Many DOT roads cross streams and wetlands and frequently flooded areas, some of which have been routed into ditches. Many of these host special status amphibians that will go as far as 3 km from their breeding sites, so check to see if they are known to occur downstream or upstream. When choosing LID, I believe it is better to choose full dispersion instead of bioswales and detention ponds because the second can be ecological traps. It truly depends on the location. Avoid doing activities however, that also depend upon or literally require 'improvement of downstream conveyances' for the MS4 to 'work' right. 'Improvement' usually seems to mean blowing up beaver dams or pro-actively lowering water tables in key habitats. Lowering water tables also may change aquifer recharge, reducing it.
