I have read all the previous comments submitted at time. I would agree 100% with the information and comments submitted by Brad Wenz. (Thank you Brad) As it is with taking corn out mid to late October it's a race against time and weather to get the crop out manure applied, and tillage done before freeze up. With the new technology that has been developed in the last 5 to 10 years soil grid sampling, variable rate fertilizer application, sensors that read real time soil nitrogen levels and allow for variable rate on different soil types as well as population rate changes for different soils. This will allow us all to do a more precise job, cutting costs and enhancing a positive environmental impact. Exciting possibilities ahead.
