estimated in Table 2. The first column in this table lists all the toxic pollutants for which EPA proposes more liberal criteria than those adopted by California for the Bay. Footnotes to this column further describe these pollutants. For example: dioxin includes 17 dioxin-like compounds included in the state criterion and current permit limits; and PAH includes the sum of 13 polycyclic aromatic hydrocarbons included in the state's PAH criterion and 8 of these compounds for which EPA proposes criteria.

The second column in Table 2 shows the lowest concentration criteria adopted by California for these pollutants in the Bay, with footnotes indicating the source of these criteria and whether they address human health or aquatic life. The third column shows the corresponding lowest concentration criteria for these pollutants proposed by EPA. Where the EPA-proposed criteria are expressed differently from the state criteria for a pollutant, calculations that more accurately compare the criteria are shown in footnote j to this column. These calculations fall into three general cases:

*Dioxin comparisons - California's dioxin criterion applies to 17 internationally recognized dioxin-like compounds, while EPA's proposal
applies to I only, 2,3,7,8-TCDD. EPA'S chief dioxin scientist and other international experts estimate that the other dioxins account for about 90% of environmental dioxin toxicity.(*14) Thus, EPA's criteria value was multiplied by 10 to estimate the toxicity from California criteria dioxins at EPA's 2,3,7,8-TCDD value of 1,4 pg/IOOL. New data may change the 90% estimate, but not the finding that EPA's proposal is weaker.

*PAH comparisons - California's PAH criterion sums the amounts of 13 compounds, while EPA proposes individual criteria for only 8 of these 13 compounds. EPA criteria values for these 8 compounds were summed for comparison to California's 13-compound criterion. This approach underestimates the amount of PAH allowed by EPA's criteria by assuming a value of zero for each of the 5 compounds which lack EPA-proposed criteria.

*Total versus dissolved metals comparisons - California metals criteria are expressed as total metal while EPA's proposals are often expressed as dissolved metal. Ultra-clean measurements of Bay waters in 1989,(*15) and 1995 (arsenic and chromium)(*3) indicate that total concentrations are often much greater than dissolved concentrations for the same metal, For example, in 5% of Bay samples total copper is at least 3.5 times dissolved copper. At these times dissolved copper levels equal to EPA's 3.1 ug/L criterion correspond to total copper levels of 10.8 ug/L or greater. Ratios for other metals based on this 5% (95th percentile) analysis, which is used by EPA to prevent excursions above criteria more than once in 3 years, are shown in footnote (*j). Analysis of additional data may alter these ratios, but will not change the conclusion that EPA'S proposed dissolved criteria will allow greater water concentrations than total metal criteria.

The estimated magnitude of increased pollutant concentrations allowed in Bay waters by EPA's proposed criteria is shown in the right-hand column of Table 2. EPA's proposal allows 430 million percent more PAH, 23,600% more lead, 3,900% more 1,4-dichlorobenzene, 910% more silver, 900% more dioxin, 630% more chlordane, 340% more DDT, 325% more mercury, 140% more PCBs and 120% more copper in the Bay as compared to state-adopted criteria, based on these estimates. Review of Table 2 also shows that allowable Bay water concentrations would double or more for 18 toxic pollutants in all.

In sum, comparison with the state criteria that would be replaced indicates that EPA's proposed criteria allow increased toxic pollution of San Francisco Bay by at least 37 toxic pollutants representing 58% of the pollutants of concern identified by the San Francisco Estuary Project, allow pollution to increase by about 1,000% or more for extremely toxic pollutants such as dioxin and PAH, and allow pollution to double or worse for 18 toxics including nearly all pollutants known to be of greatest concern in the Bay.

None of the state criteria which the EPA proposals are compared to were set aside because they are scientifically invalid, Rather, some of these criteria, which were adopted in the 1991 Bays and Estuaries Plan, were set aside by a state court on procedural grounds only,(*12) and still form the basis for permit limits written by the state for the Bay.(*21) EPA's proposed criteria allow toxic pollutant concentrations greater than those found by the state to be scientifically appropriate for protection of aquatic life and public health.

Response to: CTR-002-003

Overall, EPA disagrees with this comment, which alleges that the CTR "weakens environmental health" for 37 of 64 "pollutants of concern."

Much of the premise for this comment is flawed, because it compares CTR ambient criteria with State and San Francisco Bay Regional Board criteria which are not in effect. The 1991 California Enclosed Bays and Estuaries Plan (EBEP) was rescinded by the State Water Resources Control Board. [Note: California's 1991 Inland Surface Water Plan (ISWP) was rescinded at the same time. Since this comment does not compare CTR criteria to ISWP criteria, however, this response does not address the ISWP.] The State Board returned the 1992 site-specific copper objective for San Francisco Bay to the Regional Board, and it has never taken effect. EPA is now promulgating the CTR to put criteria in place in California where currently there are no applicable EPA-approved criteria in effect, including where criteria were affected by these State actions. The CTR criteria do not revise or replace those State

criteria, because those criteria simply do not exist for CWA purposes.

The commenter also compares CTR criteria to criteria in the 1986 San Francisco Bay Basin Plan. For waters where the criteria that were included in the 1986 amendments to the Water Quality Control Plan for the San Francisco Bay Region (the Basin Plan) and were approved by EPA are still in effect under the 1995 Basin Plan amendments, EPA is not promulgating CTR criteria. The 1986 criteria will therefore remain in effect for those waters. (See response to CTR-016-001.) For those criteria, the commenter's concerns have been addressed.

Another flaw in this comment is that CTR criteria are evaluated for 64 "pollutants of concern" which were identified by the San Francisco Estuary Project. While most of these pollutants are priority pollutants subject to the requirements of CWA section 303(c)(2)(B), 17 are not. The CTR is limited to the promulgation of numeric water quality criteria for priority pollutants, to fully implement section 303(c)(2)(B) in California. It is beyond the scope of the CTR to include other pollutants, even if they are pollutants of concern for the Bay. The commenter may seek to have the State, through its Regional Board, address the possibility of adopting or revising criteria for those non-priority pollutants through its triennial review process, but that approach would not affect the CTR.

With those general observations, EPA responds as follows to the following specific concerns included in this comment:

A. The CTR allows "greater ambient water concentrations" for 30 pollutants

The commenter's discussion of this concern is confusing because only 24 specific pollutants are identified by the commenter (in its Table 2) for this concern, and footnotes for 6 of these indicate that these 6 actually represent enough additional pollutants to make the total number of individual pollutants greater than 30. EPA is responding, therefore, based on the 24 pollutants identified in Table 2.

EPA is "promulgating around" several of these pollutants for those waters of San Francisco Bay where State-adopted, EPA-approved criteria from the 1986 Basin Plan remain in effect, as discussed above. For those waters of San Francisco Bay where EPA is promulgating these 24 criteria, however, EPA agrees that 10 of the 24 CTR criteria in Table 2 (all of the Table 2 criteria, with the exception of nine metals, DDT, endrin, endosulfan, PAHs and dioxins, which are discussed below) would allow greater ambient concentrations than the EBEP criteria would have allowed if it was presently in effect. These CTR criteria, however, are based on sound science, which supports a finding that these criteria are fully protective of the designated uses listed in the CTR. For some criteria, the CTR criteria are based on additional scientific data developed not only since those State criteria were first proposed, but in some cases since the National Toxics Rule (NTR) was adopted by EPA in 1992. The new data further supports the conclusion that the CTR criteria are fully protective of designated uses listed in the CTR. The scientific bases for all of the CTR criteria are set forth in the California Toxics Rule Administrative Record Matrix. See also, National Recommended Water Quality Criteria, 63 Fed.Reg. 68354, December 10, 1998, as corrected, 64 Fed.Reg. 19781, April 22, 1999.

EPA disagrees with the commenter's contention that the CTR will allow increased concentrations of metals in San Francisco Bay. First, EPA notes that the CTR does not include criteria for most metals in much of the San Francisco Bay. Most of the metals criteria in the 1986 Basin Plan (which includes all of the commenter's nine metals, except copper), that were approved by EPA, remain in effect, therefore ambient concentrations for those metals criteria are not affected by the CTR. EPA is, however, promulgating metals criteria for the South Bay (below Dumbarton Bridge) and a saltwater aquatic life copper criterion for waters of the Bay with salinities greater than 5 ppt, because there are no comparable

Basin Plan criteria for those pollutants presently in effect. Since the CTR does include these metals criteria for these waters of San Francisco Bay, EPA has considered the commenter's comparison of ambient concentrations for pollutants in the Bay, which the commenter predicts will result from application of the different metals criteria, and EPA disagrees with those comparisons.

The commenter has compared CTR metals criteria, which are expressed as dissolved metals, with EBEP and copper site-specific criteria, which were expressed as total recoverable metals, by performing a calculation (the "5% analysis") on the CTR metals criteria prior to comparing them with EBEP metals criteria. This is not a recognized basis for comparison between dissolved and total recoverable metals criteria, however, and it is not adequately explained or supported. EPA therefore cannot accept the results of this analysis, which yields greatly exaggerated concentrations of the CTR metals criteria. EPA does not propose an alternative basis for a general comparison between dissolved and total recoverable metals, because the relationship between the two forms of metal varies depending on site-specific and time-specific conditions (which the State must address through the use of translators when implementing the criteria). Instead, EPA relies on sound scientific information which supports the conclusion that the CTR dissolved metals criteria are themselves protective of the designated uses that they are adopted to protect (see the California Toxics Rule Administrative Record Matrix). See also, National Recommended Water Quality Criteria, 63 Fed.Reg. 68354, December 10, 1998, as corrected, 64 Fed.Reg. 19781, April 22, 1999.

EPA also disagrees with the commenter's comparison between CTR criteria and four other EBEP criteria. The commenter compared sums of individual CTR criteria concentrations and compared them with "single" EBEP criteria. The four single EBEP criteria, however, represent four pollutant groups that the State created by combining individual pollutants into groups under the four pollutant names. (The EBEP groups are "DDT", "Endrin", "Endosulfan" and "PAHs".) The CTR, on the other hand, includes individual pollutants without grouping them. The commenter added the concentrations for individual CTR criteria for each of the 4 EBEP criteria groups and compared the sums with the single concentrations for each of the 4 EBEP criteria. This approach resulted in some very questionable comparisons.

For the DDT group, the CTR human health criteria for DDT, DDE and DDD are 0.59 ng/L, 0.59 ng/L and 0.83 ng/L, respectively. The sum of these criteria would be 2.01 (rounded to 2) ng/L, not 2.6 ng/L as the commenter contends. For the PAH group, the sum of the CTR's eight individual criteria would be 392 ng/L, not 135,000,000 ng/L as the commenter contends. For the Endrin group, the commenter has ignored applicable CTR aquatic life criteria. These aquatic life criteria are significantly more stringent than the CTR human health criteria which the commenter used as the sole basis for comparison. Had the commenter compared the EBEP human health criterion for Endrin to the sum of the appropriate CTR criteria for Endrin and Endrin Aldehyde (using the CTR's chronic saltwater aquatic life number for Eldrin and the human health fish consumption number for Endrin Aldehyde), the figures would have shown the CTR to be equivalent to the EBEP criterion, not less stringent.

Notwithstanding these errors, the commenter's approach is simply not a basis for revising the CTR criteria for pollutants in these four groups. As stated above, the comparisons are made to State criteria which are no longer in effect. The CTR is promulgated to put criteria in place where there presently are no State-adopted EPA-approved criteria in effect. The CTR is promulgated to meet the requirements of CWA section 303(c)(2)(B), which requires adoption of numeric criteria only for those toxic pollutants listed pursuant to section 307(a)(1) for which EPA has already adopted section 304(a) criteria. EPA has adopted section 304(a) criteria for the individual pollutants, not for the pollutant groups. As stated in the preamble to the proposed CTR and in response to CTR-016-002, EPA will work with the State to approve acceptable State-adopted criteria and intends to stay the CTR when EPA approves such criteria.

The commenter includes a further concern regarding polynuclear aromatic hydrocarbons (PAHs), which is one of these four pollutant groups. The commenter alleges that the CTR includes criteria for eight of the 13 PAHs which are included in the single EBEP criterion for PAHs, and omits the other five. This is not entirely correct. (Even if it were correct, it would not alter the fact that comparing the sum of eight PAHs to a single PAH criterion is invalid.) Of the five pollutants which the commenter alleges are omitted from the CTR, two are, in fact, included in the CTR, but under slightly different names. (Benzo(a)Anthracene (CAS number 56553) and benzo(b)Flouranthene (CAS number 205992) replace the EBEP's 1,2-benzanthracene and 3,4-benzoflouranthene, respectively. The CTR and the EBEP used different naming conventions, but the pollutants are the same chemicals.) It is true, however, that the CTR does not include numeric criteria for three of the 13 PAHs. As discussed in part C and D, below, acenaphthylene, phenanthrene and benz(ghi)perylene are no longer considered carcinogens, and EPA has not developed criteria levels for these toxic pollutants as non-carcinogens. In the absence of such guidance, numeric criteria for these three pollutants are not included in the CTR. [Note: benzo(ghi)Perylene (CAS number 191242) also is the same as one of the EBEP's PAHs (1,12-benzoperylene), but with a different name.] The CTR is consistent with the NTR (40 CFR 131.36 (b)(1)) in regard to all of the PAHs.

It should be further noted that for much of San Francisco Bay, the applicable Basin Plan includes a single criterion for PAHs comparable to the EBEP PAHs criterion, which EPA has previously approved. To the extent that the Basin Plan criterion may be more stringent than the CTR objectives for individual PAHs, it would take precedence over the CTR criteria as a basis for controlling PAHs in the part of the Bay where it applies.

The remaining pollutant among the 24 is "dioxin". The commenter has multiplied the single CTR dioxin criterion by 10 before comparing it with the single EBEP dioxin criterion. The commenter multiplied the CTR criterion for 2,3,7,8-TCDD "to account for...16 other dioxins" before comparing it with the EBEP criterion for "TCDD equivalents". The commenter then concluded that EPA was allowing a 900% increase in "dioxin". EPA disagrees with the 900% figure, because the relationship between this figure and the 16 other dioxins is unexplained. EPA does agree that the CTR could allow for greater concentrations of all dioxins and dioxin-like compounds in San Francisco Bay than the EBEP's dioxin criterion might have allowed, but does not agree that this is inevitable.

The EBEP's single dioxin criterion ("TCDD Equivalents") represented the sum of 17 dioxins and dioxin-like compounds. The CTR, on the other hand, includes a single dioxin criterion for a single dioxin compound (2,3,7,8-TCDD). The numeric values for the two criteria (the ambient concentration limits allowed by the two criteria) are the same.

EPA notes that 2,3,7,8-TCDD is the only EBEPdioxin compound included on the CWA section 307(a)(1) list. It is also the only 307(a)(1)-listed dioxin for which there is a CWA section 304(a) criterion. The CTR is promulgated to meet the requirements of CWA section 303(c)(2)(B), which requires adoption of numeric criteria only for those toxic pollutants listed pursuant to section 307(a)(1) for which EPA has already adopted section 304(a) criteria. EPA is therefore not required to include criteria for any dioxin compound other than 2,3,7,8-TCDD in the CTR. For California waters, if designated or beneficial uses may be impaired by the discharge of other dioxin or dioxin-like compounds, numeric water quality-based effluent limits may be included in NPDES permits through the use of the narrative criterion. EPA strongly encourages the State to adopt either the same national/international convention of toxicity equivalence (TEQ) to account for the presence of other dioxins, furans and other dioxin-like compounds, which the State adopted in its EBEP, or a more recent, comprehensive convention. EPA believes that the State should apply this recognized method for regulating dioxin compounds and believes that this would

address the commenter's concerns.

The EBEP relied on the TEQ convention's nationally/internationally consistent set of toxicity equivalence factors (TEFs) as multipliers for the 17 dioxins, to convert them to the single TCDD Equivalents criterion. Thus, the EBEP's TCDD Equivalents criterion results from the same calculations that EPA believes should be applied to the CTR's 2,3,7,8,-TCDD criterion.

If the State of California did not apply the TEQ convention to the CTR criterion to account for the presence of other dioxins, furans and other dioxin-like compounds, it is possible that, under the CTR, the total concentrations of alldioxin and dioxin-like compounds in the Bay could allowably exceed the EBEP concentration limit even though 2,3,7,8-TCDD by itself does not exceed that limit. For this reason, EPA strongly encourages the State to limit these other compounds through the application of TEQ,.

If the TEQ convention were adopted, and TEF applied to the CTR criterion, the commenter's comparison between the CTR and the EBEP numbers could reasonably conclude that there was no difference between the two. (Alternatively, the commenter might have concluded that the CTR was more inclusive than the EBEP. The commenter refers to 17 dioxin compounds which are included in the EBEP's criterion for TCDD equivalents. The CTR's 2,3,7,8-TCDD criterion is intended to include all dioxins and dioxin-like compounds for which there are TEFs, which are far more than 17.) As long as California applies the national/international TEQ/TEF conventions to implementation of the 2,3,7,8-TCDD criterion in the CTR, as it applied them to implementation of the TCDD Equivalents criterion in the EBEP, then greater concentrations of dioxins will not be allowed to be discharged under the CTR.

B. The CTR includes" new, extremely liberal criteria" for 4 pollutants

This part of the comment is very vague. It appears from the context of this concern, however, that "extremely liberal" means something less than "allows greater ambient water concentrations", for which the preceding group of criteria is criticized. For these four pollutants, the commenter does not allege that the CTR criteria are unprotective of the designated uses. In fact, the CTR criteria for these pollutants (acenapthene, ethylbenzene, antimony and hexachlorobutadiene) are based on recent, sound science which supports the determination that the criteria are protective of the designated uses (see the California Toxics Rule Administrative Record Matrix). See also, National Recommended Water Quality Criteria, 63 Fed.Reg. 68354, December 10, 1998, as corrected, 64 Fed.Reg. 19781, April 22, 1999.

C. The CTR "fails to replace previous state criteria" for 3 pollutants

Of these 3 criteria, one (tributyltin) is not a priority pollutant. This pollutant, as discussed above, is therefore beyond the scope of the CTR, regardless of whether the State had previously adopted statewide criteria for it.

For the other two pollutants (acenaphthylene and phenanthrene), both EPA and the State have previously included human health criteria based on carcinogenicity in proposed or final water quality standards. EPA included such criteria in the 1991 proposed NTR (56 Fed.Reg. 58442-58443), and California adopted them in the 1991 EBEP (EBEP, Table 2 and Appendix 1). However, in the 1992 final NTR, EPA deleted these criteria, having found that there was inadequate toxicity data to assess their carcinogenic potential and that any criteria for these pollutants should therefore be based on

non-carcinogenic effects. Since there were no reference doses to calculate non-carcinogenic criteria for these pollutants, no numeric criteria were included for them in the final NTR. (57 Fed.Reg. 60868, 60887.) There has been no change from this position since 1992, and they are therefore not included in the CTR.

D. The CTR "includes no criteria for 18 pollutants which had no state-adopted criteria"

Of these 18 pollutants, identified in Table 2 of this comment, only two are priority pollutants. The other 16 are beyond the scope of the CTR.

Of the two pollutants which are priority pollutants, benz(ghi)perylene was withdrawn from the final NTR and is therefore not included in the CTR for the same reasons discussed in Part C, above, for acenaphthylene and phenanthrene. For naphthalene, EPA has not published 304(a) criteria. CWA section 303(c)(2)(B), which the CTR is implementing in California, requires that numeric water quality criteria be adopted only for those priority pollutants for which 304(a) criteria have been published, therefore naphtalene is beyond the scope of the CTR.

Comment: 6) In the forward to the rule the suggestion is made that no new SSOs will be approved by USEPA after the rule is promulgated due to lack of resources and the level of effort necessary for such action. Although we appreciate your candor, we do not believe that that is an appropriate response given the potential waste of public and private funds to comply with inappropriate standards.

Response to: CTR-003-006

EPA disagrees with this comment. We believe that the commenter misunderstood the cautionary language that was part of the proposed rule. The CTR does not preclude state adoption of criteria after the CTR has been promulgated. As EPA stated in the preamble to the proposed CTR, when the State has completed its own process, and EPA approves the State's new or revised criteria, EPA intends to stay the CTR. Similarly, if the State adopts site-specific criteria (including site-specific Basin Plan criteria adopted by Regional Boards which have completed the State review and adoption process), and EPA has approved them based on their individual merits, EPA intends to stay that portion of the CTR that applies more general criteria to the specific site. Each individual stay on a site-specific basis would require federal rulemaking on a case-by-case basis, and generally require more detailed effort on the Agency's part than a statewide stay.

Moreover, it is possible that State-adopted criteria could become effective for CWA purposes within the State even prior to EPA approval or rulemaking, although this would change if a rule that EPA has

recently proposed is promulgated as proposed. The "Alaska Rule," 64 Fed.Reg. 37072, July 9,1999. Until the Alaska Rule goes final, the State could adopt new or revised standards which are more stringent than the CTR, and those standards would be effective for CWA purposes within the state without any EPA action. Moreover, prior to a final Alaska Rule, the State could adopt statewide standards, and if EPA approved those standards and stayed the CTR based on them, then subsequent site-specific criteria would apply within the State when adopted by the State without requiring additional EPA approval or rulemaking. If the Alaska Rule becomes final as proposed, however, regardless of whether the CTR has been stayed, only state-adopted criteria which are more stringent than the otherwise applicable standards could be applied within the State, prior to EPA approval of those standards.

Comment: Available Regulatory Relief under the California Toxics Rule

The Preamble to the California Toxics Rule (CTR), and the rules accompanying Economic Analysis (EA), place a great deal of emphasis on the ability of dischargers to use alternative regulatory approaches to comply with CTR criteria if the cost of treatment technology was prohibitively expensive. For example, the EA assumes that, if the estimated annualized cost for removing a pollutant exceeded a cost trigger,(*1) "dischargers would explore the use of alternative regulatory approaches to comply with CTR-based effluent limits." EA at. pg. 4 (emphasis added). Based on this assumption, no treatment cost was estimated for the facility. (*2)

The types of alternative regulatory approaches assumed available for dischargers in California include phased total maximum daily loads (TMDLs), water quality standard variances, site-specific criteria, change in designated use, and alternative mixing zones. EA at pg. 4-5. The following sections will discuss each of EPA's proposed methods for regulatory relief and explain whether or not these methods can truly be used to provide relief from the CTR-based permit limits as anticipated by EPA. It should be noted that the actual language of the rule itself does riot mention any of the methods of regulatory relief. Therefore, this analysis will be based solely upon the language contained in the Preamble to the CTR.

Site-Specific Criteria

Another one of the avenues of potential regulatory relief discussed in the Preamble to the CTR is the adoption of site-specific water quality criteria. The Preamble provides that the "State has the discretion to develop site-specific criteria when appropriate e.g., when statewide criteria appear over or under protective of designated uses. The Preamble goes on to explain the site-specific criteria adoption process as follows:

Periodically, the State through its RWQCBs will adopt site-specific criteria for priority toxic pollutants

within respective Basin Plans. These criteria are intended to be effective throughout the Basin or throughout a designated water body. Under California law, these criteria must be publicly reviewed and approved by the RWQCB, the SWRCB, and the State's Office of Administrative Law (OAL). Once this adoption process is complete, the criteria become State law. These criteria must be submitted to the EPA Regional Administrator for review and approval under CWA section 303. These criteria are usually submitted to EPA as part of a RWQCB Basin Plan Amendment, after the Amendment has been adopted tinder the State's process and has become State law. CTR Preamble at pg. 42165.

The Preamble explains that the State of California has recently reviewed and updated all of its RWQCB Basin Plans. All of these Basin Plans, some of which contain site-specific criteria, have completed the State review and adoption process and have been submitted to EPA for review and approval. The key to whether or not these site-specific criteria will provide regulatory relief is when the EPA approval/disapproval occurs. Three different timing scenarios and results are possible:

1 . If EPA approves any State-adopted site-specific criteria before promulgation of the final CTR is published, then the EPA Administrator may make a finding, in that final rule that it will be unnecessary to promulgate criteria for the approved site-specific pollutants and associated water bodies.

2. If EPA disapproves any State-adopted site-specific criteria, the proposed statewide criteria contained in the CTR would apply for those pollutants and associated water bodies instead of the site-specific criteria.

3. However, if EPA promulgates statewide federal criteria as proposed in the CTR, prior to a decision on any State-adopted site-specific criteria, the more stringent of the two criteria would be used for water quality programs. Both federal and State water quality programs must be satisfied, and applications of the more stringent of the two criteria would satisfy both. CTR preamble at pg. 42165.

Thus, the only way less stringent site specific criteria can be used for regulatory relief is if those criteria are approved by EPA prior to the publication of the final CTR. Otherwise, either the CTR or the more stringent of the two (CTR vs. site-specific) criteria apply.

One final note regarding site-specific criteria is that the Preamble to the CTR restricts the ability to use native aquatic life as a way to set site-specific criteria. Instead of allowing a discharger to substitute local species from the receiving waters into which it discharges, the Preamble only allows a discharger to supplement the eight specified families of aquatic life required for criteria development with the addition of native species.(*9) It is doubtful whether this requirement will aid dischargers who are seeking regulatory relief.

(*1) This cost trigger is $200 per toxic pounds-equivalent for a facility under the low-end scenario, and $500 per toxic pounds-equivalent for a category of dischargers under the high-end scenario, See EA at pg. 4.

(*2) In addition, pollutant load I reductions word not calculated or credited for any pollutant for which an alternative regulatory approach was pursued. Id.

(*9) "A minimum data set of eight specified families is required for criteria development (details are given in the 1985 Guidelines, page 22). 'f he eight specific families are intended to be representative of a wide spectrum of aquatic life. For this reason it is not necessary that the specific organisms tested be actually present in the water body. States may develop site-specific criteria using native species, provided that the broad spectrum represented by the eight families is maintained. All aquatic organisms and their common uses are meant to be considered, but not necessarily protected, if relevant data are

available." CTR Preamble at pg. 42168.

Response to: CTR-004-008

EPA disagrees with this comment. Regarding this commenter's discussion as to how the CTR may relate to State-adopted site-specific criteria, See response to CTR-016-002.

EPA disagrees with the part of this comment which suggests that the preamble to the proposed CTR restricts the use of native aquatic species in setting site-specific criteria. The commenter correctly quotes the preamble to the proposed CTR, however it appears that there must be a misunderstanding on the commenter's part regarding the quoted language. The commenter mistakenly assumes that native species may only be used to "supplement", rather than to "substitute" for species identified by EPA. It has been EPA's consistent position, however, that states may use native species rather than species identified by EPA, provided they do so within the framework of EPA's guidance (which requires the use of a broad spectrum of species, represented by eight families of species), in setting ambient water quality criteria. See Water Quality Standards Handbook: Second Edition (U.S. EPA-823-B-94-005a, August 1994), Chapter 3 (esp section 3.7); "Summary of Revisions to Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses" (50 Fed.Reg. 30792, July 29, 1985).

Comment: 7. Separate, scientifically defensible, reasonably achievable aquatic life criteria for copper should be adopted for San Pablo Bay in the vicinity of the District's discharge, or alternatively EPA should state in the Preamble that the Regional Board should: (1) allow a dilution credit for the District based on modeling studies; and (2) apply metals translator determined based on EPA procedures from the results of the Regional Monitoring Program. To comply with the Clean Water Act and EPA regulations, EPA should consider specific water bodies. To fulfill the spirit of Presidential Executive Order 12866 and the requirements of the Unfunded Mandates Reform Act and the Regulatory Flexibility Act, EPA should evaluate regulatory alternatives based on an analysis of costs and benefits. Based on the analysis of costs and benefits performed by the District (see Attachment 1), EPA should either adopt the criteria that is currently achieved, or alternatively specify implementation criteria that will allow the current discharge to continue. The District has performed dilution studies (see Attachment 2) and performed reasonable potential analyses using dilution and metals translators (see Attachments 3 and 4). These show that with the use of these implementation provisions, the proposed criteria can be achieved in-stream. Without EPA specifying that dilution studies and metals translators should be utilized in the District's case, it is possible that the CTR could impose enormous costs on the District (and the small entities it serves) without providing any environmental benefit. In that case, the CTR would be inconsistent with the Clean Water Act, EPA regulations, Presidential Executive Order 12866, the

Unfunded Mandates Reform Act and the Regulatory Flexibility Act.

Response to: CTR-005-008a

EPA disagrees with the commenter's request that EPA either adopt site-specific copper criteria for San Pablo Bay or state in the preamble that the Regional Board should allow dilution credit and application of a metal translator for the commenter's discharge.

In support of its request for the adoption of "scientifically defensible, reasonably achievable aquatic life criteria for copper" (emphasis added), the commenter has submitted its own analysis of costs and benefits. EPA has conducted an analysis of costs and benefits for this rule pursuant to Executive Order 12866 (see discussion in preamble to final rule); however, the criteria themselves are not based on economic considerations. In accordance with 40 CFR 131.11, criteria must be based on sound scientific rationale and must protect the designated use. There is no provision for EPA to consider the attainability or the scientific validity of the criteria with regard to specific dischargers or class of dischargers in adopting ambient water quality criteria in the CTR. Economic factors may be considered in designating uses (40 CFR 131.10); however, they may not be used to justify criteria which are not protective of those uses.

That being said, it should nevertheless be understood that EPA does support State adoption of site-specific criteria. As explained in the preamble to the proposed CTR, and further discussed in the response to CTR-016-002, EPA will work with the State to approve acceptable State-adopted criteria (including site-specific criteria) and intends to stay the CTR when EPA has approved such State criteria. In the meantime, in the absence of such criteria for aquatic life for copper in waters of San Francisco Bay, with salinity greater than 5 ppt, EPA is promulgating criteria based on EPA's section 304(a) national marine water copper aquatic life criterion, which is consistent with the requirements of the CWA. (40 CFR Section 131.11(b).) See also responses to CTR-016-001 and -002.

Regarding the suggestion that EPA specify the use of dilution and metals translators for this discharger, EPA disagrees. With the exception of compliance schedules, the CTR does not include implementation provisions; the CTR is promulgated to add numeric criteria for toxic pollutants where they did not exist. The State may address these issues in a separate implementation plan, which it is currently developing. ("Policy for implementation of Toxics Standards for Inland surface Waters, Enclosed Bays and Estuaries of California", released for public comment, September 11, 1997.)

Finally, regarding the commenter's assertion that the CTR could be inconsistent with Executive Order 12866, the Regulatory Flexibility Act and the Unfunded Mandates Reform Act see the discussion of EPA's compliance with these requirements in the preamble to the final rule.

Comment: The San Luis & Delta-Mendota Water Authority has entered into a Use Agreement with the Bureau of Reclamation for discharge of drainage water through a portion of the San Luis Drain to the San Joaquin River. A consensus letter to the Central Valley Regional Water Quality Control Board signed November 3, 1995, discussed the selenium water quality objectives in the San Joaquin River, Mud Slough, Salt Slough and wetland channels. The letter states "Please note that the parties have not reached a consensus on the appropriate long-term water quality objectives. However, the parties have committed to participate in a cooperative review process by which to evaluate any new scientific information relative to the subject." This letter was signed by the San Luis & Delta-Mendota Water Authority, the U.S. Bureau of Reclamation, the U.S. Environmental Protection Agency, and the U.S. Fish and Wildlife Service.

The proposed California Toxics Rule should not be adopted without adequately addressing the difference for high-sulfate waters. The Rule should also not be adopted if it undercuts EPA's commitment to the cooperative review of appropriate long-term standards in the San Joaquin River Basin.

Response to: CTR-008-002

EPA disagrees with this comment. Concerning future review of standards in the San Joaquin River Basin, that course of action is in no way precluded by the CTR. As explained in the preamble to the proposed CTR, and further discussed in the response to CTR-016-002, EPA will work with the State to approve acceptable State-adopted criteria (including site-specific criteria) and to stay the CTR where such State criteria are in effect. In the case of the San Joaquin River basin, EPA is committed to cooperative review of site-specific standards. Moreover, where site-specific criteria have already been adopted by the State in accordance with State law, but not yet acted upon by EPA, and those criteria are more stringent than applicable CTR criteria, those are the controlling criteria for CWA purposes within the State even without a stay of the applicable CTR criteria and are thus implementable by the State. (This would not be affected by the "Alaska Rule" which EPA proposed July 9, 1999, 64 Fed.Reg. 37072. See p. 37076.) This is the case with the selenium criterion adopted by the Central Valley Regional Board for Mud and Salt Sloughs and some adjacent basin waters in the Board's 1996 Basin Plan amendment. Since the State must use the most stringent criteria in effect for its water quality programs, the State may use this site-specific selenium criterion notwithstanding the CTR selenium criterion, thus the commenter's concerns should have no practical effect.

EPA has reviewed the information provided concerning the effect of high-sulfate waters on the toxicity of selenium to the extent it applies in the referenced waters. EPA concludes, based on information provided by the U.S. Fish and Wildlife Service (FWS), that this comment provides no basis for changing the numeric selenium criteria contained in the CTR. The letter of October 10, 1997, from Wayne S. White, Field Supervisor, FWS, to Diane Frankel, EPA, responds to the information provided with this comment. (The FWS letter is itself included as a comment on the proposed CTR in the administrative record.) In summary, the FWS letter says that most of the references relied on by this commenter suffer from an inability to transfer laboratory results to the field. They are based on the real but simplified interference between selenate and sulfate. They use relatively high levels of sulfate which are not unrealistic in themselves; however, the reduction in selenium bioaccumulation from selenate that they measure is not elimination of bioaccumulation from that form of selenium. Also, the results apply only to the selenate form of selenium. The other forms of selenium are far more bioaccumulative than selenate, are free of any interference from sulfate and, over time, come to dominate the bioaccumulation process.

Comment: The City is concerned that any site specific objectives have to be implemented through federal rulemaking. The EPA was quite explicit in advising both the State and the regulated community not to expect prompt response from EPA on such requests. The State has a number of watershed projects underway in conjunction with EPA. The expressed lack of potential to ever see the implementation of site-specific requirements based upon the most representative and expansive scientific database for a given watershed have a chilling effect on these efforts. This would beextremely unfortunate because EPA's goal of "place-based" management approaches will suffer a significant set-back in California. Millions of dollars spent on good science to develop the most cost-effective local water quality solutions, may be for naught. This is an unintended negative outcome that the Agency surely does not desire. The City recommends that the final CTR Rule explicitly provide that site specific objectives and requirements for criteria included in the rule can be accomplished through Basin Plan Amendments approved by SWRCB and EPA. Given the sheer size and diversity of California's watersheds and receiving waters, the most effective way to implement appropriate water quality controls is through watershed-specific characterizations implemented by the Regional Boards. Without the ability to affect site-specific objectives in this manner, its tool is undermined if not negated.

Response to: CTR-009-003

EPA disagrees with this comment. We believe that the commenter misunderstood the cautionary language that was part of the proposed rule. The CTR does not preclude state adoption of criteria after the CTR has been promulgated. As EPA stated in the preamble to the proposed CTR, when the State has completed its own process, and EPA approves the State's new or revised criteria, EPA intends to stay the CTR. Similarly, if the State adopts site-specific criteria (including site-specific Basin Plan criteria adopted by Regional Boards which have completed the State review and adoption process), and EPA has approved them based on their individual merits, EPA intends to stay that portion of the CTR that applies more general criteria to the specific site. Each individual stay on a site-specific basis would require federal rulemaking on a case-by-case basis, and generally require more detailed effort on the Agency's part than a statewide stay.

Moreover, it is possible that State-adopted criteria could become effective for CWA purposes within the State even prior to EPA approval or rulemaking, although this would change if a rule that EPA has recently proposed is promulgated as proposed. The "Alaska Rule," 64 Fed.Reg. 37072, July 9,1999. Until the Alaska Rule goes final, the State could adopt new or revised standards which are more stringent than the CTR, and those standards would be effective for CWA purposes within the state without any EPA action. Moreover, prior to a final Alaska Rule, the State could adopt statewide standards, and if EPA approved those standards and stayed the CTR based on them, then subsequent site-specific criteria would apply within the State when adopted by the State without requiring additional EPA approval or

rulemaking. If the Alaska Rule becomes final as proposed, however, regardless of whether the CTR has been stayed, only state-adopted criteria which are more stringent than the otherwise applicable standards could be applied within the State, prior to EPA approval of those standards.

EPA further disagrees with any suggestion that the State itself could, in the future, modify CTR criteria. State adoption of site-specific criteria (including site-specific criteria adopted by the Regional Board which have completed the State adoption process) is a separate State action, under State law, which does not modify federal criteria. It would be up to EPA to modify the CTR to "make way" for the State's criteria, once those criteria have been approved by EPA. As discussed above, if the State were to adopt criteria that were more stringent than applicable CTR criteria, those criteria could be effective for CWA purposes within the State under State law, prior to EPA approval of such criteria or modification of the CTR.

Comment: EPA's proposed California Toxics Rule is extremely disturbing because it significantly

weakens standards for numerous pollutants of concern in San Francisco Bay. Standards for more than half of the pollutants of concern identified by the S.F. Estuary Project will be weakened, including dioxin, PCB, mercury, PAHs, and chlordane. These pollutants were found in elevated levels in Bay fish by the S.F. Regional Water Board's study on contaminants in fish and resulted in the fish consumption advisory put out by Cal-EPA. Research conducted by Save S.F. Bay Association found people eating two to three times the amount of Bay fish considered safe. EPA's proposal will make this situation much worse and result in higher exposure levels to thousands of people. Moreover, pollution levels for a number of other pollutants will significantly increase, such as lead, copper, zinc, fluoranthene, and many others.

Response to: CTR-010-001

EPA disagrees with this comment. See response to CTR-002-003, which responds in detail to specific concerns regarding pollutant increases in San Francisco Bay, CTR-016-002, which discusses San Francisco Bay Basin Plan criteria which will not be superceded by the final CTR, and CTR-002-002a, which responds to specific concerns regarding fish consumption.

CROSS REFERENCES C-13
E-01d

Comment: The City of Simi Valley discharges approximately 10 million gallons per day (mgd) of tertiarytreated wastewater (as well as municipal storm water) to the Arroyo Simi, an effluent dependent water body. Through much of the year, Arroyo Simi is dry several miles downstream from the City. The Arroyo Simi Characterization Report, completed by the City in 1995, concluded that the arroyo does not support a significant fishery, and observed only arroyo chub, mosquito fish and blunt-nosed minnow in the stream. Although designated as a potential municipal water supply in the Basin Plan, the arroyo waters are not used for municipal purposes. Effluent monitoring are limited, but available data indicate that the City's discharge may have a reasonable potential to exceed the proposed aquatic life criteria for several metals and the proposed human health criteria for several carcinogens.

Since Simi Valley is largely a residential community with supporting commercial development and little industry, and since the City already has an effective pretreatment program, it is unlikely that pollution prevention efforts would effectively reduce the problematic constituents. More likely, the City would be faced with end-of-pipe treatment controls such as lime precipitation and carbon adsorption to achieve the proposed criteria. The costs would undoubtedly be significant and the benefits relatively minor.

Under these circumstances, it appears reasonable to adopt criteria for Arroyo Simi, and similar effluent dependent waters, that are reasonably achievable without costly end-of-pipe controls and that reflect the actual use of the water (i.e., generally such waters are used for fishing or drinking). One way to address

this issue, consistent with the requirements of the Clean Water Act, would be to adopt specific human health criteria for Arroyo Simi and other effluent dependent streams based on a cancer risk coefficient of 10E-5 or in some cases 10E-4. Based on the limited data collected by the City, risk levels of 10E-4 would have to be adopted for dioxins, aldrin, alpha-BHC and 4,4,-DDD (see Table 1). Risk levels of 10E-5 would be sufficient for chloroform and endoslfan 11 (Id.).

Response to: CTR-011-001b

EPA disagrees that it must or should establish separate criteria for effluent dependent waters in this rule. In establishing water quality criteria for California, EPA is implementing section 303(c)(2)(B) of the CWA which requires adoption of criteria for all toxic pollutants for which EPA has issued criteria guidance and for which the discharge of such pollutants could reasonably be expected to interfere with the designated uses adopted by the state. EPA based the criteria contained in the CTR on its most recent national criteria guidance, which are designed to derive criteria that will be protective of aquatic life and human health. As long as a waterbody currently has a designated use for the protection of aquatic life and/or human health, application of the national 304(a) criteria are appropriate for fulfilling section 303(c)(2)(B). The CTR itself does not adopt uses or modify any uses previously adopted by the State. EPA presumes that the State has designated appropriate uses for its waters. Proposals to revise State-adopted uses must be brought to the State pursuant to its procedures for review of its water quality standards.

That being said, it should nevertheless be understood that EPA does support State adoption os site-specific criteria. As explained in the preamble to the proposed CTR, and further discussed in response to CTR-016-002, EPA will work with the State to approve acceptable State-adopted criteria (including site-specific criteria) and to stay the CTR where EPA has approved such State criteria.

With respect to risk level applicable to human health criteria when, as here, EPA establishes a water quality standard, EPA intends in its discretion to use a risk level of 1 x 10-6, although the State may in its discretion choose another risk level for protection of human health, if the State has appropriately consulted the public. As discussed in responses to CTR-011-0001a and CTR-058-001 (Category C-13; Risk Level), EPA follows the risk-level policies of the affected state, when promulgating criteria as regulations.

Comment: Existing State Standards for the San Francisco Bay Region Previously Approved by US EPA

US EPA has asked people commenting on the proposed California Toxics Rule to identify any state-adopted numerical objectives that are still in effect following the decision in the Water Quality

Control Cases, Judicial Council Coordination Proceeding No. JC2610. The San Francisco Bay Regional Board was not a party to that lawsuit. Accordingly, there are several numerical objectives for toxic substances contained in the Water Quality Control Plan for the San Francisco Bay Region (Basin Plan) that remain valid following the court ruling. They were adopted after a full public review process in 1986 and subsequently approved by US EPA in 1987. These objectives are contained in Tables 3-3 and 3-4 of the Basin Plan and are reproduced in an attachment to this letter.

Staff have reviewed these objectives and have determined that many are identical to those proposed in the California Toxics Rule except that the Region's existing standards are expressed as total recoverable and not in the dissolved form. Of those objectives that are not identical, ambient levels of arsenic, lead, and zinc are so far below both existing and proposed standards that the Regional Board does not consider modifying the values a priority. Levels of copper, nickel, mercury, and PAHs, however, are of greater concern in the Region.

In reviewing both the proposed and past US EPA criteria, we have consistently found that site-specific objectives are preferable to more generalized objectives for the complex, dynamic hydrogeological and biogeochemical systems in the San Francisco Bay Estuary. Generalized national criteria development processes seek to minimize the uncertainty of laboratory-based predictions (as in the selection of dissolved criteria) yet do not attempt to reduce any of the environmental uncertainties that arise when laboratory results are extrapolated to extremely complex and variable field conditions. As a result, some of the proposed national criteria are seriously under protective of beneficial uses in San Francisco Bay, while others are overprotective and will ultimately cause compliance problems for dischargers under the existing implementation policies contained in our Basin Plan.

As you are aware, the Regional Board has been working to develop objectives appropriate for San Francisco Bay for copper and nickel since 1988 and is in the process of conducting similar technical analyses for mercury, dioxins, and PAHS. Our technical assessment of the proposed selenium, mercury, and dioxin criteria is presented in greater detail below. The goal of this undertaking is to develop site-specific objectives and pollutant-specific implementation policies for San Francisco Bay.

Because EPA's proposed criteria do not consistently incorporate the most current environmental information, and, in particular do not reflect the complex conditions in the Estuary, we feel it is more appropriate to retain the existing numerical objectives in the Basin Plan and to update them through our regional planning process.

Accordingly, we ask that EPA revise the proposed rule and exclude the existing fresh and salt water pollutant objectives listed in the attachment for waters within the San Francisco Bay Region (as defined in the California Water Code). This exclusion would amend the table on "Water and use classification and Applicable Criteria" to read:

All waters within the San Francisco Bay Region that include a MUN use designation:

* -assigned all criteria in Columns B1 and B2-for all pollutants except for arsenic, chromium (VI), copper, mercury, nickel, silver, and zinc

* -and all criteria in Columns C1 and C2-for all pollutants except for arsenic, cadmium, chromium (VI), lead, mercury, nickel, silver, and zinc

* -and Column D-1-all pollutants

and

All waters within the San Francisco Bay Region that do not include a MUN use designation:

* assigned all criteria in Columns B1 and B2-for all pollutants except for arsenic, chromium (VI), copper, mercury, nickel, silver, and zinc

* and all criteria in Columns C1 and C2-for all pollutants except for arsenic, cadmium, chromium (VI), lead, mercury, nickel, silver, and zinc

* and Column D-2 - all pollutants

It should be noted that this recommended action will result in two saltwater standards for PAHs; one will be a 24-hour average value of 15.0 ppb (the existing objective), the other will be the chronic human health-based federal standard.

Response to: CTR-016-001

EPA has reviewed this comment, as well as the Water Quality Control Plan for the San Francisco Bay Region (Basin Plan), and its amendments, including the 1995 Basin Plan, which the comment addresses. As EPA explained in the preamble to the proposed CTR, EPA intended to amend the text of the final rule to provide that CTR criteria would not apply where there is a site-specific State criterion in effect, approved by EPA, which the State or others identify in comments on the proposed CTR. (62 Fed.Reg. 42165.) This comment has identified such criteria. Based on our review, and discussions with the San Francisco Bay RWQCB, we have determined that those standards for the San Francisco Bay Region for priority toxic substances contained in Tables 3-3 and 3-4 of the 1995 Basin Plan (Tables III-2A and B of the 1986 Basin Plan), are the same as those adopted by the State in 1986 and approved by EPA in 1987, and they remain in effect for those waters of San Francisco Bay where they are presently in effect following final promulgation of the CTR. EPA believes that these are still appropriate criteria values. CTR criteria will therefore not apply to those parameters and waters covered by these San Francisco Bay Region Basin Plan WQS. National Toxics Rule (NTR) criteria for cyanide (40 CFR 131.36(d)(10)) will also continue to apply since the CTR does not supercede the NTR, as it applies in California.

EPA furthermore disagrees that CTR should exclude any of the pollutants proposed in this comment for all waters of San Francisco Bay that have the listed use designations. There are waters of San Francisco Bay (waters of the South Bay below Dumbarton Bridge) for which the criteria addressed in this comment are simply not in effect under the 1995 Basin Plan. CTR criteria are therefore adopted for these waters, and there is no conflict among criteria, since the CTR is filling a gap, not superceding State criteria.

The CTR also applies to any estuarine waters of San Francisco Bay which became subject to different criteria in 1995 when the San Francisco Regional Board eliminated the previously-approved geographic boundary between waters subject to freshwater and saltwater criteria and instead adopted methods for determining, on a salinity basis, where freshwater and saltwater criteria would be applied in San Francisco Bay. Because EPA has not approved the 1995 Basin Plan amendments, and since the 1986 Basin Plan criteria which EPA did approve no longer apply to those waters, EPA adopting CTR criteria for those waters is necessary to implement CWA section 303(c)(2)(B). It is expected, however, that few permits will be affected by this application of CTR criteria.

EPA disagrees that the CTR should exclude all of the pollutant criteria as proposed in this comment. It is beyond the scope of this rule to pick and choose among the CTR criteria which shall apply to waters of

San Francisco Bay on any basis other than whether or not they are subject to an EPA-approved State-adopted criterion, as described above. (For example, under the 1995 Basin Plan, there is currently no criterion for copper in waters of San Francisco Bay with salinity greater than 5 ppt, and EPA therefore will adopt CTR saltwater copper criteria for those San Francisco Bay waters.) Thus, regarding the various pollutants specifically addressed by this commenter, EPA will identify, in the footnotes to section 131.38(b)(1), those criteria which do not supercede EPA-approved San Francisco Bay Region Basin Plan criteria which are presently in effect.

Comment: Development of New Standards by Regional Boards - Clarification of Federal Rulemaking

It is very clear in the proposed rule that it is EPA's intention to promulgate federal standards only where there is an absence of state standards, and that when the state has completed its own process, that EPA intends to stay the proposed rule. At the same time, however, the proposed rule contains the following cautionary language:

"If this proposed rule is still in effect, as with the State adoption of site-specific criteria, EPA would have to undertake rulemaking to make necessary changes to this rule .... EPA, however, cautions California and the public that promulgation of this federal rule removes most of the flexibility available to the State for modifying its standards on a discharger-specific or stream-specific basis. For example, variances and site-specific criteria development are actions sometimes adopted by states. These are optional policies under terms of the federal water quality standards regulation. Except for the water-effect ratio procedure for certain metals, EPA has not incorporated either optional policy, in general, in this proposed rulemaking, that is, EPA has not generally authorized State modifications of federal water quality standards. Each of these types of modifications will, in general, require federal rulemaking on a case-by-case basis to change the federal rule. Because of the time consuming nature of reviewing such requests, limited federal resources, and the need for the Agency to move into other priority program areas in establishing environmental controls, EPA alerts California and the public that a prompt Agency response it unlikely. The best course of action, if such provisions are desired, is for the State to adopt its own standards and take advantage, if it so chooses, of the flexibility offered by these optional provisions."

We interpret this language to mean that EPA is not authorizing a modification of the federal standards as part of this rulemaking (except through use of WERs). However, this language suggests that EPA also believes itself to be unable to state standards developed by Regional Boards in a timely manner. We must point out that the site-specific objectives setting process carried out by the Regional Boards in the State of California is not a "modification" of federal standards, but a complete, state standard setting process. Furthermore, the Regional Boards are required and authorized under the CWA and state law to

review and, as appropriate, consider modification of the promulgated standards as they apply to specific water bodies within each region as part of the triennial review process. In both cases, we feel very strongly that EPA is obligated to review state standards developed at the regional level in a timely manner. We also believe that EPA's intent to stay federal standards when the statewide objective setting process is complete should apply equally to state standards adopted by the Regional Boards.

Accordingly, we are asking that EPA specifically clarify its intent with respect to state standards developed by Regional Boards. In addition, we strongly recommend that EPA revise the proposed rulemaking to include a description of conditions under which EPA may initiate a stay of federal standards as part of this rulemaking, thereby alleviating the administrative burden of conducting federal rulemaking changes every time a new state standard is developed and approved.

Response to: CTR-016-002

EPA disagrees with this comment. We believe that the commenter misunderstood the cautionary language that waspart of the proposed rule. The CTR does not preclude state adoption of criteria after the CTR has been promulgated. As EPA stated in the preamble to the proposed CTR, when the State has completed its own process, and EPA approves the State's new or revised criteria, EPA intends to stay the CTR. Similarly, if the State adopts site-specific criteria (including site-specific Basin Plan criteria adopted by Regional Boards which have completed the State review and adoption process), and EPA has approved them based on their individual merits, EPA intends to stay that portion of the CTR that applies more general criteria to the specific site. Each individual stay on a site-specific basis would require federal rulemaking on a case-by-case basis, and generally require more detailed effort on the Agency's part than a statewide stay.

Moreover, it is possible that State-adopted criteria could become effective for CWA purposes within the State even prior to EPA approval or rulemaking, although this would change if a rule that EPA has recently proposed is promulgated as proposed. The "Alaska Rule," 64 Fed.Reg. 37072, July 9,1999. Until the Alaska Rule goes final, the State could adopt new or revised standards which are more stringent than the CTR, and those standards would be effective for CWA purposes within the state without any EPA action. Moreover, prior to a final Alaska Rule, the State could adopt statewide standards, and if EPA approved those standards and stayed the CTR based on them, then subsequent site-specific criteria would apply within the State when adopted by the State without requiring additional EPA approval or rulemaking. If the Alaska Rule becomes final as proposed, however, regardless of whether the CTR has been stayed, only state-adopted criteria which are more stringent than the otherwise applicable standards could be applied within the State, prior to EPA approval of those standards.

EPA notes that State-adopted criteria (including site-specific criteria) which are less stringent that CTR criteria may be approved by EPA and result in a stay of the CTR if such criteria are based on sound scientific rationale which ensures that designated uses will be protected.

EPA also disagrees with the suggestion that EPA include provisions in this CTR rule to allow EPA to use direct final rulemaking if it stays the CTR, or site-specific portions of the CTR, in the future. Since EPA cannot at this time predict what State criteria would replace CTR criteria when such stays are issued, EPA cannot predict whether such federal rulemakings might appropriately be adopted as direct final rules. Whether EPA meets the criteria for using direct final rulemaking in this context is a decision EPA will make when it undertakes such rulemaking.

Comment: Thank you for the opportunity to provide comments on the recently promulgated California Toxics Rule. The members of the Santa Ana River Dischargers Association (SARDA) are especially appreciative of EPA's effort to review the site-specific water quality objectives (SSOs) proposed for our watershed.

The SSOs for cadmium, copper, lead and ammonia were developed jointly by state and federal regulators in 1992-93. During this period, the Regional Water Quality Control Board - Santa Ana Region held several public hearings to review the merits of the proposed SSOs. As part of the formal procedures to amend the Santa Ana River Basin Plan, the Regional Board received several documents providing scientific evidence that the SSOs would fully protect all designated beneficial uses including aquatic life.

EPA has received several copies of the final report for the Santa Ana River Use-Attainability Analysis. As direct participants in the design and methodology of the study, EPA received draft and final versions of all work papers and reports. In addition, another complete copy of the documents were submitted to the agency as part of the administrative record supporting the State Board decision to approve basin plan amendments adopting the SSOs.

Because the previous copies were submitted nearly four years ago, we believe it would be helpful to submit a new copy for the record. It is our sincere hope that these documents will facilitate EPA's review of the proposed SSOs.

Enclosed are the respective volumes which comprise the UAA Final Report. There are many other pages of written materials supporting the adoption of site-specific water quality objectives previously submitted to EPA and included in the State of California's formal administrative record on the basin plan amendments. If EPA desires additional copies of any of the other documents, SARDA would be pleased to re-submit them as well.

The SSOs proposed for the Santa Ana River are nearly identical to the water quality objectives EPA set forth in the California Toxics Rule. We in SARDA were pleased that EPA's scientists concur in the conclusion that water quality objectives based on dissolved metal concentrationswould fully protect the Santa Ana River. If anything, it appears that the SSOs proposed within the UAA Final Report were conservative. Since then, EPA has sponsored new scientific research which corroborates the original UAA recommendations.

Because the California Toxics Rule uses the same approach as the UAA in setting water quality objectives for cadmium and copper, SARDA strongly supports the CTR objectives for those metals. We also agree with EPA's written statements acknowledging the binding character of organic carbon and the role it plays in rendering heavy metals non-toxic. We enthusiastically endorse the agency's decision to

include Water Effects Ratio as a formal factor to be considered when formulating water quality objectives. It will do much to adjust national criteria to local conditions.

Unlike copper and cadmium, the SSO for lead was based on EPA's "Most-Sensitive Species Methods." As such, SARDA believes that it is more appropriate to adopt the UAA-SSO rather than the CTR formula when setting water quality objectives for lead in the Santa Ana River. Therefore, we urge the agency to join the State Water Resources Control Board in approving the SSO for lead.

Since the UAA was completed, and the basin plan amended, the SARDA agencies have diligently implemented the final recommendations. When chlorine and ammonia were found to be contributing to toxicity in the river, dischargers constructed new facilities to significantly reduce the concentration of these pollutants. Today, SARDA members routinely pass their whole effluent toxicity tests. Annual instream bioassessments, conducted voluntarily by SARDA, consistently demonstrate that our effluent quality fully supports the designated beneficial use.

SARDA is also pleased to report that the concentrations of heavy metals remain well below permitted levels and are often significantly less than historical averages. The fear that SSOs would license widespread increases in pollution never came to pass.

We believe the Santa Ana River UAA was successful in developing more appropriate site-specific objectives as a result of EPA's direct participation in designing, conducting and reviewing the scientific inquiry. The other SARDA agencies join me in thanking EPA's staff for the considerable time and expertise they contributed to this extraordinary effort.

If EPA requires any additional materials, or wishes to discuss the documentation submitted in support of the proposed SSOs, please call me at (909) 797-5119. All of the SARDA agencies are prepared to assist in any way we can. Thank you again for the opportunity to comment on the California Toxics Rule.

Sincerely,

Chairman Santa Ana River Dischargers Association

Response to: CTR-017-001

EPA is pleased to hear the story of success in reducing the toxicity in the Santa Ana River. EPA also appreciates the strong support for the CTR criteria for cadmium and copper, which, as the commenter points out, are nearly identical to the SSOs adopted by the State for the Santa Ana River.

Concerning the site-specific criterion for lead in the Santa Ana River that has been adopted by the State, EPA appreciates the commenter's support of the site-specific criterion over the CTR criterion for protection of fresh water aquatic life. However, EPA has not yet approved this site-specific criterion, and in the absence of EPA-approved State-adopted site-specific criteria, EPA must promulgate CTR criteria to meet the requirements of CWA section 303(c)(2)(B). Nevertheless, where site-specific criteria have already been adopted by the State in accordance with State law, but not yet acted upon by EPA, and those criteria are more stringent than applicable CTR criteria, those are the controlling criteria for CWA purposes within the State even without a stay of the applicable CTR criteria and are thus implementable by the State. (This would not be affected by the "Alaska Rule" which EPA proposed July 9, 1999, 64 Fed.Reg. 37072. See p. 37076.) This is the case with the site-specific criterion for lead adopted by the State for the Santa Ana River. Since the State must use the most stringent criteria in effect for its water quality programs, the State may use this site-specific lead criterion notwithstanding the CTR fresh water

aquatic life criterion for lead, thus the commenter's concerns should have no practical effect.

Comment: B. Site-Specific Modifications

EPA has indicated that it will not allow the state to approve site-specific modifications of the federal criteria regardless of the merit of the situation. The only notable exception is EPA's indication that amendment of these criteria may only be accomplished by a petition for rulemaking which amends the CTR. EPA's self-imposed limitation on CTR modification exacerbates the overly broad nature of the rule and arbitrarily inflicts wasteful expenditures of local resources on meeting objectives that have no actual environmental or public health need. The Agency is authorizing limited waivers to criteria compliance where it can be demonstrated that factors listed in 40 C.F.R. section 131.10(g) apply (e.g., natural conditions prevent attainment of uses). However, these waivers are very limited in scope, are rarely approved, and are not expected to provide relief to the typical circumstances that justify less restrictive criteria (e.g., exposure and organism sensitive assumptions are not relevant, warranting criteria recalculation).

The failure of EPA to build appropriate flexibility into the CTR is contrary to Presidential directives contained in the "Reinventing Environmental Regulation" issued in March 1995. By arbitrarily restricting the ability to modify criteria site-specifically (as outlined in detail in EPA's Water Quality Standards Handbook), EPA will maximize the economic impacts of this rulemaking rather than minimize the costs as required by applicable Executive Office directives and underlying regulatory provisions.

There is no legal or technical basis for restricting the modification of the Section 304(a) criteria. EPA has often referred to the ability to modify federal criteria as the means for ensuring that the criteria are appropriately applied. Similar to the "upset defense" that EPA was directed to include in nationwide effluent guidance to ensure that those requirements were not applied to inappropriate operational conditions, the Agency must grant the State of California the ability to modify the criteria for cause so that the criteria are not applied inappropriately. If this authority is not included in the rule, application of the CTR will clearly be overly broad and will exceed EPA's authority to establish appropriate water quality criteria.

