

Thomas Doherty

The horizontal drilling thru shale fields and the fracking process creates wells that can not be fully sealed. The result is disturbed methane that migrates up thru the myriad of rock fissures to eventually be released to the atmosphere. From there it is a greenhouse gas that warms the climate, increases wild weather related destruction and raises the seas. Even new wells have the leaking problem after a few years.

As such I urge you to not allow fracking or fracked waste disposal in NJ or the sensitive Delaware River Basin.
