

Larry Green

Even though it is laudable that an improvement plan has been submitted to improve water quality in the Salt River in western Wyoming and lower E.coli counts in the river, it makes no sense from a public health and safety point of view to wait five years to test and publish E.coli count data for the Salt River. The river corridor is heavily used by families with young children floating in inner tubes and all manner of air mattresses. They all ingest significant amounts of contaminated water along with their out of state friends. The " fisherman" traffic on the river increases yearly. To assume E.coli counts will drop and don't need more frequent monitoring is an unsafe gamble.