Response to: CTR-020-003

EPA disagrees with this comment. We believe that the commenter misunderstood the cautionary language that was part of the proposed rule. The CTR does not preclude state adoption of criteria after the CTR has been promulgated. As EPA stated in the preamble to the proposed CTR, when the State has completed its own process, and EPA approves the State's new or revised criteria, EPA intends to stay the

CTR. Similarly, if the State adopts site-specific criteria (including site-specific Basin Plan criteria adopted by Regional Boards which have completed the State review and adoption process), and EPA has approved them based on their individual merits, EPA intends to stay that portion of the CTR that applies more general criteria to the specific site. Each individual stay on a site-specific basis would require federal rulemaking on a case-by-case basis, and generally require more detailed effort on the Agency's part than a statewide stay.

Moreover, it is possible that State-adopted criteria could become effective for CWA purposes within the State even prior to EPA approval or rulemaking, although this would change if a rule that EPA has recently proposed is promulgated as proposed. The "Alaska Rule," 64 Fed.Reg. 37072, July 9,1999. Until the Alaska Rule goes final, the State could adopt new or revised standards which are more stringent than the CTR, and those standards would be effective for CWA purposes within the state without any EPA action. Moreover, prior to a final Alaska Rule, the State could adopt statewide standards, and if EPA approved those standards and stayed the CTR based on them, then subsequent site-specific criteria would apply within the State when adopted by the State without requiring additional EPA approval or rulemaking. If the Alaska Rule becomes final as proposed, however, regardless of whether the CTR has been stayed, only state-adopted criteria which are more stringent than the otherwise applicable standards could be applied within the State, prior to EPA approval of those standards.

EPA further disagrees with any suggestion that the State itself could, in the future, modify CTR criteria. State adoption of site-specific criteria (including site-specific criteria adopted by the Regional Board which have completed the State adoption process) is a separate State action, under State law, which does not modify federal criteria. It would be up to EPA to modify the CTR to "make way" for the State's criteria, once those criteria have been approved by EPA. As discussed above, if the State were to adopt criteria that were more stringent than applicable CTR criteria, those criteria could be effective for CWA purposes within the State under State law, prior to EPA approval of such criteria or modification of the CTR.

With respect to EPA's compliance with applicable Executive Office directives see the preamble to the final rule.

Comment: It is with a sense of reluctance that Sunnyvale joins in CASA/Tri-TAC's adverse comments on the CTR and the EA, and Sunnyvale does so in a spirit of constructive criticism and with an expectation that the Agency will make the necessary adjustments in its approach towards the CTR before the final rule is promulgated. In addition, in the same spirit and with the same expectation, Sunnyvale would like to make the following points on its own behalf:

4. Need for Expedited Approval of Site-Specific objectives. Sunnyvale is dismayed by the seemingly intransigent position taken by EPA in the preamble to the CTR to the effect that EPA is unlikely to act expeditiously to stay the application of CTR-based criteria with regard to water bodies in California which are covered by future site-specific objectives adopted by California water pollution control agencies and approved by EPA once the CTR becomes a final rule. The Agency's position is inconsistent with its otherwise reasonable and laudable support for local water quality planning efforts. It seems to Sunnyvale that EPA should reward a local planning effort which has complied with all EPA guidance and has produced site-specific water quality objectives which are more appropriate to the affected water body than the state and nationwide criteria in the CTR. What is the reason for EPA's attitude?

EPA has in the past threatened to delay approving state adopted site-specific objectives once a federal promulgation is in place. These threats are generally made when EPA is attempting to urge a state or states to develop state criteria in order to avoid a federal promulgation. However, the principal policy reason to take this position disappears as soon as the statutorily-required criteria have been put in place by EPA. Thereafter, EPA should show support for California's efforts to make appropriate adjustments in EPA's CTR criteria, especially where the adverse impacts of the CTR are being mitigated by the regulatory relief afforded by the State's efforts.

If EPA is concerned about the resources required to go through notice-and-comment rulemaking before it can stay the effect of the CTR, then Sunnyvale urges EPA to seek means to simplify and streamline the EPA rulemaking process. We urge the Agency to apply the lessons learned in the Agency's implementation of the air program in this situation. A proposal by EPA in the final CTR to go directly to final rulemaking to stay the effect of particular CTR criteria would be justified where, in the future, the State and the Agency have complied with the exhaustive EPA guidance on development of scientifically-justifiable site specific water quality objectives. A simple notice of final rulemaking should be amply sufficient to comply with the requirements of the Administrative Procedures Act. We urge the Agency to use the creative resources of the office of General Counsel to explore the merits of this suggestion.

Unless EPA is able to act expeditiously to approve newly-developed site specific criteria, the Agency could be the bottleneck in implementing some highly desirable place-based watershed management planning. Please reconsider your position in this matter in the final rulemaking on the CTR.

Response to: CTR-021-007

EPA disagrees with this comment. We believe that the commenter misunderstood the cautionary language that was part of the proposed rule. The CTR does not preclude state adoption of criteria after the CTR has been promulgated. As EPA stated in the preamble to the proposed CTR, when the State has completed its own process, and EPA approves the State's new or revised criteria, EPA intends to stay the CTR. Similarly, if the State adopts site-specific criteria (including site-specific Basin Plan criteria adopted by Regional Boards which have completed the State review and adoption process), and EPA has approved them based on their individual merits, EPA intends to stay that portion of the CTR that applies more general criteria to the specific site. Each individual stay on a site-specific basis would require federal rulemaking on a case-by-case basis, and generally require more detailed effort on the Agency's part than a statewide stay.

Moreover, it is possible that State-adopted criteria could become effective for CWA purposes within the State even prior to EPA approval or rulemaking, although this would change if a rule that EPA has recently proposed is promulgated as proposed. The "Alaska Rule," 64 Fed.Reg. 37072, July 9,1999. Until the Alaska Rule goes final, the State could adopt new or revised standards which are more stringent

than the CTR, and those standards would be effective for CWA purposes within the state without any EPA action. Moreover, prior to a final Alaska Rule, the State could adopt statewide standards, and if EPA approved those standards and stayed the CTR based on them, then subsequent site-specific criteria would apply within the State when adopted by the State without requiring additional EPA approval or rulemaking. If the Alaska Rule becomes final as proposed, however, regardless of whether the CTR has been stayed, only state-adopted criteria which are more stringent than the otherwise applicable standards could be applied within the State, prior to EPA approval of those standards.

EPA also disagrees with the suggestion that EPA include provisions in this CTR rule to allow EPA to use directfinal rulemaking if it stays the CTR, or site-specific portions of the CTR, in the future. Since EPA cannot at this time predict what State criteria would replace CTR criteria when such stays are issued, EPA cannot predict whether such federal rulemakings might appropriately be adopted as direct final rules. Whether EPA meets the criteria for using direct final rulemaking in this context is a decision EPA will make when it undertakes such rulemaking.

Comment: 6. SITE SPECIFIC CRITERIA

The DFG does not object to the development of site-specific criteria provided that they are developed utilizing sound scientific methodologies. The proposed rule indicates that EPA will be reviewing several of the existing site-specific criteria already established in various Basin Plans throughout the State to determine consistency with the proposed rule. The DFG is very interested in participating in the development of site-specific criteria and request that we be included in reviewing any new site-specific proposals or revisiting existing criteria, if that is deemed necessary.

Response to: CTR-026-006

EPA has reviewed and approved some site-specific criteria already established in various Basin Plans throughout the State. The relationship between the CTR and site-specific criteria for the Sacramento River; the San Joaquin River; and the Grassland Water District, San Luis National Wildlife Refuge, and Los Banos State Wildlife Refuge are described in the preamble to the proposed CTR. (62 Fed.Reg. 42165-42166.) For the San Francisco Bay Region, see the response to CTR-016-001. EPA has not acted on any State-adopted site- specific criteria since the proposed CTR was published.

The comment author suggests that the California DFG participate in the development of any new and revised site-specific criteria. We agree with that comment and assume that California's normal process will provide for that participation.

Comment: Regulatory Flexibility and Relief

The District supports EPA's use of "sound science" and current data in developing the proposed criteria in the California Toxics Rule (CTR). The District strongly supports language in the Preamble that references and endorses recommendations of the State Task Forces including use in permitting of:

* reasonable potential analyses * dissolved metals criteria * translators * water effects ratios * site specific objectives * innovative TMDL processes such as effluent trading * performance based interim limits * chronic and acute mixing zones, and * compliance schedules in NPDES permits.

Response to: CTR-032-002e

EPA appreciates this comment which provides general support for the CTR process and for EPA's ongoing efforts to support State water quality standards development.

Comment: Mercury Criteria

The District supports the proposed revised human health criteria for mercury based on updated IRIS information. The District also supports EPA's decision (CTR P. 42180) not to apply the bioaccumulation factor (BAF) developed for the Great Lakes Initiative to the CTR mercury criteria. We agree that mercury methylation rates vary widely and are not well understood, particularly for amalgam related mercury. We believe that adoption of a national BAF under consideration as part of the "Mercury Study Report to Congress: SAB Review Draft" is inappropriate for California, particularly for the complex San Francisco Bay system. CDA recommends that EPA direct the State to develop a site specific objective

(SSO) for mercury for San Francisco Bay based on a site specific BAF and data on natural cleanup processes and methylation processes. The proposed CTR criteria should serve as interim criteria until the SSO is developed and adopted.

Response to: CTR-032-006b

EPA appreciates the support by this commenter of the human health criteria for mercury contained in the CTR. To the extent that this commenter goes further and comments on the criteria that might result in the future from EPA's Report to Congress on Mercury (December, 1997), EPA disagrees. EPA does not find it appropriate at this time to direct the State to develop site-specific criteria for mercury for San Francisco Bay (or any other specific waterbody), especially if the purpose is to forestall the application of national criteria that are not yet even defined. That decision is wholly within State authority, however; should they choose to develop site-specific criteria, these criteria would be subject to EPA review and approval based on their individual scientific validity.

Comment: B. Criteria

pp. 42165-42166 -- Site-Specific Criteria We support the process described in the Preamble, whereby the State through its Regional Water Quality Control Boards (RWQCBs) may adopt site-specific criteria as amendments to Basin Plans, which are then subject to approval by the State Water Resources Control Board (SWRCB)and the State's Office of Administrative Law. We strongly urge EPA to make timely determinations for all site-specific criteria currently under review to ensure that appropriate action is taken by EPA before the CTR becomes a final regulation, as well as to conduct timely reviews for those site-specific criteria that may be submitted for approval in the future. We suggest that it is possible to simplify the regulatory process for staying the effect of the final CTR as regards any pollutant for which a site-specific objective has been developed by the State and approved by EPA. If EPA were to state in the final rule that it proposes to approve without further notice and comment any site-specific objective which has gone through the State and EPA approval process, we see no need for additional notice and comment before EPA publishes notice of final rulemaking to modify the CTR. This process is similar to the so-called "parallel processing" procedure used by EPA's air program with respect to the approval of amendments to State Implementation Plans.

We do, however, object to the statement in the Preamble regarding the adoption of site-specificcriteria after the CTR becomes final:

However, if EPA promulgates statewide federal criteria as proposed in this rule, prior to a decision on any State-adopted site-specific criteria, the more stringent of the two criteria would be used for water

quality program. Both federal and State water quality programs must be satisfied, and application of the more stringent of the two criteria would satisfy both.

Based on EPA's own guidance, we do not believe that it is necessary for EPA to select the more stringent of the two criteria, if the site-specific criteria is less stringent but has been developed in a scientifically defensible manner (EPA, 1994b). In addition, this policy directly contradicts the assumption made in the draft Economic Analysis that an "alternative regulatory approach" would be pursued, including the use of site-specific criteria. A discharger would not pursue the development of site-specific criteria as a regulatory relief option, as was assumed in the Economic Analysis for the CTR, if EPA's policy is to approve only more stringent site-specific criteria. EPA's policy would expressly prohibit site-specific objectives from providing any relief from compliance costs. We therefore recommend that EPA include a policy in the CTR indicating that the Agency will approve site-specific criteria submitted by the State that are scientifically defensible, even if they are less stringent than CTR criteria, particularly if they are necessary to avoid excessive compliance costs.

Response to: CTR-035-014

EPA disagrees with this comment. We believe that the commenter misunderstood the cautionary language that was part of the proposed rule. The CTR does not preclude state adoption of criteria after the CTR has been promulgated. As EPA stated in the preamble to the proposed CTR, when the State has completed its own process, and EPA approves the State's new or revised criteria, EPA intends to stay the CTR. Similarly, if the State adopts site-specific criteria (including site-specific Basin Plan criteria adopted by Regional Boards which have completed the State review and adoption process), and EPA has approved them based on their individual merits, EPA intends to stay that portion of the CTR that applies more general criteria to the specific site. Each individual stay on a site-specific basis would require federal rulemaking on a case-by-case basis, and generally require more detailed effort on the Agency's part than a statewide stay.

Moreover, it is possible that State-adopted criteria could become effective for CWA purposes within the State even prior to EPA approval or rulemaking, although this would change if a rule that EPA has recently proposed is promulgated as proposed. The "Alaska Rule," 64 Fed.Reg. 37072, July 9,1999. Until the Alaska Rule goes final, the State could adopt new or revised standards which are more stringent than the CTR, and those standards would be effective for CWA purposes within the state without any EPA action. Moreover, prior to a final Alaska Rule, the State could adopt statewide standards, and if EPA approved those standards and stayed the CTR based on them, then subsequent site-specific criteria would apply within the State when adopted by the State without requiring additional EPA approval or rulemaking. If the Alaska Rule becomes final as proposed, however, regardless of whether the CTR has been stayed, only state-adopted criteria which are more stringent than the otherwise applicable standards could be applied within the State, prior to EPA approval of those standards.

EPA further disagrees with any suggestion that the State itself could, in the future, modify CTR criteria. State adoption of site-specific criteria (including site-specific criteria adopted by the Regional Board which have completed the State adoption process) is a separate State action, under State law, which does not modify federal criteria. It would be up to EPA to modify the CTR to "make way" for the State's criteria, once those criteria have been approved by EPA. As discussed above, if the State were to adopt criteria that were more stringent than applicable CTR criteria, those criteria could be effective for CWA purposes within the State under State law, prior to EPA approval of such criteria or modification of the CTR.

EPA notes that State-adopted criteria (including site-specific criteria) which are less stringent that CTR

criteria may be approved by EPA and result in a stay of the CTR if such criteria are based on sound scientific rationale which ensures that designated uses will be protected.

EPA also disagrees with the suggestion that EPA include provisions in this CTR rule to allow EPA to use direct final rulemaking if it stays the CTR, or site-specific portions of the CTR, in the future. Since EPA cannot at this time predict what State criteria would replace CTR criteria when such stays are issued, EPA cannot predict whether such federal rulemakings might appropriately be adopted as direct final rules. Whether EPA meets the criteria for using direct final rulemaking in this context is a decision EPA will make when it undertakes such rulemaking.

This commenter also urged EPA to act, prior to finalizing the CTR, to approve or disapprove any State-adopted site-specific criteria which had been submitted to EPA but EPA had not yet acted upon. This has not been possible, due to the focus of resources on the CTR itself. However, EPA reiterates that any criterion adopted by the State, and currently in effect under State law, which is more stringent than the comparable CTR criterion, could be used for water quality programs within the State without any stay of the CTR.

Comment: 1. The rule proposes that the more stringent of site-specific and national criteria be used in determining reasonable potential to exceed water quality standards and in development of limits where site-specific criteria have not yet been established. This proposal ignores the scientific basis of a site-specific criterion and that such a criterion is specifically more relevant and appropriate than a national criterion if derived correctly. EPA has acknowledged that national criteria can be more stringent than necessary to protect designated uses because they are designed to protect a wide variety of surface waters, and that a site-specific criterion can be sufficiently protective while being less stringent than a national criterion (Water Effect Ratio Guidance, 1994). This rule is arbitrarily dismissing the use of site-specific criteria which may be more technically defensible than national criteria, while being protective.

Response to: CTR-037-001a

EPA disagrees with this comment. EPA notes that State-adopted criteria (including site-specific criteria) which are less stringent that CTR criteria may be approved by EPA and result in a stay of the CTR if such criteria are based on sound scientific rationale which ensures that designated uses will be protected. The CTR does not preclude state adoption of criteria, including criteria which may be less stringent than CTR criteria. State-adopted criteria(including site-specific criteria) which are less stringent that CTR criteria may be approved by EPA and result in a stay of the CTR if such criteria are based on sound scientific rationale which ensures that designated uses will be protected.

To the extent that this commenter is concerned that the CTR criteria supercede existing State-adopted site-specific criteria which are less stringent than CTR criteria and have not been approved by EPA, EPA agrees that this is the effect of adoption of the CTR, but disagrees that this provides a basis for "promulgating around" such unapproved site-specific criteria. Because EPA has not completed it evaluation of these criteria and EPA needs to have criteria in place to implement section 303(c)(2)(B), EPA has chosen to put in place criteria based on EPA's national section 304(a) criteria recommendations to most efficiently ensure protection for all California waters. EPA will then complete its review of site-specific criteria. To do otherwise would risk that coverage did not occur for some waters should EPA not find the site-specific value to be scientifically defensible. However, as stated in the preamble to the proposed CTR, EPA will make a determination on all State-adopted site-specific criteria which have been submitted to EPA for review. When EPA approves any new or revised State criteria, EPA intends to stay the CTR. It was not possible for EPA to make determinations on pending site-specific criteria prior to the final CTR.

Comment: 6. Separate, site-specific human health criteria for carcinogens should be adopted for Schell Slough based on a 10 (-4) risk level and for Second Napa Slough based on a 10 (-5) risk level. Based on effluent sampling performed by the District, the District would be unable to comply with criteria for numerous carcinogens based on a 10 (-6) risk level (alpha-BHC, gamma-BHC, bromodichloromethane, indeno(1,2,3-cd)pyrene, chlordane, and 4,4'-DDT) without costly end-of-pipe controls. These controls would not produce a commensurate environmental benefit. At a 10 (-4) risk level, the District's discharge would not cause an in-stream exceedance of these criteria in Schell Slough, and at a 10 (-5) risk level, the discharge would not cause an in-stream exceedance in Second Napa Slough. The District does not believe these sloughs are heavily fished and therefore criteria based on 10 (-4) and 10 (-5) risk levels would likely provide greater protection than indicated by the risk levels. The District notes that none of these constituents were identified in EPA's economic analysis as significant contributors to baseline cancer risks for recreational anglers consuming San Francisco Bay fish (see Exhibit 8-7 in EPA's economic analysis).

Response to: CTR-038-007

EPA disagrees that it must or should establish separate, site-specific criteria in this rule for receiving waters where dischargers may be unable to meet the CTR criteria. In accordance with 40 CFR 131.11, criteria must be based on sound scientific rationale and must protect the designated use. There is no provision for EPA to consider the attainability or the scientific validity of the criteria with regard to specific dischargers or class of dischargers in adopting ambient water quality criteria in the CTR. Economic factors may be considered in designating uses (40 CFR 131.10); however, they may not be used to justify criteria which are not protective of those uses. The CTR itself does not adopt uses or

modify any uses previously adopted by the State. EPA presumes that the State has designated appropriate uses for its waters. Proposals to revise State-adopted uses must be brought to the State pursuant to its procedures for review of its water quality standards.

That being said, it should nevertheless be understood that EPA does support State adoption of site-specific criteria. As explained in the preamble to the proposed CTR, and further discussed in response to CTR-016-002, EPA will work with the State to approve acceptable State-adopted criteria (including site-specific criteria) and to stay the CTR where EPA has approved such State criteria.

With respect to risk level applicable to human health criteria when, as here, EPA establishes a water quality standard, EPA intends in its discretion to use a risk level of 1 x 10-6, although the State may in its discretion choose another risk level for protection of human health, if the State has appropriately consulted the public. As discussed in responses to CTR-011-0001a and CTR-058-001 (Category C-13; Risk Level), EPA follows the risk-level policies of the affected state, when promulgating criteria as regulations.

The comment that the carcinogens that are asserted to be compliance problems are not identified in EPA's economic analysis as a significant contributor to baseline cancer risks for recreational anglers consuming San Francisco Bay fish may merely reflect a lack of information on these pollutants in sample locations that were selected for the benefits analysis. The fact that no baseline risks were found for the purposes of the analysis does not necessarily mean that the risk from these pollutants do not exist anywhere in the Bay or should not be prevented.

Comment: 7. Separate, sites-specific aquatic life criteria for copper and human health criteria for mercury should be adopted for Schell Slough, or alternatively EPA should specify implementation procedures for these criteria that will preclude unreasonable controls such as end-of-pipe treatment. To comply with the Clean Water Act and EPA regulations, EPA should consider specific water bodies. To fulfill the spirit of Presidential Executive Order 12866 and the requirements of the Unfunded Mandates Reform Act and the Regulatory Flexibility Act, EPA should evaluate regulatory alternatives based on an analysis of costs and benefits. Based on the assessment of costs and benefits described in "3" above, EPA should either adopt the criteria that is currently achieved, or alternatively specify implementation procedures that would allow the current discharge to continue (e.g., allowable Mixing zones and averaging periods and, for copper, a translator and water-effect ratio). Again, the District is amenable to continuing to address these constituents through pollution prevention measures and to assessing the actual impacts of these constituents in Schell Slough. Without EPA specifying such implementation procedures in the CTR, it is possible that the CTR could impose significant costs on the District (and the other small communities its serves) without providing a commensurate environmental benefit. In that

case, the CTR would be inconsistent with the Clean Water Act, EPA regulations, Presidential Executive Order 12866, the Unfunded Mandates Reform Act and the Regulatory Flexibility Act.

Response to: CTR-038-008a

EPA disagrees with this commenter's suggestion that separate, site-specific criteria for copper and mercury be adopted for Schell Slough, based on considerations of costs and benefits. EPA has conducted an analysis of costs and benefits for this rule pursuant to Executive Order 12866; however, the criteria themselves are not based on economic considerations. In accordance with 40 CFR 131.11, criteria must be based on sound scientific rationale and must protect the designated use. There is no provision for EPA to consider the attainability or the scientificvalidity of the criteria with regard to specific dischargers or class of dischargers in adopting ambient water quality criteria in the CTR. Economic factors may be considered in designating uses (40 CFR 131.10); however, they may not be used to justify criteria which are not protective of those uses.

That being said, it should nevertheless be understood that EPA does support the State's adoption of site-specific criteria. As explained in the preamble to the proposed CTR, and further discussed in response to CTR-016-002, EPA will work with the State to approve acceptable State-adopted criteria (including site-specific criteria) and to stay the CTR when EPA has approved such State criteria.

This commenter further suggests that EPA specify implementation procedures for certain criteria as an alternative to the proposed site-specific criteria. The CTR was not intended to include implementation provisions. The CTR is promulgated to add numeric criteria for priority toxic pollutants where they did not exist. To the extent that this commenter is proposing implementation provisions that are not inconsistent with CWA requirements, such provisions may be considered by the State for inclusion in its implementation plan (Draft Policy for Implementation of Toxics Standards for Inland Surface Waters and Enclosed Bays and Estuaries of California, September 11, 1997).

Finally, regarding the commenter's assertion that the CTR could be inconsistent with Executive Order 12866, the Regulatory Flexibility Act and the Unfunded Mandates Reform Act without further revision (such as suggested by the commenter), see the discussion of EPA's compliance with these requirements in the preamble to the final rule.

Comment: As EPA notes in the preamble to the rule, "adoption of water quality standards is primarily theresponsibility of the states." 62 Fed. Reg. at 42166. In exercising that responsibility, the States have considerable discretion in applying the scientific and technical data available to them. A pervasive concern with the proposed rule is a lack of consistency by EPA in according appropriate deference to the

State of California's prior decisions, already approved by EPA. Where convenient, the proposed rule relies on the State's previous efforts, including for example the State's preference that health risks be based upon a 10-6 risk level and the novel notion of interim permit limits. However, as regards the rule's most important feature and indeed the only raison d'etre for the rule - the numeric criteria - EPA almost completely abandons the State's prior technical determinations on the numeric criteria appropriate for California where the State' s prior decision was more protective of the environment and human health then the currently proposed criteria. This is true for EPA's decision to go from total recoverable metals criteria to dissolved metals criteria, a proposal that is inconsistent with the State's prior approved decision and which will result in significant increases in total pollutants allowed to be discharged into San Francisco Bay and elsewhere in the State. The State's prior decisions also were abandoned for dioxin and mercury, including failing to consider all of the dioxin congeners, failing to consider the bioaccumulation of mercury (a well-documented characteristic of that potent toxic pollutant) and failing to consider the higher rates of fish consumption found in California and in discrete populations of subsistence and recreational anglers.

Response to: CTR-039-001

EPA disagrees with the suggestion that EPA should have deferred to the State's prior WQS decisions, previously approved by EPA. To the extent that the commenter is referring to criteria in the Inland Surface Waters Plan (ISWP) and the Enclosed Bays and Estuaries Plan (EBEP), EPA responds that those were considered along with all of the other scientific information that makes up the record for this rule. However, those statewide plans are no longer in effect, and EPA is not bound by them. EPA adopts criteria based on sound scientific rationale, which protect the designated uses of waters of the United States in California. Additional scientific information has become available for some pollutants since California adopted the ISWP and EBEP in 1991, which forms the basis for adopting CTR criteria which differ from some of the criteria previously adopted for the same waterbodies.

EPA further disagrees with passing statements in this comment criticizing EPA's use of dissolved rather than total recoverable metals, failure to consider all dioxin congeners, failure to consider bioaccumulation of mercury and failure to consider higher rates of fish consumption in California. For a detailed discussion of the points made regarding dioxin, see response to CTR-002-003 and CTR-002-006. Regarding EPA's use of dissolved rather than total recoverable metals see response to CTR-026-004. Regarding bioaccumulative properties of mercury, see CTR-002-007b. Regarding rates of fish consumption, see response to CTR-002-002a and the preamble of the final rule.

To the extent that this comment is referring to site-specific criteria for San Francisco Bay, EPA is revising the final CTR to ensure that EPA-approved State-adopted site-specific criteria shall remain in effect and not be superceded by CTR criteria for the same pollutants for those waters of the Bay where such site-specific criteria are currently in effect. See response to CTR-016-001.

Comment: VII. EPA CAN ADJUST ITS PROPOSED RULE TO REFLECT REGIONAL CONDITIONS AND PROTECT USES IN SPECIFIC REGIONS

As EPA notes in the preamble, when it considered the State's 1991 criteria, it approved the proposed criteria for selenium for everywhere in the State except San Francisco Bay and the Delta. 62 Fed. Reg. at 42164. There is no reason that EPA cannot adjust its proposed to rule to reflect the available scientific data that may only be available in certain regions of the State, including for example, data relating to mercury bioaccumulation in San Francisco Bay fish. The concept of treating dischargers from different areas fairly should not be applied so as to punish those regional ecosystems where agencies have been more proactive in collecting necessary data. Rather, dischargers should be treated equally stringently where data from one region indicates that uses are threatened by a particular pollutant throughout the State.

CONCLUSION

In conclusion, BayKeeper is very concerned with the proposed rule. The State obviously must have numeric criteria for toxic pollutants. Great strides have been made, especially in the San Francisco Bay area, to reduce the mass of toxic pollutants entering the Bay. The proposed criteria likely will bring to a halt the most innovative programs to reduce toxic pollution. Instead of promoting innovation and driving dischargers' ability to achieve, some day, the penultimate goal of the Clean Water Act to eliminate all discharges of pollution to the Nation's waters, the proposed rule will only perpetuate mediocre toxic pollution control efforts and fail to reverse the ecological damage from toxic contamination, including dangerous levels of contaminants in fish already observed in Bay fish and the continuing decline of aquatic ecosystems around the State.

BayKeeper appreciates this opportunity to express our views on the proposed rule. If you have any questions, please feel free to call me at 1-800--KEEP-BAY.

Response to: CTR-039-009

EPA disagrees with this comment. In 1991, when EPA took action on the first phase of the Enclosed Bays and Estuaries Plan (EBEP), EPA did not disapprove the salt water aquatic life criterion for selenium. Instead, EPA made it clear that use of that criterion in permits issued for the San Francisco Bay and Delta would be unacceptable. This was consistent with the EBEP provision which stated that more stringent objectives and control measures could be applied by the Regional Boards in some estuarine waters. (Letter of November 6, 1991, to W. Don Maughan, Chairman, State Water Resources Control Board, from Daniel W. McGovern Regional Administrator, EPA RegionIX.) In December 1992, EPA adopted freshwater aquatic life criterion for the San Francisco Bay Estuary as part of the National Toxics Rule (NTR) because the San Francisco Bay Regional board had not itself specified that it would apply the freshwater criterion, consistent with EPA's November 6, 1991 letter. (57 Fed. Reg. 60898.) This was not the promulgation of a site-specific criterion for the San Francisco Bay and Delta, however. Although the freshwater criterion was the same as the freshwater selenium criterion in the Inland Surface Water Plan (ISWP), it was also EPA's national fresh water selenium criterion. As explained in the Preamble to the final NTR (Id.), EPA simply was unable adopt site-specific criteria as part of the NTR. The same is true of the CTR.

As noted in footnotes to the CTR selenium criterion, the CTR does not supercede that provision of the NTR (40 CFR 131.36(d)(10)).

Regarding general concerns included in this comment regarding the effect of the CTR on criteria developed for San Francisco Bay, see responses to CTR-016-001 and CTR-002-003.

Comment: The Preamble to the California Toxics Rule (CTR), and the rules accompanying Economic Analysis (EA), place a great deal of emphasis on the ability of dischargers to use alternative regulatory approaches to comply with CTR criteria if the cost of treatment technology was prohibitively expensive. For example, the EA assumes that, if the estimated annualized cost for removing a pollutant exceeded a cost trigger,(*1) "dischargers would explore the use of alternative regulatory approaches to comply with CTR-based effluent limits." EA at.pg. 4 (emphasis added). Based on this assumption, no treatment cost was estimated for the facility.(*2)

The types of alternative regulatory approaches assumed available for dischargers in California include phased total maximum daily loads (TMDLs), water quality standard variances, site-specific criteria, change in designated use, and alternative mixing zones. EA at pg. 4-5. The following sections will discuss each of EPA's proposed methods for regulatory relief and explain whether or not these methods can truly be used to provide relief from the CTR-based permit limits as anticipated by EPA. It should be noted that the actual language of the rule itself does not mention any of the methods of regulatory relief. Therefore, this analysis will be based solely upon the language contained in the Preamble to the CTR.

Site Specific Criteria

Another one of the avenues of potential regulatory relief discussed in the Preamble to the CTR is the adoption of site-specific water quality criteria. The Preamble, provides that the "State has the discretion to develop site-specific criteria when appropriate e.g., when statewide criteria appear over- or under-protective of designated uses. The Preamble goes on to explain the site-specific criteria adoption process as follows:

Periodically, the State through its RWQCBs will adopt site-specific criteria for priority toxic pollutants within respective Basin Plans. These criteria are intended to be effective throughout the Basin or throughout a designated water body. Under California law, these criteria must be publicly reviewed and approved by the RWQCB, the SWRCB, and the State's Office of Administrative Law (OAL). Once this adoption process is complete, the criteria become State law. These criteria must be submitted to the EPA Regional Administrator for review and approval under CWA section 303. These criteria are usually submitted to EPA as part of a RWQCB Basin Plan Amendment, after the Amendment has been adopted

under the State's process and has become State law. CTR Preamble at pg. 42165.

The Preamble explains that the State of California has recently reviewed and updated all of its RWQCB Basin Plans. All of these Basin Plans, some of which contain site-specific criteria, have completed the State review and adoption process and have been submitted to EPA for review and approval. The key to whether or not these site-specific criteria will provide regulatory relief is when the EPA approval/disapproval occurs. Three different timing scenarios and results are possible:

1. If EPA approves any State-adopted site-specific criteria before promulgation of the final CTR is published, then the EPA Administrator may make a finding in that final rule that it will be unnecessary to promulgate criteria for the approved site-specific pollutants and associated water bodies.

2. EPA disapproves any State-adopted site-specific criteria, the proposed statewide criteria contained in the CTR would apply for those pollutants and associated water bodies instead of the site-specific criteria.

3. However, if EPA promulgates statewide federal criteria as proposed in the CTR, prior to a decision on any State-adopted site-specific criteria, the more stringent of the two criteria would be used for water quality programs. Both federal and State water quality programs must be satisfied, and application of the more stringent of the two criteria would satisfy both. CTR Preamble at pg. 42165.

Thus, the only way less stringent site specific criteria can be used for regulatory relief is if those criteria are approved by EPA prior to the publication of the final CTR. otherwise, either the CTR or the more stringent of the two (CTR vs. site-specific) criteria apply.

One final note regarding site-specific criteria is that the Preamble to the CTR restricts the ability to use native aquatic life as a way to set site-specific criteria. Instead of allowing a discharger to substitute local species from the receiving waters into which it discharges, the Preamble only allows a discharger to supplement the eight specified families of aquatic life required for criteria development with the addition of native species.(*9) It is doubtful whether this requirement will aid dischargers who are seeking regulatory relief.

(*1) This coat trigger is $200 per toxic pounds-equivalent for a facility under the low-end scenario, and $500 per toxic pounds-equivalent for a category of dischargers under the high-end scenario. See EA at pg. 4.

(*2) In addition, pollutant load reductions were not calculated or credited for any pollutant for which an alternative regulatory approach was pursued. Id.

(*9) "A minimum data set of eight specified facilities is required for criteria development (details are given in the 1985 Guidelines, page 22). The eight specific families are intended to be representative of a wide spectrum of aquatic life. For this reason it is not necessary that the specific organisms tested be actually present in the water body. States may develop site-specific criteria unsing native species, provided that the broad spectrum represented be the eight families is maintained. All aquatic organisms and their common uses are meant to be considered, but not necessarily protected, if relevant data are available." CTR Preamble at pg. 42168.

Response to: CTR-040-050

EPA disagrees with this comment. See response to CTR-004-008.

It should be noted that the actual language of the rule itself doesnot mention any of the methods of regulatory relief. Therefore, this analysis will be based solely upon the language contained in the Preamble to the CTR.

Site Specific Criteria

Another one of the avenues of potential regulatory relief discussed in the Preamble to the CTR is the adoption of site-specific water quality criteria. The Preamble, provides that the "State has the discretion to develop site-specific criteria when appropriate e.g., when statewide criteria appear over- or under-protective of designated uses. The Preamble goes on to explain the site-specific criteria adoption process as follows:

Periodically, the State through its RWQCBs will adopt site-specific criteria for priority toxic pollutants within respective Basin Plans. These criteria are intended to be effective throughout the Basin or throughout a designated water body. Under California law, these criteria must be publicly reviewed and approved by the RWQCB, the SWRCB, and the State's Office of Administrative Law (OAL). Once this adoption process is complete. the criteria become State law. These criteria must be submitted to the EPA Regional Administrator for review and approval under CWA section 303. These criteria are usually submitted to EPA as part of a RWQCB Basin Plan Amendment, after the Amendment has been adopted under the State's process and has become State law. CTR Preamble at pg. 42165.

The Preamble explains that the State of California has recently reviewed and updated all of its RWQCB Basin Plans. All of these Basin Plans, some of which contain site-specific criteria, have completed the State review and adoption process and have been submitted to EPA for review and approval. The key to whether or not these site-specific criteria will provide regulatory relief is when the EPA approval/disapproval occurs. Three different timing scenarios and results are possible:

1. If EPA approves any State-adopted site-specific criteria before promulgation of the final CTR is published, then the EPA Administrator may make a finding in that final rule that it will be unnecessary to promulgate criteria for the approved site-specific pollutants and associated water bodies. 2. EPA disapproves any State-adopted site-specific criteria, the proposed statewide criteria contained in the CTR would apply for those pollutants and associated water bodies instead of the site-specific criteria. 3. However, if EPA promulgates statewide federal criteria as proposed in the CTR, prior to a decision on any State-adopted site-specific criteria, the more stringent of the two criteria would be used for water quality programs. Both federal and State water quality programs must be satisfied, and application of the more stringent of the two criteria would satisfy both. CTR Preamble at pg. 42165.

Thus, the only way less stringent site specific criteria can be used for regulatory relief is if those criteria are approved by EPA prior to the publication of the final CTR. Otherwise, either the CTR or the more stringent of the two (CTR vs. site-specific) criteria apply.

One final note regarding site-specific criteria is that the Preamble to the CTR restricts the ability to use native aquatic life as a way to set site-specific criteria. Instead of allowing a discharger to substitute local species from the receiving waters into which it discharges, the Preamble only allows a discharger to supplement the eight specified families of aquatic life required for criteria development with the addition of native species.(*9) It is doubtful whether this requirement will aid dischargers who are seeking regulatory relief.

(*1) This coat trigger is $200 per toxic pounds-equivalent for a facility under the low-end scenario, and $500 per toxic pounds-equivalent for a category of dischargers under the high-end scenario. See EA at pg. 4.

(*2) In addition, pollutant load reductions were not calculated or credited for any pollutant for which an alternative regulatory approach was pursued. Id.

(*9) "A minimum data set of eight specified facilities is required for criteria development (details are given in the 1985 Guidelines, page 22). The eight specific families are intended to be representative of a wide spectrum of aquatic life. For this reason it is not necessary that the specific organisms tested be actually present in the water body. States may develop site-specific criteria using native species, provided that the broad spectrum represented be the eight families is maintained. All aquatic organisms and their common uses are meant to be considered, but not necessarily protected, if relevant data are available." CTR Preamble at pg. 42168.

Comment: 6. EPA should adopt separate, site-specific human health criteria for Old Alamo Creek based on a 10 (-4) risk level. As previously indicated the City would have to construct costly end-of-pipe controls to comply with the human health criteria for several carcinogens. The subject criteria are based on a cancer risk level of 10 (-6). These controls would not produce a commensurate environmental benefit. At a 10 (-4) risk level, the City's discharge would not cause an in-stream exceedance of these criteria. The City does not believe Old Alamo Creek is heavily fished and therefore criteria based on a 10 (-4) risk level would likely provide greater protection than indicated by the risk level. The City notes that none of these carcinogens were identified in EPA's economic analysis as a significant contributor to baseline cancer risks for recreational anglers consuming freshwater fish in California (see Exhibit 8-9 in EPA's economic analysis).

Response to: CTR-043-006a

EPA disagrees with this commenter's suggestion that separate, site-specific human health criteria be adopted for Old Alamo Creek, based on considerations of costs and benefits. EPA has conducted an analysis of costs and benefits for this rule pursuant to Executive Order 12866 (see discussion in preamble to final rule); however, the criteria themselves are not based on economic considerations. In accordance with 40 CFR 131.11, criteria must be based on sound scientific rationale and must protect the designated use. There is no provision for EPA to consider the attainability or the scientific validity of the criteria with regard to specific dischargers or class of dischargers in adopting ambient water quality criteria in the CTR. Economic factors may be considered in designating uses (40 CFR 131.10); however, they may not be used to justify criteria which are not protective of those uses.

That being said, it should nevertheless be understood that EPA does support the State's adoption of site-specific criteria. As explained in the preamble to the proposed CTR, and further discussed in response to CTR-016-002, EPA will work with the State to approve acceptable State-adopted criteria (including site-specific criteria) and to stay the CTR when EPA has approved such State criteria.

With respect to risk level applicable to human health criteria when, as here, EPA establishes a water quality standard, EPA intends in its discretion to use a risk level of 1 x 10-6, although the State may in its discretion choose another risk level for protection of human health, if the State has appropriately consulted the public. As discussed in responses to CTR-011-001a and CTR-058-001 (Category C-13; Risk Level), EPA follows the risk-level policies of the affected state, when promulgating criteria as regulations.

Comment: We have reviewed the proposed CTR and offer the following comments:

6. EPA should adopt separate, site-specific human health criteria for Tule Canal based on a 10 (-4) risk level. Based on effluent sampling, the City would have to construct costly end-of-pipe controls to comply with criteria for aldrin (and perhaps other carcinogens) based on a 10 (-6) risk level. These controls would not produce a commensurate environmental benefit. At a 10 (-4) risk level, the City's discharge would not cause an in-stream exceedance of these criteria in Tule Canal. The City does not believe Tule Canal is heavily fished and therefore criteria based on a 10 (-4) risk level would likely provide greater protection than indicated by the risk level. The City notes that aldrin was not identified in EPA's economic analysis as a significant contributor to baseline cancer risks for recreational anglers consuming freshwater fish in California (see Exhibit 8-9 in EPA's economic analysis).

Response to: CTR-044-007b

EPA disagrees with this commenter's suggestion that separate, site-specific human health criteria be adopted for Tule Canal, based on considerations of costs and benefits. EPA has conducted an analysis of costs and benefits for this rule pursuant to Executive Order 12866 (see discussion in preamble to final rule); however, the criteria themselves are not based on economic considerations. In accordance with 40 CFR 131.11, criteria must be basedon sound scientific rationale and must protect the designated use. There is no provision for EPA to consider the attainability or the scientific validity of the criteria with regard to specific dischargers or class of dischargers in adopting ambient water quality criteria in the CTR. Economic factors may be considered in designating uses (40 CFR 131.10); however, they may not be used to justify criteria which are not protective of those uses.

That being said, it should nevertheless be understood that EPA does support the State's adoption of site-specific criteria. As explained in the preamble to the proposed CTR, and further discussed in response to CTR-016-002, EPA will work with the State to approve acceptable State-adopted criteria (including site-specific criteria) and to stay the CTR when EPA has approved such State criteria.

With respect to risk level applicable to human health criteria when, as here, EPA establishes a water quality standard, EPA intends in its discretion to use a risk level of 1 x 10-6, although the State may in its discretion choose another risk level for protection of human health, if the State has appropriately consulted the public. As discussed in responses to CTR-011-001a and CTR-058-001 (Category C-13; Risk Level), EPA follows the risk-level policies of the affected state, when promulgating criteria as regulations.

Comment: The Preamble to the California Toxics Rule (CTR), and the rules accompanying Economic Analysis (EA), place a great deal of emphasis on the ability of dischargers to use alternative regulatory approaches to comply with CTR criteria if the cost of treatment technology was prohibitively expensive. For example, the EA assumes that, if the estimated annualized cost for removing a pollutant exceeded a cost trigger,(*1) "dischargers would explore the use of alternative regulatory approaches to comply with CTR-based effluent limits." EA at.pg. 4(emphasis added). Based on this assumption, no treatment cost was estimated for the facility.(*2)

The types of alternative regulatory approaches assumed available for dischargers in California include phased total maximum daily loads (TMDLs), water quality standard variances, site-specific criteria, change in designated use, and alternative mixing zones. EA at pg. 4-5. The following sections will discuss each of EPA's proposed methods for regulatory relief and explain whether or not these methods can truly be used to provide relief from the CTR-based permit limits as anticipated by EPA. It should be noted that the actual language of the rule itself doesnot mention any of the methods of regulatory relief. Therefore, this analysis will be based solely upon the language contained in the Preamble to the CTR.

Site Specific Criteria

Another one of the avenues of potential regulatory relief discussed in the Preamble to the CTR is the adoption of site-specific water quality criteria. The Preamble, provides that the "State has the discretion to develop site-specific criteria when appropriate e.g., when statewide criteria appear over- or under-protective of designated uses. The Preamble goes on to explain the site-specific criteria adoption process as follows:

Periodically, the State through its RWQCBs will adopt site-specific criteria for priority toxic pollutants within respective Basin Plans. These criteria are intended to be effective throughout the Basin or throughout a designated water body. Under California law, these criteria must be publicly reviewed and approved by the RWQCB, the SWRCB, and the State's Office of Administrative Law (OAL). Once this adoption process is complete. the criteria become State law. These criteria must be submitted to the EPA Regional Administrator for review and approval under CWA section 303. These criteria are usually submitted to EPA as part of a RWQCB Basin Plan Amendment, after the Amendment has been adopted under the State's process and has become State law. CTR Preamble at pg. 42165.

The Preamble explains that the State of California has recently reviewed and updated all of its RWQCB Basin Plans. All of these Basin Plans, some of which contain site-specific criteria, have completed the State review and adoption process and have been submitted to EPA for review and approval. The key to whether or not these site-specific criteria will provide regulatory relief is when the EPA approval/disapproval occurs. Three different timing scenarios and results are possible:

1. If EPA approves any State-adopted site-specific criteria before promulgation of the final CTR is published, then the EPA Administrator may make a finding in that final rule that it will be unnecessary to promulgate criteria for the approved site-specific pollutants and associated water bodies. 2. EPA disapproves any State-adopted site-specific criteria, the proposed statewide criteria contained in the CTR would apply for those pollutants and associated water bodies instead of the site-specific criteria. 3.

However, if EPA promulgates statewide federal criteria as proposed in the CTR, prior to a decision on any State-adopted site-specific criteria, the more stringent of the two criteria would be used for water quality programs. Both federal and State water quality programs must be satisfied, and application of the more stringent of the two criteria would satisfy both. CTR Preamble at pg. 42165.

Thus, the only way less stringent site specific criteria can be used for regulatory relief is if those criteria are approved by EPA prior to the publication of the final CTR. Otherwise, either the CTR or the more stringent of the two (CTR vs. site-specific) criteria apply.

One final note regarding site-specific criteria is that the Preamble to the CTR restricts the ability to use native aquatic life as a way to set site-specific criteria. Instead of allowing a discharger to substitute local species from the receiving waters into which it discharges, the Preamble only allows a discharger to supplement the eight specified families of aquatic life required for criteria development with the addition of native species.(*9) It is doubtful whether this requirement will aid dischargers who are seeking regulatory relief.

(*1) This coat trigger is $200 per toxic pounds-equivalent for a facility under the low-end scenario, and $500 per toxic pounds-equivalent for a category of dischargers under the high-end scenario. See EA at pg. 4.

(*2) In addition, pollutant load reductions were not calculated or credited for any pollutant for which an alternative regulatory approach was pursued. Id.

(*9) "A minimum data set of eight specified facilities is required for criteria development (details are given in the 1985 Guidelines, page 22). The eight specific families are intended to be representative of a wide spectrum of aquatic life. For this reason it is not necessary that the specific organisms tested be actually present in the water body. States may develop site-specific criteria using native species, provided that the broad spectrum represented be the eight families is maintained. All aquatic organisms and their common uses are meant to be considered, but not necessarily protected, if relevant data are available." CTR Preamble at pg. 42168.

Comment: II. EPA Should Allow Variances and Site-Specific modifications.

Beyond the issue of whether EPA has the authority to issue the proposed rule, there are other significant problems with the proposal. For example, the Agency has made the inexplicable decision not to include provisions that would allow for issuance of variances or site-specific modifications to the criteria. This is

despite the Agency's recognition that a variance procedure is an "important procedure to assist the State in effectively implementing water quality standards." (62 Fed. Reg. at 42185). EPA gives absolutely no explanation for its decision not to allow use of this procedure. Moreover, the Agency concedes that "promulgation of this federal rule removes most of the flexibility available to the State for modifying its standards on a discharger-specific or stream-specific basis. " Instead, an applicant would have to ask EPA to begin a "federal rulemaking on a case-by-case basis to change the federal rule." (62 Fed. Reg. at 42186) EPA makes it quite clear that applicants should not expect any relief from that avenue, because the Agency simply has more important things to do:

Because of the time consuming nature of reviewing such requests, limited federal resources, and the need for the Agency to move into other priority program areas in establishing environmental controls, EPA alerts California and the public that a prompt Agency response is unlikely.

Despite this cavalier dismissal of the need for actually acting on variance and site criteria applications, the Agency does not hesitate to mention those mechanisms in its economic analysis as being available to moderate the impact of the proposed rule. The Agency specifically mentions variances and site-specific criteria when it states that "these implementation procedures can have an effect on how water quality standards, based on today's proposed rule, will impact NPDES permit holders." (62 Fed. Reg. at 42192). In fact, that statement is clearly false, given EPA's decision not to include variance or site-specific criteria procedures in the proposed rule. The Agency should reconsider that decision and insert those provisions.

Response to: CTR-050-005a

EPA disagrees with this comment. We believe that the commenter misunderstood the cautionary language that was part of the proposed rule. The CTR does not preclude the issuance of variances from CTR criteria or future state adoption of site-specific criteria.

Variances would modify applicable CTR criteria for individual dischargers. Site-specific criteria would modify CTR criteria for individual waterbodies. Since the State lacks authority to modify federally promulgated CTR criteria itself (See response to CTR-035-014), EPA must approve individual variances and site-specific criteria and stay the applicable CTR criteria to allow these State modification actions to take effect under the CWA. (As stated in the preamble to the proposed CTR, the State must also adopt a variance policy, and EPA must approve the policy, before the State may issue variances to individual dischargers.) EPA stated in the proposed CTR preamble that when the State has completed its own process for modifying criteria, and EPA approves the State's new or revised criteria, EPA does intend to stay the CTR.

Because there is uncertainty as to how the State will implement CTR criteria in individual permits, EPA's economic analysis of the CTR included a wide range of estimated costs and benefits. The analysis was not based on any certainty that variances and site-specific modifications of criteria would be available to every permittee; on the other hand, the analysis assumed that the State was likely to choose implementation provisions that provide some degree of flexibility or relief to point source dischargers. For a discussion of the approach taken in the economics analysis, see the preamble to the final rule.

Comment: We have reviewed the proposed California Toxics Rule. We have comments about several of the proposed provisions in the Toxics Rule. Many of our concerns are similar to those detailed in the September 25 letter from the Saii, Francisco Bay Regional Water Quality Control Board.

Site Specific Objectives

We are concerned that the language in the proposed Toxics Rule would hamper future Regional Board efforts to establish site specific objectives. EPA cautions California and the public that promulgation of this federal rule removes most of the flexibility available to the State for modifying its standards on a discharger-specific or stream-specific basis. Also, EPA states that they may be unable to review state developed standards in a timely manner. However, the Regional Boards are required and authorized under the Clean Water Act and state law to review and, as appropriate, consider modification of promulgated standards as they apply to specific water bodies within each region as part of the triennial review process. We suggest that the language in the proposed Toxics Rule be amended to encourage, rather than discourage, development of site specific objectives.

Response to: CTR-051-001

EPA disagrees with this comment. We believe that the commenter misunderstood the cautionary language that was part of the proposed rule. The CTR does not preclude state adoption of criteria after the CTR has been promulgated. As EPA stated in the preamble to the proposed CTR, when the State has completed its own process, and EPA approves the State's new or revised criteria, EPA intends to stay the CTR. Similarly, if the State adopts site-specific criteria (including site-specific Basin Plan criteria adopted by Regional Boards which have completed the State review and adoption process), and EPA has approved them based on their individual merits, EPA intends to stay that portion of the CTR that applies more general criteria to the specific site. Each individual stay on a site-specific basis would require federal rulemaking on a case-by-case basis, and generally require more detailed effort on the Agency's part than a statewide stay.

Moreover, it is possible that State-adopted criteria could become effective for CWA purposes within the State even prior to EPA approval or rulemaking, although this would change if a rule that EPA has recently proposed is promulgated as proposed. The "Alaska Rule," 64 Fed.Reg. 37072, July 9,1999. Until the Alaska Rule goes final, the State could adopt new or revised standards which are more stringent than the CTR, and those standards would be effective for CWA purposes within the state without any EPA action. Moreover, prior to a final Alaska Rule, the State could adopt statewide standards, and if EPA approved those standards and stayed the CTR based on them, then subsequent site-specific criteria would apply within the State when adopted by the State without requiring additional EPA approval or rulemaking. If the Alaska Rule becomes final as proposed, however, regardless of whether the CTR has been stayed, only state-adopted criteria which are more stringent than the otherwise applicable standards could be applied within the State, prior to EPA approval of those standards.

Comment: EPA should have considered the CTR specifically as it applies to San Francisco Bay. As noted previously, implementation of the CTR and full compliance by Bay Area POTWs will result in a reduction of between 1-10% of the toxic load on San Francisco Bay. Since 90-99% of the toxic load will still be present from such sources as non-point, riverine, agricultural drainage, acid mines, atmospheric deposition, etc., it is reasonable to conclude that full compliance by POTWs will result in no significant improvement to the Bay. In other words, the benefits will actually approach zero. Annual costs for Bay Area POTWs will range from $130,000,000 to $185,000,000 or more. Such an expenditure for essentially no benefit is clearly not in the best interests of the public or the environment. It is, therefore, reasonable to conclude that in its current form, the CTR should exempt San Francisco Bay, or at least exempt POTWs discharging to the Bay. EPA should acknowledge that Bay Area POTWs have had NPDES permits with effluent limitations for toxic pollutants for many years. Exempting POTWs from the CTR would not have any impact on current standards.

Response to: CTR-052-008

EPA disagrees with this comment. EPA did consider the CTR specifically as it applies to San Francisco Bay, and has modified the CTR accordingly. (See response to CTR-016-001.)

EPA acknowledges that a number of Bay Area POTWs have NPDES permits with effluent limitations for toxic pollutants; however, that information does not serve as justification for exempting the Bay, or certain dischargers to the Bay, from the CTR, where it applies. Water quality standards are developed to protect the designated uses of the waters of the United States, and the standards contained in the CTR are EPA's view of the standards necessary to protect designated uses.. The CTR applies to all sources of toxics discharged to water of the Bay (except where EPA-approved San Francisco Bay Basin Plan criteria apply), not merely to publicly owned treatment works (POTWs). These ambient WQS can also assist in the reduction of pollution from non-point sources, through the TMDL process.

For a discussion of EPA's economic analysis for the CTR in general, see the preamble to the final rule.

Comment: C. RECOMMENDATIONS FOR MODIFICATIONS TO THE CTR AND EA

Specify in the Preamble that EPA would support a scientifically defensible, reasonably achievable site specific objective (SSO) for copper for San Francisco Bay. The analysis by Larry Walker used data from the San Francisco Bay Regional Monitoring Plan and concludes that a translator of 1.6 should be used to result in a total recoverable concentration of 5.0 ug/L. Note that this value compares favorably with the existing SSO of 4.9 ug/L. Most of the copper attainability issues, including the Authority's, would be resolved by this approach.

Response to: CTR-052-017

EPA disagrees that EPA should specifically express support for a "scientifically defensible, reasonably achievable" (emphasis added) site-specific criterion for copper in San Francisco Bay, using a translator of 1.6. This comment confuses the adoption of appropriate copper criteria with the approval of a translator to implement such criteria. Translators are implementation mechanisms which are not included in the CTR, but may be adopted by the State.

Regarding the achievability of any criterion for any particular discharger, there is no provision for EPA to consider the attainability or the scientific validity of the criteria with regard to specific dischargers or class of dischargers in adopting ambient water quality criteria in the CTR. In accordance with 40 CFR 131.11, criteria must be based on sound scientific rationale and must protect the designated use. Economic factors may be considered in designating uses (40 CFR 131.10); however, they may not be used to justify criteria which are not protective of those uses.

That being said, it should nevertheless be understood that EPA supports State adoption of site-specific criteria. As explained in the preamble to the proposed CTR, and further discussed in the response to CTR-016-002, EPA will work with the State to approve acceptable State-adopted criteria (including site-specific criteria) and intends to stay the CTR where such State criteria are in effect. In the meantime, in the absence of such criteria for aquatic life for copper in waters of San Francisco Bay, with salinity greater than 5 ppt, EPA is promulgating criteria based on EPA's section 304(a) national marine water copper aquatic life criterion, which is consistent with the requirements of the CWA. (40 CFR Section 131.11(b).) See also responses to CTR-016-001 and CTR-016-002.

CROSS REFERENCES C-02b; E-01c; R; S

Comment: Separate, scientifically defensible, reasonably achievable aquatic life criteria for copper should be adopted for San Francisco Bay, or alternatively EPA should specify in the Preamble implementation policies for copper that will result in reasonable control measures actions. To comply with the Clean Water Act and EPA regulations, EPA is required to consider specific water bodies. To fulfill the spirit of Presidential Executive Order 12866 and the requirements of the Unfunded Mandates Reform Act, EPA is required to evaluate regulatory alternatives based on an analysis of costs and benefits. Based on BADA's analysis of costs and benefits, EPA should either adopt copper criteria that are reasonably achievable or alternatively specify implementation policies that will avoid costly end-of-pipe controls. Potential implementation measures that could be specified include use of the following in calculating effluent limitations: actual dilution based on modeling studies; copper translators; probability of compliance less than 99.9%; and water-effect ratios determined for different segments of the Bay. Unless EPA specifies these or similar implementation policies in the rule, it is possible that the CTR could result in significant costs ($12 million per year to $78 million per year) while resulting in minor environmental benefit (a 1% reduction in copper loading to the Bay). In that case, the CTR would violate the Clean Water Act, EPA regulations, Presidential Executive Order 12866, the Unfunded Mandates Reform Act and the Regulatory Flexibility Act. (see the discussion under Item 11 below.)

Response to: CTR-054-008b

EPA disagrees with the commenter's request that EPA either adopt site-specific copper criteria for San Francisco Bay or, in the CTR preamble, specify the use of certain implementation policies for copper.

In support of its request for the adoption of "scientifically defensible, reasonably achievable aquatic life criteria for copper" (emphasis added), the commenter cites its own analysis of costs and benefits. EPA has conducted an analysis of costs and benefits for this rule pursuant to Executive Order 12866 (see discussion in preamble to final rule); however, the criteria themselves are not based on economic

considerations. In accordance with 40 CFR 131.11, criteria must be based on sound scientific rationale and must protect the designated use. There is no provision for EPA to consider the attainability or the scientific validity of the criteria with regard to specific dischargers or class of dischargers in adopting ambient water quality criteria in the CTR. Economic factors may be considered in designating uses (40 CFR 131.10); however, they may not be used to justify criteria which are not protective of those uses.

That being said, it should nevertheless be understood that EPA supports the adoption of site-specific criteria by the State. As explained in the preamble to the proposed CTR, and further discussed in the response to CTR-016-002, EPA will work with the State to approve acceptable State-adopted criteria (including site-specific criteria) and intends to stay the CTR when EPA has approved such State criteria. In the meantime, in the absence of such criteria for aquatic life for copper in waters of San Francisco Bay, with salinity greater than 5 ppt, EPA is promulgating criteria based on EPA's section 304(a) national marine water copper aquatic life criterion, which is consistent with the requirements of the CWA. (40 CFR Section 131.11(b).) See also responses to CTR-016-001 and CTR 016 -002.

Regarding the suggestion that EPA specify the use of dilution, metals translators and water effect ratios, or similar implementation provisions, EPA disagrees. With the exception of compliance schedules, the CTR does not include implementation provisions; the CTR is promulgated to add numeric criteria for toxic pollutants where they did not exist. The State may address these issues in a separate implementation plan, which it is currently developing. ("Policy for implementation of Toxics Standards for Inland surface Waters, Enclosed Bays and Estuaries of California", released for public comment, September 11, 1997.)

Finally, regarding the commenter's assertion that the CTR could be inconsistent with Executive Order 12866, the Regulatory Flexibility Act and the Unfunded Mandates Reform Act without further revision (such as suggested by the commenter), see the discussion of EPA's compliance with these requirements in the preamble to the final rule.

Comment: The Preamble to the California Toxics Rule (CTR), and the rules accompanying Economic Analysis (EA), place a great deal of emphasis on the ability of dischargers to use alternative regulatory approaches to comply with CTR criteria if the cost of treatment technology was prohibitively expensive. For example, the EA assumes that, if the estimated annualized cost for removing a pollutant exceeded a cost trigger,(*1) "dischargers would explore the use of alternative regulatory approaches to comply with CTR-based effluent limits." EA at.pg. 4(emphasis added). Based on this assumption, no treatment cost was estimated for the facility.(*2)

The types of alternative regulatory approaches assumed available for dischargers in California include phased total maximum daily loads (TMDLs), water quality standard variances, site-specific criteria, change in designated use, and alternative mixing zones. EA at pg. 4-5. The following sections will discuss each of EPA's proposed methods for regulatory relief and explain whether or not these methods can truly be used to provide relief from the CTR-based permit limits as anticipated by EPA. It should be noted that the actual language of the rule itself doesnot mention any of the methods of regulatory relief. Therefore, this analysis will be based solely upon the language contained in the Preamble to the CTR.

Site Specific Criteria

Another one of the avenues of potential regulatory relief discussed in the Preamble to the CTR is the adoption of site-specific water quality criteria. The Preamble, provides that the "State has the discretion to develop site-specific criteria when appropriate e.g., when statewide criteria appear over- or under-protective of designated uses. The Preamble goes on to explain the site-specific criteria adoption process as follows:

Periodically, the State through its RWQCBs will adopt site-specific criteria for priority toxic pollutants within respective Basin Plans. These criteria are intended to be effective throughout the Basin or throughout a designated water body. Under California law, these criteria must be publicly reviewed and approved by the RWQCB, the SWRCB, and the State's Office of Administrative Law (OAL). Once this adoption process is complete. the criteria become State law. These criteria must be submitted to the EPA Regional Administrator for review and approval under CWA section 303. These criteria are usually submitted to EPA as part of a RWQCB Basin Plan Amendment, after the Amendment has been adopted under the State's process and has become State law. CTR Preamble at pg. 42165.

The Preamble explains that the State of California has recently reviewed and updated all of its RWQCB Basin Plans. All of these Basin Plans, some of which contain site-specific criteria, have completed the State review and adoption process and have been submitted to EPA for review and approval. The key to whether or not these site-specific criteria will provide regulatory relief is when the EPA approval/disapproval occurs. Three different timing scenarios and results are possible:

1. If EPA approves any State-adopted site-specific criteria before promulgation of the final CTR is published, then the EPA Administrator may make a finding in that final rule that it will be unnecessary to promulgate criteria for the approved site-specific pollutants and associated water bodies. 2. EPA disapproves any State-adopted site-specific criteria, the proposed statewide criteria contained in the CTR would apply for those pollutants and associated water bodies instead of the site-specific criteria. 3. However, if EPA promulgates statewide federal criteria as proposed in the CTR, prior to a decision on any State-adopted site-specific criteria, the more stringent of the two criteria would be used for water quality programs. Both federal and State water quality programs must be satisfied, and application of the more stringent of the two criteria would satisfy both. CTR Preamble at pg. 42165.

Thus, the only way less stringent site specific criteria can be used for regulatory relief is if those criteria are approved by EPA prior to the publication of the final CTR. Otherwise, either the CTR or the more stringent of the two (CTR vs. site-specific) criteria apply.

One final note regarding site-specific criteria is that the Preamble to the CTR restricts the ability to use native aquatic life as a way to set site-specific criteria. Instead of allowing a discharger to substitute local species from the receiving waters into which it discharges, the Preamble only allows a discharger to supplement the eight specified families of aquatic life required for criteria development with the addition

of native species.(*9) It is doubtful whether this requirement will aid dischargers who are seeking regulatory relief.

(*1) This coat trigger is $200 per toxic pounds-equivalent for a facility under the low-end scenario, and $500 per toxic pounds-equivalent for a category of dischargers under the high-end scenario. See EA at pg. 4.
(*2) In addition, pollutant load reductions were not calculated or credited for any pollutant for which an alternative regulatory approach was pursued. Id.
(*9) "A minimum data set of eight specified facilities is required for criteria development (details are given in the 1985 Guidelines, page 22). The eight specific families are intended to be representative of a wide spectrum of aquatic life. For this reason it is not necessary that the specific organisms tested be actually present in the water body. States may develop site-specific criteria using native species, provided that the broad spectrum represented be the eight families is maintained. All aquatic organisms and their common uses are meant to be considered, but not necessarily protected, if relevant data are available." CTR Preamble at pg. 42168.

Comment: Third, regarding the criteria being proposed for adoption in the draft CTR, EBMUD recommends that EPA should:

* Should clearly recognize within the CTR that the existing, approved Basin Plan for the San Francisco Bay includes requirements specifically designed to address wet weather overflows and grants provisions for exemptions where an inordinate burden would be placed on the discharger relative to the beneficial uses protected. It should also be acknowledged through inclusion in the CTR that the requirements and applicable exemptions previously justified and approved by EPA and the State should not be affected by the proposed rule.

Response to: CTR-056-015b

EPA disagrees that the CTR must specifically acknowledge implementation provisions in the San Francisco Bay Basin Plan which are designed to address wet weather overflows. EPA also disagrees with any suggestion that such provisions be included in the CTR itself. The CTR is promulgated to add numeric criteria for priority toxic pollutants where they did not exist. The CTR does not modify existing Basin Plan implementation provisions, which remain in effect if they were duly adopted under State law,

although the application of Basin Plan compliance schedule provisions may be affected by the compliance schedule provisions in the CTR. (EPA notes, however, that wet weather implementation provisions, which were adopted in the San Francisco Bay Regional Board 1995 Basin Plan amendments, have not been approved by EPA.) Although the State cannot use implementation provisions such as variances to modify federal standards, EPA intends to stay applicable CTR criteria if the State adopts its own criteria and EPA has approved them. (See response to CTR-016-002.) EPA is also working with the State and other stakeholders to address issues related to water quality-based permitting inmunicipal stormwater permits.

Comment: Implementation

Although the proposed Rule discusses implementation issues such as TMDLs, variances, SSOs, and interim permits, it lacks evidence of support for any of these provisions. We believe that this will have the effect of reducing the State's confidence or perceived authority in granting any of these provisions to individual POTWs. For example, Page 42186 of the CTR lists six criteria that must be used by the State to determine the non-attainability of a water quality standard; we are doubtful that any of these criteria would be strictly applicable to our facilities with respect to lindane and DDT. We believe CTR variance criteria should include economic considerations for specific discharger implementation efforts. Unless the EPA provides more support for these provisions, we fear that the State will either not grant us a legitimate variance or will waiver in its commitment to act at all.

Response to: CTR-057-010c

EPA disagrees that the CTR should revise the variance criteria or provide more support for implementation provisions. The CTR is promulgated to add numeric criteria for toxic pollutants in waters of the U.S. in California where they did not exist. The CTR does not modify existing requirements of 40 CFR Part 131, which applies nationally. Those requirements limit the use of variances to six grounds (the six "criteria" referred to by the commenter), which are merely reiterated in the Preamble to the proposed CTR. (62 Fed.Reg. 42186.) The CTR also does not include its own variance provisions. However, the CTR does not modify existing State implementation provisions (including those in Basin Plans), which remain in effect if they were duly adopted under State law (although the application of Basin Plan compliance schedule provisions may be affected by the compliance schedule provisions in the CTR).

Given the scope of the CTR, the economic considerations proposed by the commenter are not relevant. Under the CWA, EPA cannot base numeric values for ambient water quality criteria on economic considerations, therefore EPA cannot "include economic considerations for specific discharger implementation efforts" in this rule. The State may address the implementation issues identified by the commenter, taking economic considerations into account as consistent with the CWA, in the separate implementation plan, which it is currently developing. EPA notes, however, that use of State implementation provisions such as SSOs and variances would require federal rulemaking to modify CTR criteria affected by such actions. See also the responses to CTR-016-002, and CTR-056-015b.

Comment: Similarly, the proposed Rule provides little support with respect to site-specific objectives. It is not clear, for instance, if a POTW could apply for an SSO once the Rule has been promulgated. The State's Site-Specific Objectives Task Force was adamant that SSOs should be an integral part of a priority-pollutant control plan, yet this philosophy is nowhere in evidence in the CTR, In view of this, we believe that the proposed Rule should specify EPA's intentions to review State-approved SSOs without setting deadlines for SSO submittals. This would allow SSOs to be triggered as needed by events not experienced or anticipated at the present time. We therefore recommend that the EPA add statements into the CTR that provide needed direction for the States in issuing decisions dealing with this any similar implementation options.

Response to: CTR-057-011

EPA disagrees with this comment. We believe that the commenter misunderstood the cautionary language that was part of the proposed rule. The CTR does not preclude state adoption of criteria after the CTR has been promulgated. As EPA stated in the preamble to the proposed CTR, when the State has completed its own process, and EPA approves the State's new or revised criteria, EPA intends to stay the CTR. Similarly, if the State adopts site-specific criteria (including site-specific Basin Plan criteria adopted by Regional Boards which have completed the State review and adoption process), and EPA has approved them based on their individual merits, EPA intends to stay that portion of the CTR that applies more general criteria to the specific site. Each individual stay on a site-specific basis would require federal rulemaking on a case-by-case basis, and generally require more detailed effort on the Agency's part than a statewide stay.

Moreover, it is possible that State-adopted criteria could become effective for CWA purposes within the State even prior to EPA approval or rulemaking, although this would change if a rule that EPA has recently proposed is promulgated as proposed. The "Alaska Rule," 64 Fed.Reg. 37072, July 9,1999. Until the Alaska Rule goes final, the State could adopt new or revised standards which are more stringent than the CTR, and those standards would be effective for CWA purposes within the state without any

EPA action. Moreover, prior to a final Alaska Rule, the State could adopt statewide standards, and if EPA approved those standards and stayed the CTR based on them, then subsequent site-specific criteria would apply within the State when adopted by the State without requiring additional EPA approval or rulemaking. If the Alaska Rule becomes final as proposed, however, regardless of whether the CTR has been stayed, only state-adopted criteria which are more stringent than the otherwise applicable standards could be applied within the State, prior to EPA approval of those standards.

Comment: PROVISIONS SDG&E DOES NOT SUPPORT

As described in the following comments SDG&E does not support the following provisions:

Site specific water quality criteria

The preamble states that, "EPA ... cautions California and the public that promulgation of this federal rule removes most of the flexibility available to the State for modifying its standards on a discharger specific or stream-specific basis" and that, "EPA has not incorporated either ... [variance or site-specific criteria development procedures] in this proposed rulemaking, that EPA has not generally authorized State modifications of federal water quality standards" determining that "these types of modifications will, in general, require federal rulemaking on a case by case basis..." (see 62 Fed. Reg. at 42186, Cols. 2 and 3). Otherwise, the federal criteria must be used over a state approved site-specific criteria where it is the more stringent and promulgated before state approval. (see 62 Fed. Reg. at 42165, Col. 3).

However, EPA clarifies that the proposal criteria are not based on a "pollutant-specific, waterbody-by-water body" evaluations. (see 62 Fed. Reg. at 42166, Col. 3 and at 42617, Col. 1). Analysis was conducted, generally speaking, utilizing eight specific families to represent a wide spectrum of aquatic life and which are not necessarily present in water bodies subject to the proposed criteria. (see 62 Fed. Reg. at 42168, Col. 2). Indeed, EPA acknowledges that the proposed criteria rely upon "several individual factors which make the criteria somewhat overprotective or underprotective.' (see 62 Fed. Reg. at 42168, Col. 1).

The proposed rule should incorporate policy and procedures by which site-specific criteria approved by the state (after rule promulgation) may be approved by EPA, though the criteria may be less stringent than in the proposed rule. In addition, the proposed rule should not preclude California from adopting water quality criteria utilizing pollutant-specific, water-body specific or other scientifically sound factors which are less stringent than those in the proposed rule (e.g., beyond WERs) which will prevail when the proposed rule is stayed and ultimately extinguished. Otherwise discharges may be subject to unnecessarily stringent and overprotective effluent limits combined with the application of the

anti-backsliding rule.

Response to: CTR-060-006

EPA disagrees with this comment. We believe that the commenter misunderstood the cautionary language that was part of the proposed rule. The CTR does not preclude state adoption of criteria after the CTR has been promulgated. As EPA stated in the preamble to the proposed CTR, when the State has completed its own process, and EPAapproves the State's new or revised criteria, EPA intends to stay the CTR. Similarly, if the State adopts site-specific criteria (including site-specific Basin Plan criteria adopted by Regional Boards which have completed the State review and adoption process), and EPA has approved them based on their individual merits, EPA intends to stay that portion of the CTR that applies more general criteria to the specific site. Each individual stay on a site-specific basis would require federal rulemaking on a case-by-case basis, and generally require more detailed effort on the Agency's part than a statewide stay.

Moreover, it is possible that State-adopted criteria could become effective for CWA purposes within the State even prior to EPA approval or rulemaking, although this would change if a rule that EPA has recently proposed is promulgated as proposed. The "Alaska Rule," 64 Fed.Reg. 37072, July 9,1999. Until the Alaska Rule goes final, the State could adopt new or revised standards which are more stringent than the CTR, and those standards would be effective for CWA purposes within the state without any EPA action. Moreover, prior to a final Alaska Rule, the State could adopt statewide standards, and if EPA approved those standards and stayed the CTR based on them, then subsequent site-specific criteria would apply within the State when adopted by the State without requiring additional EPA approval or rulemaking. If the Alaska Rule becomes final as proposed, however, regardless of whether the CTR has been stayed, only state-adopted criteria which are more stringent than the otherwise applicable standards could be applied within the State, prior to EPA approval of those standards.

EPA notes that State-adopted criteria (including site-specific criteria) which are less stringent that CTR criteria may be approved by EPA and result in a stay of the CTR if such criteria are based on sound scientific rationale which ensures that designated uses will be protected.

Comment: Site-specific criteria - p 42165. State-Adopted Site-Specific Criteria with EPA Approval - This section requests information on previously adopted site-specific criteria. The Basin Plan for the San Francisco Bay Area includes such criteria in narrative form in Chapter 4 (page 4-15, Wet Weather Overflows) in order to implement the Combined Sewer Overflow Control Policy (50 FR 18688).

Response to: CTR-090-018

EPA disagrees with any suggestion that narrative wet weather overflow provisions in the San Francisco Bay Basin Plan be addressed by the CTR. The CTR is promulgated to add numeric criteria for priority toxic pollutants where they did not exist. The CTR does not modify existing Basin Plan implementation provisions, or other narrative Basin Plan provisions, which remain in effect if they were duly adopted under State law. (EPA notes, however, that such provisions, which were adopted in the San Francisco Bay Regional Board 1995 Basin Plan amendments, have not been approved by EPA.)

In inviting commenters to identify existing State site-specific criteria (page 42165 of the preamble to the proposed CTR, 62 Fed.Reg.42160) EPA intended to seek identification only of numeric site-specific criteria. EPA regrets any misunderstanding which omission of the term "numeric" may have caused, but believes that the preamble to the proposed rule clearly explained the scope of the CTR, such that it would be clear that the CTR would not withhold promulgation of numeric criteria in favor of State narrative provisions, nor would the CTR incorporate existing State narrative criteria provisions.

Comment: State Adoption of Site Specific Criteria

The preamble recognizes that the State has the discretion to develop site-specific criteria when appropriate for example, when statewide criteria appear over or underprotective of designated uses. Under California law, site specific criteria are adopted as amendments to regional Basin Plans, which are then reviewed by the State Water Resources Control Board (SWRCB) and the Office of Administrative Law. These criteria are then submitted to the, EPA Regional Administrator for review and approval under Clean Water Act Section 303. The City recommends that EPA formally adopt a policy in the CTR to continue and support this regulatory process, specifically during the interim period as the State develops its statewide water quality framework. The City also requests that EPA Region IX conduct prompt reviews of all currently submitted site-specific data, together with timely reviews of site-specific data submitted with these comments and any site-specific data submitted in the future. The City has attached its recently completed site-specific water quality investigation for copper in South San Francisco Bay for formal review by Region IX and inclusion in the record of this rulemaking (Attachment 3).

The City also urges EPA to revise language in the preamble limiting the use of the site-specific criteria process after federal promulgation and prior to a decision on any State adopted site-specific criteria. We also urge EPA to revise the statement that the more stringent of the two criteria would be used for water quality programs, in the event of two promulgations. Such language severely limits this regulatory approach, and State flexibility in the development of scientifically defensible site-specific criteria. The City reiterates its recommendation that EPA develop a viable policy which supports site-specific criteria development, that ensures EPA's continued review and oversight process, and that emphasizes scientific defensibility and not the stringency of the value produced.

Response to: CTR-092-010

0EPA disagrees with this comment. We believe that the commenter misunderstood the cautionary language that was part of the proposed rule. The CTR does not preclude state adoption of criteria after the CTR has been promulgated. As EPA stated in the preamble to the proposed CTR, when the State has completed its own process, and EPA approves the State's new or revised criteria, EPA intends to stay the CTR. Similarly, if the State adopts site-specific criteria (including site-specific Basin Plan criteria adopted by Regional Boards which have completedthe State review and adoption process), and EPA has approved them based on their individual merits, EPA intends to stay that portion of the CTR that applies more general criteria to the specific site. Each individual stay on a site-specific basis would require federal rulemaking on a case-by-case basis, and generally require more detailed effort on the Agency's part than a statewide stay.

Moreover, it is possible that State-adopted criteria could become effective for CWA purposes within the State even prior to EPA approval or rulemaking, although this would change if a rule that EPA has recently proposed is promulgated as proposed. The "Alaska Rule," 64 Fed.Reg. 37072, July 9,1999. Until the Alaska Rule goes final, the State could adopt new or revised standards which are more stringent than the CTR, and those standards would be effective for CWA purposes within the state without any EPA action. Moreover, prior to a final Alaska Rule, the State could adopt statewide standards, and if EPA approved those standards and stayed the CTR based on them, then subsequent site-specific criteria

would apply within the State when adopted by the State without requiring additional EPA approval or rulemaking. If the Alaska Rule becomes final as proposed, however, regardless of whether the CTR has been stayed, only state-adopted criteria which are more stringent than the otherwise applicable standards could be applied within the State, prior to EPA approval of those standards.

EPA notes that State-adopted criteria (including site-specific criteria) which are less stringent that CTR criteria may be approved by EPA and result in a stay of the CTR if such criteria are based on sound scientific rationale which ensures that designated uses will be protected.

This commenter also urged EPA to act, prior to finalizing the CTR, to approve or disapprove any State-adopted site-specific criteria which had been submitted to EPA but EPA had not yet acted upon. This has not been possible, due to the focus of resources on the CTR itself. However, in the final CTR, EPA has made revisions to ensure that EPA-approved State-adopted site-specific criteria shall remain in effect and not be superceded by CTR criteria for the same pollutants for those waters of the Bay where such site-specific criteria are currently in effect. See response to CTR-016-001.

Comment: MR. LOZEAU: I'm Michael Lozeau. I'm the executive director of San Francisco Baykeeper and Deltakeeper.

I've done a preliminary review of the rule. But with that in mind, I'm just going to list all our current concerns. I'll start with the simplest perhaps and work my way towards the more complicated ones.

The first thing I noticed in the rule is there's some deference to regional boards, regional board standards that have been issued and approved by EPA. But there's no full listing in the proposed rule, and there's a suggestion that the burden is on the board to come forward and remind EPA of the standards it's already looked at and approved.

I would urge EPA to be proactive about that, so that representatives from regional boards, from all nine regional boards, don't have to make sure that they remind you of the standards that already exist before you perhaps wipe them out with this new rule, especially in the Bay Area where we have a number of standards which have been applied and do exist, which I think would be more appropriate certainly for the Bay Area than a statewide standard.

Response to: CTRH-001-047

EPA believes that it has addressed this comment, particularly with regards to San Francisco Bay. (See responses to CTR-016-001 and CTR 016-002.) EPA approved, State-adopted site-specific criteria for

waterbodies other than San Francisco Bay were not identified in response to the proposed rule, and EPA was unable to obtain a comprehensive listing of such other criteria. For these reasons, EPA has not "promulgated around" any site-specific criteria other than those in San Francisco Bay identified in the final CTR and those discussed in the preamble to the proposed CTR (62 Fed.Reg. 42165-42166), which are also identified in the final CTR. This is consistent with the approach set forth in the Preamble to the proposed CTR. (62 Fed.Reg. 42165.)

Comment: 1) The placement of the WER in the equation for the calculation of criteria is an excellent idea which, given affordable implementation methods, should better tailor the criteria to the site. We would, however, appreciate clearer definition as to how this is to be implemented. Will the EPA approve WER study plans and results or is the State the lead agency? Do WER's need to be placed in basin plans or is this similar to total to dissolved ratios which are permitting issues versus objective setting issues?

Response to: CTR-003-001

The rule promulgates a default WER of 1. The rule states that if other than a WER of 1 will be used, it must be developed in accordance with EPA's WER guidance or the State's methodology, after that methodology has been adopted as part of the State's water quality planning process and approved by EPA. WERs developed under one of these processes are not subject to further EPA review and approval.

WERs may be used on a water body basis for a particular pollutant or as part of a permit for an individual discharger for a specific pollutant. EPA encourages the State (and dischargers) to develop and use WERs on a water body basis, since this approach is technically sound, and efficient use of resources, and allowable for the NPDES permitting authority. WERs developed on a water body basis should be included and adopted in the appropriate Regional Water Quality Control Board Basin Plan. WERs that are developed on a permit basis are subject to the NPDES permit approval process.

Comment: Because the California Toxics Rule uses the same approach as the UAA in setting water quality objectives for cadmium and copper, SARDA strongly supports the CTR objectives for those metals. We also agree with EPA's written statements acknowledging the binding character of organic carbon and the role it plays in rendering heavy metals non-toxic. We enthusiastically endorse the agency's decision to include Water Effects Ratio as a formal factor to be considered when formulating water quality objectives. It will do much to adjust national criteria to local conditions.

Comment: II. Use of New Scientific Information

The City acknowledges and supports EPA's update of several water quality criteria including those for mercury, cadmium and arsenic. While a number of criteria were updated to reflect current scientific information, there are a few notable exceptions. The following briefly addresses the key updates and omissions that should be addressed in the final publication of this rule.

2. Water Effects Ratio The preamble explains that the intent of the metals criteria is to control the bioavailable fraction of the metal. Because there is no reliable analytical procedure to measure the bioavailable fraction, most acute and chronic metals criteria are now applied as dissolved criteria and a water effects ratio ("WER") is included as part of the criteria to properly adjust the analytical measurement to reflect the bioavailable fraction. Contrary to the statement that the metals criteria are only intended to address bioavailable metals, the preamble states that acceptance of a WER study is discretionary. This is inappropriate and must be amended in the final rule publication. EPA should not be suggesting that Regional Boards may ignore relevant scientific information.

EPA has also dictated use of the Agency's Interim Guidance on the Determination and Use of Water-Effect Ratios (the "WER Guidance") which is very conservative and costly to follow. Moreover, WER guidance is not designed to address short term events such as storm water discharges. Given that the duration of the tests required to be used greatly exceeds the duration of storm water events, it is apparent that the WER guidance should not be applied to these conditions without considerable modification. The recent Society for Environmental Toxicology and Chemistry ("SETAC") evaluation of EPA metals criteria and implementation policies (entitled "Reassessment of Metals Criteria for Aquatic

Life Protection" [1996]) recommends that whole effluent bioassays using metal sensitive organisms be used to determine the appropriateness of applying EPA's metal criteria to derive stringent effluent limitations. The use of complex and expensive WER tests is not necessary as the use of metal sensitive organisms (such as daphnids), which were originally used to calculate EPA's criteria, will reliably assess whether or not the metals present in the sample are in a bioavailable form. Senior EPA officials were involved in preparing the SETAC recommendation, and the publication is intended to reflect to consensus of the nationally recognized experts on this subject. The Agency has in the past relied upon these same experts in updating the EPA's metals criteria (e.g., the January 1993, EPA-sponsored scientific workshop on the development and implementation of metals criteria in Annapolis, Maryland [the "Annapolis Conference"]).

Because of the excessive cost and time necessary to conduct detailed WER tests in accordance with EPA's published guidance, more simplified and appropriate procedures need to be established. The metals criteria should include a screening procedure which will allow the use of metal sensitive organisms to assess whether or not the metal is in a bioavailable form. If the metal is not bioavailable, then the permitting authority should not establish limitations based upon EPA's criteria.

Response to: CTR-020-005

EPA does not mean to suggest in its language concerning WERs, that California Regional Water Quality Control Boards ignore relevant scientific information. Rather, EPA's intent is simply to clarify that the State has the authority to approve or disapprove site-specific determinations of WER values, derived with methodology approved by EPA.

Additionally, EPA does not mean to suggest that the Agency's "Interim Guidance on the Determination and Use of Water-Effect Ratios" is the only available methodology for determining WERS, as discussed further in the response to CTR-020-006. See also the response to CTR-003-001 for discussion of the general approach for implementation. The commenter wants a simpler EPA WER guidance but does not suggest how to do this and why it would be scientifically defensible.

Comment: II. Use of New Scientific Information The City acknowledges and support EPA's update of several water quality criteria including those for mercury, cadmium and arsenic. Whle a number of criteria were updated to reflect current scientific information, there are a few notable exceptions. The following briefly addresses the key updates and omission that should be addressed in the final publication of this rule.

(a) Water Effect Ratio Approach is Mathematically Flawed

As part of the CTR, EPA has required that the Agency's February 22, 1994 water effects ratio procedure be used to appropriately adjust the dissolved metals criteria to reflect the bioavailable fraction. See, WER Guidance. Since the issuance of that document, EPA has prepared an internal evaluation of the reasonableness of the WER Guidance (Delos: "Probabilistic Analysis of the Level of Protection Provided by the Interim Guidance on Determination of Water Effect Ratios" [March 1994]). That analysis found:

...the Guidance procedures tend to produce a lower WER than the unbiased WER... the option favored in the February 22 cover memo to the Guidance is particularly biased (by a factor of 2-4)...

Thus, it is apparent that EPA is aware that the published WER Guidance is flawed and will lead to calculation of unnecessarily restrictive limitations under the most common circumstances where the procedure is applied (low dilution receiving waters). Given this information, it is clearly inappropriate for EPA to mandate the use of the 1994 WER Guidance as the basis for determining all WERs under the CTR.

In addition to those issues identified in EPA's internal review, the procedures outlined in the WER Guidance contain a major, conceptual, technical error that will lead to routine miscalculation of the WER. This error was first brought to EPA's attention in September 1992 by Dr. Herb Allen, one of the nation's leading experts on metals speciation (Exhibit 1).

The basic technical oversight of the WER Guidance is that organometallic complexing manifests itself as a non-linear titration, not a linear ratio. This mode of action was verified decades ago by many researchers. On behalf of EPA, DiToro also verified this phenomenon during EPA's sediment criteria research, and it is the underlying principle in using acid volatile sulfide levels as the indicator of when metals may exhibit toxicity. As discussed in Dr. Allen's most recent analysis (Exhibit 2), metals will not exhibit toxicity where the amount of binding sites is stoichiometrically in excess of the available metal. This is demonstrated by Figure 6 contained in Exhibit 2 for a range of ligand concentrations. Both the acute and chronic criteria will be increased by a specific fixed amount, not a ratio. Thus, the proper way to account for metals inactivation measured by a WER procedure is arithmetically, not multiplicatively.

The error in the appropriate adjustment to the criteria increases as the LC50 used to calculate the WER becomes increasingly greater than the chronic criteria that is being adjusted by the WER. Given that the chronic criteria is always less than the LC50 used to adjust the criteria, EPA's WER procedure will always produce an inappropriately low adjustment factor. The following examples illustrate the magnitude of the error that may occur by using a multiplicative rather than additive approach. The first example is typical of EPA's copper criteria. Where the laboratory derived LC50 is 20 ug/l and the effluent influenced LC50 is 60 ug/l, a WER of three (3) would be calculated. These same data verify that a 40 ug/l copper binding capacity is exhibited by the effluent influenced sample.

Under EPA's procedure, a chronic criteria adjustment to 18 ug/l would occur (assuming 6 ug/l chronic criteria) although the actual chronic endpoint is 46 ug/l based on the titration effect. Thus, EPA's approach is in error by a factor of 2.55 or 155 percent. The criteria calculation error becomes even more dramatic as the acute/chronic ("A/C") ratio is increased. For pollutants such as lead with a high A/C ratio (about 50), the error would easily be a factor of 50 because acute tests are used to calculate the WER. The solution to the problem is straightforward: EPA should inform the public that the binding capability of the mixture should be determined arithmetically (one may geometrically average the results consistent with the acute and chronic criteria development) and add this to the chronic test result to produce the proper instream criteria.

Finally, the WER Guidance is in error in its expensive requirement that WERs be conducted for a series of dilutions under the concern that the WER may decrease more rapidly than the dilution increases. As demonstrated by Dr. Allen in Figure 3, Exhibit 2, organometallic binding is not linear. Binding does not decrease more rapidly or even as rapidly as dilution even for binding agents with relatively low stability constants. Thus, if the pollutant is demonstrated to be non-toxic at low dilution, one may fully expect the pollutant to remain non-toxic as dilution increases. Recognition of this phenomenon can greatly simplify the WER procedures and reduce the exorbitant costs of running all the tests outlined in the WER Guidance.

Based upon these and other concerns, the proposed rule should delete the requirement to utilize the WER Guidance for all WER analyses. As requested and supported by the available technical information, the CTR should allow for use of simplified approached to adjusting the proposed metals criteria.

Response to: CTR-020-006

EPA disagrees that it has mandated or required the of use of the Agency's "Interim Guidance on the Determination and Use of Water-Effect Ratios". As an alternative to following this guidance the rule specifically provides the option of using "other scientifically defensible methods adopted by the State as part of its water quality standards program and approved by EPA."

The commenter recommends use of what could be called a "water-effect difference" (WED), although this particular terminology is not used in the comment. If the test species exhibited effects at concentrations near the criterion, the WED would yield the same result as the WER. If the test species exhibited effects at concentrations significantly above than the criterion, then the WED would yield a different result than the WER. Under certain conditions (e.g., metals interacting with strong binding agents), the WED calculation will yield an accurate result, while the WER will yield an over-protective result. Under other conditions (e.g., metals interacting with weak ligands) the WED will yield an under-protective result, while the WER will yield an accurate result. Analysis of the behavior of EPA's current guidance indicates that it often tends to yield conservative results.

With regard to the issue of the complexity and expense involved in of the WER procedure, EPA has been cooperating with states and dischargers who are experimenting with simplified procedures that yield the essential information using fewer samples ([Date] letter from Evelyn S. MacKnight, EPA Region 3, to James Newbold, Pennsylvania Dept. of Environ. Protection). Furthermore, EPA is developing a biotic ligand modeling approach that will determine the appropriate site-specific criteria adjustment solely from site-specific chemical measurements. Because the state of the science is moving forward in this area, EPA has provided for the use of alternative procedures, and anticipates that future developments will yield procedural improvements approvable under the rule. EPA believes that the current guidance on WERs yields dependable results, but that the upcoming biotic ligand model will simultaneously improve the accuracy of site-specific criteria adjustments (eliminating the above described WER versus WED issue) and simplify their derivation. EPA thus believes that the rule's provisions, coupled with its ongoing scientific development efforts, are directly responsive to the issues raised in the comment.

Comment: Sunnyvale is very supportive of many fine concepts advanced in the proposed CTR, and we join with CASA/Tri-TAC in complimenting the Agency on its proposed positions with regard to such matters as: (a) the use of interim effluent limitations in NPDES permits during the pendency of TMDL and other special studies; (b) the allowance of water effects ratios in adjusting the criteria for metals without the necessity for additional rulemaking to establish site-specific objectives; (c) the use of the dissolved state for the metals criteria; (d) the use of cooperative, intergovernmental, and stakeholder-involved approaches towards the development of TMDLs;(e) the allowance of dilution for both chronic and acute pollutants; and (f) the allowance of compliance schedules in NPDES permits.

Comment: PROVISIONS OF THE PROPOSED RULE WE SUPPORT

Not withstanding the above comments, we believe there are certain elements of the proposed rule with respect to establishing water quality standards that we can support:

* Metal criteria expressed in the dissolved fraction rather than expressed in the total recoverable fraction.

* Metal criteria that are developed as a function of the water-effect-ratio (WER).

* The current proposed human health criterion for mercury.

* The current preamble language regarding metal translators and mixing zones.

We believe the above provisions provide a more acceptable, scientific approach to the water quality-based pollution control approach. We recommend these provisions of the current rule remain as proposed.

Response to: CTR-027-012b

EPA acknowledges the commenter's support.

Comment: Regulatory Flexibility and Relief

The District supports EPA's use of "sound science" and current data in developing the proposed criteria in the California Toxics Rule (CTR). The District strongly supports language in the Preamble that references and endorses recommendations of the State Task Forces including use in permitting of:

* reasonable potential analyses * dissolved metals criteria * translators * water effects ratios * site specific objectives * innovative TMDL processes such as effluent trading * performance based interim limits * chronic and acute mixing zones, and * compliance schedules in NPDES permits.

Response to: CTR-032-002d

EPA acknowledges the commenter's support.

Comment: Second, we commend EPA for its inclusion in the CTR of several innovative and flexible regulatory approaches, such as metals criteria expressed as dissolved rather than total recoverable concentrations, and the revised human health criterion for mercury. In addition, in light of the issues surrounding the human health criteria for arsenic we support EPA's decision not to promulgate human health criteria at this time. With respect to implementation issues discussed in the Preamble, we support EPA's policies and guidance regarding the application of mixing zones and dilution credits. the use of interim permit limits while Total Maximum Daily Loads (TMDLs) and other special studies are being performed, and EPA's guidance to Regional Water Quality Control Boards (RWQCBs) that they may use any of the methods described in EPA's guidance document on the use of translators. We also support EPA's proposal to create a rebuttable presumption for Water Effects Ratios (WERs), allowing the RWQCBs and SWRCB to develop site-specific WERs that can be approved by EPA during the NPDES permit approval process. We believe that this approach will help facilitate the development of appropriate site-specific adjustments for metals criteria.

Comment: pp. 42173-42174 - Application of metals Criteria (Water Effect Ratios) We support EPA's proposal to allow the development of site-specific WERs as set forth in EPA's WER guidance or determined by another scientifically defensible method. We also support the application of the WER on a watershed or water body basis to the extent that it is a technically sound and cost-effective approach. However, we would note that there may be instances where a "site" should be defined to be only a portion of a water body or watershed (e.g. the entire San Francisco Bay should not be considered a single "site"). We strongly endorse the inclusion in the proposed rule of a provision, such as was included in the National Toxics Rule, to create a rebuttable presumption of a default WER value of 1.0, unless a site-specific WER is determined. We understand that to mean that an EPA rulemaking process to adopt site-specific WERs would not be required, and that instead, EPA is "pre-authorizing" the use of correctly applied water effect ratios that are approved by the State. (EPA would still have the opportunity to review each WER through the normal NPDES permit approval process.)

Response to: CTR-035-019

EPA agrees with the commenter's discussion. EPA would approve the methodology. The state would approve the WERs derived in accord with the methodology.

Comment: PROVISIONS SUPPORTED

We support a number of provisions of the Rule, including: (1) adoption of metals criteria as dissolved concentrations; (2) expression of the metals criteria as a function of the water-effect ratio; (3) adoption of the proposed new human health criterion for mercury- and (4) the Preamble discussions regarding metals translators and mixing zones. These provisions provide a firmer scientific base for the water quality-based approach to pollution control and are a marked improvement over the old Inland Surface Waters Plan. We would urge EPA to retain these provisions in the final Rule.

Comment: Second, the District supports with reservations EPA's proposals on two subjects directly related to dissolved metals criteria, i.e. the proposed guidance on both (1) translators to convert from dissolved metals criteria to total recoverable permit limits and (2) the water-effect ratio (WER) as the method to compare the bioavailability and toxicity of a pollutant in receiving waters and in laboratory waters. Both of these two proposals must be implemented on a site-specific basis using local data, not statewide or watershed-wide data. Translators, however, should be developed whenever a discharger is willing to conduct studies in accordance with EPA-approved methods. The proposed procedure for a default value of 1.0 for a WER should mean that when a site-specific WER is to be determined, an additional EPA rulemaking process would not be required. Instead, this rule should pre-authorize the use of correctly applied WERs that are approved by the State.

Response to: CTR-041-003b

EPA agrees with the comments on translators. EPA does not agree with the comment that WERs cannot be derived on a statewide or watershed-wide basis. Some states have found it useful to pool data from several sites (hydrologically noncontiguous) and project WER values to sites having similar water quality characteristics. Because most pollution control decisions are insensitive to uncertainties in the WER estimation (that is, a range of different possible WER values will yield the same decision), it can be efficient to reserve WER derivations with the greatest site-specificity for those situations where the decision is most sensitive to uncertainties. See also the response to CTR-003-001 for discussion of the general approach for implementing WERs.

Comment: We have reviewed the proposed CTR and offer the following comments:

2. The following provisions of the rule are supported:

(1) adoption of metals criteria as dissolved concentrations;

(2) expression of the metals criteria as a function of the water-effect ratio;

(3) adoption of the proposed new human health criteria for mercury; and

(4) the Preamble discussions regarding metals translators, mixing zones, and interim permit limits.

Were the old human health criterion for mercury (0.012 ug/ l) to be adopted, the City would have to remove its discharge from Tule Canal and go to land disposal. The capital cost to do this would be $22.1 million and the total present worth cost would be $23.1 million (see Exhibit B, Required Capital improvements and Costs for Beryllium and Mercury). This would translate to an annual cost of $3.1 million per year (at 7% over 10 years) and would require that monthly sewer service charges be increased by more than 100%.

Comment: BADA supports adoption of the metals criteria as dissolved concentrations and the expression of the criteria as a function of the water-effect ratio. These changes place the metals criteria on a firmer

scientific base than the old State Plans. Moreover, previous BADA studies have shown that adoption of the copper criterion as total recoverable could cost Bay Area POTWs several billion dollars while reducing copper loads to the Bay by only several percent (see Attachment 1). Further, building the water-effect ratio into the criteria will lessen the administrative burden on all parties when it becomes necessary to pursue the development of such a ratio. For these reasons, it would not be in the public interest nor consistent with Presidential Order 12866 or the Unfunded Mandates Reform Act to adopt the metals criteria as total recoverable concentrations or to require approval of a site-specific objective whenever a water-effect ratio is developed.

Comment: Page 42173, third column, first two paragraphs, discuss the water effects ratio approach for adjusting national criteria. This approach does not adequately or reliably incorporate aquatic chemistry into water quality criteria adjustment. The approach tends to over-regulate because of the failure to equilibrate between the chemical forms in ambient waters and those in the test system. The statement in the third paragraph, "This approach is technically sound, an efficient use of resources... " is not appropriate since it leads to over-regulation of chemical constituents in wastewater and stormwater runoff. Enclosed is a summary report "Regulating Copper in San Francisco Bay: Importance of Appropriate Use of Aquatic Chemistry and Toxicology, " (1997) on the over-regulation of Cu in San Francisco Bay that developed due to the inability of the water effects ratio to develop site-specific criteria that properly reflect the toxicity of Cu in San Francisco Bay waters.

Response to: CTR-061-014

EPA does not agree with the commenter that a reasonably accurate water-effect ratio cannot be derived, either using current guidance or using other scientifically sound procedures allowed by the rule. See response to CTR-020-006.

Comment: Application of Metals Criteria

The City supports EPA's proposal to provide for the adjustment of metals criteria through the application of the water-effects-ratio (WER) procedure to ensure that such criteria are appropriate for chemical conditions present in the water body. The City agrees with EPA that ideally, the WER process should be applied on a watershed or water body basis in California. However, the City does have sincere concerns with how a watershed and/or waterbody is defined. The City wishes to be on record that a significant body of sci ' entific information supports the contention that San Francisco Bay South of the Dumbarton Bridge (South San Francisco Bay) constitutes a distinct waterbody for purposes of the WER process. Furthermore, the City recommends that the Rule be revised to allow use of the WER procedure to develop site-specific criteria, without requiring a formal rulemaking process.

Response to: CTR-092-004

EPA recognizes the concerns expressed, but believes that the commenter's concerns may be unfounded. The CTR does not define or restrict the boundaries of any California site, or impede the appropriate definition of such boundaries. The rule also does not require or intend to require that the adoption of site-specific WERs go through a formal rulemaking. See the response to CTR-003-001.

Comment: Validity Of The Proposed Copper Criteria For South San Francisco Bay

Attachment 3 to this letter is a technical report entitled "Development of a Site-Specific Water-Effect Ratio for Copper in South San Francisco Bay", dated September 1997 and prepared by the City of San Jose Environmental Services Department.

This attachment is also incorporated as part of our comments and is being submitted for inclusion in the record for this rulemaking. Because EPA is proposing to promulgate water quality criteria for all waterbodies in the State of California, we believe that it is required toconsider site-specific data to the extent that it is available, especially, where, as in the case of the submitted data, it appears that there is a less costly/appropriately protective alternative to the proposed criteria.

Response to: CTR-092-013a

EPA disagrees with the commenter. EPA cannot efficiently include all site-specific data in its rulemaking process. Furthermore, EPA does not believe that it is either technically or administratively advantageous or efficient for the rule to specify particular site boundaries or WERs within such boundaries. Nevertheless, because it is necessary to provide for the use of site-specific data collected either before or after promulgation, the rule expresses the criteria in terms of WER values, which like

water hardness, are specified subsequent to the rulemaking. Thus, the rule has a provision allowing the the state to consider the data cited by the commenter in this context. See the response to CTR-003-001 for discussion of the general approach for implementation.

Comment: In summing up -- not summing up, just as a parting shot -- I do appreciate the fact that in working up the toxics rule here that EPA has done certain things which in fact we see as improvements in actually making the standards fit with what we think -- have come to see as perhaps the actual impacts of the stormwater part of this. And by that, I'm referring to the dissolved metals criteria and the water effect ratio in there, and the human health criteria revisions for mercury and the other -- the other items.

I appreciate some of the stuff in there, and -- with the exception of the preamble language. And you really need to get that out of there. We're going to pursue this as far as we have to.

I appreciate your hearing me.

Comment: MS. PLA: My name is Michelle Pla. I'm with the Public Utilities Commission, City and County of San Francisco.

I made the comment on my card that I also said that I would try to be constructive, and so I'm going to follow my mentor here, Phil Bobel, and say that there are some things in this rule that we're very pleased to see.

We're very pleased to see use of the latest scientific information, particularly the use of latest IRIS, I-R-I-S, numbers-for human health. We're very pleased that you're using dissolved versus total recoverable form for the metals.

We're very pleased to see recognition of the water effects ratios. We're pleased to see recognition for a multi-tiered mixing zone for acute and chronic human health effects and hope that the state pays particular attention to that.

We do have a problem with the way you've described compliance schedules and hope to be working strictly by the state on that as well. We think that the five-year system is fairly shortsighted, and -we can't even do FMDSLs in five years.

Response to: CTRH-001-024d

EPA acknowledges the commenter's support.

Comment: I've been saving the good news for last.

Fourth, and by no means last in priority for CASA, we wish to register our support for several parts of the preamble to the CTR.

We support application of interim limits in NPDES permits while TMDLs and other special studies are being performed.

We also support EPA's approach to water effects ratios for determining site-specific criteria.

We also support the inclusion of a provision allowing the compliance schedules in permits in the rule, although we recommend that it be modified to allow the regional boards to include compliance schedules of up to 15 years in permits, if they deem it appropriate.

Thank you for the opportunity to present our views. As I said earlier, we will be submitting detailed comments on the proposed rule by the end of the comment period, which hopefully will be extended in response to our and others' requests.

Response to: CTRH-001-039a

Comment: Some of the flexibility that the City highly supports is the water effect ratio investigations to adjust statewide criteria to site-specific conditions; the interim limits concept while special studies are being conducted by the dischargers and other entities; a variance procedure to allow dischargers to achieve progress toward effluent limit attainment without violating applicable water quality standards; dissolved criteria for metals to reflect the toxicological conditions; translators to adjust dissolved criteria to total permit limitations; trading programs to attain and maintain water quality; and a mixing zone that reflects true instream pollutant conditions and that protects beneficial uses.

Comment: At Federal Register, Page 42168, third column, EPA provides that "States may develop site-specific criteria using native species, provided that the broad spectrum represented by the eight families is maintained." In California, as in other arid and semi-arid western states, there are unique aquatic habitats that by their inherent physical chemical and hydrologic nature, are naturally very limited in species diversity as well as density. It would seem that in such cases, what is important and relevant is that the site-specific criteria be most representative of the specific waters and its natural constraints, not that criteria reflect the broad spectrum of species that do not and can not inhabit these waters. The City recommends that the requirement to maintain the eight families broad spectrum be deleted and replaced with a requirement that the site-specific criteria be based upon native species representative of the specific waters in question. In a similar situation, an EPA Administrative Law Judge found that:

"...a proposed test must be reasonably related to determining whether the discharge could lead to real world toxic effects. The Clean Water Act objective to prohibit the discharge of toxic pollutants in toxic amounts concerns toxicity in the receiving waters of the United States, not the laboratory tank."

In the Matter of Metropolitan - Dade County, Miami - Dade Wastewater Authority, NPDES Permit No. Fl, Oct., 1996. Certainly, this precept also applies when establishing a water quality criterion that is intended to protect a specific receiving water. That is, to be relevant to the site-specific waters, the criterion upon which discharge permit limitations are to be developed must be based upon species that are representative of the specific waters. The broad spectrum criteria make sense and are reasonable when applied state-wide. But application of broad spectrum criteria to a site-specific situation would seem to be the antithesis of site-specific water quality controls by definition.

Response to: CTR-009-004

In the CTR, EPA is not promulgating a site-specific criteria methodology. EPA's statement on page 42168 column 2 (not 3) is meant to provide guidance on the derivation of site-specific criteria.

EPA agrees with the general concern that its guidance might be incorrectly interpreted to mean that a site-specific taxonomic data set should have more diversity than the site actually has. EPA does not intend for its guidance to be interpreted in this manner.

Nevertheless, because the Rule does not provide for the Recalculation Procedure, the CTR criteria would continue to apply even if California adopted a Recalculation-based site-specific criterion, unless EPA amended the rule not to apply at that site.

Comment: The CTR freshwater aquatic life criteria, in general, may not be appropriate for effluent-dominated water bodies and ephemeral streams. Some of these water bodies and the aquatic communities they support exist primarily because of discharges of reclaimed wastewater. Such water bodies are used to transport reclaimed water discharges to a downstream use area and/or are used for the disposal of surplus reclaimed water which occurs when demand is temporarily less than supply. The CTR freshwater aquatic life criteria may create requirements for reclaimed wastewater dischargers which are not economically feasible to meet and could affect the viability of reclamation activities. In Southern California, water reclamation is vital to ensuring a reliable regional water supply.

Response to: CTR-025-005

The commenter here recommends that different uses be adopted for certain waters in California. Designated uses are outside the scope of this rule. EPA has not attempted to determine the beneficial uses or the attainability of designated uses for California in this rule. This rule is to provide criteria for toxic pollutants for California based on the uses established by the State. EPA's criteria will protect these uses.

Comment: The subject rule has a significant impact on our facility discharge and the citizens of the City. We therefore present the following comments for your consideration to re-open the comment period for this rule in order to facilitate a more complete review by public and in particular by those in the POTW community:

* Propose that USEPA should accept separate significantly defensible reasonably achievable aquatic life criteria for streams and creeks that are dominated all or part of the year by discharges from anthropogenic

sources, such as POTWs (i.e., effluent dependent waters).

Response to: CTR-082-005

EPA does not agree. EPA has not developed separate criteria for effluent-dependent waters because these waters have designated uses for human health and/or aquatic life that correspond to the criteria in the rule. However, the State may consider, and EPA encourages, such criteria developments as part of the State's Phase II of the ISWP/EBWP readoption or as part of its RWQCB Basin Plan updates. In the meantime, EPA's criteria will protect all beneficial uses assigned to each inland surface water and enclosed bay and estuary.

Comment: We support the deletion of site specific objectives for cadmium and copper set for in the 1995 Water Quality Control Plan for the Santa Ana River Basin. We believe the site specific objective for lead in the plan is appropriate and should be approved by the U. S. Environmental Protection Agency. This recommendation is premised on the Santa Ana Regional Water Quality Control Board amending the Basin plan to incorporate revised correction factors and recalculations for this metal based upon the most current U.S. EPA guidance and criteria documents.

Response to: CTR-033-002

We agree with the commenter's support of the Regional Water Quality Control Board, Santa Ana River Basin, and its request that we promulgate water quality standards for cadmium and copper in place of the site-specific standards contained in the 1995 Water Quality Control Plan for portions of the Santa Ana River Basin. The final CTR will continue to reflect that position as expressed in the proposed CTR.

EPA also appreciates the commentor's support of the site-specific criterion for lead in portions of the Santa Ana River Basin which the State has adopted and submitted to EPA for approval. However, EPA has not yet approved this site-specific criterion, and in the absence of EPA-approved State-adopted site-specific criteria, EPA must promulgate CTR criteria to meet the requirements of CWA section 303(c)(2)(B). Nevertheless, where site-specific criteria have already been adopted by the State in accordance with State law, but not yet acted upon by EPA, and those criteria are more stringent than applicable CTR criteria, those are the controlling criteria for CWA purposes even without a stay of the applicable CTR criteria and are thus implementable by the State. (This would not be affected by the "Alaska Rule" which EPA proposed July 9, 1999, 64 Fed.Reg. 37072. See p. 37076.) This is the case with the site-specific criterion for lead adopted by the State for certain waters in the Santa Ana River Basin. Since the State must use the most stringent criteria in effect for its water quality programs, the State may use this site-specific lead criterion notwithstanding the CTR fresh water aquatic life criterion for lead, thus the commenter's concerns should have no practical effect.

Comment: CRITERIA

* SCAP recommends that EPA adopt separate criteria for water bodies in California that are dependent for all or part of the year on flows from wastewater treatment plants (known as "effluent dependent waters" or EDWs). SCAP believes that there are appropriate ways to modify aquatic life and human health criteria to tailor them to the unique conditions of the EDWs in the arid environment found throughout most of southern California. Potential methods include adjustment of the uncertainty and/or modifying factors used to calculate reference doses (RfDs) for noncarcinogenic human of 10E-4 health criteria, use or 10E-5 risk levels (instead of 10E-6) for carcinogenic human health criteria, adjustment of bioconcentration factors for human health criteria, and the use of site-specific water effects ratios for aquatic life criteria. Further comments regarding these methods are included in Attachment 1.

Response to: CTR-034-007

EPA disagrees that it must or should establish separate criteria for effluent dependent waters in this rule. In establishing water quality criteria for California, EPA is implementing section 303(c)(2)(B) of the CWA which requires adoption of criteria for all toxic pollutants for which EPA has issued criteria guidance and for which the discharge of such pollutants could reasonably be expected to interfere with the designated uses adopted by the state. EPA based the criteria contained in the CTR on its most recent national criteria guidance, which are designed to derive criteria that will be protective of aquatic life and human health. As long as a waterbody currently has a designated use for the protection of aquatic life and/or human health, application of the national 304(a) criteria are appropriate for fulfilling section 303(c)(2)(B). As a policy matter, EPA believes that the CTR, a massive undertaking in and of itself, is an essential first step toward reinstating a strong water quality program in California. Under the Clean Water Act, EPA has no obligation to develop such site-specific criteria or the data upon which such site-specific criteria would be based. If, however, the State wishes to develop site-specific criteria or to change the uses of the waterbody -- pursuant to the regulations at 40 CFR Part 131, and "Region 9's Interim Final Guidance for Modifying and Protecting Effluent-Dependent Ecosystems," EPA would consider and possibly approve such a site specific criterion or such a revision to designated uses.

With respect to risk level applicable to human health criteria when, as here, EPA establishes a water quality standard, EPA intends in its discretion to use a risk level of 1 x 10-6, although the state may in its discretion choose another risk level for protection of human health. If the State has appropriately consulted the public.

With respect to adjustment of bioconcentration factors, the commenter did not explain how or why

bioconcentration factors should be adjusted.

Further, EPA believes that the proposed CTR embodies a number of features that will facilitate the site-specific application of criteria when they are implemented by the state in the future. In proposing an equation rather than a single number for the metals listed in the table in proposed Section 131.38(b)(2) with variables including hardness and water effect ratios (WERs), and in the discussion on the application of metals criteria contained in Section 131.38(c)(4), EPA considers the proposed aquatic life criteria to be highly adjustable to or reflective of site-specific conditions characteristic of EDWs. The inclusion of WERs in these criteria embodies one method of developing water quality objectives for EDWs described in the "Report of the Effluent-Dependent Waters Task Force for Consideration of Issues Related to the Inland Surface Waters Plan" (State Water Resources Control Board, October 1995), which was a broad-based effort to address the specific characteristics of EDWs statewide (see also response to comment number CTR-057-003 below). Another method contained in that report which has been included in the proposed criteria is the use of dissolved metals in lieu of total recoverable metals. Finally, the aquatic life criteria for pentachlorophenol are expressed as a function of pH, allowing for adjustment of the numeric objectives on a site-specific basis.

Furthermore, the above-mentioned report at no point suggests that the resource-intensive task it describes of developing site-specific criteria for EDWs should be carried out by EPA. Rather, on numerous occasions the report recommends that the State or Regional Boards should perform that function. EPA agrees that the appropriate forum for addressing the recommendation in this comment is in subsequent water quality standards revisions carried out by the State, in the adoption of Basin Plans, or in implementation of these criteria in discharge permits or nonpoint source controls.

Potential methods for adjusting criteria for EDWs, with the exception of the inclusion of water effect ratios (WERs) as an optional component of determining appropriate metals criteria, should be applied in the context of State or Regional Board water quality standards-setting actions. EPA's action in promulgating statewide criteria is to reduce risks to all exposed populations, including especially sensitive subpopulations. However, site-specific criteria may be developed subsequently by the State where warranted to provide necessary additional protection, or otherwise to adjust the level of protection as appropriate to reflect site-specific conditions following a Section 304 standards-setting process including the opportunity for public involvement. As described above, EPA has included WERs in the proposed metals criteria listed in the table in Section 131.38(b)(2) for protection of aquatic life.

Comment: We are concerned that the proposed rule would be equally applicable to effluent-dominated water bodies, particularly in the arid West. In these water bodies habitat is often fully or seasonally dependent on existing discharges and removal, due to redirection and treatment, could result in habitat loss.

Response to: CTR-036-009

For purposes of this rulemaking, EPA is presuming that the State has adequately determined the designated uses for its waters. EPA is merely adding criteria for priority toxic pollutants on a statewide basis sufficient to protect the State's designated uses. EPA believes that a use attainability analysis would provide appropriate means for resolving potential tradeoffs between maintaining discharges to support habitat and meeting stringent effluent standards in a particular waterbody. The results of such an analysis may determine whether site-specific modifications to criteria appropriate. EPA believes that the best forum for conducting these special studies and site-specific analyses is in the context of the statewide revisions of water quality standards and policies for their implementation, undertaken triennially by the State, or in the revision of regional Basin Plans. To assist with these analyses, EPA Region 9 has issued "Guidance for Modifying Water Quality Standards and Protecting Effluent-Dependent Ecosystems," (Interim Final, June 1992). This guidance introduces the "Ecological Benefit Comparison" approach with particular attention to application to EDWs. If it can be demonstrated that using an effluent to maintain riparian and aquatic habitats constitutes a net ecological benefit over removal of the effluent, the guidance describes the circumstances under which a designated but not existing use can be modified or removed. Such an approach may be applied both to aquatic life and to human consumption uses. As was recommended by the Report of the EDWs Task Force, convened by the State in 1995, Statewide plan and regional Basin Plan modifications are the preferred regulatory pathways for conducting and adopting such analyses.

Comment: RECOMMENDED MODIFICATIONS

To address our concerns, we recommend the following modifications which do not undermine the toxic pollutant control actions envisioned in EPA's economic analysis (e.g., BMPs for stormwater and source control). In fact, some of these recommendations would provide incentives for greater movement toward achieving the water quality criteria than would occur under the Rule as it is currently proposed.

III. Recommendation: Adopt separate, scientifically defensible, reasonably achievable aquatic life criteria for effluent-dominated/effluent-dependent streams.

* Available discharge data for effluent-dominated streams in Sacramento indicate that a number of the proposed criteria are not presently being achieved and cannot be achieved with implementation of BMPs or other reasonable controls (See Attachment A). This is also true for many municipal stormwater programs in California.

* The application of the proposed statewide criteria to effluent-dominated waters would force the Sacramento Stormwater Management Program, and other stormwater programs, to remove these discharges, essentially drying up the waters for most of the year. The costs would be significant and the benefits assessed in EPA's economic analysis (enhanced fishing, passive benefits, and reduced cancer risk) would be zero. The removal of these discharges would likely be detrimental rather than beneficial. The effluent-dependent aquatic and riparian habitat, which previously supported aquatic life and wildlife, would no longer exist.

* Effluent-dominated and effluent-dependent water bodies, which are common in California, require separate and distinct water quality criteria. Such a move is common sense and would be in accordance with the spirit (if not the letter) of Presidential Executive Order 12866 and the Unfunded Mandates Reform Act.

* Additionally, the CWA requires that water quality standards be established taking into consideration their use and value for public water supplies, propagation of fish and wildlife, recreational purposes, and also taking into consideration their use and value for navigation (See CWA section 303(c)(2)(A)). Consistent with this statutory mandate, EPA regulations require that water quality standards be based on identification of specific water bodies where toxic pollutants may be adversely affecting water quality or the attainment of the designated water use, or where the levels of toxic pollutants are at a level to warrant concern and must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use. Clearly the intent of both the CWA and EPA regulations is that water quality standards be tailored to the characteristics of the waters in question, rather than based on the "one-size-fits-all" approach used in the proposed Rule. This is not the cumbersome task suggested by the Preamble, at least with respect to developing criteria appropriate for effluent-dependent waters. But, even if it were a cumbersome task, the difficulty of complying with the law is not an excuse for noncompliance.

* EPA could fulfill its obligation under the CWA and EPA regulations with respect to

effluent-dominated waters simply by proposing criteria for these waters that are generally achievable by present stormwater discharges. Then, using the more stringent statewide criteria as a tracer, control measures and BMPs could be implemented to reduce the discharge of problematic pollutants to the MEP.

Response to: CTR-040-016a

Regarding the first and third recommendations under part III, see the response to CTR-034-007.

Regarding the second recommendation under part III; with respect to the comment about removal of discharges see the response to comment number CTR-036-009 above. Further, with respect to comments that compliance with water quality criteria would incur costs that exceed benefits, EPA believes Sacramento County's has overestimated its incremental expense resulting from implementation of the CTR (for further detail see the response to comment in Section J, "Stormwater Economics," Issue 1). In any case, the Clean Water Act requires the states, or EPA to establish criteria that are protective of the designated uses, regardless of costs. This means that EPA must develop scientifically-based criteria that are protective of designated uses. In existing state water quality standards, however, the designated uses are not refined as suggested in Region 9's Guidance for Modifying and Protecting Effluent Dependent Ecosystems to suggest a use that would have different criteria. Until that is done, EPA is establishing criteria that protect the current designated use.

Regarding the fourth recommendation under part III, see the response to comment number CTR-034-007.

Regarding the fifth recommendation under part III, the Clean Water Act requires EPA to establish criteria that will be protective of designated uses. Establishing criteria for waters based on controls dischargers can currently achieve in their discharges may not ensure that criteria are protective of designated uses.

Comment: 5. The CTR should address effluent dominated waterbodies.

The CTR, as currently proposed, does not recognize that many of the waterbodies in the state are classified as "effluent dominated." In many areas of the state, particularly in Southern California, storm water and wastewater discharges are the primary or only source of water to urban creeks and waterways. To meet CTR criteria on discharges to these waterbodies, zero discharge or advanced treatment technologies may be required. The cost to accomplish this would be substantial and the benefit would be marginal, if not negative. A negative benefit would be realized if the removal of storm water and wastewater discharges to these waterbodies causes damage to the aquatic organisms and wildlife that are supported by and rely upon these effluent dependent waterbodies.

Request: Caltrans requests that the CTR be amended to include separate and distinct water quality criteria for effluent dominated or storm water runoff dependent waterbodies.

Response to: CTR-042-005

Comment: 7. EPA should adopt separate, scientifically defensible, reasonably achievable aquatic life criteria for streams and creeks that are dominated all or part of the year by discharges from anthropogenic sources. The application of the proposed statewide criteria to waters dominated by discharges from anthropogenic sources would force point source dischargers to remove their discharges, in many cases drying up the waters for most of the year. The costs would be significant and the benefits, at least the benefits assessed in EPA's economic analysis (enhanced fishing, reduced cancer risk, and passive benefits), would be negligible. In fact, the removal of these discharges could be detrimental rather than beneficial. The aquatic and riparian habitat, which previously supported aquatic life and wildlife, would no longer exist. This common type of water body (i.e., effluent dependent waters) demands separate and distinct water quality criteria by any reasonable yardstick, including common sense and the spirit (if not the letter) of Presidential Executive Order 12866 and the Unfunded Mandates Reform Act. Additionally, as previously stated, EPA regulations require that water quality standards be based on identification of specific water bodies where toxic pollutants may be adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern and must adopt criteria for such toxic pollutants Applicable to the water body sufficient to protect the designated use." Clearly the intent of these regulations is that water quality standards be tailored to the characteristics of the waters in question, rather than the "one-size-fits-all" approach in the proposed rule. This is not the cumbersome task suggested by the Preamble at least with respect to developing criteria appropriate for effluent dependent waters. But, even if it were a cumbersome task, the difficulty of complying with the law is not an excuse for noncompliance. EPA could fulfill its obligation under the Act and EPA regulations with respect to effluent dependent waters simply by proposing criteria for these waters that are presently achievable by municipal wastewater and stormwater discharges and then using the more stringent statewide criteria as a trigger for development and implementation of controls that will reduce the discharge of problematic pollutants to the maximum extent practical.

Comment: We have reviewed the proposed CTR and offer the following comments:

7. EPA should adopt separate, scientifically defensible, reasonably achievable aquatic life criteria for streams and creeks that are dominated all or part of the year by discharges from anthropogenic sources. The application of the proposed statewide criteria to waters dominated by discharges from anthropogenic sources--would force point source dischargers to remove their discharges, in many cases drying up the waters for most of the year. The costs would be significant and the benefits, at least the benefits assessed in EPA's economic analysis (enhanced fishing) reduced cancer risk, and passive benefits), would be negligible. In fact, the removal of these discharges could be detrimental rather than beneficial. The aquatic and riparian habitat, which previously supported aquatic life and wildlife, would no longer exist. This common type of water body (i.e., effluent dependent waters) demands separate and distinct water quality criteria by any reasonable yardstick, including common sense and the spirit (if not the letter) of Presidential Executive Order 12866 and the Unfunded Mandates Reform Act. Additionally, as previously stated, EPA regulations require that water quality standards be based on identification of specific water bodies where toxic pollutants may be adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern and must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use." Clearly the intent of these regulations is that water quality standards be tailored to the characteristics of the waters in question, rather than the "one-size-fits-all" approach in the proposed rule. This is not the cumbersome task suggested by the Preamble at least with respect to developing criteria appropriate for effluent dependent waters. Bur, even if it were a cumbersome task, the difficulty of complying with the law is not an excuse for noncompliance. EPA could fulfill its obligation under the Act and EPA regulations with respect to effluent dependent waters simply by proposing criteria for these waters that are presently achievable by municipal wastewater and stormwater discharges and then using the more stringent statewide criteria as a trigger for development and implementation of controls that will reduce the discharge of problematic pollutants to the maximum extent practical.

Comment: Effluent-Dependent Water Bodies

On Page 42164, the proposed Rule states that the EPA disapproved the deferral of water quality objectives in the ISWP for effluent dominated streams (Category "a") and agricultural drainage on the basis of imprecise and overly broad definitions. Since the ISWP was invalidated, the issue of effluent-dependent water bodies (EDW) was analyzed in detail via the State's Public Advisory Task Force process. Through our participation on the EDW Task Force (which included representatives from the EPA), we can confidently state that the issue has since been much better defined and that there is a full consensus that these water bodies need to be recognized in the establishment of water quality criteria.

In developing its list of non-compliant water bodies under the 303(d) provision, the State in essence acknowledged that EDWs are problematic simply because they support beneficial uses that would not otherwise exist without the flows of point and non-point discharges. This situation is compounded by the fact that all waters of the State, regardless of provenance, are classified as potential sources of domestic water supply; again, this is a potential benefit that would not otherwise be possible without effluent discharges, and this benefit should be recognized in the proposed Rule.

From this, we conclude that the proposed Rule is not complete because it does not recognize the importance of EDWs as was conclusively demonstrated by the EDW Task Force. . The EDW concept should not be abandoned, and we strongly urge the EPA to replace its statements on Page 42164 with a brief acknowledgment of the findings and recommendations of the EDW Task Force. We believe that this will provide additional impetus for the State to incorporate EPA-approved EDW provisions in its own plan.

Response to: CTR-057-003

EPA participated in the EDW Task Force with other stakeholders representing the industrial, municipal, storm water, agricultural, environmental, water supply, public health and regulatory sectors. The goal of the Task Force was to develop recommendations for the State Water Resources Control Board (SWRCB) regarding how to provide reasonable protection for appropriate beneficial uses of EDWs. After considering the complexities of the analyses necessary to characterize and determine appropriate water quality objectives for EDWs, the Task Force recommended the following two-step approach to regulating them. The first step is to modify the present designated beneficial uses such that they more accurately reflect actual uses. The second step is to adopt water quality objectives appropriate for each use designation. The needs for developing this approach would be: to define EDWs in the new State plans, to define EDW-specific use categories, to define and categorize all EDWs by use categories in the State, and to adopt appropriate water quality objectives for EDWs. While emphasizing again that this work should be done within the context of either SWRCB or Regional Board standards-setting actions, EPA

acknowledges and agrees with the recommended approach. EPA further notes that the Task Force report also recommends that the SWRCB should develop technical evaluation criteria for a number of the steps identified above, and that the SWRCB should consider convening a technical advisory committee to address these issues. Until the recommended technical evaluation criteria are established and implemented, EPA considers that criteria should be adopted on a statewide basis.

Comment: Due to the time constraints of the comment period, we have focused our review and comments primarily on those criteria that we anticipate may cause compliance issues for one or more of the Sanitation Districts' WRPs (see below). Based on our initial review of the proposed rule, the Sanitation Districts recommend that adoption of some of the criteria be deferred. As explained in the attached comments, we believe that there are significant scientific issues regarding the human health criteria for several trihalomethanes that call into question the accuracy and appropriateness of the proposed criteria. In addition, we reconunend that EPA defer adoption of those criteria that are below detection limits and that have not been demonstrated to be adversely affecting water quality or the attaimnent of designated uses on a water body-specific basis in California. In addition, we recommend that EPA not adopt criteria for effluent dependent waters, unless they have been adjusted to reflect the characteristics of this type of water body.

Criteria for Effluent Dependent Waters

As discussed above, the water quality standards regulations (specifically, 40 CFR section 131.11) requires EPA to examine the specific water bodies and uses to be protected before adopting criteria in water quality standards. As EPA is aware, streams and washes in and areas have unique characteristics, and in many locations in southern California, POTW discharges have transformed ephemeral streams into what are essentially perennial streams. These are often referred to as "effluent dependent waters" or EDWs. The impact of this has been to create new riparian habitats that provide valuable ecological benefits. However, this has also raised many questions regarding what water quality standards should be applied to EDWs. For instance, since the use of treated wastewater for drinking water is restricted by the Department of Health Services, it is questionable whether the municipal drinking water designated use (MUN) is appropriate for EDWS. LACSD believes that, based on the requirements of the water quality standards regulations, that EPA has not demonstrated that the proposed CTR criteria are appropriate for EDWs, and that a more appropriate course of action would be for EPA to adopt separate criteria for water bodies in California that are dependent for all or part of the year on flows from wastewater treatment plants.

Appropriate ways to modify aquatic life and human health criteria for EDWs could include adjustment of the uncertainty and/or modifying factors used to calculate reference doses (RfDs) for noncarcinogenic human health criteria, use of 10E-4 or 10E-5 risk levels (instead of 10E-6) for carcinogenic human health criteria, adjustment of bioconcentration factors for hwnan health criteria, the use of site-specific water effects ratios for aquatic life criteria, and the adjustment of the low flow values, frequency of exceedence and/or criteria averaging periods used in deriving or applying the criteria. As an agency that owns and operates numerous treatment plants that discharge into EDWs, and that has a substantial base of knowledge regarding the quality of the effluent and the conditions in the ambient environment in the vicinity of these discharges, we would be pleased to work with EPA to craft water quality criteria for toxic pollutants that are appropriate for EDWs in southern California.

Response to: CTR-059-010

In response to the recommendation that EPA not adopt criteria for effluent dependent waters unless they have been adjusted to reflect the characteristics of this type of water body, see the response to comment number CTR-034-007.

Concerning the comment that water quality standards regulations require EPA to examine specific water bodies and their uses before adopting criteria for them, see response to comment number CTR-040-016a. Concerning what designated uses are appropriate for EDWs, see response to CTR-036-009. See also responses to comment CTR-005-006a, CTR-036-005, and CTR-038-006a in the Legal Concerns Category (C-21). For purposes of this rulemaking, EPA is presuming that the State has adequately determined the designated uses for its waters. EPA is promulgating criteria for priority toxic pollutants on a statewide basis sufficient to protect the State's designated uses.

Concerning appropriate ways to modify aquatic life and human health criteria for EDWs, with the exception of application of water effect ratios (WERs), EPA considers that the methods suggested should be applied in the context of State or Regional Board water quality standards-setting actions. EPA's action in promulgating statewide criteria is to reduce risks to all exposed populations, including especially sensitive subpopulations. However, site-specific criteria may be developed subsequently by the State where warranted to provide necessary additional protection, or otherwise to adjust the level of protection as appropriate to reflect site-specific conditions following a Section 304 standards-setting process including the opportunity for public involvement. As described above, EPA has included WERs in the proposed metals criteria listed in the table in Section 131.38(b)(2) for protection of aquatic life.

With respect to adjusting frequency of exceedence and/or criteria averaging periods, EPA refers the commenter to Appendix D of EPA's "Technical Support Document For Water Quality-Based Toxics Control" (EPA/505/2-90-001, March 1991), in particular to the discussion entitled "Considerations for Proposing Site-Specific Increases or Decreases in the Averaging Frequency of Allowed Excursions." Although more frequent than once-in-three-years excursions might be acceptable in certain situations, where, for example, areas of refuge for aquatic organisms are available or for certain lower-order streams, the converse may also be true depending on the size of the drainage and the persistence of the pollutant in question. As stated previously, EPA considers it inappropriate for EPA to develop site-specific criteria for California EDWs. The averaging periods of EPA proposed criteria for toxics are based on data from nation-wide laboratory toxicity tests. The once-in-three-years frequency of exceedence is based on field data. With the concurrence of EPA, States may adopt site-specific criteria, including potentially different averaging periods and frequencies of allowed excursions, for individual or appropriate categories of water bodies. The kinds of data necessary to justify adoption of such criteria may be determined by reviewing the studies referenced in Appendix D of the Technical Support Document and following procedures described in Chapter 3 of EPA's Water Quality Standards Handbook

(EPA-823-94-005a, August 1994

With regard to the adjustment of low-flow values (although this issue concerns implementation of proposed criteria, and is thus also more appropriate for the State to consider), the once-in-ten-year seven-day average low flow design condition (7Q10) has historical precedent and is part of many States' water quality standards. In addition, this value approximates the same degree of protection as the three-year return interval of the proposed acute and chronic criteria. Given the state of the science, and the limitations of available data, EPA as a matter of policy takes the position that it should assure adequate protection and takes a conservative approach to establishing water quality criteria. This policy is also consistent with and recognizes historic program practices and procedures used by both the Agency and the States in implementing the water quality standards and related implementation programs. (Guidelines for Developing or Revising Water Quality Standards, April 1973, p.7.)

Comment: * EPA should consider adopting separate, scientifically defensible and reasonably achievable aquatic life criteria for waters that are effluent-dependent for all or part of the year. In addition, the aquatic life criteria should be applied to those waters identified in the Basin Plans instead of "all waters. "

Response to: CTR-081-004a

Concerning the issue of adopting separate aquatic life criteria for effluent-dependent waters, see the response to CTR-034-007.

Concerning the issue of application of those criteria to waters identified in the Basin Plans, EPA considers that, withrespect to protection of aquatic life, the proposed CTR criteria apply to all waters in the State of California except for those covered by the NTR, as amended or those covered by an EPA approved site-specific criterion or basin plan objective. If the aquatic life use designation is considered inappropriate, it may be removed only where a use attainability analysis is conducted and approved, as described further in response to CTR-036-009.

Comment: While the draft regulations demonstrate clear progress on these and other issues, there remain some unresolved problems that could compromise our ability to serve our customers. We offer these comments in the hope of minimizing those potential impacts.

Incorporation of the Inland Surface Water Plan Task Force Recommendations

A final issue is whether the draft CTR gave adequate consideration of the recommendations of the state's Inland Surface Water Plan (ISWP) Task Force. The ISWP Task Force was created specifically to address the court-mandated need for multiple-stakeholder input in the state's implementation of the Clean Water Act. The ISWP Task Force included at least two groups (Toxics task force and Effluent Dependent Waterbody task force) specifically charged with making recommendations for the adoption of toxics criteria in the state's inland waters.

The absence of any criteria for toxics in effluent,-dependent waterbodies causes us to wonder how the draft CTR incorporated the recommendations of the ISWP task force. The issue here is that criteria that are too strict may cause dischargers to seek alternative disposal options, which could result in stream wildlife impacts greater than those resulting from substandard water. This issue is paramount in the state's arid regions, where the availability of water of any quality can dictate whether aquatic life exists at all. The rebuttal position that dischargers should be forced to treat the water anyway ignores the fact that, if treated to these standards, the water becomes valuable for other uses such as recycling, which dischargers are legally-entitled to pursue. Indeed, state water policy is to encourage water recycling

efforts specifically to offset the need to import water from the state's less arid regions and the Colorado River Basin.

Response to: CTR-089-006

Comment: The final issue that I would like to present concerns the need for recognition in the CTR for effluent dependent waters. Many POTWs in Southern California discharge to waterways that would otherwise be nonexistent during the dry seasons. This has allowed for the establishment of aquatic habitats and other beneficial uses in those waterways. Since it is not an isolated concern, this issue needs to be recognized. If CTR rule-making is limiting itself to establishing a conservative water quality criteria that assures protection of all waters regardless of its condition, then a mechanism needs to be provided in CTR to deal with the EDS issues. EPA cannot simply deny us the designation of Categories A, B and C in the old Inland Surface Water Plan; instead, this issue must be addressed.

Response to: CTRH-002-020

Concerning the first part of this comment see the response to CTR-036-009 above.

Concerning the comment that a mechanism needs to be provided in CTR to deal with the EDW issues, EPA considers that by incorporating variables of hardness, water effect ratios and pH as appropriate into the proposed CTR criteria as described further in response to CTR-034-007 above, it has provided such a mechanism. Beyond such adjustments, criteria would have to be further revised by means of a use attainability or other site-specific analysis, which should be conducted at the State or local level as described in response to the fourth recommendation in CTR-040-016a, above.

Concerning the comment that EPA cannot simply deny California the designation of Categories (a), (b) and (c) in the old Inland Surface Waters Plan: EPA's action in only partially approving California's Inland Surface Waters and Enclosed Bays and Estuaries Plans was to conclude that deferral of adoption of toxics criteria for categories (a) and (b) and the exemption from coverage of category (c) were inconsistent with CWA section 303(c)(2)(B). EPA would be willing, pursuant to its Guidance for Modifying and Protecting Effluent Dependent Ecosystems, to consider application of alternate uses that would lead to less stringent criteria. Thus, EPA did not "deny ... the designation" of EDWs, as is alleged in this comment, as much as disapprove the deferral and exemption of these waters from having any criteria for toxics.

CROSS REFERENCES I-04

Comment: In addition, we would like to emphasize the following concerns which greatly impact the Los Angeles County Stormwater Program:

6. The proposed criteria will apply to all inland surface waters and enclosed bays and estuaries, regardless of the designated or attainable uses for a water body. This is of particular concern for waters that only have flows during wet weather events or that are point source effluent dominated water bodies. Blanket application of water quality criteria to all waters without designated uses is inconsistent with Federal and State water quality laws. Water quality standards are made up of two components--designated uses and the appropriate criterion to ensure the designated use can be achieved. Assigning criteria to a water body without first considering the designated uses is inappropriate and could result in over restrictive, unnecessary permit limits potentially resulting in significant compliance costs to a discharger.

It is common in California for urban stormwater runoff discharges to be the primary or only source of waters to urban creeks and waterways, that is, there would be little or no flow during most of the year were it not for urban stormwater or other point source discharges. Given the potential compliance problems for stormwater discharges forcertain constituents (even after a fully implemented BMP program), a municipality could be forced to remove stormwater discharges from the creek. The costs would be significant and the benefit little, if any. In fact, the removal of these discharges would be environmentally damaging to aquatic life and wildlife that were supported by the effluent/runoff dependent waters.

Therefore, the proposed rule should be revised to avoid blanket application of the proposed criteria to all surface waters and to require appropriate beneficial and attainable uses of all waters be determined prior to imposing water quality criteria in the water body. The rule should also be revised to implement separate and distinct water quality criteria for water bodies that are primarily effluent or runoff-dependent.

Response to: CTR-013-006b

As discussed in the preamble, the purpose of today's rule is to establish numeric criteria for those navigable waters in California that do not have criteria for priority toxic pollutants in place. The State has in place specific use designations that were duly adopted by the State through its Regional Water Quality Control Board's Basin Plans which include aquatic life, human health and other uses to be protected in particular waterbodies. Thus, EPA, in this rulemaking, is not revising those use designations established by the State.

Furthermore, EPA encourages the commenter to work with the State in its review and adoption of the Basin Plans to refine those use designations that the commenter believe might be inappropriate. Such review could encompass a use attainability analysis to determine if the designated uses need to be changed to reflect uses that are no longer attainable, provided that the existing uses (those uses established on or after November 28, 1975) are still protected. A use attainability analysis is an assessment of physical, chemical, biological and economic factors that affect the attainment of a use.

Comment: II. Use of New Scientific Information

The City acknowledges and supports EPA's update of several water quality criteria including those for mercury, cadmium and arsenic. While a number of criteria were updated to reflect current scientific information, there are a few notable exceptions.

The following briefly addresses the key updates and omissions that should be addressed in the final publication of this rule.

6. Human Health Criteria Application

These stringent criteria, which are based upon the assumption that two liters of water is consumed per day, are specified to apply to all surface waters with a MUN designation. This is a default designation for many waters in the various Basin Plans and means that ditches and other water bodies that clearly have no actual or extremely limited drinking water use potential will be regulated more stringently than tap water for many pollutants. This is an overly broad application of the federal criteria and is unnecessary to ensure appropriate public health protection. EPA should revise the rule to specify that consumption-based criteria will only apply to waters in the vicinity of water intakes which will allow for consideration of fate and transport of pollutants before determining that a potential public health threat exists. Likewise, fish consumption-based criteria should only apply where the Department of Fish & Game determines that there is a reasonable likelihood of the presence of a game fishery. If such a fishery is not present, there will be no human exposure to the pollutants justifying implementation of stringent point or non-point controls.

Response to: CTR-020-017

EPA disagrees that the application of the human health criteria in waters that have a MUN designation is unnecessary to protect public health in California. EPA believes that the application of the human health criteria that considers exposure from both fish and drinking water consumption in waters that have a

MUN designation is appropriate and consistent with State practices and regulatory requirements (Section 131.11 of the Water Quality Standards Regulation requires the adoption of criteria to protect the uses of state waters). The State assigns the MUN designation to waters that are potential or actual drinking water supplies. Since EPA has no intention of changing the uses designated by California in this rulemaking. EPA encourages the commenter to work with the State in its review and adoption of the Basin Plans to refine or modify those use designations that the commenter believe might be inappropriate.

Comment: 1 . DESIGNATED USES AND ANTIDEGRADATION POLICY

The DFG is concerned with the issues of "designated uses" and an "antidegradation policy" as they apply to the formation of water quality standards. It is our understanding that water quality standards are comprised of, or defined by, three components: 1) designated uses, 2) numeric water quality criteria, and 3) an antidegradation policy. The CTR is not clear on which designated uses are being identified and when they were established. The rule needs to identify what designated uses are being assigned and when these uses were or should be attained. At issue is which uses should be maintained and protected, and what the baseline should be for designating the various beneficial or designated uses for inland freshwater and bay and estuarine waters of the state. We believe that any baseline for applying the antidegradation policy should establish what the quality of the water would have been historically in the absence of human impacts. Under the Porter Cologne Act, the State's primary water quality statute, the dischargeof waste into state waters is not a right but a privilege. Since the discharge of waste is not considered a beneficial use, it should not be permitted in public waters unless it is determined that all beneficial uses, especially publicly entrusted fish and wildlife resources, are fully protected. This is especially true for wetlands throughout the State. The proposed rule is not clear as to when the baseline starts (i.e., historical vs. statutory). The DFG believes that, to the extent practicable, designated uses should be reflective of what has been realized in the past. If the CTR is utilizing a statutory date for which baseline designated uses were identified, then the CTR needs to include a justification for such a date.

With respect to antidegradation, it is not clear whether or not the proposed rule is subject to these requirements. It is our understanding that when a proposed action would allow less stringent criteria than previously proposed or adopted, and if that action would result in more loading of a particular constituent into waters of the State, then an appropriate antidegradation analysis shall be required. It is not clear what process EPA has undertaken to adequately address antidegradation issues related to the proposed new criteria. It may be that the applicability of the antidegradation policies are more pertinent with respect to site-specific criteria that may be included in the final rule. We recommend that the CTR adequately address this issue and apply the antidegradation policy where necessary.

Response to: CTR-026-001b

See response to CTR-013-006b. For a response to antidegradation issues, see response to CTR-026-001a.

The purpose of this rule is to establish numeric criteria for those waters identified in the State's Basin Plans that were duly adopted by California's Regional Water Quality Control Boards that do not have water quality criteria for priority toxic pollutants in place. These Plans have specific use designations for waterbodies that were duly adopted by the State through its Regional WaterQuality Control Boards' basin plans that identify aquatic life and human health uses to be protected in particular waterbodies. EPA, in this rulemaking, is not revising or establishing the use designations for waters contained in the State's Basin Plans. The review of those uses designations established by the State are outside of the scope of today's rule. Furthermore, EPA does not believe that an evaluation of the use designations or a discussion on the dates those uses were assigned is within the scope of this rulemaking action. However, EPA does note that in today's rule and in the proposed rule (see 40 CFR 131.36(d)(1) through (d)(3)), the Agency identifies the water use classifications that are subject to this Federal rule.

Comment: 7. The proposed criteria will apply to all inland surface waters and enclosed bays and estuaries regardless of the designated or attainable uses for a water body. This is of particular concern for waters that only have flows during wet weather events, or that are point source effluent dominated water bodies. Blanket application of water quality criteria to all waters without designated uses is inconsistent with federal and state water quality laws. Water quality standards are made up of two components - designated uses and the appropriate criteria to ensure the designated use can be achieved. Assigning criteria to a water body without first considering the designated uses is inappropriate and could result in overly restrictive, or unnecessary permit limits, potentially resulting in significant compliance costs to a discharger.

It is common in California for urban stormwater runoff discharges to be the primary or only source of waters to urban creeks and waterways; that is, there would be little or no flow during most of the year were it not for man's activities. Given the potential compliance problems for stormwater discharges for certain constituents (even after a fully implemented BMP program) a municipality could be forced to remove stormwater discharges from the receiving water. The costs would be significant and the benefit little, if any. In fact, the removal of these discharges would be environmentally damaging to aquatic life and wildlife that were supported by the effluent/runoff dependent waters.

Recommendation: The proposed rule should be revised to avoid blanket application of the proposed criteria to all surface waters, and to require appropriate beneficial and attainable uses of all waters be determined prior to imposing water quality criteria in the water body. The rule should also be revised to

implement separate and distinct water quality criteria for water bodies that are primarily effluent or runoff dependent waters. An example of such flexibility is the use of a less stringent cancer risk factor such as 10E-4 or 10E-5 for the human health criteria for effluent dominated streams.

Comment: EPA should apply the aquatic life criteria only to those waters identified in Regional Water Quality Control Plans ("Basin Plans") as having full aquatic life use designations, rather than to "all waters," in the same way that the human health criteria for water and organisms are applied only to those waters designated in Basin Plans with the municipal drinking water supply, beneficial use ("MUN" use).

Comment: p. 42207 -- Beneficial Use Designations (Applicability of Criteria) We are concerned about what appear to be overly broad statements in the proposed regulation regarding the applicability of the criteria. We recommend that EPA remove the following statement contained in section 131.38(d)(1) of the regulation: "Although the State has adopted several use designations for each of these waters, for purposes of this action, the specific standards to be applied in paragraph (d)(2) of this section are based on the presence in all waters of some aquatic life designation and the presence or absence of the MUN use designation (municipal and domestic supply)" (62 Fed. Reg. 42207) (emphasis added). We also

request that EPA delete from the regulation the statement that begins this paragraph, which states that "Except as specified in paragraph (d)(3) of this section, all waters assigned any aquatic or human health use classifications in the Water Quality Control Plans for the various Basins of the State... are subject to the criteria in paragraph (d)(2) of this section, without exception." We recommend that EPA modify the applicability of the rule to reflect its full evaluation of those specific water bodies where each pollutant is found to be "adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern" (40 CFR section 131.11) (see comments on p. 1-2).

Further, we believe that, contrary to EPA's assertion on p. 42168 of the Preamble that the aquatic life criteria are applicable to all waters of the U.S., the freshwater aquatic life criteria may be inappropriate for application to streams and creeks that are dependent on flows for all or part of the year on discharges from anthropogenic sources, such as POTWs. We request that EPA establish separate, scientifically defensible aquatic life criteria for such water bodies. Several of our comments above have suggested ways that may be appropriate to modify certain types of criteria. Until this issue is addressed, we oppose the application of the criteria contained in the proposed CTR to effluent-dependent waters in the State of California.

Comment: V. Recommendation: Delete all provisions in the Rule that preempt the States flexibility in permitting. The Rule provides specific direction on the adoption of averaging periods, low flow values, effluent limitations for criteria not being adopted as a part of the Rule, and that the aquatic life criteria be applied to all waters irrespective of designated use, etc..

* The Preamble and the Rule's economic analysis make a point that the State has considerable flexibility in establishing permit limitations. In making, that point, EPA implies that the State may implement the criteria in a manner that would have little or no adverse economic impact on dischargers.

* However, the Rule contains a number of implementation provisions that are not required under Section 303(c)(2)(B), but serve to preempt the State's flexibility. These provisions include, but are not necessarily limited to the adoption of averaging periods and low flow values, directives regarding the establishment of effluent limitations for criteria that are not being adopted as a part of the Rule, and application of the aquatic life criteria to all waters irrespective of the designated use.

* Not only does EPA not have a duty to adopt these provisions, but also the provisions are more restrictive than those required by the CWA or EPA regulations, They clearly restrict the State's flexibility. In fact, other states have adopted, and EPA has approved, implementation provisions (e.g., averaging periods and low flow values) which are less restrictive.

* For these reasons, EPA should remove all such implementation provisions from the Rule.

Comment: * EPA should consider adopting separate, scientifically defensible and reasonably achievable aquatic life criteria for waters that are effluent-dependent for all or part of the year. In addition, the aquatic life criteria should be applied to those waters identified in the Basin Plans instead of "all waters."

Response to: CTR-081-004b

Today's rule applies to those navigable waters in California that do not have numeric criteria for priority toxic pollutants in place. This encompasses waters of the U.S. for which the State has duly adopted use

designations through its Regional Water Quality Control Plans, including those waters that are effluent and flow dependent streams. The criteria in this rule are based generally on EPA's national criteria guidance which are applicable and appropriate for all waters of the U.S. However, if a state finds that the ambient water quality criteria for a waterbody are inappropriate, then EPA's Water Quality Standards Regulation provide for a use attainability analysis and establishment of appropriate use designations.

For waters of the U.S. which have human health uses designated in the Regional Board's Basin Plans, aquatic life is present and fish or other aquatic organisms are being caught and consumed. Therefore aquatic life criteria and human health criteria based on the consumption of fish are applied to those waters except where the State has conducted and EPA has approved a use attainability analysis to remove or modify the aquatic life use or fish consumption use. Furthermore, for waters with a MUN designation, human health criteria that considers exposure from water and fish are applied to those waters. These approaches are consistent with EPA's Water Quality Standards Regulation (40 CFR Part 131) which requires States to include uses identified in Section 101(a) of the Clean Water Act, where attainable, and to establish criteria to protect those use designations.

Comment: 6. TOTAL HARDNESS DEPENDENT FRESHWATER METALS CRITERIA

The DFG does not object to the development of freshwater metals criteria that take into account the effect of total hardness on metals toxicity, with the exception of the comments on criteria development stated above. The DFG does recommend, though, that the proposed rule clarify the tables (page 42169) that reflect this approach. The tables may be viewed as the specific criteria rather than examples of metals criteria based on the total hardness value of 100 mg/l CaCO[subs]3.

Response to: CTR-026-005

EPA acknowledges the commenter's concern that the hardness-dependent metals criteria may be incorrectly misconstrued as single fixed values, particularly since fixed numbers and hardness-dependent numbers appear in the same table. However, footnote "e" of the table explains the hardness dependency. EPA does not know of a better manner in which to present this information, and the commenter did not offer an alternative as to how to make the information clearer to the a casual reader.

Comment: 2) We agree with commentors who argued that a 4-day average period and a once in three year exceedance frequency is unnecessarily restrictive for chronic criteria exceedances. In fact, it would seem reasonable to assume that isolated exceedances of chronic criteria would have no discernable long term effect on a water body. Further, so long as acute criteria are not also exceeded, a rapid recovery period would seem likely, What case studies and/or laboratory results does EPA have to support this finding? Also, what data is EPA relying on for the three year excursion frequency for acute failures? Based on the evidence of recent major environmental calamities, aquatic systems appear to right themselves very quickly after initial cleanup, typically within one year.

Comment: The rule states that the CMC "equals the highest concentration of a pollutant to which aquatic life can be exposed for a short period of time without deleterious effects." What is a "short period of time" defined as? This definition, as it stands, is vague to the point it will require, and be subject to, various interpretations by different entities and individuals. It puts the regulated community in the position of having to make independent judgments as to what the proscribed activity is, case-by-case. This is inappropriate, and will lead to unnecessary conflict. The City recommends that EPA define "short period of time" more precisely, and present the scientific basis for such definition in the final rule.

Response to: CTR-009-007

EPA does not agree that it is necessary to further define "short period of time" within the rule. The reason that it is not numerically specified is that the appropriate averaging period varies from pollutant to pollutant, and is not as well defined as, nor is as important as, the criteria concentrations, which are numerically specified in the rule. EPA is deferring to the State implementation procedures for the application of acute averaging periods into NPDES permit limit calculations, because these implementation procedures primarily involve mixing zone policies, which are at State responsibility, and are not part of this rule.

Comment: II. Use of New Scientific Information The City acknowledges and supports the EPA's update of several water quality criteria including those for mercury, cadmium and arsenic. While a number of criteria were updated to reflect current scientific information, there are a few notable exceptions. The following briefly addresses the key updates and omissions that should be addressed in the final publication of this rule.

4. Averaging Period for Acute Criteria

The proposed rule does not establish a specific averaging period for acute criteria, apparently abandoning the published criteria recommendation that acute criteria should be applied as one hour averages. EPA now states that the exposure time should be "short." While Stockton concurs that a one hour averaging period is not supported by the underlying data and is inconsistent with the permit development procedures in EPA's 1991 Technical Support Document for Water Quality-based Toxics Control ("TSD"), the failure to explain why EPA is no longer recommending a one hour averaging period will lead to confusion and misapplication of the criteria. At a minimum, EPA should explain that "short" means at least 24 hours so that inconsistencies in permitting do not occur.

Thus, the final CTR should discuss the technical basis for this change and identify the acceptable exposure period.

Response to: CTR-020-008

EPA does not agree. The appropriate acute averaging period is not necessarily greater or equal to 24 hours for each of the pollutants. See response to CTR-009-007.

Comment: II. Use of New Scientific Information The City acknowledges and supports EPA's update of several water qulaity criteria including those for mercury, cadmium and arsenic. While a number of criteria were updated to reflect current scientific information, there are a few notable exceptions. The following briefly addresses the key updates and omissions that should be addressed.

(a) EPA's Characterization of Metals as Fast Acting Toxicants is Erroneous

Water quality criteria established pursuant to Section 304(a) of the CWA classify pollutants as acute, chronic, or human health-based depending on the pollutant's mode of toxicological activity. The classification of a pollutant significantly affects the manner in which criteria are applied and effluent limitations are derived. Many factors affect the proper translation of water quality criteria into NPDES permit limits, including modeling, permit averaging periods, low flow return frequency, mixing zones, and assumptions made in the modeling process. In addition, criteria require appropriate "duration" and "frequency of exposure" factors which are directly related to the time required for exposure to a pollutant to elicit a biological response (e.g., mortality). Any arbitrary reduction of the allowable exposure period (or the acceptable return frequency) establishes more stringent criteria than necessary to ensure use protection.

EPA's proposed acute averaging period recommendation (short) has a substantial effect on mixing zone calculations. This policy assumes that short term exposures to concentrations slightly in excess of the acute criteria can produce mortality to swimming or drifting organisms (ie., the "fast acting toxicant assumption"). If 24-48 hour exposures are acceptable, the acceptable and protective mixing zones would increase substantially. This reduces the costs of compliance and the need to construct expensive diffusers except in situations where true acute toxicity concerns exist.

The CWA section 304(a) criteria and EPA's 1991 TSD establish EPA's position on criteria application. As more ftilly set forth below, EPA's assumption that all heavy metals are "fast acting toxicants" is not supported by EPA's recently completed research which was expressly intended to evaluate this issue as part of the February 15, 1995 National Toxics Rule settlement. EPA has recently acknowledged this fact with respect to copper in its Marine Copper Criteria published on April 14, 1995. Consistent with its CWA section 304 mandate, EPA must modify all metals criteria to accurately reflect the latest infon-nation regarding the toxicological rate of action for metals. To do otherwise is arbitrary and capricious, and EPA must provide the public with the results of the recent scientific research about characteristics of each pollutant and their proper averaging period.

Response to: CTR-020-009

EPA does not agree. EPA has not assumed that all toxicants are fast-acting for purposes of applying the CMC to define permit limits. The provisions of the rule were specifically designed not to incorporate such an assumption. EPA is deferring to the State implementation procedures for the application of acute averaging periods into NPDES permit limit calculations.

Comment: II. Use of New Scientific Information The City acknowledges and supports EPA's update of several water quality criteria including those for mercury, cadmium and arsenic. While a number of criteria were updated to reflect current scientific information, there are a few notable exceptions. The following briefly addresses the key updates and omissions that should be addressed in the final publication of this rule.

(1) Short (One Hour) Acute Averaging Period for Metals is Unnecessarily Restrictive and Without Any Technical Basis

The chronology of EPA's one hour averaging period illustrates a continued adherence to the outdated "fast acting toxicant" assumption that is unsupported. As the following discussion shows, the Agency has acknowledged a dearth of scientific support for the one hour assumption through repeated Freedom of Information Act ("FOIA") requests. Recently EPA released the analytical data underlying its time/toxicity assumptions for metals which confirm metals are not "fast acting."

Acute criteria are generally developed based on 48-96 hour exposures.(*1) In establishing its criteria, EPA arbitrarily reduced "acute" exposures to one hour without any supporting data and continues to assert that the one hour or short acute averaging period is appropriate. Actually, acute criteria underwent two transformations. EPA initially determined the 96 hour no effect concentration to establish the numeric criteria; it then arbitrarily reduced the allowable exposure period from 96 hours to one hour without a corresponding adjustment to the numeric criteria or a determination that this additional adjustment was necessary.

(2) Initial Agency Research on Issue

EPA has been in the process of reconsidering the historically recommended one hour acute averaging period for over eight years. In October 1989, the Agency completed an internal report specifying that existing averaging periods for acute and chronic criteria may be unduly restrictive and that more reasonable approaches may be implemented.(*2)

In response to comments on EPA's 1991 TSD, the Agency admitted that:

The one hour acute averaging period was derived primarily from the data on response time for toxicity to ainmonia, a "fast acting toxicant."(*3)

Research performed by Mancini (1983), cited in the 1991 TSD, verifies EPA's assumption is incorrect.(*4) Erickson (1989) noted that for fathead minnows, copper LC50s increase gradually by a

factor of two (2) between the 96 hour and 12 hour exposure durations. LC50s were ten-fold higher at two to three hours than at 96 hours.(*5) This is hardly a "fast acting" toxicant. Research by Brown (1974) indicated that a one hour exposure of rainbow trout to copper elicited no acute response at twenty times 96-hour LC50 concentrations.(*6)

(3) EPA Commits to Reevaluate the Fast Acting Toxicant Assumption

At the January 1993 Annapolis Conference, EPA and academic scientists, including state regulatory officials, called on the Agency to assess whether overly conservative assumptions are leading to permit limitations which can be orders of magnitude more stringent than needed to protect aquatic life uses. EPA identified several high priority research goals, including the accurate assessment of toxicological kinetics of metals and committed to address whether metals are, in fact, "fast acting" toxicants.(*7)

At a public meeting of EPA's Criteria Review Committee in June 1993, the Science Advisory Board presented copper mortality data that confirmed copper concentrations many orders of magnitude higher than current acute criteria would be required to elicit mortality within a one hour exposure time (Exhibit 3). EPA stated its intention was to utilize such time/mortality studies to derive an appropriate criteria averaging period:

The Committee tentatively intends to incorporate the use of a kinetic model of toxicity into the Guidelines. This model allows more rigorous use of data from toxicity tests, and should better represent the effects of time-varying concentrations occurring in ambient applications... The data on the time course of mortality would yield a rate coefficient indicating how quickly mortality occurs. This rate coefficient would replace the current averaging period.(*8)

Unfortunately, EPA revealed a lack of urgency in addressing the toxicological speed of action issue for metals, leaving many dischargers exposed to unnecessarily stringent requirements. An October 27, 1993 letter from the Assistant Administrator for Water stated:

"...the analysis is not yet complete. Once completed, we will circulate it for public review... Completion, of course, is dependent on available resources, particularly in light of competing statutory and court-ordered mandates."(*9)

Ironically, EPA in the same letter disclosed that the one hour averaging period for metals is a "default value" without any technical basis:

"EPA does not have any specific data on metals discharged near or above criteria levels showing acute impacts in one which is expected to be protective for both fast-acting and slower toxicants."(*10)

In early 1994, EPA asserted it was actively addressing the recommendations made at the Annapolis Conference that toxicant speed of action be revised, and in correspondence to the Pennsylvania League of Cities and Municipalities, the Agency asserted that data analyses were underway at that time:

"You have raised several questions concerning the speed of action of toxic effects of metals. We agree that this issue warrants further investigation. Our plan is to definitively address the issue with a new criteria methodology which will explicitly incorporate data with regard to speed of action on a pollutant-by-pollutant basis. Our present policy is to make a single, conservative assumption on speed of action for all pollutants, in the absence of appropriate data and methodologies to do the pollutant-by-pollutant analysis. We are investigating whether we have sufficient information to issue interim guidance now, modifying this policy on speed of action for some pollutants or classes of

pollutants."(*11)

(4) Results of AnaIysis Confirm Metals Are Not Fast Acting

In a February 28, 1994 response to a FOIA request, EPA acknowledged that data pertaining to toxicity/time relationships for metals are available and that preliminary analyses of available data indicate that the one hour period is unnecessarily conservative:

...the averaging period for copper, zinc, and lead would be about 1 day, while cadmium and arsenite would have an averaging period of about 2.5 days.

... for the above metals [copper, zinc, lead, cadmium, and arsenite] their action can be "fast" in the sense that a short exposure can be lethal, but only at somewhat higher concentrations than those which are lethal for exposures of a day or longer. Even the more fast-acting of the above metals would not require an averaging period as short as a few hours, but a major fraction of a day or longer.(*12)

In an August 22, 1994 letter to Rep. Robert Borski, EPA's Assistant Administrator for Water asserted that the Agency was diligently pursuing completion of studies to better define the toxicological speed of action for metals.

"Consistent with the recommendations from this group, EPA hopes to improve our water quality based approach and better characterize the conservative and nonconservative assumptions associated with the methodology. This would include the guidance addressing fast- and slow-acting metals in the Spring of 1995."(*13)

In September 1994, the EPA Aquatic Life Guidelines Committee met to address issues concerning the derivation of aquatic life criteria, including potential modifications to earlier assumptions related to the speed of action:

"Whereas the 1985 Guidelines use only the survival results at the end of 48- or 96-hour tests, the new framework would also use survival counts taken at various times throughout the tests. These data would be evaluated within the framework of a kinetic-based toxicity model (Mancini, 1983; Erickson, et al., 1989), intended to consider the speed at which effects appear in different individuals and different concentrations."(*14)

From the most recent Agency information available, it is apparent that EPA has completed the studies and re-evaluations of criteria development data necessary to derive appropriate averaging periods for metals. EPA has indicated to at least one state that studies of the toxicological kinetics of metals have been completed and that the Agency has concluded that a 24 hour acute averaging period is protective of aquatic life uses based on those studies, as follows:

"The NJDEP has discussed criteria durations with Charles Delos, Ecological Risk Assessment Branch, Health and Ecological Criteria Division, USEPA, Washington, D.C. Our understanding is that the recent reevaluation of "fast acting" toxicants has been completed for cadmium, chromium, copper, lead, mercury, nickel, silver and zinc. The results of that reevaluation indicate that an acute criteria duration of 24 hours would be protective for these metals."(*15)

EPA acknowledged that a 24 hour acute averaging period is appropriate for copper in its April 14, 1995 Ambient Water Quality Criteria for Copper - Saltwater Copper Addendum. This conclusion was consistent with the evaluation presented by Erickson in 1993 and the subsequent letter to the New Jersey

DEP.

(5) Conclusion

Based on the data provided by EPA pursuant to FOIA, there is no scientific basis to assume all pollutants, particularly metals, are "fast acting" toxicants and that the time period necessary to ensure avoidance of acute impacts is "short." In newly issued marine criteria, the Agency acknowledged that a 24 hour averaging period is appropriate for copper (one of the fastest acting metals) and thus should similarly modify criteria application procedures for other metals to be consistent with the available data. The continued application of a one hour or short averaging period for metals in the CTR is scientifically flawed, inconsistent with the available data, and arbitrary and capricious. EPA should re-propose the CTR with the metals acute averaging periods changed from one hour to 24 hours consistent with the research and EPA's conclusions on the marine copper criteria. To the degree that data are available regarding other constituents, the appropriate acute averaging period should be specified for these criteria. If no information is available and the criteria are based upon 96 hour no effect results, the applicable averaging period should not be less than 24 hours, which constitutes a significant margin of safety given the data available in the record and the 96 hour exposure duration used to establish the acute criteria.

Response to: CTR-020-010

EPA does not agree that a "short period of time" equals one hour. In consideration of the developments described in the comment, the one-hour averaging period that EPA had previously specified for the CMC, for example in the 1991 TSD, was not incorporated into the rule. See also responses to CTR-020-009 and CTR-009-007.

Comment: II. Use of New Scientific Information

The City acknowledges and supports EPA's update of several water quality criteria including those for mercury, cadmium and arsenic. While a number of criteria were updated to reflect current scientific information, there are a few notable exceptions.

The following briefly addresses the key updates and omissions that should be addressed in the final publication of this rule.

3. Chronic Criteria Averaging Periods

Chronic criteria averaging periods have not been updated despite a commitment by EPA to reevaluate this factor as part of the NTR settlement. EPA acknowledges that the chronic criteria are based primarily upon 28 day or longer tests. The chronic criteria are set at the continuous exposure, no effect level. There is no clear rationale why the continuous-safe exposure period was reduced to four days. This affects the selection of design flow used to apply the criteria (7/Q/10 vs. 30/Q/5) and the manner in which the chronic criteria may be applied to wet weather flows. Given EPA's conclusion that these

criteria establish long term no effect exposure levels, continued use of a four day averaging period is unduly restrictive and inconsistent with EPA's regulatory mandate to only establish criteria and implementing procedures that are "necessary" to protect aquatic life uses (40 C.F.R. section 131.2)

(a) Continued Recommendation of Four Day Averaging Is Inconsistent with the National Guidelines

The National Guidelines and EPA's 1991 TSD recognize that the federally recommended return frequency and low flow (7/Q/10) for applying chronic criteria were based on studies of ecosystems recovering from high exposures (spills) causing acute stress. The application of acute criteria to stringent low flows and use of acute bioassay tests has addressed that concern and prevents acute stress from occurring more frequently than once in ten years. Therefore, it is no longer rational to conclude that minor chronic stress needs to be regulated as rigorously as avoidance of acute stresses (which was one of the underlying purpose of the reduced averaging period and return frequency policy). To a certainty, there is no information in EPA's record showing that exceeding chronic criteria levels over a four day period once in three years has ever been associated with discernible adverse impacts. To the opposite, field studies reported in the 1991 TSD indicate that chronic criteria are very conservative and that longer term exposures which allow four day averages well above the chronic value do not result in adverse impacts on beneficial uses when applied on a once in three year exceedance frequency.

The preamble to the CTR speculates that it is necessary to utilize a four day averaging period to reflect the shorter life span of certain organisms. The only organisms with such short life spans are insects that reproduce rapidly and abundantly. The conservative three year return frequency is not related to the time period necessary for insects to recover from minor chronic stress. This value was based on fish re-population which occurs much more slowly. Accordingly, there is no apparent technical relationship between the underlying basis for the acceptable return frequency and the need to add further conservatism to the chronic averaging period. As the return frequency was based on fish populations, the acceptable averaging period should also reflect that type of organism. Clearly, a thirty day averaging period, consistent with the duration of the chronic tests, should be acceptable and ftilly protective of beneficial uses.

EPA's latest research, which was released pursuant to FOIA requests, indicates that for chronic criteria, a two to five percent exceedance frequency (versus 0.4 percent) should not result in adverse use impacts and would be acceptable. Moreover, as noted above, all research on the standards to permits process confirms that the existing procedures add an additional "level of protection" to conservatively developed criteria. Given this information, EPA should update its chronic criteria application procedures to at least reflect those found approvable - chronic criteria thirty day averaging for Maryland and Colorado

Response to: CTR-020-014

The final rule has been modified to allow the state, with EPA approval subsequent to public comment, to use alternate values for the chronic averaging period and for the exceedance frequency. EPA is certain that the four-day chronic averaging period and three-year return interval provide, at a minimum, a very high degree of protection, as explained in the 1991 Technical Support Document for Water Quality-based Toxics Control. Nevertheless, to allow consideration of current and future developments in the science underlying these parameters, the rule incorporates the flexibility of allowing the State to use of alternate values, with EPA approval, following public comment on any change.

Comment: II. Use of New Scientific Information

The City acknowledges and supports EPA's update of several water quality criteria including those for mercury, cadmium and arsenic. While a number of criteria were updated to reflect current scientific information, there are a few notable exceptions.

The following briefly addresses the key updates and omissions that should be addressed in the final publication of this rule.

4. Statistical Modeling

The proposed rule specifies the exceedance frequency (once in three years) and averaging period and list a number of return flows that may be used to ensure that the specified return frequency is not exceeded. The preamble also discusses the availability of alternate modeling approaches to more directly demonstrate that criteria compliance will occur as intended, such as statistical or probabilistic modeling. However, the CTR itself fails to specify that statistical modeling may be used to apply the criteria. This should be clarified in the final rule.

Response to: CTR-020-015

EPA favors the use of statistical and dynamic modeling and does not intend for the rule to preclude such modeling. In implementing the rule's criteria, the state may employ either steady state design flows or statistical or dynamic modeling.

Comment: p. 42174 --Chronic Averaging Period In general, we believe that EPA's proposed use of 4-day averaging periods for chronic (CCC) averaging periods is too short. The averaging period of four days recommended in EPA guidance is much shorter than the toxicity tests upon which the chronic criteria are

based, which is typically 20-30 days. This has the effect of incorporating an additional level of conservatism that has been estimated to be equivalent to a safety factor of two (Delos, 1990). Therefore, EPA should adopt longer averaging periods for chronic criteria for some constituents (for instance, for those metals for which the scientific studies show that metals do not act as fast as the criteria averaging periods would indicate). We recommend that EPA review the toxicity tests used and establish averaging periods that match the effects duration, even if they are different for different criteria. In addition, EPA should provide that any NPDES permits issued after the CTR is finalized should be subject to a reopener to allow for the insertion of a different averaging period in effluent limitations if the ongoing EPA analysis of the chronic design conditions as part of the revisions to the 1985 guidelines (referenced on p. 42174) leads to longer averaging periods.

Response to: CTR-035-020

EPA does not agree that a 4-day chronic averaging period is always too short. This averaging period is primarily based on the shortest duration in which effects appear in the Ceriodaphnia 7-day chronic test. However, EPA agrees that the 4-day chronic averaging period may not be appropriate for all pollutants, and has modified the final rule to allow use of alternate averaging periods. See also responses to CTR-020-014 and CTR-060-012.

Comment: p. 42182 -- Averaging Period for Acute Criteria (CMCs) EPA should identify a specific duration for acute (CMC) criteria beyond the current description of "short term" and provide an explanation of this choice. We believe that in many cases (e.g. metals) recent data suggest that the constituents are not as fast-acting as once-believed and that 24-hours is a more appropriate acute averaging period than the 1-hour averaging period previously used. Therefore, we recommend that EPA adjust the acute averaging periods to reflect such information.

Comment: p. 42184 -- Frequency of exceedence We believe that adoption in the regulation of the proposed exceedence frequency, once in three years for acute and chronic criteria, should be deferred until EPA completes its review of this issue. As EPA points out, there are numerous scientific issues being reexamined. For streams in and areas, for instance, EPA should consider that annual flooding and scouring may occur, as well as droughts (leading to no flow during the dry season), and the natural communities adapted to these environments may be capable of recovering from such major disturbances in a year or less. Since EPA does not include any evidence in this rulemaking to support the application of this allowable frequency in California, we recommend that EPA not formalize this policy in the CTR.

Comment: 7. EPA is requiring, by rule, that the averaging period for the CMC be 1 hour. However, EPA is also working towards new methods to calculate water quality criteria which acknowledge that the CMC averaging period should probably be closer to 24 hours. This is not being acknowledged in the rule even though the Agency has released this information at various meetings. The one hour averaging period for the CMC is overly stringent and should not be adopted by rule. The averaging period for the CMC being proposed is not technically defensible and arbitrary, therefore it should be removed from the rule until EPA finalizes its study of the issue.

Comment: 9. EPA is requiring that criteria not be exceeded more than once every three years, on average, EPA, however, is ignoring the fact that this exceedance rate is based on catastrophic events and that minor exceedances require much less time for biological communities to reach their pre-exceedance conditions. This rule is adopting a requirement which often-times will be overly protective with little or no environmental benefit. The basis of the three year exceedance requirement has been acknowledged by EPA's Aquatic Life Criteria Work Group as conservative and unnecessary when exceedances are minor. The rule must be modified to accommodate minor exceedances if justified scientifically. EPA must technically justify the exceedance frequency that it is requiring by rule to insure that resources will not be expended needlessly by permittees.

Comment: V. Recommendation: Delete all provisions in the Rule that preempt the States flexibility in permitting. The Rule provides specific direction on the adoption of averaging periods, low flow values, effluent limitations for criteria not being adopted as a part of the Rule, and that the aquatic life criteria be applied to all waters irrespective of designated use, etc..

* The Preamble and the Rule's economic analysis make a point that the State has considerable flexibility in establishing permit limitations. In making, that point, EPA implies that the State may implement the criteria in a manner that would have little or no adverse economic impact on dischargers.

* However, the Rule contains a number of implementation provisions that are not required under Section 303(c)(2)(B), but serve to preempt the State's flexibility. These provisions include, but are not necessarily limited to the adoption of averaging periods and low flow values, directives regarding the establishment of effluent limitations for criteria that are not being adopted as a part of the Rule, and application of the aquatic life criteria to all waters irrespective of the designated use.

* Not only does EPA not have a duty to adopt these provisions, but also the provisions are more restrictive than those required by the CWA or EPA regulations, They clearly restrict the State's flexibility. In fact, other states have adopted, and EPA has approved, implementation provisions (e.g., averaging periods and low flow values) which are less restrictive.

* For these reasons, EPA should remove all such implementation provisions from the Rule.

Response to: CTR-040-018a

EPA does not agree that the averaging periods and low flow values apply to the criteria other than those adopted by this rule. They do not to apply to other State criteria. However, EPA agrees that other averaging periods and exceedence frequencies may be appropriate for the criteria concentrations included in this rule, and has provided for such in the final rule. See response to CTR-020-014.

Comment: PROVISIONS SDG&E DOES NOT SUPPORT

As described in the following comments SDG&E does not support the following provisions:

Over-conservativeness of chronic aquatic criteria due to averaging period

The preamble to the rule (see 62 Fed. Reg. at 42,174, Col. 2) states that most of the toxicity tests used to calculate the chronic criteria were conducted over a 28 day period. However, even though the preamble (see 62 Fed. Reg. at 42,174, Col. 1) acknowledges that "...aquatic organisms can generally tolerate higher concentrations of pollutants over shorter periods of time", EPA proposes in this rule to set the chronic averaging period to 4 days. Consequently, concentrations from longer term (i.e., 28-days) tests, which would generally result in lower concentrations which are considered toxic, are being implemented as 4-day average criteria, even though criteria developed from toxicity tests conducted over a 4-day period would generally result in criteria which are higher. This approach results in criteria that are more restrictive than necessary to protect the state's beneficial uses. The criteria should either: 1) be restated as 28-day average criteria; or 2) be recalculated as criteria representative of 4-day average tests.

Response to: CTR-060-012

The averaging period is shorter than the toxicity tests on which the criterion is based because (a) exposure concentrations in the toxicity tests are nearly constant, (b) exposure concentrations in the field, over the duration of the averaging period, can be rather variable, and (c) variable concentrations yield greater toxicity than a constant concentration equal to the mean of the variable concentrations. Consequently, if the laboratory toxicity tests had employed variable concentrations, the reported effect concentrations (as the mean over the test duration) would be lower than if the test employed constant concentrations. To account for this phenomenon, the criteria averaging period is shorter than the tests on which the criterion is based. Note, however, that EPA is employing flexibility into the rule in order to provide for advances in the state of the science in setting averaging periods. See the response to CTR-020-014.

Comment: 2. PARTIAL PROTECTION BY THE PROPOSED AQUATIC LIFE CRITERIA (FRESHWATER OR SALTWATER)

On page 42168, the proposed rule includes the following language: "EPA's guidelines are designed to derive criteria that protect aquatic communities by protecting most of the species and their uses most of the time." The CTR goes on to state that this approach results in only a "small possibility" of substantial overprotection or underprotection. Obviously, it is underprotection that is of concern to the DFG. The DFG has very serious concerns that criteria are being proposed that protect "most" of the species "most" of the time. We are aware of the protocols that require a minimum of eight specified families be used to develop criteria and that it may be difficult to determine criteria that are one hundred percent protective; however, this does not preclude the real possibility that certain designated uses and aquatic organisms will not be maintained, and or protected, as a result of the proposed criteria. The DFG is also concerned that criteria and protocols developed for specific constituents do not take into account the additive or synergistic effects that contaminant combination may have on aquatic organisms. Another factor that needs to be considered is bioaccumulation, as well as the effect this may have on organisms at higher trophic levels.

As trustee of all the fish and wildlife resources in the State, it is our agency's responsibility to ensure appropriate protection of all fish and wildlife resources, not just "most", and this includes adequate water quality standards. Due to our concerns and the very real possibility of underprotection to aquatic organisms and designated uses, the DFG believes that it may be appropriate to derive the criteria as proposed, and subsequently develop some additional safety factors for inclusion. It is our understanding that this approach was used in the formulation of water quality objectives for protection of aquatic organisms in the California Ocean Plan. In the short term , the safety factor could possibly be realized by the development of a comprehensivebiological monitoring program to determine whether the proposed criteria are indeed fully protective.

Response to: CTR-026-002b

EPA agrees that the numeric values of those criteria that are not expressed as formulas do not account for additive or synergistic effects. However, EPA does not agree that this would mean that the criteria are not sufficient to protect the designated use. EPA has examined the potential for additivity. Data available to EPA suggest that in real world situations, additivity is usually not a significant issue, because most of the toxic stress is usually attributable to a single pollutant, even in systems receiving complex mixtures of discharges from large metropolitan areas.

To illustrate this, consider some 50 samples that EPA collected throughout New York Harbor, an large area extending from the Hudson River to New York Bight, and receiving a large volume of wastewater and runoff from a highly diverse set of discharges, representing a wide range of municipal, industrial, and agricultural activities. Six metals, Ag, Cd, Cu, Ni, Pb, and Zn were measured using clean techniques. For each sample, the toxic equivalents of each metal were calculated as the metal concentration divided by the its criterion. Assuming perfect additivity of toxicity, the toxic equivalents in each sample were added together to obtain the total toxic equivalents. One metal consistently dominated the toxic equivalents in each sample. On average, the combined toxic equivalents of all six metals was only 10 percent greater than the toxic equivalent of the dominant single metal. Among the 50 samples, the maximum ratio of the combined toxic equivalents to the dominant single toxic equivalent was only 19 percent greater than the single dominant toxic equivalent. Consequently, even assuming perfect additivity, the combined contribution of the other metals was minor compared to the contribution of the dominant toxicant.

The comment provides no data indicating that additivity or synergism are in reality significant problems. Nevertheless, the rule's provisions are capable of handling such problems if they exist. First, criteria expressed as formulas with hardness account for the effects of hardness (or lack thereof) and of parameters covarying with hardness. Second, the rule's provision for the water-effect ratio represents the current best technique for adjusting for unknown additive, synergistic, or antagonistic effects, if they exist. Consequently, EPA believes that its criteria are fully protective. Also see response to CTR-026-002a.

Nevertheless, as the commenter represents the State of California, EPA notes that to allay its concerns, if any remain, the State may adopt its own standards more stringent than those promulgated here by EPA.

Comment: The Center for Marine Conservation (CMC) is a nationwide, nonprofit advocacy group dedicated to the conservation and enhancement of coastal and ocean life and resources. CMC submits these comments on behalf of its 16,000 members in California and over 120,000 members nationwide.

CMC applauds EPA's efforts to bring California into compliance with the Clean Water Act 303(c)(2)(B). Implementing numeric criteria that will protect the beneficial uses of California's waters is of great importance to the health of coastal and marine ecosystems, and so to CMC and its members. The

reliance in many areas of the state on narrative criteria threatens the health of most of the state's waters, thereby impacting both human health and the health of the state's economy that relies on clean water.

While CMC strongly supports the swift adoption of an Enclosed Bays and Estuaries Plan and an Inland Surface Waters Plan that contain numeric criteria for toxic pollutants, CMC also is concerned that many of the specific criteria contained in the proposed rule are weaker than those contained in published guidance. CMC also believes that the proposed rule can better protect certain subpopulations from harm caused by consumption of contaminated fish and shellfish. Finally, CMC is concerned that the economic analysis of the proposed rule over-emphasizes costs and under-reports the many benefits of improving water. quality throughout the state. These three points are reviewed below.

In Light of Significant Threats to Water Quality, the Proposed Rule Should Contain the Most Stringent Criteria That Are Scientifically Defensible

Many of the criteria in the proposed rule are weaker than criteria in current published guidance. The proposed rule summarily states that the difference between the proposed, weaker criteria and the published guidance documents is "insignificant"(*4); however, in light of the current contamination problems in California's waters today, any move backwards, particularly when spread out over the state, must be viewed as significant.

Any weakening of the criteria should be subject to close scrutiny and the most rigorous analysis, which the proposed rule itself does not do. Among other things, the criteria in the proposed rule may be underprotective because additive and synergistic effects were not considered; and because the effects on wildlife, which can be particularly significant for bioaccumulative chemicals, were ignored.(*5) In addition, the proposed rule contains dissolved rather than total recoverable metals criteria, despite the fact that EPA acknowledges that total recoverable metals criteria are "scientifically defensible" and that they are more protective than dissolved metals criteria because they consider "sediment, food-chain effects and other fate-related issues," rather than simply water column impacts.(*6)

Clean Water Act section 303(c)(2)(B) mandates the development of numeric criteria that will "support such designated uses [that are adopted by the State]." The statistics available on the health of the state's waters indicates that their use already is significantly threatened or impaired by toxics. The strongest criteria supportable by science are necessary to reverse this trend and begin to restore the state's waters.

(*4) 62 Fed. Reg. 42159, 42168 (Aug. 5, 1997).

Subject Matter Code: C-28 Detection Limits

Comment ID: CTR-005-009
Comment Author: Novato Sanitary District
Document Type: Sewer Authority
State of Origin: CA
Represented Org:
Document Date: 09/23/97
Subject Matter Code: C-28 Detection Limits
References:
Attachments? Y
CROSS REFERENCES

Comment: 8. EPA should not adopt criteria for any pollutant where the method detection limit exceeds the objective and there is insufficient detectable, reliable data to determine if the pollutant could reasonably be expected to interfere with designated uses. The proposed rule includes criteria for a number of constituents where there is insufficient data to determine whether the discharge of such pollutants could reasonably be expected to interfere with the designated uses. EPA has chosen to promulgate criteria for these constituents even though section 303 (c)(2)(B) of the Clean Water Act requires States to adopt numeric criteria only for constituents "...the discharge or presence of which in the affected waters could reasonably be expected to interfere with those designated uses adopted by the State, as necessary to support such designated uses."

Clearly, this "play-it-safe" approach goes beyond the requirements of the Clean Water Act and is therefore unnecessary. By taking this approach, however, EPA is unable to fulfill its duty (under Presidential Order 12866, the Unfunded Mandates Reform Act), and the Regulatory Flexibility Act) to assess the costs, benefits, and impacts of the rule on local government and small entities. While this may be the "safe" approach for EPA, it places dischargers throughout the State at risk. As analytical detection limits improve down the road, dischargers may find they are unable to achieve the criteria without costly end-of-pipe controls. But, by then, it will be too late for EPA to evaluate the costs and benefits of the criteria and alternative criteria. For these reasons, EPA should not adopt criteria for those constituents. If EPA does not do this, it should evaluate the costs and benefits of the criteria, as well as alternative criteria, using worst case assumptions (i.e., assume that discharge levels and ambient levels are at the detection limits).

Response to: CTR-005-009

See response to CTR 034-010b and CTR-060-010

EPA disagrees that the Agency should exclude those criteria that are below the method detection limits from this rule. EPA's water quality standards regulation at 40 CFR 131.11 requires that criteria be adopted by the States at concentrations necessary to protect the designated use. Given this requirement, consideration of analytical detectability is not an appropriate factor to consider when calculating water quality criteria to protect designated uses since they are not related to actual environmental impacts. In consideration of both statutory (CWA Section 303(c)) and regulatory (the Water Quality Standards Regulation at 40 CFR 131.11) requirements that water quality standards, which includes water quality criteria, must be protective of the designated uses of waterbodies, EPA has determined that such consideration of analytical detection limit is not an appropriate factor to consider in developing the water quality criteria component of water quality standards since the detection limits are not related to actual

environmental impacts. This has been EPA's longstanding position since the inception of the water quality standards program in 1965 (see also EPA's discussion on this issue in the National Toxics Rule at 57 FR 60876, 57 FR 60870).

EPA's methodology for deriving aquatic life criteria are primarily based on laboratory bioassays with sensitive aquatic organisms. The results from these tests are analyzed by mathematical procedures outlined in EPA's aquatic life criteria methodology guidelines. EPA's human health criteria are based on protocols generally using toxicity studies performed on laboratory animals such as rats and mice. Thus, EPA's aquatic life and human health criteria are based solely on health effects without regard to chemical analytical methods or techniques. Deleterious effects can occur to both humans and aquatic organisms at concentrations that are below the analytical detection levels.

As previously noted, EPA's Water Quality Standards Regulation requires that criteria be adopted at concentrations that are necessary to protect designated uses. The criteria promulgated today meet that requirement while EPA's policy with respect to regulatory compliance, which is discussed below, takes analytical sensitivity and precision into consideration.

In the preamble of the proposed rule, EPA referenced the Agency's 1990 guidance (Strategy for the Regulation of Discharges of PHDDs and PHDFs from Pulp and Paper Mills to Waters of the united States, memorandum from the Assistant Administrator for Water to the Regional Water Management Division Directors and NPDES State Directors) on how water quality based effluent limits for constituents with water quality criteria that are below the sensitivity of official analytical methods can be established. However, EPA acknowledges that in more recent guidance than that cited in the preamble to the proposed rule the Agency recommends use of the Minimum Level (ML) rather than the Method Detection Limit (MDL) for reporting sample results to assess compliance with a water quality based effluent limitation (WQBEL). See Technical Support Document for Water Quality-based Toxics Control, U.S. EPA Office of Water, EPA/505/2-90-001 (March 1991) at page111. The ML, also called the quantification level, is the level at which the entire analytical system gives recognizable mass spectra and acceptable calibration points, i.e., the point at which the method can reliably quantify the amount of pollutant in the sample. More recently, in the Final Great Lakes Water Quality Guidance (see 50 FR 15424, March 23, 1995), EPA included a provision which allowed permitting authorities to utilize the minimum level (ML) for the method specified in the permit to monitor the amount of pollutant in an effluent down to the quantification level. States can use their own procedures to average and otherwise account for monitoring data, e.g., quantifying results below the ML. These results are then used to assess compliance with the WQBEL. See 40 CFR Part 132, Appendix F, Procedure 8.B.

Further, EPA notes that the purpose of today's rule is to establish ambient water quality criteria for priority toxic pollutants in California. Implementation of the criteria, including compliance with water quality based effluent limitations in permits are outside the scope of today's rule. However, the State of California, in its draft implementation procedures for the criteria included in today's rule (entitled "Draft Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California," September 11, 1997) has proposed provisions to address this issue. The State has elected the utilize the minimum levels in determining compliance with WQBELs.

EPA disagrees that there is insufficient data to support the inclusion of priority toxic pollutants in today's rule. In EPA's December 12, 1988 guidance to States on complying with CWA Section 303(c)(2)(B) (Notice of Availability published at 54 FR 346, January 5, 1989), EPA noted that at a minimum, States should adopt criteria for a pollutant if that pollutant was currently present or could potentially be present in State waters the future. EPA's guidance highlighted the Agency's position that any information indicating that a pollutant was discharged or present in a waterbody is justification that a pollutant could

be reasonably expected to interfere with the designated uses, and therefore would need to be included in a State's water quality standards regulation. EPA has determined that adequate information exists in the rulemaking record to show that the priority toxic pollutants in today's rule can be reasonably expected to interfere with the designated uses of waters in California. Moreover, since these criteria are ambient criteria, they do not in and of themselves require control of a discharge. Only where a discharge has a reasonable potential to exceed the water quality criterion would an effluent limit for that pollutant be placed in an NPDES permit. See Response to CTR-003-010b and CTR-036-005.

In promulgating today's rulemaking, EPA is complying with the same Section 303(c)(2)(B) guidance issued to the States. Thus, the lack of widespread monitoring data or data that does not meet analytical detection limitations is not a sufficient basis for excluding numeric criteria for priority toxics from today's rule. As EPA previously stated, consideration of analytical detection limits is not appropriate in establishing criteria. EPA also notes that the commenters did not submit any analyses or information to support the assertion that the coverage of priority toxic pollutants included in today's rule is based on insufficient or reliable data. In addition, EPA further notes that the priority toxic pollutants included in today's rule are the same priority toxic pollutants that the State of California had previously adopted in the Inland Surface Waters Plan and Enclosed Bays and Estuaries Plan to comply with CWA Section 303(c)(2)(B). Thus, the inclusion of the numeric criteria for priority toxic pollutants in today's rule is justified.

EPA disagree with the commenter's assertion that the Agency, by including criteria that are below detection limits, cannot comply with statutory requirements of UMRA, RFA and Executive Order 12866. (See Sections G, I, and J of the preamble for EPA's analysis of this rule's compliance with thesestatutes and the executive order, respectively). EPA notes that the criteria included in today's rule establish ambient water quality criteria in California to comply with CWA Section 303(c)(2)(B) to protect the designated uses of the State's waterbodies. As EPA noted in the responses to comments raised on establishing criteria below detection limits, EPA's policy with respect to regulatory compliance for the criteria takes analytical sensitivity into account.

Comment: It is not possible to determine what risk levels would be needed to preclude end-of-pipe treatment for other human health criteria because in most cases the method detection limits exceed the criteria (see Table 2). The City recommends that EPA delay adoption of criteria for these constituents until sufficient detected data is available to assess attainability and perform the economic analysis required by Presidential Order 12866 and the Unfunded Mandates Reform Act. We understand that Section 303 (c)(2)(B) of the Clean Water Act does not require EPA to adopt criteria for constituents that could reasonably be expected to interfere with designated uses. In the absence of data on certain constituents, EPA could easily defend a position not to adopt criteria for those constituents.

Comment: In addition, we would like to emphasize the following concerns which greatly impact the Los Angeles County Stormwater Program:

4. The proposed rule adopts criteria for pollutants where the method detection limit exceeds the criteria, and there is insufficient detectable, reliable data to determine if the pollutant could reasonably be expected to interfere with designated uses. The proposed rule contains many criteria in which the criteria are less than current acceptable laboratory detection limit. In other words, if a stormwater sample indicated a non-detect value in its stormwater discharge for certain pollutants, it cannot be determined if the proposed criteria were exceeded or if exceeded, what would be the reductions and costs necessary to achieve compliance.

If the proposed rule is adopted with these criteria, the discharger may find that they are in violation of the criteria, as laboratory techniques are improved in the future. By that time, the discharger has no recourse to require the USEPA to evaluate the cost and benefit of the criteria or alternative criteria. Furthermore, in that event, the discharger may face enforcement action and costly end-of-pipe controls.

We recommend that the USEPA not adopt criteria for any pollutant where the method detection limit exceeds the criteria and there is insufficient detectable, reliable data to determine if the pollutant could reasonably be expected to interfere with designated uses.

Comment: IV. Compliance / Detection Level

The rule specifies that limits may be set below the detection level for a pollutant but that compliance will be determined upon detection level for the pollutant. Thus, a non-detect will be considered in compliance with a permit limitation. The City concurs with the position that a non-detect reading should be considered in compliance with a limitation that is set below the reliable detection level.

Comment: It is with a sense of reluctance that Sunnyvale joins in CASA/Tri-TAC's adverse comments on the CTR and the EA, and Sunnyvale does so in a spirit of constructive criticism and with an expectation that the Agency will make the necessary adjustments in its approach towards the CTR before the final rule is promulgated. In additon, in the same spirit and with the same expectation, Sunnyvale would like to make the following points on its own behalf:

2. Obligation to Assess Alternative Cancer Risk Levels for Human Health-Based Criteria. Sunnyvale is gravely concerned that EPA has used the wrong approach in proposing to establish human health criteria for organic pollutants, particularly those pollutants for which the proposed criteria are below the method level of detection ("MDL"). Sunnyvale recommends that EPA should thoroughly assess all of the potential impacts, including costs and benefits, of the 10E-4 and 10E-5 risk levels before proposing the human health-based criteria. As pointed out in the EOA Letter, there is a significant potential for advancing technology to lower the MDL for many pollutants to the point where laboratory equipment is able to measure some or all of the organic compounds for which EPA is proposing to establish criteria at the new level. It is intuitively obvious that the costs of attaining criteria set at the 10E-6 level will be significantly greater than attainment of a 10E-5 or 10E-4 level, particularly where, as pointed out in the EOA Letter, the only available method of treatment is granular activated carbon. Sunnyvale is concerned that the EA does not adequately address the potential for these costs, and, consequently, does not take these potential costs into account in determining whether to exercise its flexibility in choosing whether to

use a 10-4 , 10-5 or 10-6 cancer risk level as the basis for its CTR promulgation.

EPA is required by Executive Order 12866, the Regulatory Flexibility Act and the Unfunded Mandates Reform Act to identify and analyze alternatives to a proposed rule. We cannot understand, therefore, why EPA has done such a cursory analysis in the preamble to the CTR and the EA of the alternatives to the use of the most stringent (10E-6) risk level for establishing criteria for human health effects of pollutants, particularly organic pollutants. EPA cannot base its selection of the 10E-6 level based upon previous regulatory pronouncements by the State of California. Any new determination by the State will be subject to the analytical requirements of Section 13241 of the Porter-Cologne Act and by review by the Office of Administrative Law. Thus, it is not a foregone conclusion that the State will ultimately select the 10E-6 level. EPA has its own legal requirements to fulfill. Accordingly, we ask that EPA not promulgate the final human health criteria for the pollutants of concern unless and until it has adequately analyzed the costs and other implications of the various alternatives to the 10E-6 level.

In conclusion, we are entirely supportive of many of EPA's innovative approaches towards development of the CTR, particularly as regards the toxic metals. However, we believe that EPA has needlessly failed to comply with many of is legal obligations, particularly as regards the development of human health-based criteria on cancer risk levels of organic pollutants. We urge the Agency to reconsider its position in the matters covered by this letter (as amplified by the EOA Letter) and the CASA/Tri-TAC letter. Sunnyvale pledges its continued participation in place-based watershed management planning in the South Bay, its cooperation with the Agency in making a success of the WPI, and to an ongoing effort by the Agency and others to reach water quality goals in the South Bay. We thank you for the opportunity to comment on the proposed CTR.

Comment: 4. The proposed rule adopts criteria for pollutants where the method detection limit exceeds the criteria, and there is insufficient detectable, reliable data to determine if the pollutant could reasonably be expected to interfere with designated uses. The proposed rule contains criteria for many pollutants in which the criteria are less than acceptable laboratory detection limits (e.g. N-Nitrosodi-n-propylamine has an analytical detection limit of 0.5 ppb and the proposed human health criteria of 0.005 ppb). Thus, if a stormwater agency notes a non-detect value in its stormwater discharge for N-Nitrosodi-n-propylamine, it cannot determine if the proposed criterion was exceeded.

Section 303(c)(2)(B) notes that States must adopt numeric criteria for constituents when "...the discharge

or presence of which in the affected waters could reasonably be expected to interfere with those designated uses adopted by the State, as necessary to support such designated uses." However, the proposed rule includes criteria for a number of constituents where there are insufficient detected data to determine whether the discharge of such pollutant could reasonably be expected to interfere with the designated uses. Furthermore, one cannot determine the reduction and costs necessary to achieve compliance.

If the proposed rule is adopted with these criteria, the discharger may find that they are in violation of the criteria as laboratory techniques are improved in the future. By that time the discharger has no recourse to require USEPA to evaluate the cost and benefit of the criteria or alternative criteria. Moreover, in that event, the discharger may face enforcement action and costly end-of-pipe controls.

Recommendation: USEPA should not adopt criteria for any pollutant where the method detection limit exceeds the criteria and there is insufficient detectable, reliable data to determine if the pollutant could reasonably be expected to interfere with designated uses.

Comment: E. EPA Needs to Clarify its Quantification Discussion and Delete References to the 1990 Dioxin Strategy

EPA states that "the use of analytical detection limits are [sic] appropriate for determining compliance" with the NPDES permit limits. 62 Fed. Reg, at 42,183, col. 3. The use of the term "detection" in that statement, rather than "quantification," may create concision and UWAG urges EPA to use the latter term. Over the past few years, EPA has consistently stated that, for determining compliance with WQBELs calculated at a level below the quantification level, the quantification level will serve as the compliance level. Use of the detection level in that context is entirely inappropriate. Measurements above the detection level, but below the quantification level, are sufficiently reliable to establish the mere presence - but not the amount - of a pollutant in a wastewater sample. Such measurements, therefore, cannot serve as the basis of compliance. Not only has EPA adopted that conclusion,(*3) but the U.S. Court of Appeals for the District of Columbia Circuit just ruled on that very issue by holding:

A standard with which compliance cannot be assessed - and it is agreed that compliance with an effluent limitation set below the level of quantification simply cannot be assessed - is no standard at all for purposes of due process.

American Iron and Steel Institute v. U.S. EPA, 115 F.3d 979, 994 (1997) (AISI).

In addition, EPA's references to its 1990 dioxin strategy document, "Strategy for the Regulation of Discharges of PHDDs and PHDFs from Pulp and Paper Mills to Waters of the U.S." (Dioxin Strategy), are troubling. As described below, the Dioxin Strategy contains two significant flaws and thus citation to it may cause confusion in the regulated community. First, the Dioxin Strategy consistently references detection limits, rather than quantification levels. The above discussion explains UWAG's concerns with that approach.

The second major flaw of the Dioxin Strategy is its approval of the application of WQBELs to internal plant waste streams. The Dioxin Strategy states:

Where final, end-of-pipe effluent limitations are determined to be impractical or infeasible to measure, permitting authorities can, in accordance with the requirements of 40 CFR 122.45(h), establish limitations for internal plant waste streams from bleached plant processes.

Dioxin Strategy, p. 20.

As recently clarified by the AISI Court, the Clean Water Act provides no authority for the establishment of anything other than end-of-pipe WQBELS. In AISI, the petitioners challenged EPA's Great Lakes Water Quality Rule, including its requirement that each permit establish a pollutant minimization program (with effluent limitations for internal plant waste streams containing the pollutant) for each pollutant with an end-of-pipe limitation below the level of quantification. Although the Court agreed with EPA that the Clean Water Act allows monitoring of discharges from internal sources, it concluded that EPA could not impose a "point-source WQBEL upon a facility's internal waste streams." 115 F.3d at 996. Thus, the Dioxin Strategy's suggestion that it is appropriate to impose internal waste stream WQBELs is contradicted by the AISI Court.

For the reasons set forth in this subsection, UWAG requests that EPA remove all references to the Dioxin Strategy from the California Water Quality Standards rulemaking. UWAG encourages EPA to reference instead its "Questions and Answers on the Great Lakes Water Quality Guidance-Set 2", dated March 20, 1996 (GLI Q&A-2). In the GLI Q&A-2, the Agency explicitly allowed states to specify - directly within NPDES permits -- that analytical results below the level of quantification may be deemed to be in compliance with the established daily maximum WQBEL, and that zero may be used in lieu of measurements below the quantification level for averaging purposes in evaluating compliance with monthly average WQBELS. GLI Q&A-2, p. 28.

(*3) EPA's official position is that "[q]uantification of measurements below the [quantification level]. . . are [sic] not acceptable. . . . " 61 Fed. Reg. 3412 (col. 1) (Jan. 31, 1996).

Comment: Experiments to determine whether a chemical is carcinogenic are performed (on animals) with high concentrations to produce statistically significant results within the time frame of the experiment. The numbers are then extrapolated to determine an estimated "safe" concentration for human populations. All of the factors in the extrapolation process use conservative assumptions (one in a million risk, bioaccumulation potential, carcinogenic potential, etc.) which builds in and multiplies safety factors. For 39 of the constituents in the CTR, the extrapolated criteria levels are below current levels of detection.

The EPA recognizes this as the proposed rule states: "EPA is aware that the criteria proposed today for some of the priority toxic pollutants are at concentrations less than EPA's current analytical detection limits. Analytical detection limits have never been an acceptable basis for setting water quality criteria since they are not related to actual environmental impacts. The environmental impacts of a pollutant are based on a scientific determination, not a measuring technique that is subject to change. Setting the criteria at levels that reflect adequate protection tends to be a forcing mechanism to improve analytical detection methods. See 1985 Guidelines p. 21. As the methods improve, limits closer to the actual criteria necessary to protect aquatic life and human health become measurable. The Agency does not believe it is appropriate to propose or promulgate criteria that are not sufficiently protective." The rule goes on to add, "the use of detection limits are appropriate for determining compliance with National Pollutant Discharge Elimination System (NPDES) permit limits."

Since the criteria are established on high dosage results that cannot be substantiated at low levels due to statistical significance and inability to see beyond detection limits, the values are predictions. Questions that come to mind are, what would this procedure determine for fat-soluble vitamins A, D and K? In high doses, these vitamins are harmful, though in low dosages, valuable. For constituents below detection, these determinations cannot be scientifically verified by analyses, only mathematically generated based on worst case assumptions. Although caution is warranted when establishing criteria, future unforeseen levels and effects cannot be predicted.

While the EPA believes that compliance determinations are based on detection limits, to assume no cost in the economic analysis for values that are below detection is not a valid assumption. As noted above, the detection limits will be forced to lower levels, and therefore become moving compliance targets without additional economic review should detection's begin to occur.

In summary, the detection levels should serve as the criteria with a "<" designator. The criteria for the affected constituents should be reviewed on a regular basis to reflect current approved analytical techniques, with lower levels promulgated after appropriate economic evaluations.

Comment: * SCAP recommends that EPA defer adoption of criteria contained in the draft CTR which are typically below detection limits. While we understand EPA's rationale for setting criteria that may not be detectable based on EPA's determination of the criteria needed to adequately protect aquatic life and human health, we believe that EPA has not fulfilled its duties under the Clean Water Act, Unfunded Mandates Act, and E.O. 12866. In accordance with federal water quality standards regulations, EPA is required to review water quality data and information on discharges to specific water bodies where toxic pollutants may be adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern and must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use (see 40 CFR section 131.11). Thus, if the pollutant has not been detected, there is no basis for determining whether the chemical is adversely affecting water quality or the attainment of designated uses.

Further, EPA cannot make an accurate determination of the costs and benefits of promulgating CTR criteria for those criteria that are below detection levels. It is quite likely that detection limits for some substances will improve in the near future, and dischargers previously projecting full attainment will no longer be able to comply. For instance, a SCAP member agency was issued an NPDES permit in the early 1990s containing effluent limits for a number of toxic pollutants. In this agency's case, lindane was not being detected at the time of permit issuance (and the detection level was higher than the permit limit). Yet, in the following years, the detection level dropped and this agency began to experience exceedences of the permit limit. Lindane cannot be readily controlled at the source by normal industrial waste source control methods because it is in widespread use by consumers. Therefore, the only reliable option for the POTW to come into compliance may be to add end-of-pipe treatment, a very expensive proposition. This scenario is likely to happen again with many of the criteria being proposed in the CTR. The potential compliance costs could be high, yet the Economic Analysis for the draft CTR could not estimate such costs. For all of the above reasons, EPA should defer adoption of these criteria until they can be detected and EPA can more fully determine the potential economic impacts of promulgation of the CTR. Instead, we recommend that a watershed approach be used to address these pollutants (see below).

Comment: EPA should defer adoption of criteria for any pollutant where the method detection limit exceeds the objective and there are insufficient reliable data to determine if the pollutant could reasonably be expected to interfere with attainment of designated uses. We believe that because of the inability to detect these substances and the lack of monitoring information indicating water quality use impairment, that EPA has not fulfilled its obligations under the Clean Water Act to conduct a water body-specific analysis of the need to promulgate criteria, nor has EPA fulfilled its obligations under the Unfunded Mandates Act and Executive Order 12866 to analyze the costs and benefits of proposed criteria that cannot be detected or for which insufficient monitoring data are available. We believe that the costs to comply with criteria for organic pollutants that are currently below detection levels could amount to as much as $630 million per year for the POTW sector.

Comment: 1. Comments on Proposed Rule A. General Comments p. 42166-67 --Legal Basis

EPA argues that:

EPA does not believe that it is necessary to support the criteria proposed today on a pollutant-specific, water body-by-water-body basis. For EPA to undertake an effort to conduct research and studies of each stream segment or water body across the State of California to demonstrate that for each toxic pollutant for which EPA has issued CWA section 304(a) criteria guidance there is a 'discharge or presence' of that pollutant which could reasonably 'be expected to interfere with' the designated use would impose an enormous administrative burden and would be contrary to the statutory directive for swift action manifested by the 1987 addition of section 303(c)(2)(B) to the CWA.

Contrary to EPA's argument, we believe that the requirement in Section 303 of the CWA that States adopt water quality standards where there is a discharge or presence of toxic pollutants in the affected waters which could reasonably expected to interfere with designated uses, applies to EPA. EPA's claim that such a review would impose an "enormous administrative burden" is not compelling, since States, in their adoption of water quality standards, must perform this pollutant specific review of each stream

segment under the express terms of Section 303(c)(2)(B). EPA's own regulations require that, in promulgating water quality standards for a State, EPA is subject to "the same policies, procedures, analyses, and public participation requirements established for States in these regulations" (40 CFR section 131.22). The regulations require States to "review water quality data and information on discharges to specific water bodies where toxic pollutants may be adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern and must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use"(40 CFR section 131.11)(emphasis added). Thus, the regulations regarding the adoption of water quality standards do not suggest that States adopt uniform water quality standards for every water body merely because there may be a large amount of work required to determine the appropriate water quality standards for each water body. We especially believe this issue to be pertinent to pollutants for which the proposed CTR criteria are below detection levels. We therefore recommend that EPA defer the adoption of criteria for constituents which are below detection limits until such time as data are available demonstrating that particular toxic pollutants are being discharged to specific water bodies at levels to warrant concern. The pollutants in this category include the following: aldrin, alpha-BHC, beta-BHC, chlordane, 4,4'-DDD, 4,4'-DDT, 4,4'-DDE, dieldrin, 2,3,7,8-TCDD (dioxin), endosulfan I, endosulfan II, endrin, endrin aldehyde, heptachlor, heptachlor epoxide, toxaphene, PCB-1016, PCB-1221, PCB-1232, PCB-1242, PCB-1248, PCB-1254, PCB-1260, hexachlorobenzene, n-nitrosodi-n-propylamine, pentachlorophenol, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoroanthene, benzo(k)fluoroanthene, chaysene, dibenzo(a,h)anthracene, and indeno(1,2,3-cd)pyrene. EPA, upon determining that promulgation of a 303(c)(2)(B) criterion is necessary, should promulgate the criterion on a water body-specific basis. Also, EPA would need to conduct an economic impact analysis at that time. Finally, as with the CTR, EPA must pursue adoption of these criteria through a rulemaking process, allowing opportunities for public review and comment in accordance with the Clean Water Act and Administrative Procedures Act.

Comment: Appropriateness of the Technical Criteria in the CTR

The proposed rule includes a number of technical elements that are of concern.

We are concerned that the proposed rule contains criteria that have concentrations lower than current acceptable laboratory detection limits. We recommend that no criteria be adopted which are below the

detection limits and that no criteria be adopted when insufficient reliable data exists to determine that the pollutant could reasonably be expected to interfere with designated uses.

Comment: 6. EPA states that analytical detection limits are appropriate for determining compliance with NPDES permit limits, which directly conflicts with the Agency's most recent guidance which recommends that MLs be used to determine compliance. This statement completely ignores the issues of analytical variability and uncertainty in data at the MDL and between the MDL and the ML, even though all parties are in consensus that values of high uncertainty should not be used to make compliance decisions. This may be a typographical error, but it needs to be addressed. Furthermore, EPA must consider the analytical limitations of currently approved procedures when adopting criteria, Compliance with criteria can not be determined readily if sufficiently-sensitive approved procedures are not available.

Comment: 8. EPA should not adopt criteria for any pollutant where the method detection limit exceeds the objective and there is insufficient detectable, reliable data to determine if the pollutant could

reasonably be expected to interfere with designated uses. The proposed rule includes criteria for a number of constituents where there is insufficient data to determine whether the discharge of such pollutants could reasonably be expected to interfere with the designated uses. EPA has chosen to promulgate criteria for these constituents even though section 303 (c)(2)(B) of the Clean Water Act requires States to adopt numeric criteria only for constituents "...the discharge or presence of which in the affected waters could reasonably be expected to interfere with those designated uses adopted by the State, as necessary to support such designated uses." Clearly, this "play-it-safe" approach goes beyond the requirements of the Clean Water Act and is therefore unnecessary. By taking this approach, however, EPA is unable to fulfill its duty (under Presidential Order 12866, the Unfunded Mandates Reform Act, and the Regulatory Flexibility Act) to assess the costs, benefits, and impacts of the rule on local government and small entities. While this may be the conservative approach for EPA, it places dischargers throughout the State at risk. As analytical detection limits improve, dischargers may find they are unable to achieve the criteria without costly end-of-pipe controls. But, by then, it will be too late for EPA to evaluate the costs and benefits of the criteria and alternative criteria. For these reasons, EPA must not adopt criteria for those constituents. If EPA does adopt criteria for those constituents, EPA must evaluate the costs and benefits of the criteria, as well as alternative criteria, using worst case assumptions (i.e., assume that discharge levels and ambient levels are at the detection limits). With respect to the District's discharge and Schell Slough and Second Napa Slough, the criteria in this category include, but are not necessarily limited to, the following : benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoroanthene, benzo(k)fluoroanthene, chrysene, dibenzo(a,h)anthracene, aldrin, 4,4'-DDD, 4,4'-DDE, dieldrin, endosulfan I, endosulfan II, endosulfan sulfate, heptachlor, heptachlor epoxide, toxaphene, PCB-1016, OCB-1221, PCB-1232, PCB-1242, PCB-1248, PCB-1254, PCB-1260, and hexachlorobenzene (see Table 3).

Comment: IV. Recommendation: Do not adopt criteria for any pollutant where the method detection limit exceeds the water quality objective and for which there is insufficient detectable, reliable data to determine if the pollutant could reasonably be expected to interfere with designated uses.

* The proposed Rule includes criteria for a number of constituents where there is insufficient data to determine whether the discharge of such pollutants could reasonably be expected to interfere with the designated uses. EPA has chosen to promulgate criteria for these constituents even though section 303(c)(2)(B) of the CWA requires states to adopt numeric criteria only for constituents "...the discharge or presence of which in the affected waters could reasonably be expected to interfere with those

designated uses adopted by the State, as necessary to support such designated uses." Clearly, this "play-it-safe" approach goes beyond the requirements of the CWA and is therefore unnecessary.

* By taking this approach, however, EPA is unable to fulfill its duty under Presidential Executive Order 12866, the Unfunded Mandates Reform Act, and the Regulatory Flexibility Act to assess the costs, benefits, and impacts of the Rule on local governments and other entities.

* While this may be the "safe" approach for EPA, it places dischargers throughout the State at risk. As analytical detection limits improve, dischargers may find they are unable to achieve the criteria without costly end-of-pipe controls. But, by then, it will be too late for EPA to evaluate the costs and benefits of the criteria and alternative criteria.

* For these reasons, EPA must set aside the "play-it-safe" approach and not adopt criteria for those constituents.

* If EPA does not do this, it must evaluate the costs and benefits of the criteria for these constituents, as well as alternative criteria, using, worst case assumptions (discharge levels and ambient levels are at the detection limits).

Comment: 3. Recommend Against Adopting Criteria with Insufficient Detectable Data

The District strongly recommends that the EPA not adopt criteria where the method detection limit exceeds the objective and there is insufficient detectable, reliable data to determine if the pollutant could reasonably be expected to interfere with designated uses. The proposed rule includes criteria for a number of constituents where there is insufficient data to determine whether the discharge of such pollutants could reasonably be expected to interfere with the designated uses. EPA has chosen to promulgate criteria for these constituents even though section 303 c(2)(B) of the Clean Water Act requires States to adopt numeric criteria only for constituents "...the discharge or presence of which in the affected waters could reasonably be expected to interfere with those designated uses adopted by the State, as necessary to support such designated uses." EPA has chosen a "safe approach" which clearly goes beyond the Clean Water Act and is clearly unnecessary. This approach does not allow EPA to fulfill its duty (under Presidential Order 12866, the Unfunded Mandates Reform Act and the Regulatory Flexibility Act) to assess the costs, benefits, and impacts of the rule on local government and small

entities. While this may be the safe approach for EPA, it places dischargers throughout the State at risk.

As analytical detection limits improve, dischargers may find they are unable to achieve the criteria without costly end-of-pipe controls. But, by then, it will be too late for EPA to evaluate the costs and benefits of the criteria and alternative criteria. For these reasons, EPA should not adopt criteria for those constituents. If EPA does adopt these criteria, EPA should, prior to that, evaluate the costs and benefits of the criteria, as well as alternative criteria, using worst case assumptions (i.e., assume that discharge and ambient levels are at the detection limits). The criteria in this category include the following: Aldrin, Alpha-BHC, Beta-BHC, Chlordane, 4,4'-DDD, 4,4'-DDT, 4,4'-DDE, Dieldrin, Endosulfan I, Endosulfan II, Endrin, Endrin Aldehyde, Heptachlor, Heptachlor Epoxide, Toxaphene, PCB- 1016, PCB-1221, PCB-1232, PCB-1242, PCB-1248, PCB-1254, PCB-1260, Hexachlorobenzene, N-Nitrosodipropylamine, Pentachlorophenol, Benzo(a)anthracene, Benzo(a)pyrene, Benzo(b)fluoroanthene, Benzo(k)fluoroanthene, Chrysene, Dibenzo(a,h)anthracene, and Indeno(1,2,3-cd)pyrene.

Comment: 3. The CTR fails to adequately address non-detected pollutants.

In numerous instances, the CTR adopts water quality criteria for pollutants that exceed the method detection limit. In these cases, insufficient data exists to determine if these pollutants will interfere with designated beneficial uses. Without such data, EPA is unable to demonstrate that there is a "discharge or presence of which in the affected waters could reasonably be expected to interfere with those designated uses adopted by the State" that would require the adoption of water quality standards to support such designated uses. See CWA section 303(c)(2)(B).

Furthermore, without such data, dischargers are unable to determine the controls necessary to meet the CTR criteria. As detection limits are lowered over time through the implementation of new laboratory techniques, dischargers may find that they are in violation of the criteria, are subject to enforcement actions and citizen suits, and must install costly end-of-pipe treatment technologies. This scenario can be avoided if EPA delays the adoption of all criteria that exceed currently available method detection limits.

Request: Caltrans requests that EPA delay the adoption of all CTR water quality criteria that exceed currently available method detection limits until such time that there exists sufficient, detectable, reliable data to determine if the pollutant could reasonably be expected to interfere with designated beneficial uses.

Comment: C. RECOMMENDATIONS FOR MODIFICATIONS TO THE CTR AND EA

Do not adopt criteria for any pollutant where the method detection limit exceeds the objective. As noted in the second paragraph of B.1, above, attainability issues will likely occur in the future as technology develops lower detection limits. There is no reason to adopt criteria for toxicants than cannot be properly measured. Once proper MDLs exist, each item can be reevaluated and the CTR (or the State Plans) can

be amended. Regulatory agencies must first determine if any of these toxicants are present in the water body to determine if an objective is warranted. The toxicants that should be removed from the CTR include the following: TCDD and equivalents, Hexachlorobenzene, Aldrin, Chlordane, 4,4'-DDT, 4,4'-DDE, 4,4'-DDD, Dieldrin, Endrin, Heptachlor Epoxide, Polychlorinated biphenyls (PCBs), and Toxaphene. There may be other toxicants where MDL is an issue for other POTWS.

Comment: Third, regarding the criteria being proposed for adoption in the draft CTR, EBMUD recommends that EPA should:

* NOT adopt criteria for any pollutant where the method detection limits (MDLs) for EPA required analytical procedures defined in 40CFR 136 exceeds the objective. In these cases there is insufficient detectable data to reliably determine if the pollutant of concern could reasonably be expected to interfere with attainment of designated uses. Furthermore, there is no assurance that technological advancements or improved methodology would permit MDLs to be further reduced before interim permit limits became final.

Comment: Analytical Detection Limits

At the time the ISWP was undergoing public review, the City's analytical detection capabilities for trace organics were also being improved. For example, the detection limit for lindane (y-hexachlorocyclohexane) was lowered from 20 ng/L in 1989 to the present detection level of 4 ng/L. At the detection limit of 20 ng/L, the practical quantitation limit (PQL) was 100 ng/L, and lindane had not yet been detected in Tillman effluent. After the new NPDES permit was issued in 1991, the effluent limit for lindane was set at 19 ng/L. With the improvement in the lindane detection limit to 4 ng/L and

the PQL at 20 ng/L, the Tillman plant began to detect lindane consistently at levels of about 30 ng/L for the past 6 years. The plant thus unknowingly inherited a lindane compliance problem. Since the ISWP did not contain a provision for this situation to be addressed, the plant began to experience chronic lindane violations that continue to this day. As described previously in our comments on the EA, the probable cost for treating lindane was estimated to be approximately $40 million per year.

This unanticipated problem, driven by improvements made in analytical methods, should likewise be anticipated in the CTR for criteria that are proposed to be set below PQLs. One possible approach would be to designate these criteria as "target numeric criteria" that would serve as placeholders until such time that improvements to detection levels (which can always be assumed to be achievable) are realized. Practical criteria could be established in the interim based on current method detection levels, which would be adjusted downward to eventually reach the target criteria levels.

Another strong justification for setting appropriate detection limit-specific criteria is based on contingency economic considerations. When "hard" criteria are set below PQLs, no compliance problem at the level between the criteria and the PQLs can be identified and taken into consideration by the EA. The EPA's economic analysis is thus inherently flawed from this point of view, because detection limits effectively represent a level of ignorance (or lack of data) that the EA does not now address.

Comment: Due to the time constraints of the comment period, we have focused our review and comments primarily on those criteria that we anticipate may cause compliance issues for one or more of the Sanitation Districts' WRPs (see below). Based on our initial review of the proposed rule, the Sanitation Districts recommend that adoption of some of the criteria be deferred. As explained in the attached comments, we believe that there are significant scientific issues regarding the human health criteria for several trihalomethanes that call into question the accuracy and appropriateness of the proposed criteria. In addition, we recommend that EPA defer adoption of those criteria that are below detection limits and that have not been demonstrated to be adversely affecting water quality or the attainment of designated uses on a water body-specific basis in California. In addition, we recommend that EPA not adopt criteria for effluent dependent waters, unless they have been adjusted to reflect the characteristics of this type of water body.

Criteria Below Detection Limits

We believe that there are fundamental problems with EPA's decision to adopt criteria that are below detection limits. This issue relates to EPA's statutory and regulatory obligations in establishing water quality criteria; namely, that EPA is subject to the same policies, procedures, analyses, and public participation requirements as States pursuant to 40 CFR section 131. These regulations require States to "review water quality data and information on discharges to specific water bodies where toxic pollutants may be adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern and must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use." (40 CFR section 131.11) For criteria where the method detection limit exceeds the objective, there are inadequate data to determine if the pollutant could reasonably be expected to interfere with attainment of designated uses. We believe that because of the inability to detect these substances and the lack of monitoring information indicating water quality use impairment EPA has not been able to fulfill its obligations to conduct a water body-specific analysis of the need to promulgate criteria.(*1)

(*1)U.S. Environmental Protection Agency, Economic Analysis of the Proposed California Water Quality Toxics Rule, Office of Water (EPA-820-B-96-001, July 1997), p. 8-18.

Second, EPA has not fulfilled its obligations under the Unfunded Mandates Reform Act and Executive Order 12866 to analyze the costs and benefits of promulgating proposed criteria which cannot be detected or for which insufficient monitoring data are available.

Given these deficiencies, we recommend that EPA defer the adoption of criteria for constituents which are below detection limits until such time as EPA has demonstrated that the levels of toxic pollutants being discharged are at a level to warrant concern. As an alternative, EPA could defer to the State for promulgation of criteria for such compounds on a water body-specific basis as part of the State's continuous water quality planning process.

Comment: PROVISIONS SDG&E DOES NOT SUPPORT

As described in the following comments SDG&E does not support the following provisions:

EPA needs to clarify its quantification discussion

The preamble to the rule (see 62 Fed. Reg. at 42,183, Col. 3) states that "EPA does believe, however, that the use of analytical detection limits are appropriate for determining compliance with National Pollutant Discharge Elimination System (NPDES) permit limits." SDG&E believes that the use of detection limits for this purpose is inappropriate. First, analytical results that are above the detection limit, but less than the quantitation limit only establish the presence of a analyte, not the actual concentration of the pollutant in the sample. Therefore, results below the quantitation limit do not provide a reliable value for determining compliance with a permit limit. Second, the document ("Strategy for the Regulation of Discharges of PHDDs and PHDFs from Pulp and Paper Mills to Waters of the U.S.") (the "Dioxin Strategy") that is referenced as the basis for using the detection limit for compliance determinations is from May 21, 1990. The Agency has expressed significant changes in its position since that time. For instance, EPA's guidance document dated March 20, 1996 ("Questions and Answers on the Great Lakes Water Quality Guidance-Set 2"; p. 28.) allows states to specify that analytical results below the level of quantification may be deemed to be in compliance with the established water quality-based effluent limitation. Additionally, a U.S. Court of Appeals for the District of Columbia Circuit ruling in 1997 held that:

A standard with which compliance cannot be assessed - and it is agreed that compliance with an effluent limitation set below the level of quantification simply cannot be assessed - is no standard at all for purposes of due process.

American Iron and Steel Institute v. U.S.EPA, 115 F.3d 979, 994 (1997) (AISI).

Rather than reference the Dioxin Strategy, EPA should reference its "Questions and Answers on the Great Lakes Water Quality Guidance-Set 2', dated March 20, 1996.

Comment: The areas with which we find concerns and the requested changes include the following:

A further problem with the analysis relates to the establishment of criteria that are below analytical detection. Our District finds 34 separate criteria that fall into this category. Lacking this credible data, it was not possible to conduct cost-benefit analyses or determine that any set of control measures would or could lead to compliance. This fundamental inability to utilize established rulemaking procedures mandates further work prior to the promulgation of the criteria.

Comment: * OVSD recommends that EPA defer adoption of criteria contained in the draft CTR, which are typically below achievable detection limits. OVSD understands that EPA's rationale for setting criteria below achievable limits is based on EPA's determination of the criteria needed to adequately protect aquatic life and human health. However, if a pollutant has never been detected in OVSD's treatment plant receiving water, there is no basis for determining whether the chemical is adversely affecting water quality or the attainment of designated uses.

Comment: While the draft regulations demonstrate clear progress on these and other issues, there remain some unresolved problems that could compromise our ability to serve our customers. We offer these comments in the hope of minimizing those potential impacts.

Analytical Detection Limits

Criteria for nine pollutants(*1) appear to have been set at levels lower than we can detect in either our laboratory or by commercial laboratories in our region, including those used by the Los Angeles

Regional Water Quality Control Board (RWQCB). While we consistently do not find these pollutants in our discharge, our detection capabilities are limited by the methods available to us for regular monitoring. Some of the proposed limits are so low that our equipment and analytical methods are incapable of detecting them, whether they are present or not. Thus, regardless of the quality of our discharge, there is no practical way to demonstrate compliance with the proposed limits for these nine pollutants.

The Los Angeles RWQCB, which must enforce these limits, is aware of this shortcoming, which applies to both the CTR and the closely-related National Toxics Rule (NTR). Recognizing the "catch-22" inherent to the proposed criteria, they have proposed an alternative, administrative method of compliance. While this alternative will allow us to comply with the CTR in a purely administrative sense, the. fact remains that we cannot actually demonstrate that our discharge meets the proposed criteria for these nine pollutants. This makes our district, the RWQCB and even the USEPA vulnerable to third-party lawsuits and creates a potential for negative public perception and bad press. As recent experience has shown(*2), advocates for public health and the environment are notoriously unforgiving of "administrative compliance". It is also unclear to us whether the administrative remedy proposed by the RWQCB is consistent with the State Implementation Policy for the CTR. This is something we could not determine in the 30 days provided to review the CTR.

(*1) Cadmium, copper, lead, mercury, selenium, silver, chloroform, chlorobromo-methane and dichlorobromomethane

(*2) During the public debates over the reauthorization of the Safe drinking Water Act, the Natural Resources Defense Council aired a number of television and press stories on the safety of public drinking water supplies, based in large part on selective interpretations of NPDES permit conditions and violations. The adoption of pollutant limits that cannot be verified exposes a vary large portion of the water and wastewater industry to allegations of health and environmental risks that can neither be proven or denied.

Comment: Major Concerns About the Proposed Criteria and Rule

1. The Proposal is Based on Poor Data and Will Not Result in Better Water Quality for California. We

stated that our own attainability analysis and that of BADA show that San Francisco,) will be impacted by this rule. Unfortunately, due to the short time for review, the poor quality of data and basis for statements and assumptions in the proposal and the problem with detection limits we cannot specifically say what will be the cost to Sari Francisco. One analysis tell us it could be $2.3 million per year annualized costs and another analysis tells us it could be much more. We strongly recommend major revision to the proposal and the economic analysis before final promulgation for the following reasons:

For many of the pollutants the detection limit is above the proposed criteria and there is insufficient water quality data to determine if the constituent could reasonably be expected to interfere with designated uses;

Comment: The second point I'll make is about the numeric criteria themselves. There's a number of reasons that we will amplify on in the written comments why we don't believe all of those should be finalized as proposed.

And the example I'd like to deal with here is the group that are below the detection level, where you're proposing a criteria that's substantially below the current detection limit. Dioxin is an example; there are others.

It would be easy to say, and we will say, that because of that situation you weren't able to do an analysis -- an economic analysis, an attainable analysis. You weren't able to tell what impact this would actually have in the real world, because all of the standard setting was below where you had data.

And so how could you possibly know whether or not the standard could be achieved, when it would be achieved, or how much it would cost, or if it could be achieved? We believe that to be a pretty fundamental shortcoming of this whole business, when you're in that area below detection limits.

But there's even a more fundamental thing I'd like the EPA to think about for those pollutants. And that is: Just how are we going to proceed? Even if you manage to get your standard finalized as proposed, what would the next step be, where you've got a standard that's below the detection limits where we can take the normal next steps?

So I think we need more creativity in this area as well. It's an area where we're going to have to all put our heads together and say, "How do we approach the set of pollutants where the level of interest -- the levels at which we're interested in the pollutant is so very low?" Maybe there is some fundamentally different approach we need to take here, and maybe now is a good time to stop, brainstorm about it, do some creative thinking.

I don't think the old -- the TMDR translated to permit limits, that's not the future for those kind of pollutants. It ain't going to work. So now would be a good time to slow down, do some rethinking of how to go about proceeding on those.

So with those two points, I'll stop and thank you for your time.

(Five-minute recess in proceedings.)

Comment: Third point, the basis for adopting a number of the specific criteria, we believe, is inadequate. These criteria fall into several categories. An example of one of these is the establishment of criteria that are below analytic detection limits, mentioned before, as was done for dioxin and a number of other parameters.

Lacking credible data it was not possible to conduct cost-benefit analysis or to determine that any set of control measures would or could lead to compliance. This fundamental inability to utilize established rulemaking procedures mandates further work prior to the establishment of criteria.

Comment: Are the criteria appropriate?

We're concerned that the proposed rule contains criteria that have concentrations lower than the current acceptable laboratory detection limits. We recommend that no criteria be adopted which are below the method detection limits and that no criteria be adopted when insufficient reliable data exists to determine that pollutant could reasonably be expected to interfere with designated uses.

Comment: 2. PARTIAL PROTECTION BY THE PROPOSED AQUATIC LIFE CRITERIA (FRESHWATER OR SALTWATER)

On page 42168, the proposed rule includes the following language: "EPA's guidelines are designed to derive criteria that protect aquatic communities by protecting most of the species and their uses most of the time." The CTR goes on to state that this approach results in only a "small possibility" of substantial overprotection or underprotection. Obviously, it is underprotection that is of concern to the DFG. The DFG has very serious concerns that criteria are being proposed that protect "most" of the species "most" of the time. We are aware of the protocols that require a minimum of eight specified families be used to develop criteria and that it may be difficult to determine criteria that are one hundred percent protective; however, this does not preclude the real possibility that certain designated uses and aquatic organisms will not be maintained, and or protected, as a result of the proposed criteria. The DFG is also concerned that criteria and protocols developed for specific constituents do not take into account the additive or synergistic effects that contaminant combination may have on aquatic organisms. Another factor that needs to be considered is bioaccumulation, as well as the effect this may have on organisms at higher trophic levels.

As trustee of all the fish and wildlife resources in the State, it is our agency's responsibility to ensure appropriate protection of all fish and wildlife resources, not just "most", and this includes adequate water quality standards. Due to our concerns and the very real possibility of underprotection to aquatic organisms and designated uses, the DFG believes that it may be appropriate to derive the criteria as proposed, and subsequently develop some additional safety factors for inclusion. It is our understanding that this approach was used in the formulation of water quality objectives for protection of aquatic organisms in the California Ocean Plan. In the short term , the safety factor could possibly be realized by the development of a comprehensivebiological monitoring program to determine whether the proposed criteria are indeed fully protective.

Response to: CTR-026-002c

The commentor is correct in stating that the values EPA is promulgating the California Toxics Rule for the protection of aquatic life are designed to protect most species most of the time. EPA understands the commentor's concern that this does not ensure protection of every species and that for some specific constituents additivity, synergism, and food web accumulation may not be considered. These limitations are a factor of the state of the science in modeling, aquatic toxicology, and chemistry rather than an

oversight by the Agency. In fact, the Agency's strategic planning and goals for the next five to ten years is to move towards criteria and guidance that address these very issues.

If the State believes there are critical species or designated uses that will not be protected by the proposed values, then a site specific criterion can be derived using the species recalculation procedure and the new criterion adopted.

With regards to the approach, the commentor suggests to increase the conservatism of the values by establishing safety factors, this is within the purview of the State. A State may always adopt a scientifically defensible value more stringent than that established by EPA. EPA has not used safety factors in promulgating these criteria, however, because EPA's methodology for deriving aquatic life criteria already incorporates rigorous data analysis procedures, including an extrapolation procedure, designed to protect a very high percentage of species, and to protect nearly all individuals even in species more sensitive than nearly all other species. This yields criteria that are adequately protective of the aquatic life uses designated by the state. Though they have limitations of their own, EPA is very supportive of States establishing biomonitoring programs. Comprehensive biomonitoring programs provide information about the health of aquatic systems that simply cannot be obtained through toxicity testing and chemistry.

Comment: The Center for Marine Conservation (CMC) is a nationwide, nonprofit advocacy group dedicated to the conservation and enhancement of coastal and ocean life and resources. CMC submits these comments on behalf of its 16,000 members in California and over 120,000 members nationwide.

CMC applauds EPA's efforts to bring California into compliance with the Clean Water Act 303(c)(2)(B). Implementing numeric criteria that will protect the beneficial uses of California's waters is of great importance to the health of coastal and marine ecosystems, and so to CMC and its members. The reliance in many areas of the state on narrative criteria threatens the health of most of the state's waters, thereby impacting both human health and the health of the state's economy that relies on clean water.

While CMC strongly supports the swift adoption of an Enclosed Bays and Estuaries Plan and an Inland Surface Waters Plan that contain numeric criteria for toxic pollutants, CMC also is concerned that many of the specific criteria contained in the proposed rule are weaker than those contained in published guidance. CMC also believes that the proposed rule can better protect certain subpopulations from harm

caused by consumption of contaminated fish and shellfish. Finally, CMC is concerned that the economic analysis of the proposed rule over-emphasizes costs and under-reports the many benefits of improving water. quality throughout the state. These three points are reviewed below.

In Light of Significant Threats to Water Quality, the Proposed Rule Should Contain the Most Stringent Criteria That Are Scientifically Defensible

Many of the criteria in the proposed rule are weaker than criteria in current published guidance. The proposed rule summarily states that the difference between the proposed, weaker criteria and the published guidance documents is "insignificant"(*4); however, in light of the current contamination problems in California's waters today, any move backwards, particularly when spread out over the state, must be viewed as significant.

Any weakening of the criteria should be subject to close scrutiny and the most rigorous analysis, which the proposed rule itself does not do. Among other things, the criteria in the proposed rule may be underprotective because additive and synergistic effects were not considered; and because the effects on wildlife, which can be particularly significant for bioaccumulative chemicals, were ignored.(*5) In addition, the proposed rule contains dissolved rather than total recoverable metals criteria, despite the fact that EPA acknowledges that total recoverable metals criteria are "scientifically defensible" and that they are more protective than dissolved metals criteria because they consider "sediment, food-chain effects and other fate-related issues," rather than simply water column impacts.(*6)

Clean Water Act section 303(c)(2)(B) mandates the development of numeric criteria that will "support such designated uses [that are adopted by the State]." The statistics available on the health of the state's waters indicates that their use already is significantly threatened or impaired by toxics. The strongest criteria supportable by science are necessary to reverse this trend and begin to restore the state's waters.

(*5) Id. at 42168.

(*6) Id. at 42172.

Response to: CTR-029-002f

Economic Analysis: I can't respond to this, not my bailiwick.

As the commentor states, the specific numbers proposed in the rule are not necessarily the same as those in existing criteria documents. The Agency disagrees with the commentor's suggestion that because they are different they are less protective. The Agency believes the values proposed in the rule are sufficiently stringent to protect the designated uses of the waters of California. The proposed values meet the aquatic life criteria derivation requirements and have undergone Agency review and public comment.

EPA understands the commentor's concern that this does not ensure protection of every species and that for some specific constituents additivity, synergism, and bioaccumulation may not be considered. These limitations are a factor of the state of the science in modeling, aquatic toxicology, and chemistry rather than an oversight by the Agency. In fact, the Agency's strategic planning and goals for the next five to ten years is to move towards criteria and guidance that address these very issues.

The metals criteria proposed in the rule are for the dissolved concentration rather than the total recoverable concentration. This is consistent with Agency policy and scientific investigations that the dissolved form of metals is that which most closely reflects the bioavailable fraction of metals in the water column. From modeling and research that has been conducted it is understood that if the dissolved criterion is met in the water column then there should not be metal toxicity in the sediment because the sediment interstitial water cannot contain more metal than the overlying water column (Ankley et al., 1996). This does not preclude small amounts of bioaccumulation of metal but to date we have not been able to demonstrate that the bioaccumulation translates into any toxic effect on higher level consumers (Lee et al., 1998; Hare et al, 1994; Hansen et al., 1996). In other words, the data so far indicates that increased body burden does not translate into increased toxicity.

The dissolved concentration must be translated into a permit limitation which is based on total recoverable. This ensures that acceptable total mass loadings are not exceeded and to ensure that the potential transformation of pollutants in effluents upon entering and mixing with the receiving water are accounted for.. In the very near future, the Agency will be publishing sediment guidelines for metals. These guidelines will compliment the water column values to ensure metals are holistically assessed and addressed.

Comment: The standards are too weak in that they fail to adequately account for the bioaccumulation of mercury in fish tissue. Studies of the Great Lakes indicate that such biaccumulation is four to twenty

times greater than what the EPA projects for California.

Response to: CTR-097-002

The agency disagrees that the proposed criteria fail to adequately account for the bioaccumulation of mercury in fish tissue. The 1980 hg criterion, which is being used nationally until a new national HH criterion is derived, does use what is in effect a BAF (practical bioconcentration factors: PBCF) to account for biomagnification. As stated in the Preamble, the HH criterion is based on an average of "practical bioconcentration factors" for mercury as described in Ambient Water Quality Criteria for Mercury (EPA 440/5-80-058; Pages C-100-101). Because these PCBFs are derived from average mercury residues from commonly consumed aquatic organisms exposed in various water bodies (lakes, rivers, estuaries, oceans) and overall average total mercury concentrations in water, they incorporate potential mercury uptake indirectly from the food chain and directly from water.

Under Section 304 (a) of the Clean Water Act, EPA is required to establish National recommended water quality criteria. As such, the criteria must be applicable across all regions of the United States and, though considered protective of aquatic organisms, are based on central tendencies rather than solely site or State-specific data. However, if the State believe there are critical species or designated uses that may not be sufficiently protected by the National-based promulgated values, a site-specific criterion can be derived using appropriate data and adopted.

Please refer to the response for CTR-002-076 for additional discussion regarding bioaccumulation.

Comment: 9. EPA should delete recommendations that permit authorities utilize EPA or other criteria that have not been adopted as a part of the CTR as a basis for permit limits under the narrative toxicity criteria for toxics. The Preamble in E.3.b and the rule in footnote n to the criteria listed in 131.38(b)(2) recommend that the permitting authority base permit limits on criteria that are not being adopted as a part of the rule. This is not only unnecessary and inappropriate, but, in essence, it effectively constitutes adoption of those non-CTR criteria without considering costs and benefits or otherwise complying with Federal law and regulations.

Response to: CTR-038-010

EPA is requiring nothing in the CTR in the language cited by the commenter. For pollutants for which no criteria are promulgated as part of this rule, EPA is simply restating that according to existing law under the CWA, not affected by this rule, that permit writers are required to implement the narrative criteria, and that for arsenic, EPA recommends, but does not require, that permit writers may use the value California established for arsenic. EPA is not promulgating a criterion for arsenic in today's rule pending a review of the risk assessment for arsenic. Because the rule is simply restating what is required under existing law, these statements are not a cost of the CTR, but of prior existing law under the CWA and its implementing regulations.

Comment: V. Recommendation: Delete all provisions in the Rule that preempt the States flexibility in permitting. The Rule provides specific direction on the adoption of averaging periods, low flow values,

effluent limitations for criteria not being adopted as a part of the Rule, and that the aquatic life criteria be applied to all waters irrespective of designated use, etc..

* The Preamble and the Rule's economic analysis make a point that the State has considerable flexibility in establishing permit limitations. In making, that point, EPA implies that the State may implement the criteria in a manner that would have little or no adverse economic impact on dischargers.

* However, the Rule contains a number of implementation provisions that are not required under Section 303(c)(2)(B), but serve to preempt the State's flexibility. These provisions include, but are not necessarily limited to the adoption of averaging periods and low flow values, directives regarding the establishment of effluent limitations for criteria that are not being adopted as a part of the Rule, and application of the aquatic life criteria to all waters irrespective of the designated use.

* Not only does EPA not have a duty to adopt these provisions, but also the provisions are more restrictive than those required by the CWA or EPA regulations, They clearly restrict the State's flexibility. In fact, other states have adopted, and EPA has approved, implementation provisions (e.g., averaging periods and low flow values) which are less restrictive.

* For these reasons, EPA should remove all such implementation provisions from the Rule.

Response to: CTR-040-018c

EPA has adopted recommendations for averaging periods and low flow values because these are intrinsic to ensuring that the numeric values are protective of the designated use. These factors are part of the ambient condition necessary, see preamble to the proposed CTR and Technical Support Document for Water Quality Based Toxics Control, U.S. EPA 1991, Section 2.3, and Appendix D.

The commenter asserts, but does not provide examples of situations where EPA has approved averaging periods and low flow values that are less restrictive than those incorporated into the final rule. Without specific examples provided, it is difficult for EPA to analyze any distinctions between these situations and the current rule. As a general matter, however, EPA uses the averaging period and low flow value when it promulgates criteria as representing EPA's best scientific judgement about these factors given all the uncertainties in deriving these factors. See Technical Support Document for Water Quality Based Toxics Control, U.S. EPA 1991, Section 2.3, and Appendix D. If a particular state elected to vary from EPA's recommendations, EPA would evaluate the basis presented and the particular facts of a given situation, and might render a different judgement. The commenter provided no specific critiques of the values used or information upon which EPA should base a decision to adjust these factors, and thus EPA has not changed them in response to comment.

Comment: One of Heal the Bay's principle activities is providing comments on NPDES permits for inland, bay and estuary discharges. For years, we have relied on narrative standards and the regional Basin Plan requirements as tools to ensure that inland, bay and estuary discharges were not impacting the beneficial uses of the receiving waters. These tools have proven inadequate for achieving the desired goal of beneficial use protection. This is why numeric criteria, like those in the proposed California Toxics Rule, are so important. The primary obstacle to implementation of the State's ISW/EB&E Plan is the requirement for the State to perform an analysis under the California Environmental Quality Act ("CEQA") for any numeric criteria adopted that is more stringent than Federal criteria. The SWRCB does not have the resources to perform these analysis for the numeric criteria recommended by the task force groups. Therefore, to move implementation of the plans forward, it was agreed that EPA would revise the California Toxics Rule and, simultaneously, the State would develop the implementation policy for the ISW/EB&E Plans. We support this effort because we strongly believe that these plans must be implemented sooner, rather than later, in order to improve impaired water quality throughout California. Therefore, we agree with the California Toxics Rule as it is proposed and do not include detailed comment on the specific criteria for individual pollutants.

Response to: CTR-053-002

EPA appreciates the commenter's support of the proposed rule.

Comment: Thank you for the opportunity to comment on the U.S. Environmental Protection Agency's (U.S. EPA) proposed California Toxic Rule (CTR). The State Water Resources Control Board (SWRCB) staff would like to recognize U.S. EPA's tremendous effort in producing the CTR. The SWCB staff are providing you with the following comments:

Page 42160: "Entities discharging pollutants to waters of the United States in California could be indirectly affected by this rulemaking....." Because the Clean Water Act requires that all NPDES permits include limits on discharges that are necessary to meet water quality standards, it appears that entities, such as industry and municipal discharges, could be directly affected by this rulemaking.

Response to: CTR-022-001

EPA disagrees with the commenter that the proposed CTR will directly impact municipal and industrial dischargers. The CTR promulgates water quality criteria which, by themselves, do not impact anyone. It is only when the State of California implements the water quality criteria through its water quality programs that impacts may occur. Different implementation methods can have significantly different impacts. Therefore, EPA's statement that the rule may indirectly impact entities discharging to waters of the U.S. in California is correct.

Page 42207: Proposed rule, Section 131.38(d)(1): Please note that the basin plans, in general, identify waters subject to water quality standards in the chapters on beneficial uses. Many basin plans do not specify water quality objectives for the priority toxic pollutants.

Please reword the second and third sentences of this subsection to read:

"These criteria apply to waters identified in the Basin Plans. More particularly, these criteria apply to waters identified in the Basin Plan chapters designating beneficial uses for waters within the region."

Response to: CTR-022-004

EPA agrees with the commenter that the second and third sentences in section 131.38(d)(1) of the rule may be confusing. We have considered your suggestion and modified the language accordingly.

Comment: p. 42167 -- No Undue or Inappropriate Burden on the State of California or Its Dischargers

The preamble states that "Today's proposed rule would not impose any undue or inappropriate burden on the State of California or its dischargers." We must disagree with this statement. While EPA's intent with this statement is perhaps to compare California to other States where water quality criteria for toxic pollutants have already been adopted, EPA's own analysis determines that the rule will cost from $15 to 87 million per year to implement which we believe to be a significant underestimate due to numerous uncertainties regarding whole categories of dischargers (i.e. nonpoint sources) and policies for implementation of the rule. Thus, it is both inaccurate and inappropriate for EPA to make the judgement that the rule will not impose an undue or inappropriate burden on the State or its dischargers.

Response to: CTR-035-013

EPA acknowledges the comment concerning the statement in the preamble that the CTR will not impose any undue or inappropriate burden on the State of California and its dischargers. EPA disagrees with the commenter that the statement in the preamble is inappropriate and inaccurate. The CTR promulgates water quality criteria for California that are required by the Clean Water Act under section 303(C)(2)(b), and that had been previously adopted by the State of California and approved by EPA. The State's criteria were rescinded after a State Court found that they had not been adopted in compliance with State law. Every other state in the nation, except California, is in substantial compliance with section 303(C)(2)(b) of the Clean Water Act. Thus, imposing these criteria on the State of California merely puts the State back into the position that it had been in, and into the same position as all other states in the nation. Thus, the criteria do not impose any undue or inappropriate burden.

With respect to the comment that the economic analysis for the proposed rule indicated that the rule would cost between 15 and 87 million dollars per year to implement, EPA acknowledges that the economic analysis indicates that some cost will be associated with how the State implements the CTR criteria into the NPDES permit program. Benefits, however, will also accrue. These costs are not significant pursuant to the language in Executive Order 12866, under which the economic analysis was completed. (See the discussion of costs and benefits in the preamble to the final rule under Executive Order 12866.)

Comment: pp. 42167-42181 -- Revised / Updated 304(a) Criteria

Please provide a table in the Preamble containing each criterion, indicating each parameter that has been changed since the promulgation in 1992 of the National Toxics Rule, references stating what documents or sources contain the pertinent information and when the changes were made, and directions for obtaining the documentation. This table should incorporate the information in the California Toxics Rule Administrative Record Matrix for human health criteria.

Response to: CTR-035-015

EPA acknowledges the comment that EPA provide a table in the preamble containing each criterion indicating how each had been changed since the National Toxics Rule, including references, documents, sources of information, when any changes were made, and directions for obtaining the information. For the aquatic life criteria, this information was provided in the preamble to the proposed rule and in the Administrative Record, and is again provided in the preamble to the final rule and in the Administrative Record. The preambles discuss and thoroughly explains all significant changes in aquatic life criteria from the National Toxics Rule. The Administrative Record contains all of the water quality criteria documents which explain how each aquatic life criterion was calculated, as well as the document entitled "The 1995 Updates: Water Quality Criteria Documents for the Protection of Aquatic Life in Ambient Water," dated September 1996. This document explains the basis of several recently updated aquatic life criteria.

The preamble also discusses and thoroughly explains several significant changes in human health criteria from the National Toxics Rule. The Administrative Record contains a document entitled The California Toxics Rule Administrative Record Matrix which contains information on the basis of each human health criterion promulgated in the CTR.

The information the commenter is requesting is contained in the preambles and the Administrative Record.

Comment: Equitable Considerations in Proposing the CTR

EPA's promulgation of the California Toxics Rule is unwarranted since California was in the process of revising the Inland Surface Waters Plan and the Enclosed Bays and Estuaries Plan that were overturned by the Superior Court in 1994. California and its water resources would be better served and better

protected by allowing the State Water Board to continue developing its statewide water quality plans unburdened by the strictures of the proposed rule.

EPA's purpose to 'help restore equity among the states; 62 Fed. Reg. 42161, also appears unfounded since the proposed rule differs in a number of ways from the criteria in the National Toxics Rule.

Response to: CTR-036-012

EPA disagrees with the comment that the CTR is unwarranted since California is in the process of revising its statewide plans, and that the State's water resources would be better served by allowing the State to continue its plans unburdened by the strictures of the proposed rule. The State's plans are not being revised; the State's plans are being completely redrafted and repromulgated by the State in compliance with State law, which the State failed to do when it adopted its plans in 1991. Thus, currently the State does not have any statewide plans in place for surface waters or enclosed bays and estuaries to revise. The rescinded plans contained, and thus the State currently lacks, both a comprehensive set of water quality objectives for priority toxic pollutants, as required by the Clean Water Act section 303(C)(2)(b), and implementation plans to implement the resulting water quality standards.

The CTR does not burden the State in any way. The State is intending to readopt its plans in two phases: the first phase will be implementation procedures and the second phase will include water quality objectives for priority toxic pollutants. In fact, the CTR will help restore a comprehensive water quality program to the State of California sooner than the completion of the two phases of the State's plans, since the State will soon complete phase one of its readoption, and EPA has completed its promulgation of the CTR. The CTR, which will create numeric water quality standards, and phase one of the State's plans, which will create implementation, will allow the State to effectively implement numeric water quality standards for priority toxic pollutants for inland surface waters and enclosed bays and estuaries as soon as the State completes phase one of its repromulgation.

When the State completes phase two, the readoption of its water quality objectives, EPA will stay the CTR after its review and approval of the statewide plan. Thus, the CTR does not hinder the State in any way, and in fact helps the State by allowing it to implement numeric water quality standards for toxic pollutants sooner than if EPA had not promulgated the CTR.

The commenter also noted that it appeared that EPA's stated purpose in the preamble to the proposed CTR, that the CTR would restore equity among the states, was unfounded because the proposed rule differed from the National Toxics Rule. EPA disagrees with this comment. The National Toxics Rule applied to several states that were not in substantial compliance with the Clean Water Act at 303(C)(2)(b) at that time. When it was promulgated, all states except those in the National Toxics Rule were in substantial compliance with the Clean Water Act water quality provisions. The State of California was required to rescind its water quality control plans after the finalization of the National Toxics Rule; thus, California became the only state in the nation that was in substantial noncompliance. Thus, the CTR restores equity among the states by restoring numeric water quality standards for toxics to California, as all other states in the nation.

The commenter also noted that the CTR differed in a number of substantial ways from the National Toxics Rule. EPA disagrees with this comment. The criteria in the CTR reflect updated information and do not substantially differ from the criteria in the National Toxics Rule. The CTR criteria reflect EPA's most recent water quality criteria guidance issued under Clean Water Act section 304(a). The preamble discusses these changes in detail. In addition, the Clean Water Act requires states to update their water

quality criteria every three years, and incorporate EPA's most recent 304(a) criteria guidance where appropriate (where a state has not adopted and/or EPA has not approved, different, scientifically-based water quality criteria). Thus, the states are required to incorporate these updates into their own water quality program

Comment: 1 . EPA has greatly understated the potential impacts of the CTR to the extent that statements in the preamble are completely misleading. On page 42160-1 of the Federal Register, EPA states:

"Potentially Affected Entities: Citizens concerned with water quality in California may be interested in this rulemaking. Entities discharging pollutants to waters of the United States in California could be indirectly affected by this rulemaking since water quality criteria are used to create water quality standards which in turn are used in developing National Pollutant Discharge Elimination System (NPDES) permit limits. Categories and entities which may ultimately be indirectly affected include:

CATEGORY --- Examples of potentially indirectly affected entities
---------- INDUSTRY --- Industries discharging pollutants to surface waters in California.

MUNICIPALITIES --- Publicly-owned treatment works discharging pollutants to surface waters in California.

This table is not intended to be exhaustive, but rather provides a guide for readers regarding NPDES regulated entities likely to be indirectly affected by this action. This table lists the types of entities that EPA is now aware could potentially be indirectly affected by this action." (emphasis added)

Based on the analysis prepared by BADA, CASA, and Tri-TAC, EPA's own acknowledgement that the CTR is primarily directed toward NPDES permit holders, the above statement is extremely misleading. EPA should be more forthcoming with information that is published in the Federal Register. If the CTR is promulgated in its current form, then the Authority recommends that the above statement be amended to read as follows:

"Affected Entities: Citizens concerned with water quality in California may be interested in this rulemaking. Entities discharging pollutants to waters of the United States in California will be directly affected by this rulemaking since water quality criteria are used to create water quality standards which in turn are used in developing National Pollutant Discharge Elimination System (NPDES) permit limits; Categories and entities which will be directly affected include:

CATEGORY --- Examples of directly affected entities ---------- INDUSTRY --- Industries discharging pollutants to surface waters in California.

MUNICIPALITIES --- Publicly-owned treatment works discharging pollutants to surface waters in California.

OTHER INDUSTRIES AND COMMERCIAL ESTABLISHMENTS --- Industries and commercial establishments discharging pollutants to publicly-owned treatment works.

MEMBERS OF THE PUBLIC --- Members of the public that pay fees to publicly-owned treatment works for wastewater collection and treatment services and/or buy products produced by the entities described as "Industry" or "Other industries and commercial establishments", above.

This table provides a guide for readers regarding NPDES regulated entities that will be directly affected by this action. This table lists the types of entities that EPA is aware will be directly affected by this action."

Response to: CTR-052-004

In response to the comment that the CTR preamble is misleading when it states that municipalities and industries may be indirectly impacted by the rule, see response to CTR-022-001.

Comment: Page 42182, second column, first paragraph, uses the term "valence states" for the two forms of Cr. A more appropriate term is "oxidation state" for elements with different numbers ofelectrons in their outer shell. In chemistry, "valence" as a number has a number of different meanings which are not the same as those used in this context.

Response to: CTR-061-015

EPA disagrees with the comment that it has used the term "valance state" incorrectly with respect to its references to Chromium, and that the correct term should be "oxidation state." EPA believes the terms are interchangeable as used in this context; both terms refer to the ability of an atom to combine with other atoms.

Comment: THE RULE SHOULD BE RE-PROPOSED

The above concerns are fundamental and the recommended modifications necessary to comply with applicable laws and regulations are substantial. For these reasons, we recommend that EPA modify the Rule to account for these and other comments and then re-propose the Rule.

Response to: CTR-040-020

For analysis of the final CTR, EPA updated its Economic Analysis to reflect the most recent data and information for each sample facility and also increased the sample size for minor facilities. Based on this revised analysis, EPA estimated that minor POTWs will incur costs of approximately $5,000 per facility per year under the low cost scenario and $7,800 per facility per year under the high cost scenario. See also response to CTR-058-018.

In response to the comment requesting that EPA re-propose and re-open the public comment period, please refer to response to CTR-005-010.

Comment: Overall Conclusions

When EPA concludes that the costs and benefits of the CTR are of similar magnitude, EPA is comparing apples with oranges.

* The costs are based on the estimated costs of point source controls, which would be required as a

result of the CTR.

* The benefits are based on the assumption that nonpoint source controls, which would not be required as a result of the CTR, will be implemented (nonpoint sources are not regulated under the Clean Water Act).

The Economic Analysis is based on procedures and assumptions that greatly understate costs and benefits.

Based on estimates prepared by municipal wastewater and stormwater organizations, the costs of the CTR could be as high as $8 billion annually, almost two orders of magnitude greater than the high-end costs estimated by EPA ($85 million annually).

Based on case study analyses of benefits by municipal wastewater and stormwater organizations, the benefits of the CTR could be immeasurable and possibly even negative (For example, the CTR could force the removal of treated wastewater and stormwater from effluent dependent waters and thereby destroy the aquatic and riparian habitat created by the discharges). In large part, the absence of benefits is due to the fact (which EPA acknowledges in its analysis) that point sources are minor sources of toxic pollutants, and the fact that the major sources (i.e., the nonpoint sources) are not regulated under the Clean Water Act or the CTR.

EPA inappropriately compares costs for reducing pollutants that would be reduced as a result of the CTR (e.g., metals) with the benefits derived from the reduction of pollutants that will not be controlled as a result of the CTR (e.g., DDT).

EPA should prepare a new economic analysis using the following approach:

* Compare costs for point sources controls with benefits that will result from implementation of those controls using representative case studies.

* Compare costs and benefits on a pollutant-by-pollutant basis.

Response to: CTR-041-018

See responses to CTR-054-013a, CTR-040-042, CTR-035-057, CTR-056-018, and CTR-021-008.

Although the standards established by the CTR apply to all sources, EPA's analysis examined only the portion of benefits expected to be achieved by controlling point sources. EPA estimated the point source share of benefits based on data and information on the relative contribution of all sources to toxic loadings in California waters. Although point sources may account for only a small portion of the load in some waters, they may account for relatively larger portions at some sites, and point source controls will contribute to meeting standards in the water bodies.

Comment: In addition, we would like to emphasize the following key issues on the California Toxic Rule (CTR), which are of major impact to our storm water program:

1 . The application of water quality standards to calculate water quality-based effluent limits for NPDES permits for municipal storm water discharges. As proposed by the USEPA, the numeric water quality standards in the California Toxics Rule will be used to calculate water quality-based effluent limitations for all NPDES permits issued by the State. We believe that this position is inconsistent with the plain

language used by Congress in incorporating the "maximum extent practicable" standard for municipal separate storm sewers systems (MS4s) into section 410(p) (3) (B) of the Clean Water Act. We recommend that the USEPA modify the Preamble to clarify that MS4s are not required to comply with water quality standards.

Response to: CTR-047-001

EPA's criteria for priority toxic pollutants were developed to protect beneficial designated uses. The criteria are independent of considerations about different categories of dischargers. In implementing water quality standards, the State has some degree of flexibility in establishing NPDES permit requirements or best management practices that would be appropriate for small municipal separate storm sewer systems.

Comment: However, the Authority is greatly disappointed that EPA chose not to follow the consensus recommendations for many of the most significant issues, including the methodology used for the EA and the choice of using the most conservative carcinogenicity factor for organic pollutants.

Response to: CTR-052-003b

While EPA agrees that the methodology recommended by the State Task Force on Economic Considerations may be one adequate method for the State to calculate the costs and benefits of State adoption and implementation of water quality standards, EPA did not use this method for its own Economic Analysis (EA) for the following reasons:

* EPA's primary responsibility in developing the EA is that it meets the requirements of Executive Order 12866. For program consistency, EPA chose to model the methodology of the EA after the Regulatory Impact Analysis of the Great Lakes Water Quality Guidance which successfully underwent the full Executive Order 12866 process.

* EPA had already established its own methodology and began work on the EA nearly one year before the Task Force began meeting. In light of the substantial resources that EPA already used in its preparation of the EA, EPA could not fundamentally switch the methodology in the middle of the project due to the limited resources that could be spent on the EA. In addition, many task force members acknowledged that the consensus recommendation was a very resource intensive method and it was uncertain whether adequate data currently existed to bring this methodology to completion. EPA did not have the resources nor the data to perform this type of analysis in the time available.

* The State Task Force recommended a methodology, for future analysis by the State, that would gather ambient data to determine waters that were impaired by toxics, and then determine what actions needed to be taken by point and non-point sources to meet new water quality criteria. EPA determined that this methodology may be appropriate for future State analysis, but was not appropriate for EPA's Economic Analysis since EAs under the CWA typically estimate only costs that EPA can implement under the Clean Water Act. Therefore, EPA's EA only calculates potential costs and benefits due to controls on NPDES point sources (excluding wet-weather discharges). EPA believes it may be more appropriate for the State to estimate potential impacts on non-point sources since it has the sole authority for implementing any controls required by non-point sources.

EPA does not agree that its decision to use a 10-6 risk level for carcinogenic pollutants conflicts with any of the State Task Force consensus recommendations. EPA does not observe in the Final Task Force Report, an explicit consensus recommendation of any specific risk level for carcinogenic pollutants.

Comment: Based on these and other issues discussed in the comments submitted by Tri-TAC & CASA, we strongly urge EPA to revise its Economic Analysis, and recommend that EPA and the SWRCB work together with stakeholders to craft a revised approach that is mutually acceptable. We would be pleased to assist in such an effort.

Comment: This comment addresses the mercury criteria for continuous concentration (CCC) proposed in 40 CFR, part 131(*1). The proposed aquatic health and human health criteria do not protect aquatic life or humans from mercury contamination. This is demonstrated by the scientific data presented herein. That information includes published and unpublished results from scientists with established reputations in environmental research.

The aquatic life mercury CCC is proposed to be raised sixty-fold, from the National Toxics Rule standard of 0.012 micrograms per liter (ppb) to 0.770 ppb. The human health criteria is proposed to be raised four-fold, from 0.0 12 ppb to 0.050 ppb. These proposed changes have potentially devastating economic and environmental costs that must be included in the EPA's cost-benefit analysis. Water treatment costs for the metals mercury, silver, and chromium account for 30% of costs projected in the, California Toxics Rule (CTR) economic analysis. However, the long term environmental and economic cost of mercury contamination may far exceed the short term economic savings resulting from an increase in the mercury CCC. This is especially true in California, a mining state that has devoted hundreds of millions of dollars to restoration and enhancement of commercial and sport fisheries by enactment of Proposition 204.

The potential long-term economic and environmental costs of this proposed legislation far exceed any short-term benefits gained by raising the mandatory action level for mercury contamination. A stated goal of the recently passed Proposition 204 legislation is the protection and enhancement of commercial

and sport fishing in the State of California. To that end, hundreds of millions of dollars have been committed to water quality improvement and fish habitat restoration. Increasing the permissible mercury limits will not only hinder those goals, but will likely cause irreversible damage to the environment well into the foreseeable future.

(*1) Water Quality Standards; Establishment of Numeric Criteria for Priority Toxic Pollutants for the State of California; Proposed Rule. U.S. Environmental Protection Agency, Region Nine; U.S. Government Printing Office: Washington D.C., 1997; Federal Register, 62, 42159-42207.

Response to: CTR-091-002a

The aquatic life criteria have been updated using EPA's peer-reviewed and accepted aquatic life methodology. The previous 304(a) criteria guidance value was based on an FDA action level for humans, not on aquatic life protection. As such, the previous criteria are not as appropriate to use as the updated criteria proposed in the CTR. The revised criteria are less stringent than the previous criteria. The human health criteria proposed in the CTR have also been updated using the risk reference dose for methylmercury. The previous 304(a) criteria guidance values were based on the risk reference dose for mercury. The revised human health criteria in the CTR are more stringent than the previous human health criteria guidance.

All water quality standards are comprised of three parts: a designated use, criterion, and an antidegradation requirement. The CTR only proposes criteria. The State of California has adopted designated uses for its water bodies (called beneficial uses) in the Regional Water Board Basin Plans. The State has also adopted antidegradation provisions in each of the Regional Board Basin Plans. These provisions require that water quality in a waterbody cannot be degraded (with narrow exceptions as discussed at 40 CFR 131.12(a) (2) which allow a lowering of water quality if the State finds that it is necessary to accommodate important economic or social development). Thus, if a waterbody has achieved a certain level of cleanliness or is in a pristine condition, discharges are not allowed to degrade the water quality. Therefore, no environmental "cost" or degradation will be incurred as a result of any new or revised water quality criteria in the CTR that may be less stringent than a previously adopted objective or a criteria guidance value. Environmental benefits that have been gained in California fisheries or anywhere else cannot be destroyed.

Comment: This letter is in regards to the U.S. Environmental Protection Agency (EPA) proposing water quality standards for priority toxic pollutants in California. This is referred to as the California Toxics Rule (CTR). Due to the fact that I work in the Water Pollution Control Industry, I am following this

issue very closely. However, this letter is coming from a concerned tax payer.

As you may already know, under provisions of the Clean Water Act every state is required to have water quality standards for priority toxic pollutants. In 1994 California's version of that provision was overturned in State court due to a violation in the implementation of the rule. Subsequently, the U.S. EPA has proposed a rule in order to bring California into compliance. The criteria proposed by the U.S. EPA are extremely stringent and could cost California taxpayers hundreds of millions of dollars.

Response to: CTR-107-001

Although EPA promulgated specific criteria for the State of California under the CTR, EPA promulgated ambient water quality criteria for the entire United States, including California, under the National Toxics Rule (NTR), and the costs of the NTR are borne by dischargers in all NTR States. The [document name] compares the NTR to the CTR and demonstrates that the CTR criteria are rarely, if ever, more stringent than the NTR criteria. Thus, dischargers face a "level playing field" across California and NTR States. See also response to CTR-021-005c.

Comment: On September 17, I attended a hearing on the proposed CTR at the EPA's regional office in San Francisco. Here are some key issues from the testimony at that hearing:

* Some of the limits are below normal detection limits, therefore agencies have no background data in order to perform accurate attainability analysis.

* The cost of implementation by the EPA is grossly underestimated. The economic analysis shows a maximum implementation cost of $87 million. If preliminary estimates by publicly owned treatment works (POTW) are correct, implementation of the CTR will far exceed the $100 million provision of the Porter-Cologne Act. If this is the case, feasibility of implementation will be in jeopardy. The City of Merced, CA estimates that their additional cost would be $4 million annually. Merced has a very small treatment facility.

* Robert Reid, speaking on behalf of California Association of Sanitation Agencies (CASA), said that four San Francisco Plants estimate their total implementation costs to be $160 million annually.

* Charles Batts of Bay Area Dischargers Authority (BADA) estimated five BADA POTWs costs to be $12 million per year to meet the strict limit on copper and $56 million per year to meet the organics limit.

* The Regional Water Quality Control Board testified that San Francisco discharges twenty percent of the four percent discharged into the San Francisco Bay by POTWs, noting that POTWs are only a minor part of the volume discharged into the Bay. Thus, the reduction to the prescribed limits would cause a negligible decrease in the total mass of pollutants discharged.

* The City of Sacramento projects a $200 million annual cost will be required to meet the copper limit.

All of the testimony at the hearing echoed these concerns. I am sure that you have access to a transcript. The Clean Water Act has been and is instrumental in cleaning up our rivers, lakes, bay and estuaries. We can continue on this steady path by setting gradual attainable limits and through increased public education. Limits on pollutants should continue to get stricter, but this has to occur on a gradual curve that will not place an unreasonable burden on the individual taxpayer.

Response to: CTR-107-002a

Regarding limits being below detection levels see response to CTR-035-064.

EPA disagrees that costs are underestimated. For further discussion, see responses to CTR-040-039 and CTR-035-011a. EPA also disagrees with the $4 million annual cost estimate for Merced, the $160 million annual estimate for the four San Francisco plants, the BADA POTW cost estimates, and the $200 million cost estimate for copper for the City of Sacramento,however, no supporting data were provided for EPA to be able to evaluate these cost estimates. EPA evaluated the City of Merced facility as one of its sample facilities and estimated costs for Merced to range from $140,000 to $590,000 annually. EPA believes that pollution prevention and process optimization would be sufficient for Merced to ensure compliance with CTR-based limits. EPA also evaluated Sacramento as another sample facility and did not estimate reasonable potential for copper. EPA's cost estimate for Sacramento for the control of lead and mercury ranged from $90,000 to $320,000 annually for pollution prevention and process optimization.

EPA disagrees with the commenter that the decrease in the mass of pollutants discharged to San Francisco Bay would be negligible (as the San Francisco POTW represents only 20% of the 4% that POTWs contribute to the total mass discharged). Commercial and industrial facilities will also be required to meet CTR-based effluent limits which may result in additional reductions in mass discharges. EPA is promulgating the CTR criteria in order to protect human health and the aquatic environment which will benefit from pollutant reductions as is described in the Economic Analysis of the final CTR.

Comment: Comment #1: Application of the Analysis to San Jose

The derivation of the baseline cost models utilized in the Economic Analysis is detailed and complex. One element of Model 2, the benchmarks for the Low End and High End Cost Scenarios, can be extracted and highlighted as problematic for San Jose. Briefly, the cost of implementation of the CTR is measured by variation, at the low end, between current effluent concentrations and the concentrations which might be allowed by the CTR; and at the high end, by the difference between current permit limits and limits which might be allowed by the CTR.

The high end benchmark assumes that POTW's are already in compliance with their NPDES permit limits so that costs of "new" regulations, e.g. the CTR, can be segmented from "old" regulations, or existing permit compliance costs. In cases where a POTW is not in permit compliance on a particular element, the Model 2 high end benchmark assumes that there is no cost incurred due to federal implementation of the California Toxics Rule. This implies that any costs incurred in meeting the CTR

are really costs of getting into compliance with State regulation.

Questions for EPA on Comment #1

Q. 1 - 1) Did EPA undertake any sensitivity analysis to measure the impact of the high end assumptions on the $87 million high end cost estimate for overall CTR implementation? What if, for analytic purposes, the high end assumption was modified such that costs of attaining permit compliance (for all POTW's who are not in compliance on some element) was considered as a proxy for Rule implementation costs -- what increment of cost would be added to the $87 million estimate?

Q. 1-2) Under the existing assumptions, what share of the $87 million high end cost was attributable to the San Jose/Santa Clara POTW? What was San Jose/Santa Clara's contribution to the low end cost?

Q. 1-3) What would San Jose/Santa Clara POTW contribution be to the modified high end case, under the assumptions stated in Q. 1 - 1, above?

Response to: CTR-092-017

The methodology used to analyze each facility was described in detail in the cost report, Economic Analysis (EA), and technical support document that accompanies the record for the final rule. Following the public comment period for the proposed rule, EPA conducted a revised analysis of the potential costs and benefits of the rule (high scenario costs are estimated to be $61 million). EPA used the same methodology for estimating costs for the final rule but developed a completely updated data set for each of the sample facilities. The updated data represent the most recent three years of data available from public sources for each facility. EPA also considered any data submitted during the public comment period. Therefore, EPA's revised analysis should reflect representative information for each facility. The revised analysis of costs is again presented in detail in the EA and technical support document for the final CTR.

EPA did not estimate the costs for facilities to come into compliance with existing permit limits (see response to CTR-092-019). EPA does not agree with the commenter that this would be a suitable proxy for CTR implementation costs because ensuring compliance with existing permit limits represents costs that facilities would incur regardless of the CTR. Such an estimate would double count those costs attributable to existing state regulations and existing permit limits, instead of accounting for only those costs attributable to the CTR. See response to CTR-092-019.

Nonetheless, if San Jose's costs were evaluated as the commenter suggests (i.e., the cost of attaining permit compliance is used as a proxy for CTR implementation costs), there would be no change from EPA's current cost estimate. Twenty-one of 25 observations for copper are below the CTR-based limitand the existing permit limit. The maximum effluent concentration exceeds the existing permit limit, however, no costs other than pollution prevention costs estimated under EPA's high scenario would be incurred to ensure compliance with the CTR-based limit.

Comment: Weaknesses in Cost Analysis

The report's cost estimates exhibit a number of significant weaknesses, as follows:

* Omission of other 'baseline'' costs may act to artificially reduce USEPA's estimates.

USEPA's baseline adjustment (U.S. EPA, 1997a, page 5-7) implies that the costs associated with meeting existing requirements which are currently not being met should be excluded from the analysis. However, to the extent that these costs are higher than the report's cost limit triggers (e.g., $200/$500), both costs and the benefits associated with them should be eliminated in the analysis. That is, USEPA's assumption that dischargers will not be required to undertake improvements above a certain expense level should be carried through the entire analysis to be consistent. Alternatively, if existing requirements must be met prior to rule compliance, these costs should be estimated and reported.

Response to: CTR-035-058

EPA's economic analysis measures the potential incremental costs and benefits of the rulemaking relative to compliance with current requirements. It is not appropriate for EPA to estimate costs and benefits associated with compliance with current requirements. To the extent that costs were eliminated from the analysis, benefits (loading reductions) were also eliminated from the analysis. That is, EPA did not count benefits without counting the costs of achieving those benefits.

Comment: PROVISIONS SDG&E DOES NOT SUPPORT

As described in the following comments SDG&E does not support the following provisions:

Economic Analysis is deficient

Secondly, it was not clear from the analysis what monitoring data and/or effluent limits were evaluated in comparison to EPA's baseline (i.e., in-plant wastestreams or once-through cooling water or combined discharge of all wastestreams) and what specific methods of compliance modifications were used to estimate compliance costs. If the wastestream evaluated was the gross combined discharge, the estimated costs are potentially severely underestimated. Once through cooling water contains ambient concentrations of pollutants when it is drawn from the source water body. If these same pollutants are the reason why the discharge does not comply with the new criteria, and the plant would have to treat the once-through cooling water to achieve compliance, the costs would be in the hundreds of million of dollars in capital costs to construct the treatment facilities necessary to comply at each power plant.

Response to: CTR-060-018

The analysis of the two sample electric utilities (Pacific Gas and Electric, Hunter's Point and San Diego Gas and Electric, South Bay) does not indicate that ambient water used for cooling would need to be treated because of the CTR. For instance, influent monitoring reports for the Hunter's Point facility indicate that all metals were consistently reported below detection levels with the exception of zinc that was detected, however, not at concentrations of concern. EPA believes that the source of pollutants in electric utilities is low volume waste such as from lubricating and metal cleaning processes. These operations generate low flow, high concentration effluents that are discharged together with cooling waters. In cases of infrequent non-compliance, as with copper at Hunter's Point, process optimization is sufficient to ensure compliance. In cases of more severe non-compliance, waste stream separation and treatment may be recommended.

Comment: B. Cost Analysis p. 2-1 (U.S. EPA, 1997b) - Model I Baseline in Cost Analysis

Model I assumes that, in the absence of the CTR, the State would, pursuant to the NPDES regulations rely on the narrative standards in Basin Plans to establish numeric water quality-based effluent limits in permits. EPA thereby contends that permit limits adopted under Model I could be based on the latest EPA 304(a) criteria. Under this scenario, EPA believes that permit limits would be "nearly identical" to those that would result from implementation of the CTR criteria, and that "the costs and benefits of the CTR would be negligible since implementation of permits under the CTR would not differ significantly from how the State may implement permits under current law." We believe this to be a flawed analysis, and that EPA must delete or modify the Model I baseline. EPA's suggestion that EPA's action has no impacts is equivocal: either EPA is taking an action in proposing the rule or it is not. If it is not taking an action, then it need not propose a rule. If it is taking an action, then this action must have implications. In any case, we believe the analysis is flawed. Under federal regulations (40 CFR section 122.44(d)(iv)), in the absence of the CTR, State permit writers could utilize many more documents than just the 304(a) criteria when adopting permit limits based on narrative standards. These sources of information could easily result in effluent limits that are more or less stringent than the CTR-proposed criteria. Thus, the Model I baseline is fundamentally flawed.

Response to: CTR-035-045

See responses to CTR-035-058 and CTR-021-005c.

EPA believes that the use of 304(a) criteria provides a reasonable estimate of current regulatory requirements because the criteria represent its national recommendations. Additionally, if permit writers deviate from the criteria, they must have a basis for doing so. For example, using field data to modify the criteria on a site-specific basis would require an amendment to the rule.

Comment: Weaknesses in Cost Analysis

The report's cost estimates exhibit a number of significant weaknesses, as follows:

* The assertion that a plausible alternative baseline (i.e., "Model I ") would indicate "no impacts" from the USEPA's rule is weak:

-- Either USEPA is taking an action in proposing the rule, or it is not. If it is not taking an action, then it need not propose a rule. If it is taking an action, then this action must have implications.

-- By definition the baseline cannot be some mythical state action that would occur if USEPA did nothing. The baseline, as described further in the Rule, is current regulation, which at this point reflects no state action in this area. If and when the state issues a regulation, the USEPA Rule can be compared with the state rule to determine benefit and cost differences.

-- The color of money stays the same whether federal or state governments take action. That is, affected parties are indifferent as to who is "scored" with water quality costs.(*5)

-- If there are potentially no costs, there are likewise potentially no benefits, an outcome which is not provided equal credence in the Analysis.

USEPA's Model I approach in this rule is the opposite of the tactic it took in proposing the 1994 State Implementation Plan (SIP) to meet air quality requirements. In Its analysis of this action USEPA provided estimates of SIP costs in the face of no state action, despite the fact that California was required to meet federal air quality standards.

(*5) However, whether the federal or state government is deemed responsible for rule costs may have important legal implications (e.g., different requirements for economic analyses).

Response to: CTR-035-057

See response CTR-040-026.

EPA believes that the potential benefits of the rule are reasonably similar to the potential costs. EPA also notes that, as described in the EA, the estimate of benefits may be underestimated as a result of omitted benefit categories while the estimate of costs was based on assumptions that tend to overstate costs. For example, reductions in noncancer health effects are omitted because there are currently few means of linking consumption of toxic contaminants by humans with cases of systemic effects (as opposed to cancer effects, for which dose-response curves have been estimated). Other omitted benefit categories include instream and near stream recreational activities other than fishing (e.g., boating, swimming, picnicking, and related activities). EPA believes other recreation benefits may be appreciable because these activities have been shown in empirical research to be highly valued, and even modest changes in participation or user values could lead to sizable benefits statewide. Some of these activities can be closely associated with water quality attributes (e.g., swimming) and others might increase due to their association with fishing, swimming, or other activities in which the participants might engage.

EPA recognizes that the benefits of the rule will not occur immediately, and has estimated lags in the realization of benefits. However, EPA believes that the standards established by the CTR can be achieved through point source controls and will result in attaining designated uses of the water bodies, and that the estimated benefits are illustrative of the types and potential benefits to be achieved from attaining these uses.

Comment: EPA's Model 1 Scenario erroneously assumes that without the CTR, implementation of the States narrative criterion "would likely result in permit limits that are nearly identical to those that would result from implementation of the CTR criteria." On the contrary, this is highly unlikely based on: (1) the Water Code requirements to consider economics in establishing objectives and adopting permits; (2) the court decision that threw out the same EPA criteria because the State failed to consider economics and other factors by the Water Code; and (3) most basin plans do not contain language that authorizes direct utilization of the criteria in implementing the narrative toxicity objective. In fact, EPA's assertion, quoted above, is contradicted a few paragraphs later: "...since the plans were revoked, permit writers no longer use the criteria contained in the plans." (see page ES-2). In fact, in the three years since the State Plans were rescinded, very few permits have been issued with limits based on EPA criteria.

Response to: CTR-040-026

EPA disagrees with the comment. EPA believes that in the absence of the CTR, implementation of the state narrative criterion would likely result in permit limits nearly identical to those that would result from implementation of the CTR criteria. While it is true that EPA acknowledged in the EA that new effluent limits are not likely to be based on the criteria contained in the old Inland Surface Waters Plan and Enclosed Bays and Estuaries Plan since these plans were withdrawn by the State, EPA has observed that, in several recently issued permits, the State has developed new effluent limits based on EPA recommended 304(a) criteria. EPA's 304(a) criteria are nearly identical to the CTR criteria. Therefore, EPA believes that its statement about the State's use of narrative criteria does not contradict itself as the commenter asserts.

Comment: Several fundamental problems exist with the analysis that was conducted in Section 2 "Methodology" of the "Analysis of Potential Costs Related to the Implementation of the California Water Quality Toxics Rule" document. Given flaws in the methodology, the results presented in Appendices I-B, II-B, and IIIB are misleading at best and in some cases incorrect. The following is a summary our comments regarding the methodology used and the results presented.

METHODOLOGY

* Page 2- 10 states: "For any pollutant for which a limit for a toxic pollutant existed in the current NPDES permit for a sample facility, it was assumed that a reasonable potential existed to exceed a CTR based limit and the pollutant was included for further analysis." This is an unreasonable assumption because many local regulators have been resistant to exclude pollutants with no reasonable potential to exceed the permit limit from NPDES permits. In other words, it is very common to find pollutants regulated in NPDES permits which either have not been detected or have been detected in levels significantly below the permit limits. Therefore, assuming that a reasonable potential to exceed the permit limit exists simply because a toxic pollutant is listed in the NPDES permit, is an incorrect assumption. Further, the propagation of this error leads to incorrect economic implications.

Based on the TSD and properly computed effluent limits, a reasonable potential analysis first needs to be conducted for each toxic pollutant to determine a maximum projected effluent quality, and that value then needs to be compared to the CTR based limit to determine if there is a reasonable potential for the limit to be exceeded. If there is a potential for the limit to be exceeded, economic estimates may then be made. In the analysis that was conducted, a reasonable potential to exceed the effluent limit was assumed for each constituent with an effluent limit in the NPDES permit, and potential costs were computed based on the difference between the current and future effluent limits regardless of plant performance. Clearly, this is a flawed, incorrect, and misleading approach,

* WLA[subs]a and WLA[subs]c are based on theoretical partitioning factors. These may or may not be representative of the conditions noted in site specific water bodies. A translator study, conducted specifically for the City of Sunnyvale demonstrates that the relationship between the partition if coefficient and TSS is not nearly as strong as that between the translator and ln(TSS) (the natural logarithm of TSS). WLA would be better computed using a site specific translator, wherever data are available. City of Sunnyvale calculations following guidance described in EPA 823-B-96-007 (The Metals Translator: Guidance for Calculating a total Recoverable Permit Limit from a Dissolved Criterion), demonstrate that significantly different results may be obtained from those presented in Exhibit 2-8 when site specific data are used;

* Another variable which significantly affects the values used to convert from dissolved criteria to total criteria is TSS. The TSS value used to compute the partitioning factor found in Exhibit 2-8 is 15 mg/L, which is lower than any data observed by the City of Sunnyvale between September 1989 and February 1991. Those data indicate that a more representative although still conservative value would be approximately 35 mg/L;

* Summary statistics of the dataset used are needed for each constituent (mean, standard deviation, and coefficient of variation). Further, the full datasets used for the analysis should be included as an appendix so that data trends may be inspected. Typically, as was the case with Sunnyvale but ignored in this analysis, metals concentrations decreased as source control measures have been implemented.

* Identification and exclusion of statistical outliers from the analysis is a critical step which is not addressed in Section 2 "Methodology". Since, the reasonable potential analysis estimates the projected maximum concentration for each constituent on the maximum observed value in the given dataset, identification and exclusion of outliers from the analyses must be considered.

* Table I-B-4 (and II-B-4, and III-B-4) should show the following columns: Reasonable Potential Analysis Projected Maximum Concentration; CTR based WQBEL; Flag; Maximum Observed Concentration; Flag. This structure would make the analyses much clearer. The determination of constituents of potential concern should then be conducted as follows: compute the projected maximum projected concentration for each pollutant, compute conservative estimates of CTR based limits (based on standard translators and TSS values), and compare the CTR based limit to the projected maximum reasonable potential value and the maximum observed concentrations. Constituents of potential concern will be those whose projected maximum concentrations are greater than the CTR based WQBEL.

Further, it needs to be noted that care must be taken to compare the projected maximum concentration with the correct (MDL or AML) CTR limit to determine if a reasonable potential exists to exceed the limit. This will primarily be a function of monitoring frequency. However, it appears that this step was overlooked in the preliminary analyses presented in Appendices I-B, II-B, and III-B. The analyses in those appendices (refer to Table I-B-4) compares the existing limit ("existing high end") to the CTR average monthly limit ("CTR"), and then bases economic extrapolation on that comparison. For example, the current daily limit for silver, 2.3 mg/L is compared to the computed average monthly CTR limit of 1.76 mg/L, and the conclusion is drawn that the City will need to decrease the amount of silver in the effluent. A more reasonable comparison would have been to compare the projected maximum concentration to the proposed CTR daily maximum limit.

* LTAs were computed using the 95%ile for chronic WLAs and the 99%ile for acute WLAs, without an explanation for the apparent disparity. Since in many cases the chronic WLA is lower than the acute WLA, the resultant CTR derived permit limits are based on the 95%ile rather than the 99%ile (e.g. a lower limit than would have been obtained if the 99%ile values were used). In order to determine if a reasonable potential exists for a pollutant to exceed a given permit limitation, consistency is necessary. It is suggested that all computations (reasonable potential analysis and CTR based WQBEL) be based on the same standard, so that the implications of the ensuing comparisons are clear. Further, a 99%ile standard is recommended to more fully account for the lognormal nature of pollutant concentrations in treated water.

* It is stated that "Costs were estimated for any pollutant for which either effluent concentrations or existing permit limitations were greater than the CTR-based WQBEL". As noted above, this analysis should be conducted only on pollutants with a reasonable potential to exceed the CTR-based WQBEL

otherwise economic computations will solely be based on the difference between old and new limits without any consideration to plant performance.

* Finally, high end scenario costs are "Based on the difference between an existing permit limit and the WQBELS". It cannot be overemphasized this is unreasonable, because there may be no reasonable potential to exceed this limit. This methodology implies that simply because an effluent limit is in an NPDES permit, a reasonable potential exists to exceed that limit, which is fundamentally incorrect.

Response to: CTR-021-017

* EPA disagrees with Sunnyvale's comment that it is unreasonable to assume that reasonable potential exists for a pollutant when it has a permit limit in its existing NPDES permit. First, EPA determines whether there is reasonable potential to exceed water quality criteria, not permit limits. Second, EPA acknowledges that the Regional Boards may base the decision to assign reasonable potential on methodologies other than those selected from the Technical Support Document for Water Quality-based Toxics Control (U.S. EPA, 1991). For example, EPA is aware that current permitting practices of some Regional Boards in the State of California include assigning permit limits to pollutants identified in the fish tissue report or pollutants included in the 303(d) list of impaired receiving water bodies. EPA incorporated the presumptions of these particular methodologies by assigning reasonable potential in the high scenario when a permit limit exists.

* Sunnyvale stated that EPA incorrectly based high scenario costs on the difference between an existing permit limit and the CTR-based effluent limit when there may be no reasonable potential to exceed the limit. EPA stands by its methodology to assign reasonable potential in the high scenario because of the existence of a permit limit (see above). EPA's methodology would, if anything, overstate potentialcompliance costs in the high scenario because it assumes that the discharger discharges the pollutant at concentrations of concern and that measures may need to be taken to control the pollutant. That is, EPA's methodology may result in estimates of compliance costs that will not be incurred.

* Sunnyvale also indicated that in the draft analysis, potential costs were computed based on the difference between the current and future effluent limits, regardless of plant performance. This statement is incorrect. Where data are available, cost decisions in the high and low scenarios are based on plant performance. However, in the absence of data, EPA's methodology tends to err on the side of estimating higher costs. EPA's rationale for its cost estimates for Sunnyvale is presented in Appendix B of the Technical Support Document for the final Economic Analysis.

* EPA agrees that site-specific translators for metals would better represent the conditions of site-specific water bodies. Therefore, EPA used site-specific translators in its final Economic Analysis whenever they were available. For example, EPA used a copper site-specific translator of 2.6 for Sunnyvale.

* In the final Economic Analysis, EPA does not use a total suspended solids (TSS) value of 35 mg/L for Sunnyvale. EPA instead used a TSS default value of 15 mg/L, which generally provides a more stringent limit for TSS dependent pollutants than using a TSS value of 35 mg/L. Regardless, TSS does not have an effect on the costs estimated for this particular facility because the two metals with reasonable potential (copper and silver) have metals translators which are not dependent on TSS. EPA used a site-specific translator for copper (2.6) and a default translator value (2) for silver because theoretical partitioning coefficients were not available.

* Sunnyvale requested that summary statistics of the data be presented in the analysis and that effluent

monitoring data be included as an appendix. Presently, the Technical Support Document for the Economic Analysis of the CTR does not include these data. However, the effluent data are publicly available and may be obtained from the Permit Compliance System Database (PCS).

* The revised Economic Analysis does not have a methodology to exclude outliers from the sample during reasonable potential and permit limit derivation. As a result, effluent variability may be greater than what it would be when outliers are extracted from the data set. A greater variability is reflected in larger projected effluent qualities (i.e., greater probability of receiving reasonable potential) and more stringent effluent limits, and, therefore, may result in higher costs. Thus, using all data points for the analysis may result in more conservative (i.e., higher) cost estimates. In addition, in order to fit data to a statistical distribution and to identify outliers, a large enough sample (e.g., greater than 20 observations) is required to ensure accuracy. EPA did not have large data sets for most of the sample facilities in the analysis. Despite this, EPA did try to consider outliers and outdated data by using both a cost decision matrix and best professional judgement to estimate costs. However, because of limited data and conservative assumptions, EPA's estimates may tend to overstate cost impacts.

* Sunnyvale proposed analyzing reasonable potential by comparing the projected effluent quality to the projected CTR-based limit. EPA considers this comparison unnecessary because, in the low scenario, EPA's estimate of reasonable potential is already based on projected effluent quality. EPA's reasonable potential approach compares projected effluent quality against water quality criteria, instead of projected CTR-based limits as recommended by Sunnyvale. Because CTR-based limits for metals are expressed as total concentrations and water quality criteria are dissolved, it is likely that Sunnyvale's methodology will result in fewer pollutants with reasonable potential and smaller costs than EPA's approach. EPA's reasonable potential methodology is based on the Technical Support Document for Water Quality-based Toxics Control (U.S. EPA, 1991) and EPA recognizes that its costing methodology may be moreconservative (i.e., erring on the side of higher costs) than other methodologies that could have been used, such as the one suggested by Sunnyvale.

* Please see response to CTR-021-012 regarding the use of the average monthly limit instead of the maximum daily limit to estimate projected compliance costs. Sunnyvale also has suggested estimating compliance costs by comparing the projected effluent quality to the projected CTR daily maximum limit. EPA does not believe that this comparison would be useful for the analysis, because, in addition to the explanation provided in the response to CTR-021-012, the Agency believes that the use of limited data and statistical procedures to determine compliance is an overly conservative approach. EPA would not use such an approach to establish compliance with water quality based limits or criteria (see CTR-040-004) and greater uncertainty would be introduced into the analysis by estimating costs based on statistically projected values rather than actually measured effluent data.

* Sunnyvale indicated that long-term averages (LTA) were computed using a 95% probability basis for chronic waste load allocations (WLA) and a 99% probability basis for the acute WLAs. This statement is incorrect. Acute and chronic LTAs both were calculated using a 99% probability basis. The probability basis selected for the analysis is provided in Section 5.5.4, Probability Basis (page 110), of the Technical Support Document for Water Quality-based Toxics Control (U.S. EPA, 1991). As indicated in that section, when a permitting authority does not have specific guidance for selection of the probability basis, LTAs are calculated using a 99th percentile level for both chronic and acute LTAs.

* Sunnyvale stated that since, in many cases, the chronic WLA is lower than the acute WLA, the resultant CTR-derived permit limit is based on the 95 percent probability rather than the 99% probability (i.e., a lower limit than would have been obtained if the 99% probability values were used). EPA believes that Sunnyvale has misunderstood the methodology used to derive permit limits. The average

monthly limit (AML) and the maximum daily limit (MDL) both are based on the most stringent (i.e., smaller) of the human health and the aquatic life acute and chronic LTAs. The AML is calculated by multiplying the smallest LTA times a multiplying factor that will result in a concentration that is the 95 th percentile level of a lognormal distribution with an upper bound equal to the chronic WLA. The MDL, on the other hand, is obtained by multiplying the smallest LTA times a multiplying factor that will result in a concentration that is the 99 th percentile level of a lognormal distribution and is less than the acute WLA. In other words, the MDL is greater than the AML mainly because it is calculated to be greater than 99% of the effluent concentrations while the AML is calculated to be greater than only 95% of the effluent concentrations. Refer to Table 5-2, Calculation of Permit Limits (page 103), of the Technical Support Document for Water Quality-based Toxics Control (U.S. EPA, 1991) for a list of multiplying factors at different probability levels. Note that the number of samples per month (n) is also used to calculate the AML.

* Sunnyvale requested that all computations (i.e., multipliers) be based on the same percentile levels in order to maintain consistency. As indicated above, the revised economic analysis of the final CTR uses the 99th percentile level to calculate LTAs. In addition, maximum daily limits (MDL) are also based on the 99th percentile level. The average monthly limits (AML), however, cannot be calculated using the same percentile level because this may result in effluent limits that are not protective of water quality. In particular, when the minimum LTA is the LTA based on chronic criteria, the resulting AML would be equal to the WLA based on chronic criteria. While individual exceedances of the AML are permitted, the WLA should never be exceeded; thus an AML calculated using the same percentile level as the MDL would not ensure compliance with chronic aquatic life criteria.

* Sunnyvale suggested that the projected effluent quality value be based on a 99% confidence level anda 99% probability basis. EPA revised its analysis to calculate projected effluent quality values using these confidence level and probability basis values.

Comment: * In general, we are pleased that EPA prepared an analysis of the economic impacts of the proposed CTR, and that a major portion of EPA's work focused on determining the potential impacts on POTWs. However, we believe that this analysis is based on improper assumptions and inaccurate cost estimates, resulting in unconvincing conclusions. Detailed comments can be found in Attachment 2. A few of the areas of concern are listed below:

* Small facilities appear to be under represented in EPA's sample of POTWS, especially for minor dischargers.

* The cost triggers used as regulatory relief thresholds are unrealistic, and are not consistent with EPA regulations and policies.

* The assumptions used to determine cost estimates for indirect dischargers appear to omit a large proportion of potentially affected industries.

* The Economic Analysis does not take into account projected population and industrial growth over time, which may influence effluent quality and quantity. Statewide, the population is projected to grow by nearly 50% by 2020.

* The use of average cost estimates masks economic impacts on individual dischargers, which may be particularly acute for small communities.

* The economic Analysis ignores the costs that may be incurred by stormwater dischargers and nonpoint sources to reduce loadings so that CTR criteria may be met in ambient waters.

Comment: pp. 2-24 - 2-32 (U.S. EPA, 1997b) - Cost Triggers for Alternative Regulatory Approaches The use of the $200 and $500 cost thresholds significantly skewed potential costs downwards by assuming that when those cost thresholds are reached, regulatory relief options would be pursued successfully, despite the fact that dischargers have absolutely no guarantees that such options will be successful, In the Preamble, in fact, EPA indicates that options such as variances and site-specific criteria will rarely, if ever, be granted. In addition, POTW experiences to date in California suggest that it is unlikely that such options will be successful. Thus, the basic premise of the analytic approach used to determine costs needs to be reconsidered. Incidentally, we also believe that the costs attributed to such activities were seriously underestimated. Information we are familiar with suggests that many of the regulatory alternatives EPA examined can cost up to several million dollars (per pollutant) (e.g. TMDLs, UAAs). Thus, we suggest that in the future when calculating the costs for such activities, EPA should use a range where $200,000/pollutant is the low end scenario and $2,000,000/pollutant is the high end scenario.

Comment: Although EPA goes to great length to label its cost analysis as "conservative" the analysis is anything but conservative:

* It is not conservative to assume that if the cost per toxic pound equivalent removed is greater than a certain threshold, the discharger would receive regulatory relief and therefore incur no treatment cost. (It is difficult to understand how EPA could rationalize basing the estimate of CTR costs on the assumption that there would be relief from the CTR if the costs were too high, especially when the CTR itself does not provide for such relief.)

Comment: EPA's cost analysis relies on an unofficial yard stick for feasibility and regulatory relief ($200 to $500 per toxic pound equivalent removed) that is different and considerably lower than the official yard stick for feasibility that is set forth in EPA's affordability guidelines. EPA uses its affordability guidelines in considering many forms of regulatory relief (e.g., dedesignation of uses). EPA's affordability guidelines set a much higher threshold. For example under these guidelines, reverse osmosis has shown to be affordable at several large POTWs.

Comment: Finally, EBMUD has serious concerns about the accuracy of EPA's draft, Economic Analysis, particularly as it pertains to the cost and benefits estimates found in the draft CTR. We believe that the costs of the CTR are significantly underestimated and the benefits are inflated. On the cost side, there are several "flaws" which should be reevaluated:

* The use of assumptions which would tend to underestimate cost.

Response to: CTR-056-018

Based in part on the comments received by EPA on the costs estimated for the proposed CTR, EPA collected new data and information for each of the sample facilities. As a result, EPA revised its estimates of costs and benefits for the final CTR.

A direct comparison of the monetized annual (steady-state) benefits of the CTR and annualized costs shows benefits and costs to be generally commensurate given the uncertainty in the analysis and that several categories of benefits are unmonetized. The low estimate of monetized benefits is $8.7 million per year and the high estimate is $40.8 million per year. Annualized costs are $33.5 million under the low scenario and $61.9 million under the high scenario.

Discounted benefits are lower than discounted costs. However, the assumption that capital is replaced every 10 years likely overstates costs. At the same time, benefits may be understated because some categories are not monetized and full benefits may be realized sooner than 10 or 20 years. Thus, EPA expects that the present value of benefits and costs is more commensurate than shown.

Comment: Economic Analysis

The Sanitation Districts commends EPA for preparing an analysis of the economic impacts of the proposed CTR, and for selecting POTWs for half of the case studies. We believe that EPA is correct in thinking that POTWs are likely to experience major impacts as a result of the promulgation of the CTR. However, we believe that this analysis is based on improper assumptions and inaccurate cost estimates, resulting in unconvincing conclusions. Our own attainability and cost analysis indicates that there are indeed fundamental flaws in the cost analysis. A few of the areas of concern are listed below:

* The cost triggers used as regulatory relief thresholds are unrealistic, and are not consistent with EPA regulations and policies.

Comment: The subject rule has a significant impact on our facility discharge and the citizens of the City. We therefore present the following comments for your consideration to re-open the comment period for this rule in order to facilitate a more complete review by public and in particular by those in the POTW community:

* The draft economic analysis seems to have serious flaws. It under-estimates the cost of the draft CTR and overstates the benefits. In the cost analysis USEPA should re-evaluate the representativeness of samples used and the omission of impacts on many factors that contribute to loadings, and hence, can be expected to have to reduce their loadings (e.g., small indirect dischargers, municipal and industrial stormwater dischargers, agricultural activities, and other nonpoint sources); the incorporation of numerous assumptions that underestimate costs, and the assumption to artificially remove costs that exceed threshold values by assuming that regulatory relief measures will be granted, despite the fact that they are not automatically granted through triggers included as part of the proposed regulation.

Comment: The areas with which we find concerns and the requested changes include the following:

* The draft Economic Analysis has, from our short review, some serious flaws. It underestimates the costs of the draft to implement the CTR and overestimates the benefits. For the cost analysis, EPA should re-evaluate the representativeness of the sample used; the omission of impacts on many sectors that contribute to loadings and, therefore, can be expected to have to reduce their loadings (e.g., small indirect dischargers, municipal and industrial stormwater dischargers, agricultural activities, and other nonpoint sources); the incorporation of numerous assumptions that underestimate costs; and your assumption that artificially removes costs that exceed threshold values be assuming that regulatory relief measures will be granted, despite the fact that they are not automatically granted through triggers included as part of the proposed regulation.

Comment: Comment #6: General Cost Analysis Concerns

The City of San Jose has several generalized concerns about the costs utilized in the Economic Analysis, which raise questions regarding the validity of that analysis, as follows:

Q.6-1) We believe the real point of undertaking the CTR is to assure water quality throughout State that protects beneficial uses. How can the existing Economic Analysis be sufficient if it does not address the cost of meeting the CTR standards from all sources of discharge? Especially given the amount and cost of aggressive intervention in reducing point source pollution undertaken in California to date?

Q.6-2) Throughout the text of the CTR and within the Economic Analysis, EPA refers repeatedly to the assumption that the State will provide regulatory relief to mitigate severe cost impacts engendered by the CTR. What happens to EPA's cost benefit analysis if even one of those assumptions of regulatory relief is not implemented by the State? While we support EPA's attempt to indicate available regulatory options for the State, local level governments and POTW's have little past experience on which to rationalize acceptance of such assumptions.

Q.6-3) EPA has not estimated the cost to local governments/POTW's/indirect dischargers of securing regulatory relief, nor has that cost been incorporated into the estimate of the CTR impact. How would EPA estimate the cost of securing regulatory relief and how would that additional cost affect the Economic Analysis? Especially since very costly studies may be required in order to qualify for regulatory relief.

Q.6-4) The preamble to the CTR discusses the linkage between the CTR and the National Toxics Rule, and EPA's intent to create a level playing field by setting the CTR standards within the National Toxics Rule Framework. There does not seem to have been a similar attempt to analytically level the playing

field vis a vis implementation costs, however, as no indexing or calibration has been undertaken to account for the cumulative costs of efforts to date (see also Q. 4-3), cost equivalency data is rooted in experience outside California, and simple average costs are used to represent widely variable ranges. How would the CTR cost/benefit relationship be affected by adjusting for California's significant previous efforts on water quality control mechanisms and California cost data?

Comment: It is with a sense of reluctance that Sunnyvale joins in CASA/Tri-TAC's adverse comments on the CTR and the EA, and Sunnyvale does so in a spirit of constructive criticism and with an expectation that the Agency will make the necessary adjustments in its approach towards the CTR before the final rule is promulgated. In addition, in the same spirit and with the same expectation, Sunnyvale would like to make the following points on its own behalf:

2. Obligation to Assess Alternative Cancer Risk Levels for Human Health-Based Criteria. Sunnyvale is gravely concerned that EPA has used the wrong approach in proposing to establish human health criteria for organic pollutants, particularly those pollutants for which the proposed criteria are below the method level of detection ("MDL"). Sunnyvale recommends that EPA should thoroughly assess all of the potential impacts, including costs and benefits, of the 10E-4 and 10E-5 risk levels before proposing the human health-based criteria. As pointed out in the EOA Letter, there is a significant potential for advancing technology to lower the MDL for many pollutants to the point where laboratory equipment is able to measure some or all of the organic compounds for which EPA is proposing to establish criteria at the new level. It is intuitively obvious that the costs of attaining criteria set at the 10E-6 level will be significantly greater than attainment of a 10E-5 or 10E-4 level, particularly where, as pointed out in the EOA Letter, the only available method of treatment is granular activated carbon. Sunnyvale is concerned that the EA does not adequately address the potential for these costs, and, consequently, does not take these potential costs into account in determining whether to exercise its flexibility in choosing whether to use a 10-4 , 10-5 or 10-6 cancer risk level as the basis for its CTR promulgation.

EPA is required by Executive Order 12866, the Regulatory Flexibility Act and the Unfunded Mandates Reform Act to identify and analyze alternatives to a proposed rule. We cannot understand, therefore, why EPA has done such a cursory analysis in the preamble to the CTR and the EA of the alternatives to the use of the most stringent (10E-6) risk level for establishing criteria for human health effects of pollutants, particularly organic pollutants. EPA cannot base its selection of the 10E-6 level based upon previous regulatory pronouncements by the State of California. Any new determination by the State will be subject to the analytical requirements of Section 13241 of the Porter-Cologne Act and by review by the Office of Administrative Law. Thus, it is not a foregone conclusion that the State will ultimately select the 10E-6 level. EPA has its own legal requirements to fulfill. Accordingly, we ask that EPA not promulgate the final human health criteria for the pollutants of concern unless and until it has adequately analyzed the costs and other implications of the various alternatives to the 10E-6 level.

In conclusion, we are entirely supportive of many of EPA's innovative approaches towards development of the CTR, particularly as regards the toxic metals. However, we believe that EPA has needlesly failed to comply with many of its legal obligations, particularly as regards the development of human health-based criteria on cancer risk levels of organic pollutants. We urge the Agency to reconsider its position in the matters covered by this letter (as amplified by the EOA Letter) and the CASA/Tri-TAC letter. Sunnyvale pledges its continued participation in place-based watershed management planning in the South Bay, its cooperation with the Agency in making a success of the WPI, and to an ongoing effort by the Agency and others to reach water qulaity goals in the South Bay. We thank you for the opportunity to comment on the proposed CTR.

Response to: CTR-021-005c

With respect to the Regulatory Flexibility Act (RFA), and as stated in the preamble to the proposed and final rules, the RFA requires agencies to assess the economic impact of a rule only on small entities that are subject to the requirements of the rule. Today's rule does not impose any impacts on small entities.

Under the CWA, states have the primary responsibility for implementing water quality standards. [See e.g., Scott v. City of Hammond, Ind., 741 F.2d 992, 994 (7th Cir. 1984).] Unlike technology-based effluent limitations guidelines which are required to be implemented into NPDES permits, 40 CFR 122. 44(a), and for which EPA conducts regulatory flexibility analyses if the RFA standard is met, states have considerable discretion in developing effluent limits for point sources as necessary to meet water quality standards.

Water quality standards consist of three elements: designated uses, which establish water quality goals for water bodies in the State (which may take into account economic considerations), water quality criteria sufficient to protect those uses (based on science without regard to cost), and an antidegradation policy to maintain water quality. 40 CFR 131.6. Water quality criteria are ambient levels or concentrations or narrative statements representing conditions necessary to protect a designated use. 40 CFR 131.3(b). Once EPA establishes water quality criteria, the end to be achieved, the State has considerable flexibility in determining the means to achieve those ends in NPDES permits, TMDLs and other water quality programs. This flexibility means that while the State's implementation of federally-promulgated water quality criteria may result in new or revised discharge limits being placed on small entities, the criteria themselves apply to water bodies, not to any dischargers, including small entities.

In issuing a permit limit, there are various mechanisms a state may use including: mixing zones, pollutant loading allocations, effluent trading, and water-effect ratios. The State also has the ability to adopt variances, designated use reclassification, and site-specific criteria if appropriate and necessary. Each of these authorities may be applied by the State when it issues an NPDES permit. In addition, the State may have authority to control water quality in other ways independent of the CWA NPDES program, such as establishing controls over non-point sources, water quantity, zoning, best management practices (such as tree planting to lower temperature and runoff or fish ladders to improve fish spawning). These mechanisms, if successful, may affect the need for or substance of a water-quality based effluent limit. Thus, because it is the State that issues the permit and because the State in implementing the criteria may apply any or all of the above authorities, these criteria alone, in and of themselves, do not impact any small entity.

Consistent with this statutorily-mandated division of responsibilities between the states and the federal government under the CWA, EPA in the CTR has set state-wide ambient criteria for toxic pollutants, but has left to the State the primary responsibility for determining how to regulate point source dischargers

and non-point source dischargers tomeet the standards. Thus, EPA's certification of the CTR under section 605(b) of the RFA is consistent with (and a direct consequence of) the design of the CWA.

Further, attempting to apply the RFA analysis to water quality criteria setting does not make sense. Most importantly, this is because water quality criteria apply to the waterbody and must protect the designated use. As such, tailoring water quality criteria to vary depending on the size of a discharging entity is not possible. See Response to Comment CTR 042-007a. Also, because water quality criteria do not apply to small entities, and because states are free to adopt whatever mix of control measures they deem necessary, it is unclear to what extent states will seek discharge reductions from small entities. Finally, the water quality criteria themselves contain no regulatory or informational requirements applicable to small entities and thus cannot be tailored to fit the scale of those entities.

EPA recognizes that it has undertaken an economic analysis pursuant to E.O. 12866 for this rule. This analysis, however, makes numerous assumptions and does not necessarily predict how the state will implement the criteria. Thus, the economic analysis represents EPA's best estimate of the costs of the rule and given the broad flexibility the state has in implementing the criteria, the costs may even be lower. In addition to this analysis, EPA did an analysis of state and local implementation procedures that may have an impact on NPDES permit holders and indirect dischargers, entitled Implementation Analysis of Ambient Water Quality Criteria for Priority Toxic Pollutants in California. These analyses constitute an analysis equivalent to a regulatory flexibility analysis.

EPA believes that CTR criteria by themselves do not directly impose economic impacts. As a result, EPA believes that the rule is not significant within the meaning of Executive Order 12866. Criteria are one of three parts of a water quality standard. A water quality standard is comprised of: a criterion, a designated use, and an antidegradation requirement. The CTR promulgates criteria for priority toxic pollutants. When these criteria are combined with State adopted designated uses and antidegradation requirements, water quality standards will be created. When the State implements these water quality standards, costs may be imposed based on many yet unknown factors including the community's decision that such costs are reasonable and appropriate to protect designated uses. Nevertheless, in the spirit of the intent of E.O. 12866, EPA prepared the EA which looks at the potential costs and benefits of the State's implementation of the resulting water quality standards based on the CTR criteria into the NPDES permit program.

EPA disagrees with the commenter's assertion that EPA may not have complied with Executive Order 12866. EPA fully complied with Section 6(a)(3)(a) of the Executive Order which requires each agency to provide OMB with a list of its planned regulatory actions, indicating those which the agency believes are significant regulatory actions.

EPA categorized the CTR as "not significant" and submitted to OMB, a draft copy of the proposed CTR along with a draft economic analysis. After review of this material, OMB agreed with EPA's determination that the proposed rule was not significant within the meaning of the Executive Order, and waived its 90-day review period for the proposed CTR. EPA performed an economic analysis even though this type of analysis is only required for significant regulatory actions within the scope of section (3)(f)(1) of the Executive Order. Therefore, even though EPA categorized the proposed CTR as "not significant", EPA fulfilled the Executive Order requirements as if it were a significant rule.

For further discussion of how today's rule complies with Executive Order 12866, the Unfunded Mandates Act, and the Regulatory Flexibility Act, see the preamble to the final rule and EPA's economic analysis of the final rule.

Comment: It is with a sense of reluctance that Sunnyvale joins in CASA/Tri-TAC's adverse comments on the CTR and the EA, and Sunnyvale does so in a spirit of constructive criticism and with an expectation that the Agency will make the necessary adjustments in its approach towards the CTR before the final rule is promulgated. In addition, in the same spirit and with the same expectation, Sunnyvale would like to make the following points on its own behalf:

3. Failure to Address Important Stormwater-Related Issues. In addition to its POTW, Sunnyvale is the owner of a system of storm drains which contribute wet weather flows to the South Bay. We are concerned that the EA entirely neglects the potential impacts of the proposed CTR on the storm drains. The EA entirely omits any meaningful analysis of the costs of bringing storm drains into compliance with the proposed CTR, thereby significantly understating the overall costs of the CTR. We believe that this omission is violative of the Agency's legal obligations under the authorities cited in the preceding paragraph.

In addition, we join in the comments being filed by the various other operators of stormwater collection systems to the effect that EPA has overstated the legal requirements for storm drains to comply with numerical criteria.

Response to: CTR-021-006b

EPA did not include benefits or costs of controlling nonpoint sources or storm water dischargers in its estimates of benefits and costs of the CTR. EPA believes that the final rule will not have a direct effect on sources not permitted under the NPDES program (e.g., nonpoint sources) or NPDES sources not typically subject to numeric water quality-based effluent limits (e.g., wet weather discharges) beyond those already being implemented under current state programs. The CTR language allows (consistent with EPA's policy) the practice of applying maximum extent practicable (MEP) to MS4 permits, along with BMPs as effluent limits to meet water quality standards where infeasible or insufficient information exists to develop water quality-based effluent limits. Any potential indirect effect on nonpoint sources and wet weather discharges, such as runoff from farms, urban areas, and abandoned mines, and contaminated sediment, is unknown at this time. Many of the programs developed to control nonpoint sources and wet weather discharges are already in place in the State of California. Costs due to these programs have already been incurred or will soon be incurred owing to existing federal, State, and local environmental programs. EPA evaluated the comments and analyses submitted by commenters providing costs for controlling nonpoint sources and none of these comments provided a definitive argument that

storm water dischargers cannot achieve compliance with the proposed water quality criteria or that compliance would result in widespread economic impact or hardship.

EPA also acknowledges that nonpoint sources and wet weather discharges are technically difficult to model and evaluate costs because they are intermittent and highly variable. Nonpoint source and wet weather discharges also occur under different hydrologic or climatic conditions than continuous discharges from industrial and municipal facilities, which are evaluated under critical low flow or drought conditions. Thus, evaluating agricultural nonpoint source discharges and storm water discharges and their effects on the environment is highly site-specific and data intensive.

Comment: b. If the CTR as proposed in the current draft is applied to municipal storm water dischargers so as to require numeric effluent limitations in municipal stormwater permits, the cost to the public will be phenomenal. In the economic analysis of the CTR, EPA failed to consider these costs, and failed to consider the costs to industrial storm water dischargers as well.

The District Is urban storm water drainage system captures through retention 90% of its annual average runoff, and discharges 90% after detention (1% is directly discharged without treatment). The system cost in 1997 dollars is estimated at $500 million.

The only option available to the District to mitigate violations of the proposed criteria would be to expand system storage to capture 100% of average annual runoff. Increasing system storage by 20,000 acre feet (estimated additional storage required for average years), at the current cost of $11,000-$20,00 per acre foot of storage, would result in a capital expenditure of $220,000,000 to $400,000,000.

Even with this exorbitant investment, in approximately half of the rain seasons storage would be exceeded, and 100% of the discharges would be expected to exceed the dissolved metals criteria noted above.

Smaller cities (under 50,000) in California are currently subject to NPDES municipal storm water discharge permits, and many more will be included upon implementation of the Stormwater Phase II program. EPA's failure to assess economic impacts on small cities would appear to be contrary to the requirements of the Federal Regulatory Flexibility Act.

The District includes in its constituency industrial businesses. The District serves these businesses and

assists in the oversight of their pollution prevention and storm water permit compliance efforts. Regardless of EPA' s approach to applying the CTR to municipal storm water permits, industrial storm water dischargers are directly and seriously affected by application of the CTR. EPA's failure to assess these economic impacts on our communities is short-sighted and a breach of good public policy.

Response to: CTR-031-006c

See responses to CTR-021-006b and CTR-040-026. For discussion of the applicability of the Regulatory Flexibility Act to this rule, see the preamble to the final rule.

Comment: Finally, we have serious concerns about the accuracy of the draft Economic Analysis and the estimates of the costs and benefits of the draft CTR (see detailed comments in Attachments I and 2). Our primary concerns related to the cost analysis include 1) that the case studies on which the cost analysis is based do not adequately represent the actual population of POTWs in California; 2) the omission of costs that could be incurred by many sectors that contribute to overall loadings, and, hence, can be expected to have to reduce their loadings (e.g., non-SIU indirect dischargers, municipal and industrial stormwater dischargers, agricultural activities, and other nonpoint sources of CTR-regulated pollutants); 3) the use of numerous assumptions that underestimate costs; and 4) the capricious removal of costs that exceed threshold values by assuming that regulatory relief measures will be granted, despite the lack of any proposed regulatory relief trigger in the proposed regulation.

To illustrate the degree of underestimation of costs for the POTW sector alone, we looked at potential compliance costs for the POTW sector. We found that the potential costs for 23 major POTWS. on an annualized basis, may reach $400 million. We believe that this analysis demonstrates that the potential cost consequences of compliance with effluent limits based on the proposed CTR criteria would easily exceed the $ 100 million annual cost threshold, especially when the costs of all 313 POTWs in the State are estimated. Thus, we believe that EPA must conclude that the proposed CTR could have significant economic impacts on local governments.

Comment: In summary, we believe that, contrary to EPA's conclusion, the proposed regulation is a significant regulatory action pursuant to Executive Order 12866 and the Unfunded Mandates Reform Act. The CTR may well impose costs that exceed $100 million per year on the regulated community, the majority of which are local public agencies, and this will have a significant impact on local governments. By another measure, by promulgating 190 new criteria for California (for about 70 different pollutants), of which 70 (37%) have been recalculated, modified, or added by EPA since the 1992 promulgation of the National Toxics Rule, the CTR certainly is a "significant regulatory action,"(*1) Further, the Agency fails to make a "reasoned determination that the benefits of the intended regulation justify its costs," as required by Executive Order 12866 or a determination that the Agency selected "the least costly, most cost-effective or least burdensome alternative" as required under the Unfunded Mandates Reform Act. Hence, in our estimation, EPA must completely overhaul the Economic Analysis, and it must be reviewed by the Office of Management and Budget because the CTR is a significant regulatory action.

(*1) These numbers include aquatic life and human health criteria that were promulgated for California in the 1992 NTR but which have been modified or recalculated and are being reproposed in the CTR.

Response to: CTR-035-010

See response to CTR-021-005c.

For a discussion of the Agency's compliance with UMRA and Executive Order (EO) 12866, see the preamble to the final rule. Although EPA was not required to conduct a regulatory impact assessment, EPA chose to conduct one. EPA believes that its analysis has shown that the benefits of the rule justify the costs. However, under the Clean Water Act, water quality criteria are not established based on costs but are based on sound science to protect designated uses of the waters. Further, such criteria are to be based on EPA's section 304(a) criteria recommendations, EPA's 304(a) criteria recommendations modified to reflect site-specific conditions, or other scientifically defensible methods. From the outset of the national water quality standards program, EPA has explained that while economic factors may be considered in designating uses, scientific and technical factors must justify criteria to meet those uses. Also see response to CTR-042-007a.

Comment: II. Compliance with Federal Executive Orders and Statutes pp. 42188-42190 -- Executive Order 12866, Regulatory Planning and Review EPA claims that it is not subject to certain requirements of the Executive Order because the Administrator has determined that the CTR is not a "significant regulatory action" within the meaning of Section 3(f)(1) of the E.O. We believe that EPA was incorrect in making this determination, for the following reasons: (1) the annual costs of the CTR will be far in excess of the $ 100 million threshold (see additional discussion below); (2) the CTR will without question materially adversely affect state and local governments; and (3) the CTR is likely to have a material adverse effect on one or more sectors of the economy, with a prime example being Silicon Valley, the heart of America's high technology industry, which happens to be located around the southern portion of San Francisco Bay. EPA itself identifies three sectors that will bear most of the projected costs of implementing the proposed rule. POTWs, chemical and petroleum industries, and metals and transportation equipment (collectively, these three sectors represent 93% and 97% of the annual costs under the low and high cost scenarios, respectively) (U.S. EPA, 1997b, pp. 3-3 and 3-7). We also believe that the proposed CTR is significantly different from rules that have been promulgated previously, including the National Toxics Rule ("NTR") (40 CFR 131.36) and the Great Lakes Initiative ("GLI") (60 Fed. Reg. 15366). While both of these previous rules promulgated water quality criteria for toxic pollutants, many of the criteria included in the CTR have been recalculated since the NTR was -promulgated in 1992 (70, or 37%, have been modified, recalculated, or added), the GLI served a somewhat different purpose than does the CTR (i.e. compliance with the Great Lakes Critical Programs Act of 1990), and, most importantly, those rules did not apply to California.(*2) Therefore, the economic analyses for those rules did not include an analysis of the economic impacts on California.

We believe that EPA also failed to fulfill its obligations under E.O. 12866, as follows: EPA did not seriously explore available regulatory alternatives, including the option of not regulating; EPA did not make a "reasoned determination that the benefits of the intended regulation justify its costs;" and EPA did not take into account the cost of cumulative regulations. In particular, we believe that for pollutants where the criteria are below commonly found laboratory detection levels, EPA did not fulfill its obligation to analyze the potential costs and benefits of the promulgation of these criteria. Because of this lack of compliance with the requirements of E.O. 12866, EPA should select the alternative of not regulating them at this time. As our ability to detect specific chemicals improves, then EPA may proceed with promulgation, provided all legal responsibilities are met. For all of the above-stated reasons, we believe that EPA must revise the CTR, and its economic analysis of the CTR, to comply with E.O. 12866.

(*2) With the exception of the NTR, which partially applied to California. However, the proposed CTR by definition does not duplicate the criteria in the NTR which already apply to California, unless revised criteria are being proposed.

Response to: CTR-035-039

Executive Order (EO) 12866 does not negate the Clean Water Act requirement that States have numeric

criteria for toxic pollutants for which EPA has issued 304(a) guidance. Within EO 12866 there are caveats to the application of the EO including section 1(a): "unless a statute requires another regulatory approach," and section 1(b): "to the extent permitted by law and where applicable."

See responses to CTR-021-005c and CTR-042-007a and the preamble to the final rule for discussions relating to the rule's compliance with EO 12866.

Comment: Cost to Implement the Proposed Rule

The inclusion of municipal stormwater discharges under the proposed rule renders the economic analysis invalid, noting municipal studies that show that stormwater discharges cannot comply with all of the proposed criteria with anything short of major national or regional product substitutions, or end-of-pipe treatment:

The Fresno Metropolitan Flood Control District conducted an attainability analysis on stormwater discharges from its urbanized area detention basins. The analysis showed that even with pollutant reductions in the basins, the proposed criteria would not be met.

The Sacramento Stormwater Program conducted an attainability analysis and found that even with an aggressive BMP program the urbanized area would not achieve certain of the water quality criteria, and that the cost of treatment would be on the order of $2 billion.

A preliminary attainability analysis conducted by Orange County, based on a limited dataset, indicates similar findings to Fresno and Sacramento in spite of the implementation of a significant BMP program over a multi-year period (see Attachment 2).

A nationwide attainability study, conducted by American Public Works Association in 1992, estimated capital costs and annual operations costs to be $406,734,900,000 and $542,036,700,000. Significantly, these estimates omitted the costs associated with engineering, administration, permitting and land acquisition.

Even if end-of-pipe treatment were to be implemented for all urban stormwater, the contribution of toxic pollutants from this source is so minor (less than 3% according to the economic analysis) that they could not be justified by the marginal water quality benefits achieved. Clearly a rule that is known from the outset to inevitably result in massive expenditures which provide little water quality benefit or inevitable municipal noncompliance is not appropriate for California.

The rulemaking process of the federal government is obligated to fully explore the economic implications of the proposed regulatory action through compliance with Executive Order 12866, the Unfunded Mandates Report Act, of 1995 (the "Reform Act"), and the Regulatory Flexibility Act (the "RFA"). In its economic analysis EPA appears to have understated costs and circumvented these requirements resulting in a lack of disclosure of the true impacts of the Rule.

Executive Order 12866 requires any "significant" federal regulatory action to be referred to the Office of Management and Budget for review before it can be approved. In this context a "significant" action includes one which will "have an annual effect on the economy of $100 million or more or adversely affect in a material way the economy". Though admitting that there "may be a cost to some dischargers" to comply with water quality standards which will be derived from these toxics criteria, EPA nonetheless argues that the proposed rule is not a significant action because it "establishes ambient water quality criteria which. by themselves, do not directly impose economic impacts." [62 Fed. Reg. 42188].

First nothing in E.O. 12866 indicates that only actions with direct economic impacts are to be considered by OMB. Second, for EPA to ignore the link between the toxics criteria contained in the proposed rule and the obligations they impose is unfounded.

In short, EPA cannot have it both ways. It cannot indicate that stormwater discharges are subject to the proposed toxics rule and then turn a blind eye toward the costs associated with implementation of this rule. The costs of the proposed rule are direct and significant, greatly exceeding the annual $100 million threshold, and therefore the rule must be submitted to OMB for review.

Comment: A further consequence of the flawed economic analysis is the conclusion that the CTR is not a major rule (i.e., one which will result in excess of $100 million per year expenditure) subject to Presidential Executive order 12866 and the Unfunded Mandates Reform Act or a rule that affects small entities protected under the Regulatory Reform Act. The District, for example, is a small community having a population of under 50,000 and, in addition, serves several small towns and communities (Sonoma, Glen Ellen, Boyes Hot Springs and Agua Caliente) that would be greatly impacted by the proposed rule.

Comment: 5. The proposed rule is inconsistent with applicable Federal law and regulations. In proposing a single set of criteria for all estuaries, the rule is inconsistent with the Clean Water Act and EPA's water quality standards regulations. The Clean Water Act requires that water quality standards be established taking into consideration their use and value for public water supplies, propagation of fish and wildlife, and recreational purposes (see CWA section 303(c)(2)(A)). Consistent with this, EPA regulations require that water quality standards be based on identification of "specific water bodies where toxic pollutants may be adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern..." For those identified waters, "states must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use" (See 40 CFR 131.11(a)(2)). Clearly the intent of both the Clean Water Act and EPA regulations is that water quality standards be tailored to the characteristics of the waters in question. In failing to properly evaluate the rule's economic impacts and in failing to adequately consider regulatory alternatives, the rule is inconsistent with Presidential Executive Order 12866 and the Unfunded Mandates Reform Act. Moreover, in failing to properly consider the impacts on small entities, such as the District and the small communities it serves, the rule is inconsistent with the Regulatory Flexibility Act.

Comment: 7. Separate, sites-specific aquatic life criteria for copper and human health criteria for mercury should be adopted for Schell Slough, or alternatively EPA should specify implementation procedures for these criteria that will preclude unreasonable controls such as end-of-pipe treatment. To comply with the Clean Water Act and EPA regulations, EPA should consider specific water bodies. To fulfill the spirit of Presidential Executive Order 12866 and the requirements of the Unfunded Mandates Reform Act and the Regulatory Flexibility Act, EPA should evaluate regulatory alternatives based on an analysis of costs and benefits. Based on the assessment of costs and benefits described in "3" above, EPA should either adopt the criteria that is currently achieved, or alternatively specify implementation procedures that would allow the current discharge to continue (e.g., allowable Mixing zones and averaging periods and, for copper, a translator and water-effect ratio). Again, the District is amenable to continuing to address these constituents through pollution prevention measures and to assessing the actual impacts of these constituents in Schell Slough. Without EPA specifying such implementation procedures in the CTR, it is possible that the CTR could impose significant costs on the District (and the other small communities its serves) without providing a commensurate environmental benefit. In that case, the CTR would be inconsistent with the Clean Water Act, EPA regulations, Presidential Executive Order 12866, the Unfunded Mandates Reform Act and the Regulatory Flexibility Act.

Comment: MAJOR CONCERNS

We do, however, have fundamental concerns with the Rule as it is presently proposed and its supporting economic analysis. We believe the Rule can be modified in a manner that will be responsive to our concerns while at the same time being consistent with applicable Federal law and regulations. Our major concerns are presented here and are followed by our recommended modifications.

II. Concern: The economic analysis upon which the Rule is based is seriously flawed.

* A consequence of the cost/benefit analysis of the Rule are several erroneous conclusions, namely that: (1) this is not a "significant regulatory action" or a major rule (i.e., one which will result in excess of

$100 million annual expenditure) subject to the requirements contained in Presidential Executive Order 12866 and the Unfunded Mandates Reform Act; and (2) this is not a rule that will have a significant economic impact on a substantial number of small entities protected under the Regulatory Flexibility Act.

Comment: 8. The proposed Rule is Inconsistent with Applicable Federal Law and Regulations

The proposed rule is inconsistent with applicable Federal law and regulations. In proposing a single set of criteria for all estuaries, the rule is inconsistent with the Clean Water Act and EPA's water quality standards regulations. (See attached Legal Analysis of the Proposed California Toxics Rule) to properly evaluate the rule's economic impacts and in failing to adequately consider alternative criteria for San Francisco Bay Area waters, the rule is inconsistent with Presidential Executive Order 12866 and the Unfunded Mandates Reform Act (Id). In failing to properly consider the impacts on small entities, the rule is inconsistent with the Regulatory Flexibility Act (Id).

Thank you for the opportunity to provide comments on this important new rule. Please call if you have any questions regarding our letter.

Comment: 2. The California Toxics Rule is inconsistent with Executive Order 12866 and the Unfunded Mandates Reform Act.

a. Executive Order 12866

Executive Order (E.O.) No. 12866 was decreed by President Clinton on September 30, 1993. This Order governs review of agency regulations and sets standards that federal agencies should use in planning, drafting, and reviewing regulations. E.O. 12866 requires agencies to:

- Assess all of the costs and benefits of available regulatory alternative, including the alternative of not regulating;

- Propose or adopt a regulation only upon a reasoned determination that the benefits of the intended regulation justify its costs;

- specify performance objectives, rather than specify the behavior or manner of compliance, to the extent feasible;

- Tailor its regulations to impose the least burden on society, taking into account, among other things,

the cost of cumulative regulations;

- Afford the public a meaningful opportunity to comment on any proposed regulation, which in most cases should include a comment Period of not less than 60 days;

- Explore and, where appropriate, use consensual mechanisms for developing regulations, including negotiated rulemaking.

EPA contends that the CTR is not a "significant regulatory action" requiring an economic analysis under the terms of E.O. 12866.(*3) This contention by EPA is erroneous since BADA's attainability analysis shows that the cost to BADA alone may exceed the $100 million cut-off for determining whether a rule is a "significant regulatory action."

Furthermore, the standard for becoming a "significant-regulatory action" is, among other things, that the proposed rule is likely to have annual effect on the economy of $ 100 million or more, OR adversely affect in a material way the economy, the environment, or local governments. Thus, EPA should not be able to allege that this is not a "significant regulatory action" because the CTR will be likely to adversely affect the economy and local governments even if the $100 million cut-off were not met.

Moreover, EPA failed to seriously explore available regulatory alternatives, including an option of not regulating; did not make a "reasoned determination that the benefits of the intended regulation justify its costs;" did not allow a 60-day comment period; and did not seriously take into account the cost of cumulative regulations.

(*3) See 62 Fed. Reg. 42,188 (Aug, 5,1997)("It has been determined that this rule is not a "significant regulatory action" under the terms of Executive Order (E.O.) 12866 and is therefore not subject to OMB review").

Comment: 7. The CTR may violate the Administrative Procedures Act, the and Unfunded Mandates Reform Act (UMRA) Executive Order (E.O.) No. 12866.

In the Preamble to the CTR, EPA repeatedly claims that the CTR will not result in expenditures of more than $100 million per year and, therefore, the statutory requirements of the UMRA and E.O. 12866 are not triggered.(*1) Caltrans' annual costs alone and only in Los Angeles will exceed the $100 million annual figure, even assuming the lowest level of treatment. Therefore, EPA's cost assumptions are challengeable as being arbitrary and capricious and in violation of the Administrative Procedures Act.(*2)

Request: Caltrans requests that EPA reconsider its cost estimates based on the comments received during the public comment period.

Caltrans would like to thank EPA for the opportunity to provide comments on this proposed regulation. It is hoped that EPA will consider and address Caltrans' comments in the final version of the CTR. Should you have any questions concerning our comments on the CTR, please feel free to address these questions to Marcia Arrant at (916) 657-5381.

(*1) See CTR, 62 Fed. Reg. at 42,188, and at 42,191 ("EPA has determined that this rule does not contain a federal mandate that may result in expenditures by State, local and tribal governments, in the aggregate, or by the private sector, of $100 million or more in any one year.")

(*2) See American Iron and Steel Institute v. EPA, 1997 WL 297251 (D.C. Cir., 1997)(the court found that EPA had arbitrarily failed to adequately address cost-justification for its elimination of mixing zones. EPA had estimated the total cost of elimination mixing zones for bioaccumulative chemicals of concern (BCCS) from all dischargers to the Great Lakes at $200,000, without even acknowledging a comment estimating the cost to one town for removal of mercury from its sewage discharge would be approximately $300,000).

Response to: CTR-042-007b

With respect to the commenter's criticism of the GLI decision, see CTR-042-007a. See CTR-021-005c for an explanation of how the Economic Analysis for the final CTR complies with EO 12866 and UMRA.

Cost estimates provided in the California Department of Transportation (Caltrans) analysis of compliance with the CTR may mix best management practices (BMPs) implementation costs to comply with local storm water permits with new compliance costs resulting from the CTR. EPA's Economic Analysis only evaluates the incremental impact of the water quality standards for toxics compared to the baseline program to avoid a double counting of costs (and benefits). For a detailed discussion of Caltrans' comments, see CTR-040-004.

Comment: 5. The proposed rule is inconsistent with applicable Federal law and regulations.

In proposing a single set of criteria for all estuaries, the rule is inconsistent with the Clean Water Act and EPA's water quality standards regulations. The Clean Water Act requires that water quality standards be established taking into consideration their use and value for public water supplies, propagation of fish and wildlife, recreational purposes (see CWA section 303(c)(2)(A)). Consistent with this, EPA regulations require that water quality standards be based on identification of "specific water bodies where toxic pollutants may be adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern..." For those identified waters,"states must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use"(See 40 CFR 131.1 I (a)(2)). Clearly the intent of both the Act and EPA regulations is that water quality standards be tailored to the characteristics of the waters in question. In failing to properly evaluate the rule's economic impacts and in failing to adequately consider regulatory alternatives, the rule is inconsistent with Presidential Executive Order 12866 and the Unfunded Mandates Reform Act. Moreover, in failing to properly consider the impacts on small entities, the rule is inconsistent with the Regulatory Flexibility Act.

Comment: We have reviewed the proposed CTR and offer the following comments:

5. The proposed rule is inconsistent with applicable Federal law and regulations.

In proposing a single set of criteria for all estuaries, the rule is inconsistent with the Clean Water Act and EPA's water quality standards regulations. The Clean Water Act requires that water quality standards be established taking into consideration their use and value for public water supplies, propagation of fish and wildlife, recreational purposes (see CWA section 303(c)(2)(A)). Consistent with this, EPA regulations require that water quality standards be based on identification of "specific water bodies where

toxic pollutants may be adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern..." For those identified waters, "states must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use"(See 40 CFR 131.11 (a)(2)) (see Exhibit G). Clearly the intent of both the Act and EPA regulations is that water quality standards be tailored to the characteristics of the waters in question. In failing to properly evaluate the rule's economic impacts and in failing to adequately consider regulatory alternatives, the rule is inconsistent with Presidential Executive Order 12866 and the Unfunded Mandates Reform Act (Id.). Moreover, in failing to properly consider the impacts on small entities, such as the City, the rule is inconsistent with the Regulatory Flexibility Act (Id.).

Response to: CTR-044-006b

See responses to CTR-021-005c, CTR-036-005, and the preamble to the final rule.

The NOAA data included five bays (San Diego, Humboldt, Monterey, Santa Monica, and San Pedro), two of which are actually covered by the CTR (San Diego and Humboldt). EPA assumed that the data for the nonenclosed bays generally will be applicable to enclosed bays. If EPA had excluded those bays not covered by the rule, the attribution assumption for point sources would actually be higher (see EA, Chapter 7). For example, for urban bays, the toxic-weighted average contribution of point sources is higher for the enclosed bay covered by the rule (San Diego Bay; 91%) compared to the nonenclosed bays (Santa Monica and San Pedro, at 88% and 83%, respectively). EPA employed toxicity-weighting to estimate relative source contribution because the toxicity of the discharge, more than volume, will influence its impact on receiving waters. The California 1996 303(d) report lists both point and nonpoint sources as probable sources of pollution for Santa Monica Bay. The list of pollutants and stressors for Santa Monica Bay includes metals, DDT, and PCBs.

Comment: We have reviewed the proposed CTR and offer the following comments:

8. EPA should not adopt criteria for any pollutant where the method detection limit exceeds the objective and there is insufficient detectable, reliable data to determine if the pollutant could reasonably be expected to interfere with designated uses. The proposed rule includes criteria for a number of constituents where there is insufficient data to determine whether the discharge of such pollutants could reasonably be expected to interfere with the designated uses. EPA has chosen to promulgate criteria for these constituents even though section 303 (c)(2)(B) of the Clean Water Act requires States to adopt numeric criteria only for constituents "... the discharge or presence of which in the affected waters could

reasonably be expected to interfere with those designated uses adopted by the State, as necessary to support such designated uses." Clearly, this approach goes beyond the requirements of the Clean Water Act and is therefore unnecessary. Additionally, this approach does not allow EPA to fulfill its duty (under Presidential Order 12866, the Unfunded Mandates Reform Act, and the Regulatory Flexibility Act) to assess the costs, benefits, and impacts of the rule on local government and small entities. While this may be the conservative approach for EPA, it places dischargers throughout the State at risk. As analytical detection limits improve, dischargers may find they are unable to achieve the criteria without costly end-of-pipe controls. But, by then, it will be too late for EPA to evaluate the costs and benefits of the criteria-and-consider alternative criteria. For these reasons, EPA should not adopt criteria for those constituents. If EPA does adopt criteria for those constituents, EPA should evaluate the costs and benefits of toxic criteria, as well as alternative criteria, using worst case assumptions (i.e., assume that discharge levels and ambient levels are at the detection limits).

Response to: CTR-044-009b

See responses CTR-044-033, CTR-021-005c, CTR-004-002, CTR-005-009, and CTR-035-064.

EPA defined toxic-impaired waters as waters rated medium or poor quality for at least one or more toxic pollutant or group of pollutants. EPA acknowledged that this definition may result in an overestimate of toxic-impairment (EA Chapter 8). However, the rating of these waters corresponds to EPA's categories of 'not fully supporting' and 'partially supporting' designated uses. The existence of waters not supporting and only partially supporting designated uses is indicative of the need for and benefits associated with pollution controls.

Comment: 2. The California Toxics Rule is inconsistent with Executive Order 12866 and the Unfunded Mandates Reform Act.

a. Executive Order 12866

Executive Order (E.O.) No. 12866 was decreed by President Clinton on September 30, 1993. This Order governs review of agency regulations and sets standards, that federal agencies should use in planning, drafting, and reviewing regulations. E.O. 12866 requires agencies to:

- Assess all of the costs and benefits of available regulatory alternatives, including the alternative of not regulating;

- Propose or adopt a regulation only upon a reasoned determination that the benefits of the intended

regulation justify its costs;

- Specify performance objectives, rather than specify the behavior or manner of compliance, to the extent feasible;

- Tailor its regulations to impose the least burden on society, taking into account, among other things, the cost of cumulative regulations;

- Afford the public a meaningful opportunity to comment on any proposed regulation, which in most cases should include a comment period of not less than 60 days;

- Explore and, where appropriate, use consensual mechanisms for developing regulations, including negotiated rulemaking.

EPA contends that the CTR is not a "significant regulatory action" requiring an economic analysis under the terms of E.O. 12866. This contention by EPA is erroneous since the standard for becoming a "significant-regulatory action" is that the proposed rule is likely to have annual effect on the economy of $100 million or more, OR adversely affect in a material way the economy, the environment, or local governments. Thus, EPA should not be able to allege that this is not a "significant regulatory action" because the CTR will be likely to adversely affect the economy and local governments even if the $100 million cut-off were not met.

Moreover, EPA failed to seriously explore available regulatory alternatives, including an option of not regulating; did not make a "reasoned determination that the benefits of the intended regulation justify its costs;" did not allow a 60-day comment periods, and did not seriously take into account the cost of cumulative regulations.

Comment: Based on our analysis of the impact of the proposed CTR, we will need to utilize reverse osmosis to meet the proposed CTR limits for copper. Based on this modification, we estimate that our potential annualized costs for compliance will be approximately $900,000. These costs are significantly higher than EPA's estimated costs per plant of $27,000 per year to $480,000 per year. Thus, we strongly believe that the draft Economic Analysis significantly underestimates the potential statewide costs associated with adoption of the CTR and should be revised.

Response to: CTR-045-012b

EPA received a number of comments regarding the ability of existing treatment technologies to meet CTR-based WQBELs for a wide variety of pollutants. The CTR, consistent with the Clean Water Act (CWA) and the National Pollutant Discharge Elimination System (NPDES) program, does not direct facilities on how to comply with permit requirements. Therefore, each regulated facility can consider a variety of options to comply with permit requirements. In estimating compliance costs, EPA selected control options for the sample facilities by taking into consideration treatment feasibility and cost.

In an effort to ensure consistency in estimating the general types of controls that would be necessary for a sample facility to comply with the final CTR, as well as to integrate into the cost analysis the alternatives available through CWA and NPDES permit programs, EPA developed and utilized a decision matrix. The underlying assumption of the decision matrix is that a facility will examine least-cost alternatives prior to incurring the expense and potential liabilities associated with constructing end-of-pipe treatment facilities. Additionally, for the low scenario only, EPA assumes that where current treatability data indicate that end-of-pipe treatment cannot achieve the WQBEL, a regulatory alternative measure, such as phased total maximum daily loads/water quality assessments, site-specific criteria modifications, standards variances, etc., will be utilized.

Under the decision matrix, EPA considered costs for minor treatment plant operation and facility changes first. Where it was not technically feasible to simply adjust existing operations, waste minimization/pollution prevention controls were considered; however, these controls were selected only where they were considered feasible based on EPA's understanding of the processes at a facility. In general, detailed treatment and manufacturing process information is not available in NPDES permit files. Therefore, EPA's assessment of feasibility was primarily based upon best professional judgement using general knowledge of industrial and municipal operations. If waste minimization was deemed not feasible to reduce pollutant levels to those needed to comply with the final Guidance criteria, EPA considered a combination of waste minimization/pollution prevention and simple treatment. If these relatively low-cost controls could not achieve the CTR-based WQBELs, then, finally, EPA assigned costs for end-of-pipe treatment.

It should be noted that under the low scenario, EPA provided one additional cost assumption. Before assuming that treatment would be installed by the facility, EPA first considered whether or not the treatment had been shown to achieve the requisite effluent concentration, and evaluated the relationship between the cost of adding the treatment versus other types of remedies or controls. If EPA concluded that treatment was not technically feasible, or that other remedies or controls would be more feasible than installing end-of-pipe treatment, EPA assumed that a facility would alternatively pursue regulatoryoptions for relief from the WQBEL. When EPA assumed that facilities would pursue a regulatory alternative, no end-of-pipe treatment cost was estimated for a facility; however, a nominal cost for efforts to reduce the pollutant using best available control methodologies was included. Where regulatory alternatives were utilized, EPA did not take credit for any load reduction for any pollutant for which regulatory alternatives were assumed. Finally, EPA estimated and included the typical cost to facilities pursuing alternatives to CTR-based WQBELs. These costs may include activities such as additional monitoring, performing special studies, etc., to support facilities' requests for alternatives to CTR-based WQBEL.

EPA's revised per plant cost estimates are $61,000 to $325,000 per year for POTWs for the low and high cost scenarios in its Economic Analysis of the final CTR. These costs are based on analyzing a sample of facilities and extrapolating to the whole universe of POTWs. Because these values represent averages for the universe of facilities throughout the state, it is possible that costs may be higher for some facilities

and that others may have very low or zero costs.

Given Sausalito-Marin City Sanitary District's (SMCSD) effluent concentration of 22 ug/L and the proposed CTR limit provided in the comment of 15.3 ug/L, a 30.4% loading reduction would be required. Since SMCSD does not provide other details of its current operations, it is not possible for EPA to evaluate whether reverse osmosis is the only feasible option which would ensure compliance with the CTR-based limit. However where sample facilities commented that they would need to install reverse osmosis and provided data to that effect, EPA's analysis of that data found that reverse osmosis would not be necessary.

Comment: IV. EPA Has Not Complied With Applicable Regulatory Review Requirements. There are several significant statutes and executive orders that require EPA to undertake analyses of the costs and benefits of its regulations, and to submit the regulations and analyses to other governmental bodies, including the Office of Management and Budget (OMB) and Congress. Those authorities include the Regulatory Flexibility Act, the Small Business Regulatory Enforcement and Fairness Act (SBREFA), the Unfunded Mandates Reform Act, the Congressional Review Act, and Executive Order 12866 (Regulatory Planning and Review). EPA apparently believes that it does not need to comply with any of those requirements for this rulemaking. (62 Fed. Reg. at 42188-42191). API believes that EPA is required to meet those obligations for the proposed criteria, and that the Agency's rationale for avoiding this responsibility has no legal basis.

EPA supports its decision not to comply with the regulatory review statutes by stating that the proposed criteria "by themselves, do not directly impose economic impacts." (62 Fed. Reg. at 42188). EPA admits that when those criteria are combined with the designated uses that have been adopted by the State, and implemented in permit limits, "there may be a cost to some dischargers." (62 Fed. Reg. at 42188) could be substantial; the Agency itself estimates that the compliance cost could be between $15 and $87 million per year.(62 Fed. Reg. at 42189). (That does not include indirect costs to the economy, which would surely put this rule above the $100 million impact threshold specified in several of the regulatory review statutes listed above.) EPA cannot ignore those costs by creating its own interpretation of those statutes in which only "direct" impacts need be considered. There is no support in the statutory language or legislative history for such a reading, and EPA has cited no such support in its Federal Register notice.

There is another problem with EPA's rationale for avoiding regulatory review: if EPA were right that "indirect" impacts do not trigger those reviews, the impacts of this rulemaking are not really "indirect."

Those impacts emerge clearly once the proposed criteria are combined with the State's designated uses. Those designations have already been established, so there is nothing uncertain or indefinite about that aspect of the water quality standards. Then, once the standards are completed, the State must implement those standards through permit limits. While there are some decisions that the State must make in determining the proper permit limits, which can influence the size of the compliance costs, EPA can readily determine a range of possible costs. In fact, the Agency has already done so, resulting in the $15 - $87 million cost range discussed above. While those costs may not be fixed with certainty, they are certainly "direct economic impacts". Therefore, even if the Agency were correct in looking at only "direct" impacts, this rulemaking poses such impacts, and EPA must comply with the statutory requirements to conduct and submit cost and benefit analyses of its proposed criteria.

V. CONCLUSION

As explained above, EPA's proposal to issue water quality criteria for toxicities in the State of California suffers from serious legal flaws. API urges the Agency to reconsider its intended course of action in light of the issues raised in these and other public comments. If you have any questions regarding these comments, or would like any additional information, please call Theresa Pugh at 202/682-8036.

Comment: C. RECOMMENDATIONS FOR MODIFICATIONS TO THE CTR AND EA

EPA should revise the proposed rule and economics analysis such that they are consistent with applicable Federal law and regulations. In proposing a single set of criteria for all estuaries, the rule is inconsistent with the Clean Water Act and EPA's water quality standards regulations. In failing to properly evaluate the rule's economic impacts and in failing to adequately consider alternative criteria for San Francisco Bay Area waters, the rule is inconsistent with Presidential Executive Order 12866 and the Unfunded Mandates Reform Act. In failing to properly consider the impacts on small entities, the rule is inconsistent with the Regulatory Flexibility Act. Specific citations for these inconsistencies are contained in comments from BADA and CASA/Tri-TAC.

Comment: Separate, scientifically defensible, reasonably achievable aquatic life criteria for copper should be adopted for San Francisco Bay, or alternatively EPA should specify in the Preamble implementation policies for copper that will result in reasonable control measures actions. To comply with the Clean Water Act and EPA regulations, EPA is required to consider specific water bodies. To fulfill the spirit of Presidential Executive Order 12866 and the requirements of the Unfunded Mandates Reform Act, EPA is required to evaluate regulatory alternatives based on an analysis of costs and benefits. Based on BADA's analysis of costs and benefits, EPA should either adopt copper criteria that are reasonably achievable or alternatively specify implementation policies that will avoid costly end-of-pipe controls. Potential implementation measures that could be specified include use of the following in calculating effluent limitations: actual dilution based on modeling studies; copper translators; probability of compliance less than 99.9%; and water-effect ratios determined for different segments of the Bay. Unless EPA specifies these or similar implementation policies in the rule, it is possible that the CTR could result in significant costs ($12 million per year to $78 million per year) while resulting in minor environmental benefit (a 1% reduction in copper loading to the Bay). In that case, the CTR would violate the Clean Water Act, EPA regulations, Presidential Executive Order 12866, the Unfunded Mandates Reform Act and the Regulatory Flexibility Act. (see the discussion under Item 11 below.)

CROSS REFERENCES B Comment Period

Comment: 2. The California Toxics Rule is inconsistent with Executive Order 12866 and the Unfunded Mandates Reform Act.

a. Executive Order 12866

Executive Order (E.O.) No. 12866 was decreed by President Clinton on September 30, 1993. This Order governs review of agency regulations and sets standards, that federal agencies should use in planning, drafting, and reviewing regulations. E.O. 12866 requires agencies to:

- Assess all of the costs and benefits of available regulatory alternatives, including the alternative of not regulating;

- Propose or adopt a regulation only upon a reasoned determination that the benefits of the intended regulation justify its costs;

- Specify performance objectives, rather than specify the behavior or manner of compliance, to the extent feasible;

- Tailor its regulations to impose the least burden on society, taking into account, among other things, the cost of cumulative regulations;

- Afford the public a meaningful opportunity to comment on any proposed regulation, which in most cases should include a comment period of not less than 60 days;

- Explore and, where appropriate, use consensual mechanisms for developing regulations, including negotiated rulemaking.

EPA contends that the CTR is not a "significant regulatory action" requiring an economic analysis under the terms of E.O. 12866. This contention by EPA is erroneous since the standard for becoming a "significant-regulatory action" is that the proposed rule is likely to have annual effect on the economy of $100 million or more, OR adversely affect in a material way the economy, the environment, or local governments. Thus, EPA should not be able to allege that this is not a "significant regulatory action" because the CTR will be likely to adversely affect the economy and local governments even if the $100 million cut-off were not met.

Moreover, EPA failed to seriously explore available regulatory alternatives, including an option of not regulating; did not make a "reasoned determination that the benefits of the intended regulation justify its costs;" did not allow a 60-day comment periods, and did not seriously take into account the cost of cumulative regulations.

Comment: UPI requests Office of Management and Budget (OMB) review of the subject reputation in accord with Executive Order (E.O.) 12866.

The EPA has not fully considered the impact and cost of Waste Load Allocation (WLA) for industrial facilities and for publicly owned treatment works (POTWs), even though the EPA supports the State Task Force conclusion which recognized that the development of Total Maximum Daily Load (TMDL) criteria was "significantly labor and data intensive" and that a "collaborative effort by....stockholders, could distribute work and associated costs". Costs were not properly determined for this significant effort or for the even larger compliance effort required for dischargers.

UPI has considered technologies and costs for compliance with the proposed regulation, recognizing that total maximum daily loads (TMDLs) would apply for a number of water quality-based effluent limitations (WQBELS) likely to be applicable to the receiving water at our facility.

UPI has determined that the only assured means of compliance with the proposed regulation is by use of equipment and operating methods that would eliminate discharge. Technologies for control are difficult, but appear to be feasible. The installed cost of such facilities at a plant such as ours which began operation early this century and contains numerous old installations was estimated at more that $25,000,000 when it was evaluated about five years ago. Such a cost for our facility when extended over just a few of the 56 major industrial facilities and 128 POTWs identified in California by the EPA would mandate OMB review of the subject regulation.

Response to: CTR-055-003

See response to CTR-021-005c. EPA disagrees with the commenter's statement that TMDLs would result in significant compliance costs. The use of TMDLs in developing permit limits would only reduce the cost impacts on facilities evaluated under the CTR because costs would not be borne solely by the point source dischargers. If EPA were to evaluate implementation costs using the TMDL process, it would allocate load reductions between point and nonpoint sources to take advantage of the most cost-effective mix of controls possible. EPA's current costing approach is conservative, erring towards higher costs by assuming that point sources would bear the cost burden alone. With a TMDL process, the result would be a more cost-effective mix between nonpoint and point source dischargers which could conceivably reduce the incremental impact on point source dischargers once current nonpoint source control programs are fully implemented.

Comment: The Sanitation Districts disagree with EPA's assertions that the CTR is not a significant regulatory action under Executive Order 12866 or the Unfunded Mandates Reform Act, and that EPA is not required to comply with the Regulatory Flexibility Act because the CTR establishes no requirements applicable to small entities. We believe the potential costs for POTWs to comply with the CTR criteria would far exceed the $ 100 million threshold, based on the fact that we estimate that the potential costs for seven Sanitation Districts' facilities to comply with the CTR to be nearly $150 million per year. Clearly, many of the 304 other POTWs in the State will also incur costs, as, will other NPDES permittees, indirect dischargers, stormwater dischargers, and nonpoint sources. Thus, EPA's cost figure of $15 - $87 million per year is simply not a credible estimate. Also, it is quite clear that the CTR is likely to adversely affect local governments, including over 40 small communities located in our service area, and that it is significantly different from other federal regulations previously promulgated in California. We believe that EPA has not complied with the mandates of Executive Order 12866, the Unfunded Mandates Reform Act and the Regulatory Flexibility Act. Accordingly, EPA must revise the economic analysis and it must be reviewed by the Office of Management and Budget and then EPA must select the most cost-effective and least burdensome regulatory alternative.

Response to: CTR-059-002a

EPA disagrees with LACSD's $150 million cost estimate, however EPA is not able to evaluate LACSD's estimate because LACSD does not provide monitoring data or any other details with which EPA can perform it's own analysis or evaluate LACSD's methodology. Based on EPA's analysis, costs to POTWs for the entire state range from $7.8 million to $41.6 million, much less than LACSD's $150 million cost estimate. See response to CTR-021-005c and the preamble for a discussion of how EPA's economic analysis meets the requirements of EO 12866, the UMRA, and the RFA.

Comment: As others have commented, we also encourage EPA to build on its efforts over the past year to coordinate with the State Water Resource Control Board (SWRCB). In particular, we recommend that in the future the two agencies take such steps as the use of simultaneous comment periods, joint preparation

of the economic analysis, and joint final promulgation, much as the "CAL-FED" agencies are doing. Simultaneous comment periods would greatly facifitate review by the public. Development of a joint economic analysis would greatly reduce the time and resources expended by the two regulatory agencies, as well as by stakeholders. Most importantly, EPA and the SWRCB should adopt the CTR and the State's Implementation Policy at the same time. This will eliminate uncertainties for permit writers and the regulated community as to how the CTR should be implemented, and encourage greater statewide consistency in the implementation of the CTR.

Comment: Due to the time constraints of the comment period, we have focused our review and comments primarily on those criteria that we anticipate may cause compliance issues for one or more of the Sanitation Districts' WRPs (see below). Based on our initial review of the proposed rule, the Sanitation Districts recommend that adoption of some of the criteria be deferred. As explained in the attached comments, we believe that there are significant scientific issues regarding the human health criteria for several trihalomethanes that call into question the accuracy and appropriateness of the proposed criteria. In addition, we reconunend that EPA defer adoption of those criteria that are below detection limits and that have not been demonstrated to be adversely affecting water quality or the attaimnent of designated uses on a water body-specific basis in California. In addition, we recommend that EPA not adopt criteria for effluent dependent waters, unless they have been adjusted to reflect the characteristics of this type of water body.

Criteria Below Detection Limits

We believe that there are fundamental problems with EPA's decision to adopt criteria that are below detection limits. This issue relates to EPA's statutory and regulatory obligations in establishing water quality criteria; namely, that EPA is subject to the same policies, procedures, analyses, and public participation requirements as States pursuant to 40 CFR section 131. These regulations require States to "review water quality data and information on discharges to specific water bodies where toxic pollutants may be adversely affecting water quality or the attainment of the designated water use or where the levels of toxic pollutants are at a level to warrant concern and must adopt criteria for such toxic pollutants applicable to the water body sufficient to protect the designated use." (40 CFR section 131.11) For criteria where the method detection limit exceeds the objective, there are inadequate data to determine if the pollutant could reasonably be expected to interfere with attainment of designated uses. We believe

that because of the inability to detect these substances and the lack of monitoring information indicating water quality use impairment EPA has not been able to fulfill its obligations to conduct a water body-specific analysis of the need to promulgate criteria.(*1)

(*1)U.S. Environmental Protection Agency, Economic Analysis of the Proposed California Water Quality Toxics Rule, Office of Water (EPA-820-B-96-001, July 1997), p. 8-18.

Second, EPA has not fulfilled its obligations under the Unfunded Mandates Reform Act and Executive Order 12866 to analyze the costs and benefits of promulgating proposed criteria which cannot be detected or for which insufficient monitoring data are available.

Given these deficiencies, we recommend that EPA defer the adoption of criteria for constituents which are below detection limits until such time as EPA has demonstrated that the levels of toxic pollutants being discharged are at a level to warrant concern. As an alternative, EPA could defer to the State for promulgation of criteria for such compounds on a water body-specific basis as part of the State's continuous water quality planning process.

Comment: The PUC is aware that the Clean Water Act does not require and in fact does not allow for economic considerations in meeting water quality requirements. However, other policies and regulatory mandates (Executive Order 12866 and the Unfunded Mandates Reform Act) require that we disclose to the public the cost of meeting water quality requirements. There is no doubt that there will be costs that California must bear to produce water quality. We must assure the public that the costs will produce benefits. We are not confident that this proposed rule can do that.

Comment: Introductory Comment

EPA states in the Executive Summary (page ES-2) to the Economic Analysis that:

"EPA did not calculate costs for any program for which it does not have enforceable authority ... (nor) for NPDES sources which are not typically subject to numeric WQBELs....."

From a national policy perspective, this narrowing, of the focus of the Economic Analysis may be a

justifiable approach to cost benefit analysis. Local government, however, is not able to disregard the potential cost effects of the CTR on urban and agricultural runoff. Those potential costs will have to be defrayed with proceeds from the same pool of local rate payers responsible for paying for point source pollutant removal programs. In California, those ratepayers have made clear both their support for environmental protection and their reluctance to pay more than is necessary for that protection. A narrow definition of those costs included in the CTR Economic Analysis continues the pattern of fragmenting responsibility and authority for the protection of waterways, which in turn hinders creation and implementation of holistic strategies which would best serve the environment at least cost.

Questions for EPA on the Introductory Comment

Q.-1) If not EPA, who has the responsibility to define the aggregated costs of all water quality-related regulations?

Q.-2) San Jose's reading of federal policy initiatives (which include, but are not limited to, the Regulatory Flexibility Act, Executive Order 12866, and the Unfunded Mandates Reform Act) indicates that EPA is empowered to analyze the economic impact of federal regulations in a way that addresses both aggregated cost impacts as well as the fiscal reality of local level government. Why was this not accounted for in the current analysis?

Comment: Comment #6: General Cost Analysis Concerns

The City of San Jose has several generalized concerns about the costs utilized in the Economic Analysis, which raise questions regarding the validity of that analysis, as follows:

Q.6-1) We believe the real point of undertaking the CTR is to assure water quality throughout the State that protects beneficial uses. How can the existing Economic Analysis be sufficient if it does not address the cost of meeting the CTR standards from all sources of discharge? Especially given the amount and cost of aggressive intervention in reducing point source pollution undertaken in California to date?

Q.6-2) Throughout the text of the CTR and within the Economic Analysis, EPA refers repeatedly to the assumption that the State will provide regulatory relief to mitigate severe cost impacts engendered by the CTR. What happens to EPA's cost benefit analysis if even one of those assumptions of regulatory relief is not implemented by the State? While we support EPA's attempt to indicate available regulatory options for the State, local level governments and POTW's have little past experience on which to rationalize acceptance of such assumptions.

Q.6-3) EPA has not estimated the cost to local governments/POTW's/indirect dischargers of securing regulatory relief, nor has that cost been incorporated into the estimate of the CTR impact. How would EPA estimate the cost of securing regulatory relief and how would that additional cost affect the Economic Analysis? Especially since very costly studies may be required in order to qualify for regulatory relief.

Q.6-4) The preamble to the CTR discusses the linkage between the CTR and the National Toxics Rule, and EPA's intent to create a level playing field by setting the CTR standards within the National Toxics Rule Framework. There does not seem to have been a similar attempt to analytically level the playing field vis a vis implementation costs, however, as no indexing or calibration has been undertaken to account for the cumulative costs of efforts to date (see also Q. 4-3), cost equivalency data is rooted in experience outside California, and simple average costs are used to represent widely variable ranges. How would the CTR cost/benefit relationship be affected by adjusting for California's significant previous efforts on water quality control mechanisms and California cost data?

Response to: CTR-092-022a

See responses to CTR-032-004, CTR-060-019, CTR-004-003. amd CTR-035-048.

Because implementation is the responsibility of the state, EPA does not control, nor does it know, what the cost impacts of implementing the CTR will be.

Comment: LEGAL ISSUES - Executive Order 12866, Unfunded Mandates Reform Act, Regulatory Flexibility Act

* SCAP disagrees with EPA's assertion that the CTR is not a significant regulatory action under Executive Order 12866. We believe that the potential costs of complying with NPDES permit limits based on the CTR criteria alone could far exceed the $100 million threshold. The CTR can also be considered a significant rule because it will "materially affect" one or more sectors of the economy, it will adversely affect local governments, and it is significantly different from other federal regulations previously promulgated in California.

Comment: pp. 42188-42189 - Potential Costs Do Not Meet the $100 Million Threshold Under E 0. 12866 (also see discussion above) As noted on p. 42188, one component of the definition of a "significant regulatory action" is that the rule may have an annual effect on the economy of $100 million or more. EPA states on p.42189 that "the annualized potential costs that direct and indirect dischargers may incur as a result of State implementation of permit limits based on water quality standards using today's proposed criteria are estimated to be between $15 million and $87 million." We believe that this range significantly underestimates the potential costs that may be realized from the implementation of this rule. This belief is based on the numerous assumptions used by EPA that would have served to underestimate

potential costs, including assumptions about regulatory flexibility that are clearly contradicted in the Preamble to the rule itself. These issues are further enumerated in Attachment 2, which contains an analysis prepared by the environmental economics firm, M. Cubed. Furthermore, we strongly believe that EPA has a duty to look at a full range of potential costs that may be incurred, and not just to look at the costs under optimistic assumptions. This duty is especially acute in light of the uncertainties of how the CTR will be implemented by the State.

We examined the potential costs for the POTW sector to determine the reasonableness of EPA's cost estimates. Our preliminary analysis indicates that for 23 major POTWs the annualized costs could reach $400 million.(*3) This estimate includes the cost to construct and operate end-of-pipe treatment processes where these would be necessary to achieve projected effluent limits. Unlike the EPA cost estimates, we have assumed that regulatory relief options may not be available, and that, based on the pollutants causing compliance problems, pollution prevention and treatment plant optimization might not be sufficient to reliably achieve compliance. Thus, we feel that this estimate reflects a more accurate depiction of the potential POTW "high-end" compliance costs that could result from the draft CTR. Based on this analysis, we believe that EPA should re-analyze the potential costs for POTWs to meet water quality-based effluent limits based on the criteria in the CTR.

As noted on p. ES-2 of the Economic Analysis (U.S. EPA, 1997a), EPA estimated only the costs to point sources, and did not estimate the potential costs for compliance for nonpoint source dischargers, despite the fact that the majority of water bodies in California are impaired due to nonpoint source discharges (SWRCB, 1996). In addition, EPA failed to estimate the costs of compliance for wet weather dischargers, such as municipal and industrial stormwater dischargers. These omissions also lead us to believe that the potential total costs of the rule are far greater than $100 million. EPA must correct these deficiencies and redo the Economic Analysis.

(*3) Backup information for these cost estimates is available upon request.

Comment: Introduction

On behalf of CASA and Tri-TAC, M.Cubed reviewed the U.S. Environmental Protection Agency 's

(USEPA) Economic Analysis (Analysis), as well as the report's underlying benefit and cost data and analyses. M.Cubed's overall reaction is that policy makers and the regulated community can place little confidence in either the benefit or cost analyses -- the uncertainties and broad assumptions contained in these analyses largely undermines their findings. Based on the information provided by USEPA, M.Cubed's judgement is that the proposed California Toxics Rule (Rule) will result in multi-million dollar annual costs -- and have substantial impacts on individual publicly-owned treatment works (POTWS) and dischargers -- and may result in no noticeable benefits to public health or the environment. A critique of specific weaknesses in the cost and benefit analyses is provided below.

Weaknesses in Overall Report Findings

The Analysis' overall findings exhibit a number of flaws, as follows:

USEPA's estimates indicate that Rule costs outweigh benefits, both on an annualized and present value basis. USEPA's claim that comparison "...of both annualized benefits and costs and discounted benefits and costs indicates that the monetized benefits of the CTR are of the same general magnitude as the costs" is simply not true (U.S. EPA, 1997a, page 9-2). For example, using USEPA's comparison of a twenty-year phase-in of benefits at a 3 percent discount rate against a ten-year phase-in of costs at a 7 percent discount rate, or benefits of between approximately $20 to $600 million against costs of about $180 million to $1 billion (setting aside the significant weaknesses in the analysis; differences in the probabilities of low or high outcomes; and questions over the appropriate discount rate to apply)(*2) indicates a low cost scenario which is nine times higher than the estimated benefits, and a high cost scenario which is almost twice as high as benefits.(*3)

Executive Order 12866, which requires the economic review, defines "significant regulatory action" as one that is likely to "adversely affect ... a sector of the economy." Yet, although the USEPA finds that two sectors will incur the majority of the regulatory costs POTWs and chemical/petroleum products -- it provides no analysis of whether or not these costs are "significant" to these sectors. Likewise, USEPA does not examine the potential costs or their implications to small businesses (e.g., health care providers; automobile repair shops), small communities, or non-significant industrial users (SIUs) in general (i.e., industries that are regulated by POTWs through local ordinances, rather than under federal rules)

USEPA's conclusion that the use of different risk levels would not significantly influencecompliance costs is not supported by its data. Based on USEPA's own data, use of a 10E-5 risk level for carcinogens would induce a 25 percent cost savings relative to a 10E-6 risk level under the low cost scenario, with a 3 percent change in pollutant loadings.(*4)

(*2) Noticeable benefits seem unlikely to emerge in the near term, if at all, due to the persistence of existing contaminants in the environment, while costs will be incur-red over one to two decades. Use of a lower discount rate for benefits would reflect the greater value future generations may place on environmental amenities, an assumption which is open to debate.

(*3) The large differences between benefits and costs is mirrored by the wide range in estimated pollution reduction. Under USEPA's low scenario, only.63 million toxic pounds- equivalent are expected to be reduced under the rule, compared to a high scenario reduction of 7 million pounds equivalent. That is, reductions under the high scenario are eleven times higher than under the low scenario.

(*4) Under the high cost scenario cost reductions are less than I percent, with a 7 percent change in pollutant loadings.

Comment: ISSUES OF CONCERN

The Unfunded Mandates Act of 1995, 62 FR 42191. The City of Redding disagrees with the conclusion that the proposed rule does not result in expenditures by state or local governments in aggregate of $100 million or more in any one year. The strict water quality criteria in the proposed rule would directly cause the state to adopt more stringent standards for dischargers, which would then require the local dischargers to implement exorbitant and costly measures against our users.

Regarding unfunded mandates, the City of Redding believes that the state and local governments would have no alternative in implementing this federal rule than to enforce exorbitant and costly measures

against our users. Therefore, the proposed rule would directly cause significant burden and costs to state and local governments.

Comment: Thank you for the opportunity to comment on the proposed California Toxics Rule. The City's comments are related to five main concepts:

3. The cost implications of these numerical standards are estimated to exceed $100 million to the City of Modesto alone, thereby triggering the President's Executive Order 12866 requiring a more detailed and comprehensive cost-benefit assessment of these proposed standards.

Specifically, the City submits the following comments:

E. Under the proposed rule, Best Management Practices (BMPS) are recommended for compliance with the California Toxic Rule. BMPs may include a variety of processes. Each of these processes may have an associated construction and operation cost. For the City of Modesto, due to the design of the wastewater and stormwater collection systems, it may cost between $25 million to $50 million to construct acceptable BMPS. Existing BMPs may not reduce the pollutant level below that listed in the proposed CRT. Therefore, it is our opinion that construction costs presented in the California Toxic Rule are significantly under estimated. Constructed treatment facilities for wastewater and storm water, beyond BMPS, could exceed $1 00 million for Modesto alone. In addition, annual operation and maintenance costs for BMPs and treatment facilities exceed $1,000,000.

In summary, the proposed regulation is significant because it may well impose costs that are greater than $100 million per year on the regulated community, the majority of which are local public agencies. Regardless of the dollar amount, it is likely to adversely affect, in a material way, the economy, the environment, and local governments.

Thank you in advance for consideration of my comments on the CTR.

Comment: 4. The economic analysis is seriously flawed. The major flaws include: (1) failing to do an appropriate sampling of dischargers having little or no dilution; (2) assuming in the high-end cost scenario that a 25% reduction could be achieved through source control and an additional 25% achieved through treatment plant optimization without capital improvements; (3) constraining estimates of potential costs through key assumptions, including the assumption that regulatory relief from the rule would be granted if costs were in excess of certain thresholds; and (4) exaggerating estimates of potential benefits by assuming an end (i.e., achievement of the proposed water quality criteria) that will not result from the rule. The result of these flaws is that potential costs are greatly understated and potential benefits are greatly overstated.

The District's analysis demonstrates that actual costs may be an order of magnitude greater than EPA's $500/lb threshold and the benefits may be nil. A further consequence of the flawed economic analysis is the conclusion that the CTR is not a major rule (i.e., one which will result in excess of $100 million per year expenditure) subject to Presidential Executive order 12866 and the Unfunded Mandates Reform Act or a rule that affects small entities protected under the Regulatory Reform Act. For example, the District serves the City of Novato which has a population under 50,000 and would be greatly impacted by the proposed rule.

Response to: CTR-005-005

See responses to CTR-005-004, CTR-054-013a, CTR-021-005c, CTR-040-029a, and CTR-042-007a.

The standards established in the CTR apply to certain California waterbodies. EPA currently only applies water quality based effluent limits to point sources, and thus the estimate of post-regulation cost reflects only the potential impact of controls on point sources. EPA's benefits analysis is based on an assumption that other controls may also be required of other sources in the future (e.g., under state of law for non-point sources). As controls on other sources are implemented (e.g., remediation of contaminated sediments; best management practices to control storm water discharges, EPA expects that concentrations in fish tissue will decline further and that the standards established by the CTR to protect human health can be achieved.

EPA also believes that the risk reducing impact of the regulation on point sources may not be fully illustrated by EPA's analysis which is based on only a small sample of point source dischargers. Baseline risk levels are based on actual fish tissue concentrations, post-regulation risk levels are estimated by examining the potential for reducing loadings at a sample of facilities. Pollutants responsible for much of the baseline health risk at specific sites, such as popular fishing areas in San

Francisco Bay, may be found in point source effluents, however, the facilities discharging these pollutants may not be included in the sample and, thus, EPA's analysis may underestimate the risk reduction impact on point sources.

Comment: The Center for Marine Conservation (CMC) is a nationwide, nonprofit advocacy group dedicated to the conservation and enhancement of coastal and ocean life and resources. CMC submits these comments on behalf of its 16,000 members in California and over 120,000 members nationwide.

CMC applauds EPA's efforts to bring California into compliance with the Clean Water Act 303(c)(2)(B). Implementing numeric criteria that will protect the beneficial uses of California's waters is of great importance to the health of coastal and marine ecosystems, and so to CMC and its members. The reliance in many areas of the state on narrative criteria threatens the health of most of the state's waters, thereby impacting both human health and the health of the state's economy that relies on clean water.

While CMC strongly supports the swift adoption of an Enclosed Bays and Estuaries Plan and an Inland Surface Waters Plan that contain numeric criteria for toxic pollutants, CMC also is concerned that many of the specific criteria contained in the proposed rule are weaker than those contained in published guidance. CMC also believes that the proposed rule can better protect certain subpopulations from harm caused by consumption of contaminated fish and shellfish. Finally, CMC is concerned that the economic analysis of the proposed rule over-emphasizes costs and under-reports the many benefits of improving water. quality throughout the state. These three points are reviewed below.

The Proposed Rule's Economic Analysis Over-Emphasizes Costs and Under reports the Benefits of Improving Water Quality Throughout the State

By EPA's own admission, the proposed rule's economic analysis over-reports costs and under-reports benefits. Specifically, the proposed rule states that "cost estimates for both scenarios, but especially for the high-end scenario, may be overstated because the analysis tended to use conservative assumptions."(*8) Conversely, "numerous categories of potential or likely benefits have been omitted" from the analysis, and these omitted benefits "are likely to be significant contributors" to an "appreciable underestimation" of the overall benefits of the rule.(*9) Categories left out of the benefits analysis include improvements in water-related, non-fishing recreation, improvements in land recreation, and improvements in human health resulting from reducing non-cancer risk."(*10)

CMC believes it is possible to quantify many of these omitted benefits to obtain a more accurate picture of the importance of this rule. For example, a recent Santa Monica Bay Restoration Project Study found that people swimming close to storm drains face a 50% increase in their risk of contracting a variety of

non-cancer ills such as gastroenteritis and ear and other infections. At a minimum, EPA's analysis could capture the benefits of improved water quality in terms of avoided sick days and avoided medical costs for such users.

CMC also believes that the economics analysis should consider other categories of benefits not mentioned at all in the proposed rule. For example, Governor Wilson's March 1997 planning document, California's Ocean Resources: An Agenda for the Future, finds that industries that depend on healthy coastal and ocean waters contribute $17.3 billion to the state's economy each year and support 370,000 jobs. The majority of this total, $10 billion, is from tourism, which is not mentioned in the proposed rule but which could benefit greatly from improved water quality. Such omitted benefits should be examined in order to have a more balanced economic analysis.

The adequacy of the proposed rule's economic analysis is important to the long-term implementation of the rule. As reported by EPA, "[t]he allegation that the State did not sufficiently consider economics when adopting Water quality objectives ... was an important issue in the litigation" that resulted in the rescission of the Enclosed Bays and Estuaries Plan and the Inland Surface Waters Plan.(*11) Moreover, an accurate description of the benefits of the proposed rule is critical to obtaining funding and public support for swift implementation of the numeric criteria. CMC thus requests that the benefits analysis be updated where possible to parallel the acknowledged "conservative" approach used in estimating the costs of the proposed rule.

(*8) Id. at 42189.

(*9) Id. at 42190.

(*10) Id.

(*11) Id. at 42165.

Response to: CTR-029-004a

The benefits of water quality improvements are highly site specific and difficult to monetize due to limitations in benefits methodology and accurate data on society's values for these improvements. For example, there are currently few means of linking consumption of toxic contaminants by humans with cases of systemic effects (as opposed to cancer effects, for which dose-response curves have been estimated). As another example, the contingent valuation (CV) is the only method for estimating passive use values, and CV surveys require substantial resources to conduct. As a result, there is limited data and information with which to estimate the benefits of the proposed rule. Since these values are not known, a parallel conservative approach is not possible. EPA presented the information on the limitations of the analysis (e.g., costs may be overstated and benefits may be understated) to assist decision makers in evaluating the results.

Illnesses contracted from swimming, such as those evaluated in the study of storm water drains in Santa Monica Bay, typically result from exposure to pathogens that will not be regulated under the CTR. Noncancer effects from the toxic pollutants that will be reduced by the rule are difficult to quantify because of a lack of information on the link between concentrations in the environment and potential cases of systemic effects.

EPA's analysis does not cover all benefit categories as the commenter notes, however, the evaluation of

all categories of benefits in a constructive manner is beyond the scope of this analysis, thus EPA has done the best possible analysis given the time and budget constraints. EPA believes that had all the benefit categories been fully evaluated, the monetized benefits for this rule would have increased significantly. However, secondary benefits (e.g., tourism) or economic impacts embody the successive rounds of spending in an economy that result from the primary benefits of a regulation. These secondary benefits (or impacts) are estimated based on the analysis of data on interindustry linkages within a region. Although these impacts may be of relevance to policy makers, the inclusion of secondary benefits may be inappropriate. This is because under conditions of reasonably full employment, the resources placed into support services (or diverted from complying entities) would be diverted from (or redirected toward) other productive purposes (i.e., net jobs would not be created or lost for otherwise unemployed individuals but, rather, workers would be drawn to or away from other jobs). Thus, these secondary impacts represent a transfer or redistribution of resources rather than changes in real economic activity.

Comment: Economic Analysis

The District supports CASA/Tri-TAC's conclusions that the Economic Analysis has significant technical weaknesses, is based on a large number of assumptions and minimal empirical data, and that it almost certainly understates costs and overestimates benefits. There is a critical need for a sound economic analysis. We also agree with their recommendation that EPA and the SWRCB undertake a collaborative process with interested members of the public to revise the Economic Analysis based on guidelines in the Economic Considerations Task Force Report.

Comment: III. Economic Analysis A. General Comments p. 9-2 (U.S. EPA, 1997a) - EPA Finds that Benefits Are of Same General Magnitude as Costs

Whether the monetized benefits and costs are compared on an annualized basis, or on a total, discounted basis, we disagree with EPA's conclusion that the benefits are of the same magnitude as the costs. When looked at in terms of a twenty-year phase-in of benefits at a 3 percent discount rate and a ten-year phase-in of costs at a 7 percent discount rate, in the low cost scenario, the costs are nine times higher than the benefits; in the high cost scenario, the costs are nearly twice as high as the benefits. Thus, we think that EPA should disclose in its conclusions and inthe summary contained in the Preamble to the CTR that the costs appear to outweigh the benefits. Thus, as discussed above, we believe EPA has to demonstrate that the benefits outweigh the costs, as required under E.O. 12866.

Comment: Introduction

On behalf of CASA and Tri-TAC, M.Cubed reviewed the U.S. Environmental Protection Agency 's (USEPA) Economic Analysis (Analysis), as well as the report's underlying benefit and cost data and analyses. M.Cubed's overall reaction is that policy makers and the regulated community can place little confidence in either the benefit or cost analyses -- the uncertainties and broad assumptions contained in these analyses largely undermines their findings. Based on the information provided by USEPA, M.Cubed's judgement is that the proposed California Toxics Rule (Rule) will result in multi-million dollar annual costs -- and have substantial impacts on individual publicly-owned treatment works (POTWS) and dischargers -- and may result in no noticeable benefits to public health or the environment. A critique of specific weaknesses in the cost and benefit analyses is provided below.

Weaknesses in Overall Report Findings

The Analysis' overall findings exhibit a number of flaws, as follows:

USEPA's estimates indicate that Rule costs outweigh benefits, both on an annualized and present value basis. USEPA's claim that comparison "...of both annualized benefits and costs and discounted benefits and costs indicates that the monetized benefits of the CTR are of the same general magnitude as the

costs" is simply not true (U.S. EPA, 1997a, page 9-2). For example, using USEPA's comparison of a twenty-year phase-in of benefits at a 3 percent discount rate against a ten-year phase-in of costs at a 7 percent discount rate, or benefits of between approximately $20 to $600 million against costs of about $180 million to $1 billion (setting aside the significant weaknesses in the analysis; differences in the probabilities of low or high outcomes; and questions over the appropriate discount rate to apply)(*2) indicates a low cost scenario which is nine times higher than the estimated benefits, and a high cost scenario which is almost twice as high as benefits.(*3)

Executive Order 12866, which requires the economic review, defines "significant regulatory action" as one that is likely to "adversely affect ... a sector of the economy." Yet, although the USEPA finds that two sectors will incur the majority of the regulatory costs - POTWs and chemical/petroleum products -- it provides no analysis of whether or not these costs are "significant" to these sectors. Likewise, USEPA does not examine the potential costs or their implications to small businesses (e.g., health care providers; automobile repair shops), small communities, or non-significant industrial users (SIUs) in general (i.e., industries that are regulated by POTWs through local ordinances, rather than under federal rules)

USEPA's conclusion that the use of different risk levels would not significantly influence compliance costs is not supported by its data. Based on USEPA's own data, use of a 10E-5 risk level for carcinogens would induce a 25 percent cost savings relative to a 10E-6 risk level under the low cost scenario, with a 3 percent change in pollutant loadings.(*4)

(*2) Noticeable benefits seem unlikely to emerge in the near term, if at all, due to the persistence of existing contaminants in the environment, while costs will be incur-red over one to two decades. Use of a lower discount rate for benefits would reflect the greater value future generations may place on environmental amenities, an assumption which is open to debate.

(*3) The large differences between benefits and costs is mirrored by the wide range in estimated pollution reduction. Under USEPA's low scenario, only.63 million toxic pounds- equivalent are expected to be reduced under the rule, compared to a high scenario reduction of 7 million pounds equivalent. That is, reductions under the high scenario are eleven times higher than under the low scenario.

(*4) Under the high cost scenario cost reductions are less than 1 percent, with a 7 percent change in pollutant loadings.

Response to: CTR-035-056a

EPA disagrees with the commenter's claim that costs outweight benefits. In the Economic Analysis of the final CTR, EPA estimates that benefits may range from $6.9 million to $74.7 million per year and costs may range from $33.5 million to $61.0 million per year. EPA believes that benefits are underestimated due to EPA's inability to monetize all categories of benefits. See also responses to CTR-056-018, CTR-029-004b, and CTR-035-057.

Regarding the issue of whether the CTR imposes significant costs on the chemical/petroleum product andPOTW industries, see the response to CTR-042-007a. Based on 40 CFR.131.11, EPA is supposed to base current criteria on sound science and the criteria must contain sufficient parameters to protect the designated uses. From the outset of the national water quality standards program, EPA has explained that while economic factors may be considered in designating uses, scientific and technical factors must form the basis for the criteria to meet those uses. However, in the spirit of EO 12866, EPA has evaluated the cost impact of the CTR on the regulated community.

EPA disagrees with the commenter that the use of different risk levels significantly influences compliance costs. Under EPA's revised low scenario, there is a 3% difference in costs and under the high scenario, there is a 10% difference in costs between the alternative 10E-5 risk level scenario and the CTR-based 10E-6 risk level scenario. Cost increments should be compared to benefits increments, not loading reductions, for a more realistic evaluation of the impact of risk levels. EPA believes that monetized benefits might be commensurate with the cost increase resulting from the lower risk level and EPA believes that costs may be overstated in the high scenario.

Comment: Weakness in cost analysis The report cost estimates exhibit a number of significant weaknesses, as follows:

* Although USEPA claims that its estimates most likely overstate potential costs, the Analysis isbased on a large number of assumptions that could act to understate rule related expenditures. Table One identifies some of these assumptions.

Table One Other Major Technical Assumptions Which Could Significantly Impact the Cost Analysis

Assumption / Potential Impact on Analysis

****

"If all monitoring data reported for a facility were reported as below analytical detection levels, even if the reported detection limit was above EPA-approved analytical detection levels, it was assumed that no reasonable potential existed to exceed CTR-based WQBELS." (U.S. EPA, 1997b, page 2-13)

RWQCB's permitting policies could undermine this assumption, thereby inducing greater impacts than assumed in the analysis (e.g., lindane in the City of Los Angeles).

****

The low-cost scenario assumes "no cost" after costs exceed $200 per toxic pounds equivalent; high-cost threshold is assumed to be $500 per toxic pounds.

If relief not given, costs would be substantially higher. Relief is estimated to cost $200,000 per facility,

despite a potential range of $20,000-$1,000,000 per pollutant. Since "the facility ultimately must achieve the CTR based WQBEL" (U.S.EPA, 1997b, page 2-31) under this method costs should properly be extended to the future (e.g, discounted). Relief provision isn't balanced with benefit reductions.

****

USEPA claims that "minor dischargers are not expected to incur significant impacts as a result of State implementation of CTR water quality criteria." (US, EPA, 1997b, page ES-1).

This statement appears to be based on a sample of three minor dischargers, an insufficient sample to reflect the entire population of these dischargers.

****

Between 10 to 30 percent of indirect dischargers could be affected by pretreatment requirements.

This percentage is based on a Great Lakes study, with no reason to believe similar patterns exist in California, Although pre-treatment costs are very industry-specific, USEPA's data is solely based on two California cases: Compliance period may not allow for optimal use of pretreatment; optimization; or end-of-pipe treatments.

****

Assumes that costs are incremental (e.g., that rule compliance would result in distinct investment from past or future behavior).

Could require the need to reorganize capital or operating expenditures, resulting in higher costs. The costs of existing unmet standards should be considered.

"...assumed that all sludges generated would be nonhazardous..that sludge would be disposed of in municipal landfills..."

"...potential costs associated with storing and transporting sludge were not considered." (U.S. EPA, 1997b, page 2-35)

Average per-facility process "optimization" costs were assumed to be $100,000, and to be fully effective in obtaining targeted reductions.

This is an optimistic assumption.

Depreciation and the cost of capital where not included in the O&M costs. Financing assumed to be available.

Some (small) POTWs may have difficulty obtaining lowcost financing, particularly as a result of

Proposition 218.

****

"...detailed treatment and manufacturing process information was not available in the NPDES permit files, ...the assessment of feasibility was based primarily upon best professional judgement using general knowledge of industrial and municipal operations." (U.S.EPA, 1997b, page 2-30)

Use of generalized knowledge may act to under- or over-estimate file costs to specific POTWs and dischargers.

****

Technical assumptions in the case studies (e.g., treatment of process waters; optimization) merit engineering review.

Examination of case-specific costs could result in different estimates.

EPA acknowledges that as permit limits are established below analytical detection levels, ambient water quality background data also may be below analytical detection levels, which may make analysis of use attainability more difficult. However, in accordance with the procedures recommended in Water Quality Standards Handbook, Second Edition (U.S. EPA 1994), analysis of use attainability encompasses evaluating physical and biological indicators as well as the ability to meet water quality criteria.

The commenter's statement that, under EPA's analysis, no reasonable potential is assigned to pollutants with projected effluent limits below detection levels is inaccurate. In EPA's high scenario, pollutants with projected CTR-based limits below detection levels are assigned reasonable potential and analyzed for potential compliance costs if they have an existing NPDES permit limit. The fact that a Regional Board assigns a permit limit to a pollutant reported below detection level indicates that the Board may require further controls to ensure compliance. In the Economic Analysis, EPA estimates that facilities would implement pollution prevention or waste minimization programs in order to achieve compliance with limits below method detection levels.

For the City of Los Angeles POTW, EPA determined reasonable potential to exceed water qualitycriteria for lindane because a (1991) permit limit exists and discharge data show reasonable potential to exceed CTR criteria. EPA did not estimate compliance costs, however, because the existing permit limit is as stringent as the projected CTR-based permit limit.

Comment: 4. The economic analysis is seriously flawed. The major flaws include: (1) failing to do an appropriate sampling of dischargers having little or no dilution; (2) assuming in the high-end cost scenario that a 25% reduction could be achieved through source control and an additional 25% achieved through treatment plant optimization without capital improvements; (3) constraining estimates of potential costs through key assumptions, including the assumption that regulatory relief from the rule would be granted if costs were in excess of certain thresholds; and (4) exaggerating estimates of potential benefits by assuming an end (i.e., achievement of the proposed water quality criteria) that will not result from the rule. The result of these flaws is that potential costs are greatly understated and potential benefits are greatly overstated. The District's analysis demonstrates that actual costs may be an order of magnitude greater than EPA's $500/lb threshold and that the benefits are very small.

Comment: MAJOR CONCERNS

We do, however, have fundamental concerns with the Rule as it is presently proposed and its supporting economic analysis. We believe the Rule can be modified in a manner that will be responsive to our concerns while at the same time being consistent with applicable Federal law and regulations. Our major concerns are presented here and are followed by our recommended modifications.

II. Concern: The economic analysis upon which the Rule is based is seriously flawed.

* Estimates of potential costs are severely constrained due to certain assumptions including the assumption that regulatory relief from the Rule will be granted if costs are in excess of certain thresholds.

* Estimates of potential benefits are exaggerated by assuming, that the proposed water quality criteria

will actually be achieved in receiving water bodies. This will not result from the implementation of the Rule because the Rule is only addressing permitted discharges to the receiving water bodies.

* The result of these flaws is that potential costs are greatly understated and potential benefits are greatly overstated.

Comment: EPA improperly lumps all criteria together in estimating costs and benefits. The result is that the pollutant reductions that form the basis for most of the costs (chromium, mercury, silver and toluene) are not generally the same pollutants that form the basis for most of the benefits (DDT, PCBs, mercury and dioxin). The cost-benefit analysis should be done on a pollutant-by-pollutant basis and it should be done on the basis of the pollutants that will be reduced as a result of the CTR.

Response to: CTR-040-042

For a discussion of the estimation of benefits and costs for individual pollutants see response to CTR-044-033.

To calculate potential human health risk reduction benefits, EPA first calculated baseline risk levels using actual contaminant concentrations found in fish tissue. EPA then multiplied the baseline risk levels by the estimated reduction in loadings expected to result from the implementation of point source controls and by the relative contribution of point source loadings to total loadings. For DDT, EPA estimated a 68.8% reduction in point source loadings under the high end cost estimate and a 0% reduction in point source loadings under the low end cost estimate. EPA's estimate of human health benefits reflects these estimated reductions. For example, potential cancer-related benefits to recreational anglers range from $0 to $4.2 million for freshwater resources and total $0 for San Francisco Bay.
In addition, the risk reducing impact of the regulation on point sources may not be fully illustrated by EPA's analysis which reflects only a sample of point source dischargers. That is, although baseline risk levels are based on actual fish tissue concentrations, post-regulation risk levels are estimated by examining the potential for reducing loadings at a sample of facilities. Pollutants responsible for much of the baseline health risk at specific sites, such as popular fishing areas in San Francisco Bay, may be found in point source effluents, however, the facilities discharging these pollutants may not be included in the sample.

Comment: 4. EPA's Economic Analysis is seriously flawed. The major flaws include:

(1) failing to do an appropriate sampling of small dischargers having little or no dilution;

(2) assuming in the high-end cost scenario that a 25% reduction could be achieved through source control and an additional 25% achieved through treatment plant optimization without capital improvements;

(3) constraining estimates of potential costs through key assumptions, including the assumption that regulatory relief from the rule would be granted if costs were in excess of certain thresholds; and

(4) exaggerating estimates of potential benefits by assuming an end (i.e., achievement of the proposed

water quality criteria) that will not result from the rule.

The result of these flaws is that potential costs are greatly understated and potential benefits are greatly overstated. Moreover, the flawed economic analysis has lead to the erroneous conclusion that the CTR is not a "significant regulatory action" or major rule subject to Presidential Executive Order 12866 and the Unfunded Mandates Reform Act or a rule that affects small entities protected under the Regulatory Flexibility Act.

Comment: EPA improperly lumps all criteria together in estimating costs and benefits. The result is that the pollutant reductions that form the basis for most of the costs (chromium, mercury, silver and toluene) are not generally the same pollutants that form the basis for most of the benefits (DDT, PCBs, mercury and dioxin). The cost-benefit analysis should be done on a pollutant-by-pollutant basis and it should be done on the basis of the pollutants that will be reduced as a result of the CTR.

Response to: CTR-044-033

See response to CTR-054-013a.

Although a small subset of toxic pollutants are responsible for cancer risk reduction benefits, EPA anticipates ecosystem-wide benefits (e.g., noncancer risk reductions, ecologic benefits) from controlling a range of toxic pollutants. EPA did estimate human health benefits on a pollutant-specific basis. For other benefit categories, EPA estimated potential benefits based on toxic-weighted loading reductions to account for the different toxicities of the pollutants.

EPA recognizes the persistence of some of the substances addressed by the CTR (e.g., DDT and PCBs) and the impact of this persistence on the realization of benefits. In the EA (Chapter 9), EPA accounted for this lag by assuming 10- and 20-year phase-in periods for benefits in its comparison of present value benefits and costs.

In addition, EPA believes that point source controls can factor into pollutant reduction scenarios, although the cost-effectiveness of point and nonpoint source controls are likely to be highly site specific. Potential "hidden" loads (contaminant concentrations which are not currently measured because they are below detection levels) from point sources may also be occurring and may increase the potential benefits of point source controls. In addition, point source loadings reductions will reduce future sediment contamination and, thereby, reduce the need for costly site-specific sediment remediation in the future. Therefore, the CTR can be viewed as both reducing current environmental risks (yielding benefits) by reducing current loadings, and reducing future environmental cleanup costs.

Comment: Second, the interaction between the CTR and the state's implementation policy is particularly important given our second concern, which is namely that the EPA's economic evaluation underestimates the costs and overestimates the benefits of implementing this rule.

Our concern about the cost estimates is based on the fact that the cost analysis appears to undervalue the magnitude of difficulty dischargers will have complying with permits issued based on this rule.

We are also concerned that the cost estimates for various compliance activities such as source control and treatment process optimization made in the case studies are overly optimistic and not reflective of the true actions that will need to be taken to insure compliance.

Overall, we are concerned that the expenditures that may be necessary for many POTWS to comply with the CTR will be large, these costs may not be matched by commensurate benefits, and that EPA has not analyzed whether point source controls are in fact a cost-effective way to achieve water quality standards.

Our preliminary analysis for just five agencies in the Bay Area to comply with the proposed standard for copper alone could amount to more than $60 million per year -- 60 million. This number would be far higher if calculated for every pollutant listed in the CTR for the entire POTW industry in California.

Since this estimate would undoubtedly exceed the high end of the range contained in EPA's analysis, we believe it is necessary for EPA to redo the economic analysis to fully comply with its legal responsibilities.

In addition, revised economic analysis is necessary to provide a sound basis for the State to use in its analysis of the economic impacts of the implementation policy.

Comment: And finally, I'd like to comment on the analysis of the economic impact of the CTR. We believe that the analysis does not portray a reasonable picture of what the potential costs and benefits may result from the promulgation of this CTR. In our opinion, the cost analysis contains many flawed assumptions that result in severe underestimation of the total potential costs, and we're particularly concerned about the use of process optimization and how it was relied upon.

Likewise, the benefits, while admittedly difficult to estimate, appear tenuous at best. The bottom line is that we are concerned that this analysis does not properly reveal that the CTR can lead to requirements for large expenditures by POTWs in Southern California with questionable benefits to the environment. We recommend that EPA carefully redo its economic analysis to portray a more accurate picture of the potential costs and benefits.

Thank you again for this opportunity. We look forward to submitting our comments in writing.

Comment: The City of Simi Valley discharges approximately 10 million gallons per day (mgd) of tertiarytreated wastewater (as well as municipal storm water) to the Arroyo Simi, an effluent dependent water body. Through much of the year, Arroyo Simi is dry several miles downstream from the City. The Arroyo Simi Characterization Report, completed by the City in 1995, concluded that the arroyo does not support a significant fishery, and observed only arroyo chub, mosquito fish and blunt-nosed minnow in the stream. Although designated as a potential municipal water supply in the Basin Plan, the arroyo waters are not used for municipal purposes. Effluent monitoring are limited, but available data indicate that the City's discharge may have a reasonable potential to exceed the proposed aquatic life criteria for several metals and the proposed human health criteria for several carcinogens.

Since Simi Valley is largely a residential community with supporting commercial development and little industry, and since the City already has an effective pretreatment program, it is unlikely that pollution prevention efforts would effectively reduce the problematic constituents. More likely, the City would be faced with end-of-pipe treatment controls such as lime precipitation and carbon adsorption to achieve the proposed criteria. The costs would undoubtedly be significant and the benefits relatively minor.

Under these circumstances, it appears reasonable to adopt criteria for Arroyo Simi, and similar effluent dependent waters, that are reasonably achievable without costly end-of-pipe controls and that reflect the actual use of the water (i.e., generally such waters are used for fishing or drinking). One way to address this issue, consistent with the requirements of the Clean Water Act, would be to adopt specific human health criteria for Arroyo Simi and other effluent dependent streams based on a cancer risk coefficient of 10E-5 or in some cases 10E-4. Based on the limited data collected by the City, risk levels of 10E-4 would have to be adopted for dioxins, aldrin, alpha-BHC and 4,4,-DDD (see Table 1). Risk levels of 10E-5 would be sufficient for chloroform and endoslfan 11 (Id.).

Comment: Finally, we have serious concerns about the accuracy of the draft Economic Analysis and the estimates of the costs and benefits of the draft CTR (see detailed comments in Attachments I and 2). Our primary concerns related to the cost analysis include 1) that the case studies on which the cost analysis is based do not adequately represent the actual population of POTWs in California; 2) the omission of costs that could be incurred by many sectors that contribute to overall loadings, and, hence, can be expected to have to reduce their loadings (e.g., non-SIU indirect dischargers, municipal and industrial stormwater dischargers, agricultural activities, and other nonpoint sources of CTR-regulated pollutants); 3) the use of numerous assumptions that underestimate costs; and 4) the capricious removal of costs that exceed threshold values by assuming that regulatory relief measures will be granted, despite the lack of any proposed regulatory relief trigger in the proposed regulation.

To illustrate the degree of underestimation of costs for the POTW sector alone, we looked at potential compliance costs for the POTW sector. We found that the potential costs for 23 major POTWS. on an annualized basis, may reach $400 million. We believe that this analysis demonstrates that the potential cost consequences of compliance with effluent limits based on the proposed CTR criteria would easily exceed the $ 100 million annual cost threshold, especially when the costs of all 313 POTWs in the State are estimated. Thus, we believe that EPA must conclude that the proposed CTR could have significant economic impacts on local governments.

Comment: Weaknesses in Cost Analysis The report's cost estimates exhibit a number of significant weaknesses, as follows:

* The Analysis does not account for changes in discharges over time. Changes in the volume and characteristics of discharges resulting from demographic,(*9) economic, and policy trends are ignored in the analysis. For example, existing economic conditions may lead to greater discharge volumes; electric industry restructuring in California may induce different operating patterns among the state's generators (e.g., Hunter's Point), and air quality rules may alter petroleum refining processes (e.g., reformulated gasoline). These impacts may be region- (e.g,, Silicon Valley) or industry-specific.

(*9) For example, the state may add another six million Californians between 1996 and 2005. See Center for Continuing Study of the California Economy, California County Projections, 1997 Edition.

Response to: CTR-035-061

EPA estimated annual (steady-state) benefits and annualized costs as well as 20- and 30-year streams of benefits and costs to account for the differences in the time frame for experiencing benefits and costs (i.e., up-front capital cost and a phase-in of benefits). EPA did not forecast economic, demographic, or policy changes across these time periods. Such a forecast would involve a great deal of uncertainty. However, EPA does not foresee changes in these variables negatively impacting the anticipated ratio of benefits and costs. Rather, EPA believes that future increases in population and economic activity will most likely increase the benefits of achieving standards for toxic pollutants in California waters compared to the cost of controls.

Comment: Based on our analysis of the impact of the proposed CTR, we will need to utilize reverse osmosis to meet the proposed CTR limits for copper. Based on this modification, we estimate that our potential annualized costs for compliance will be approximately $900,000. These costs are significantly higher than EPA's estimated costs per plant of $27,000 per year to $480,000 per year. Thus, we strongly believe that the draft Economic Analysis significantly underestimates the potential statewide costs associated with adoption of the CTR and should be revised.

Comment: EPA has greatly underestimated the costs of compliance in the EA. Information developed by CASA and Tri-TAC for just 23 POTWs indicates that annualized costs for those facilities may reach $400,000,000. These are the 23 plants that have had the opportunity to fullyreview their effluent data. Using this cost data, and extrapolating it for all affected California POTWs leads to a potential cost ranging from $570,000,000 to $995,000,000, depending on the assumptions used.

Response to: CTR-052-006

EPA disagrees with the $400 million cost estimate, however, neither EBDA nor CASA/Tri-TAC provide any details of the CASA/Tri-TAC analysis (e.g., names of the 23 major POTWs, the pollutants assigned costs, and cost estimation methodology), thus EPA cannot evaluate the $400 million cost estimate. In CASA/Tri-TAC's comment, Attachment 1 notes that CASA "assumed that regulatory relief options may not be available, and that, based on the pollutants causing compliance problems, pollution prevention and treatment plant optimization might not be sufficient to reliably achieve compliance." However, CASA/Tri-TAC did not provide any data substantiating this assumption. EPA's cost estimate in the Economic Analysis (EA) of the final CTR for all California POTWs affected by this rule ranges from $7.8 million to $41.6 million in the low and high cost scenarios, respectively. EPA stands by it's cost estimates provided in the EA of the final CTR which is based on available permit, permit application, and effluent monitoring data evaluated using a cost decision methodology which allowed for a case-by-case evaluation of costs for a sample set of facilities.

Comment: Impact on East Bay Dischargers Authority Ratepayers

The Authority and its member agencies serve approximately 700,000 people in southern and eastern Alameda County. Using an annualized cost of $44,257,000 results in an annual cost of $63.22 per person per year. Using an average of 3.25 persons per household results in an annual cost of $205.48 per household per year. Current sewer rates for Authority agencies are as low as $113 per year. Compliance

with the CTR would result in a new sewer rate of $318.48, or an increase of 282%. Clearly, the costs do not justify the benefits.

Response to: CTR-052-011

EPA disagrees with the $44 million annualized cost estimate for Alameda County, however, EBDA does not provide any details of how this cost was estimated (e.g., pollutants requiring reductions, pollutant concentrations, treatments required), thus EPA could not evaluate the cost estimate. EPA's cost estimate in the economic analysis of the final CTR for all California POTWs ranges from $7.8 million to $41.6 million annually in the low and high cost scenarios, respectively. EPA stands by it's cost estimates provided in the EA of the final CTR which is based on available permit, permit application, and effluent monitoring data evaluated using a cost decision methodology which allowed for a case-by-case evaluation of costs for a sample set of facilities.

Comment: The areas with which we find concerns and the requested changes include the following:

* Based on our very preliminary analysis of the impacts of the proposed CTR, we will need to add at a minimum reverse osmosis treatment at the regional plant to meet the rulemaking. Based on this modification, we estimate that our potential annualized costs for compliance will be $10,250,000. These costs are significantly higher than EPA's estimated costs per plant of $27,000 per year to $480,000 per year. Based upon this finding, we strongly believe that the draft Economic Analysis significantly underestimates the potential statewide costs associated with adoption of the CTR and should be revised.

Comment: * Based on the comments at the hearing of September 17, and our own estimates, the EPA's economic analysis has serious flaws and does not reflect the full costs for implementation of the CTR. The comments of the California Association of Sanitation Agencies should be given significant weight in this regard.

* For example, the WCA plants will not be able to meet the new criteria for copper, lead, and nickel, as well as some organics. This is true even after maximizing source control, pollution prevention, and process control improvements. Both our plants would need additional "end-of-pipe" treatment, such as reverse osmosis.

* Based on our analysis of the proposed CTR, we will need to implement reverse osmosis in order to meet the requirements of the proposed CTR. Based on this, we estimate that our potential annualized costs for compliance will be $11,220,000. These costs are significantly higher than EPA's estimated costs per plant of $27,000 to $480,000 per year. Thus, we believe strongly that the draft Economic Analysis significantly underestimates the potential statewide costs associated with adoption of the CTR and should be revised.

Response to: CTR-081-005b

EPA disagrees that its Economic Analysis (EA) underestimates costs. West County Agency does not provide the details of their $11.2 million cost estimate, thus EPA cannot evaluate its validity or conduct its own analysis. Based on EPA's sample of 14 POTWs in California, EPA predicts that the state-wide cost impact on POTWs would range from $7.8 million to $41.6 million per year. See the EA for details on the EPA's methodology and costs.

See responses to CTR-056-018, CTR-004-003, and CTR-045-012b.

Comment: The subject rule has a significant impact on our facility discharge and the citizens of the City. We therefore present the following comments for your consideration to re-open the comment period for this rule in order to facilitate a more complete review by public and in particular by those in the POTW community:

* Based on our analysis the impact of the USEPA proposed CTR will need significant in-plant

modifications, changes in effluent disinfection practices, and possibly incorporating nitrification and de-nitrification processes to fully comply with the proposed CTR. Based on these modifications, we estimate that our potential annualized costs for compliance will be around $5,900,000. These costs are significantly higher than USEPA's estimated costs per plant of $27,000 to $480,000 per year. Therefore we strongly believe that the draft economic analysis significantly underestimates the potential statewide costs associated with adopting the CTR and should be revised.

Comment: The District supports the following positions of CASA and SCAP where changes need to be made in the proposed California Toxics Rule:

Based on the District's analysis of the impact of the proposed California Toxies Rule, the District will need to add reverse osmosis to existing treatment processes to meet the proposed California Toxics Rule. Based on this modification, it is estimated that our potential annual costs for compliance will be $2.97 million, including retirement of capital. This cost is significantly higher than the EPA's estimated costs per plant of $27,000 per year to $480,000 per year. Thus we strongly believe that the draft economic analysis significantly underestimates the potential costs associated with adoption of the California Toxics Rule and should be revised.

Comment: While the draft regulations demonstrate clear progress on these and other issues, there remain some unresolved problems that could compromise our ability to serve our customers. We offer these comments in the hope of minimizing those potential impacts.

Adequacy of the Economic Analysis

We are, quite frankly, astounded that the draft CTR asserts negligable economic impacts as a result of the proposed regulations. Even a cursory examination of the criteria contained in the draft CTR suggest economic impacts well-beyond those assumed by the US EPA's economic model. These include over $650,000 in estimated annualized costs to abandon existing chlorine disinfection facilities and replace them with some other disinfection method such as ultra-violet radiation or ozone, or the addition of GAC filters or air-stripping towers. Each of these modifications may create new and additional compliance problems with other state and federal regulatory requirements and standards, with unknown costs to mitigate them. Clearly the potential magnitude of these economic impacts argues against the use of a generalized model for estimating statewide impacts.

SUMMARY

We hope these comments will help to make the final CTR a better document and a better law. Overall, the draft CTR reflects substantial thought and effort on how best to implement the Clean Water Act's mandate of reducing pollutant discharges to the nation's receiving waters. The draft CTR clearly advances this goal, but our hope is that those agencies and parties most-directly affected by it will be allowed additional time to review it to their satisfaction. We strongly encourage a more detailed assessment of the actual economic impacts that could result from these new regulations. The ability of public utilities to fund new projects has never been lower, and every rate increase requires sound and well-founded justification. No ratepayer should be asked to shoulder the cost of new regulations without a clear and detailed explanation of what it is going to cost, and what benefits will result. State mandated costs require state funding.

We appreciate this opportunity to comment on the draft California Toxics Rule. Please do not hesitate call myself or Dr. Randal Orton in our Resource Conservation and Public Outreach Department to tell us how we can help you further.

Response to: CTR-089-005

EPA disagrees with the $650,000 cost estimate to install a new disinfection method or additional treatment that will control chlorination/disinfection byproducts (DBPs) as EPA did not estimate that any sample facilities would need to install new equipment in order to ensure compliance with CTR-based effluent limits for DBPs. Of the 27 sample facilities examined, EPA assigned costs to 7 facilities for process optimization and to 4 facilities for pollution prevention efforts to control DBPs. EPA's estimated costs for process optimization for the sample facilities range from $25,000 to $230,000 depending on the size of the facility. Estimates for pollution prevention included costs for other, non-disinfection related pollutants and ranged from $50,000 to $2 million.

Comment: We're very concerned about the economic analysis. We understand that you can -- this is based on federal orders, executive order and some legislation, in that this is not the normal thing that you do, but we're really concerned that there are some really real significant flaws here.

I'm also very concerned that there's some real misleading of the people of California of what it's going to cost the water bodies in the state to meet these levels. And to say that you think it's going to be 84 million a year is entirely misleading.

It really concerns me that people are going to glom on that number, say, "Gee, this isn't going to cost us much," if you believe that economic analysis. There's very few sources of pollution which you address with the $84 million. It is not looking at the sources and not looking at actually getting those water bodies to those levels. So I would really recommend that you be really careful about those numbers.

Put yourself in my situation. We know in San Francisco that we're going to have a problem meeting aldrin peaks (phonetic) and the dioxin.

We think -- we don't have exact numbers on this right now, but we think that if we have to go to a worst-case scenario -- in other words, if we cannot meet those numbers with source control, we cannot meet those numbers by alternatives, we'll have to -- have to go to carbon or something like this. That could cost $100 million in -- up to 100 million in coastal costs, and $1 million in O & M a year.

Now, I'm going to go to my board of supervisors and say, "Please allow me to pass a bond issue so that I can meet these discharge requirements for discharge to the San Francisco Bay." We're not talking about the Pacific ocean now, just the bay.

And they say to me, "If we give you that money to build those facilities, will the people that fish in the San Francisco Bay, that live in San Francisco, be able to eat the fish?"

And I'm going to say no. I can't guarantee that, because we're a minor source. We're less than 20 percent of 4 percent of the total sources of discharge to San Francisco Bay.

So I think you need to be careful about how you throw these numbers around, because it's going to put us in a position of never being able to do anything either.

You need to think about this economic analysis, because I don't think it's real. And I don't think the benefits that you've shown either are very real, and we'll make more extensive comments in our written form on that.

Comment: 3. The proposed rule could cost the District between $2.7 and $7.1 million per year without providing significant benefits. The current Basin Plan for San Francisco Bay does not allow dilution for shallow water dischargers. A review of the Draft Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California, September 12, 1997, indicates that the draft policy would allow the current Basin Plan dilution policy to continue. Under the zero dilution policy and other historic permitting practices of the San Francisco Bay Regional Board (e.g., the Board has not considered translators in establishing permit limits), the District would be unable to comply with the proposed copper criteria for aquatic life protection (CMC and CCC), the proposed nickel criterion for aquatic life protection (CCC), and the proposed human health criterion for mercury.

The District, in 1996, made a thorough analysis of the costs and benefits of complying with the proposed copper criterion of 3.1 ug/I dissolved copper and the 4.9 ug/l site-specific objective developed by the Regional Board staff. That analysis indicated that the least costly alternative to comply with these objectives would be to construct a deep water outfall at a capital cost of $28 million and a total annual cost of $2.7 million. This would have the effect of doubling our current sewer service charges. The deep water outfall would not reduce the mass of copper discharged to the Bay. The sole benefit would be to achieve the copper criterion in the immediate vicinity of the outfall (the area affected is on the order of 0.6 acres).

The next most cost-effective alternatives were to go to land disposal or reverse osmosis treatment, both of which would have a total annual cost of $7.1 million. These alternatives would reduce the mass of copper discharged to San Pablo Bay by only 0. 16%. The cost per toxic pound equivalent removed for the deep water outfall is infinite, since no copper would be removed. If one were to assume that the copper discharged to deep water is removed, the cost per toxic pound equivalent removed would be $8,470/lb. For the alternatives that actually remove copper from the Bay, the cost per toxic pound equivalentremoved would be $22,300/lb for land disposal and $28,500/lb for reverse osmosis. The detailed report containing this analysis is presented in Attachment 1.

In conclusion, the adoption of the proposed copper criteria for San Pablo Bay could, under the high-end cost scenario of State implementation, result in very high costs without providing any significant water quality benefit. The District would concur that the low-end cost scenario could be zero (i.e., if the Regional Board were to allow a dilution credit and metals translators).

Response to: CTR-005-004

The Novato Sanitary District estimate is out of the range of the costs EPA estimated for the same

industrial category and within the same range of discharge flow. However, the information submitted by the District is not sufficient to compare the facility with sample facilities of the same industrial category and flow range because existing permit limits for copper, nickel and mercury are not indicated in the comment supporting documentation. However, review of the NPDES permit issued in 1992, which was to expire in 1997, indicates that final effluent limits for copper, nickel and mercury are 2.9 ug/L, 8.3 ug/L, and 0.03 ug/L, respectively. Even though Novato was not a sample facility evaluated by EPA, it appears that these limits are likely to be more stringent than CTR-based limits that would be calculated for this facility using standard U.S. EPA implementation procedures such as those EPA assumed for the CTR EA. In the case of nickel, for example, the most stringent CTR criterion (dissolved) is 8.2 ug/L and a metal translator would be used to convert this criterion to total. Consequently, the CTR-based criterion would likely be less stringent than the existing limit and no costs would be attributed to the rule. In the case of mercury, the 1992 limit of 0.03 ug/L is already more stringent than a projected CTR-based limit of 0.05 ug/L.

If a facility chooses to calculate permit limits with consideration of metal translators or water effect ratios, the facility will not likely need to implement high cost alternatives such as deep water outfall, land disposal, or reverse osmosis. Moreover, U.S. EPA is aware that the use of metal translators to implement water quality criteria for metals does not constitute a regulatory relief alternative under the proposed Inland Surface Waters Policy. In practice, the use of metals translators may be a standard step for the calculation of effluent limits in the State of California and consistent with EPA's policy concerning the implementation of dissolved water quality criteria.

EPA did not calculate a per household cost as part of the CTR analysis. By dividing the POTW portion of the revised high-end cost estimate ($41.6 million) by the State's current estimated number of households in California (11.1 million) results in an estimated cost of $3.75 per household per year. It is unknown, however, whether all of the costs incurred by POTWs would be passed directly on to households. Nonetheless, EPA believes that $3.75 per year is not an unreasonable rate increase to protect the waters of the State of California.

Comment: pp. 42188-42189 - Potential Costs Do Not Meet the $100 Million Threshold Under E 0. 12866 (also see discussion above) As noted on p. 42188, one component of the definition of a "significant regulatory action" is that the rule may have an annual effect on the economy of $100 million or more. EPA states on p.42189 that "the annualized potential costs that direct and indirect dischargers may incur as a result of State implementation of permit limits based on water quality standards using today's

proposed criteria are estimated to be between $15 million and $87 million." We believe that this range significantly underestimates the potential costs that may be realized from the implementation of this rule. This belief is based on the numerous assumptions used by EPA that would have served to underestimate potential costs, including assumptions about regulatory flexibility that are clearly contradicted in the Preamble to the rule itself. These issues are further enumerated in Attachment 2, which contains an analysis prepared by the environmental economics firm, M. Cubed. Furthermore, we strongly believe that EPA has a duty to look at a full range of potential costs that may be incurred, and not just to look at the costs under optimistic assumptions. This duty is especially acute in light of the uncertainties of how the CTR will be implemented by the State.

We examined the potential costs for the POTW sector to determine the reasonableness of EPA's cost estimates. Our preliminary analysis indicates that for 23 major POTWs the annualized costs could reach $400 million.(*3) This estimate includes the cost to construct and operate end-of-pipe treatment processes where these would be necessary to achieve projected effluent limits. Unlike the EPA cost estimates, we have assumed that regulatory relief options may not be available, and that, based on the pollutants causing compliance problems, pollution prevention and treatment plant optimization might not be sufficient to reliably achieve compliance. Thus, we feel that this estimate reflects a more accurate depiction of the potential POTW "high-end" compliance costs that could result from the draft CTR. Based on this analysis, we believe that EPA should re-analyze the potential costs for POTWs to meet water quality-based effluent limits based on the criteria in the CTR.

As noted on p. ES-2 of the Economic Analysis (U.S. EPA, 1997a), EPA estimated only the costs to point sources, and did not estimate the potential costs for compliance for nonpoint source dischargers, despite the fact that the majority of water bodies in California are impaired due to nonpoint source discharges (SWRCB, 1996). In addition, EPA failed to estimate the costs of compliance for wet weather dischargers, such as municipal and industrial stormwater dischargers. These omissions also lead us to believe that the potential total costs of the rule are far greater than $100 million. EPA must correct these deficiencies and redo the Economic Analysis.

(*3) Backup information for these cost estimates is available upon request.

Comment: As background, the Sonoma Valley County Sanitation District (District) provides secondary

treatment of wastewater from the towns and communities of Sonoma, Glen Ellen, Boyes, Hot Springs and Aqua Caliente. These are small residential communities with supporting commercial development and only two significant industrial users, a winery and a State hospital. The plant serves a combined population of approximately 26,000, has a capacity of 3.0 million gallons per day (mgd). Between November 1 and April 30 of each year, the plant discharges effluent to the upper end of Schell Slough. During the remainder of the year the effluent is reclaimed for agricultural irrigation. Schell Slough extends approximately 5 miles downstream from the discharge before it terminates at its confluence with Second Napa Slough. Approximately 5.7 miles of waterways connects the Schell Slough system / Second Napa Slough confluence to both the Napa River and San Pablo Bay.

Under the Basin Plan dilution policy, the treatment plant discharge to Schell Slough does not receive a dilution credit, and as a result receiving water criteria are applied directly as effluent limitations in our permit. The District has conducted a dilution analysis using a model of Schell Slough and downstream waters (see attachment). The analysis found that during periods of low natural runoff, the discharge receives a 1:1 dilution about 3 miles downstream and a 10:1 dilution shortly after entering Second Napa Slough 5 miles downstream.

The District has implemented a pollution prevention program. As a result of a corrosion control program implemented by our agency, copper levels in the plant effluent have been reduced from over 40 ug/l several years ago to between 10 and 20 ug/l today. Based on studies conducted by the Novato Sanitary District, which has the same water supply and similar effluent copper levels, it can be concluded that the remaining copper levels in the Sonoma plant effluent are largely the result of corrosion of copper pipes in local households and businesses. Thus, there are no feasible pollution prevention measures that can be taken to bring about further source reduction of copper.

The District has recently conducted an effluent monitoring program to assess compliance with EPA-recommended water quality criteria, using clean sampling techniques and appropriate QA/QC. We are conscious of the difficulty of analyzing for certain constituents and have taken precautions to ensure that we get accurate results. For example, in the case of mercury, we are using ultra clean sampling techniques and sending our samples to Frontier GeoScience, the recognized national expert in mercury analysis. This sampling program has identified several significant attainability problems with respect to the proposed CTR criteria.

3. The proposed rule could cost the District approximately $7 million per year without providing commensurate environmental benefits. The current Basin Plan for San Francisco Bay does not allow dilution for shallow water dischargers. A review of the Draft Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California, September 12, 1997, indicates that the draft policy would allow the current Basin Plan dilution policy to continue. Under the zero dilution policy and other historic permitting practices of the San Francisco Bay Regional Board (e.g., the Board has not considered translators in establishing permit limits), the District would be unable to comply with the proposed aquatic life criteria for copper (CMC and CCC) and the proposed human health criteria for mercury, alpha-BHC, gamma-BHC (lindane) and bromodichloro-methane (see Table 1). Based on constituents detected in 1 or 2 of the 6 samples, one PAH (indeno (1,2,3-cd)pyrene) and several pesticides (chlordane, 4,4'-DDT, and endrin) may also present attainability problems (see Table 2). To achieve the CTR criteria for these constituents would require reductions of greater than 80% for copper and reductions of between 49% and 75% for mercury, and between 83% and 98% for alpha-BHC and gamma BHC. Such reductions would require tertiary lime precipitation and reverse osmosis for mercury and copper and carbon adsorption for the organics. The costs of these facilities for a 3.0 mgd plant would be on the order of $7 million per year ($5 million per year for lime precipitation and reverse osmosis and $2 million per year for carbon adsorption)(see Table 4).(*1) This compares to the present
