Table 4
Groundwater Data Compared to Groundwater-Based Intervention Limits
Elk River Landfill
Elk River, Minnesota

Barr Standard Footnotes and Qualifiers

--	Not analyzed/Not available.
B	The analyte was detected in the associated laboratory blank sample(s).
J	Estimated detected value. Either certain QC criteria were not met or the concentration is between the laboratory's detection and quantitation limits.
J+	The result is an estimated quantity and may be biased high.
J-	The result is an estimated quantity and may be biased low.
U	The analyte was analyzed for, but was not detected.
UJ	The analyte was analyzed for, but was not detected. The reported value is approximate and may be inaccurate or imprecise.

Laboratory Qualifiers

B	The same analyte is found in the associated blank.
C3	The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.
C5	The reported concentration is an estimate. The continuing calibration standard associated with this data responded high. Data is likely to show a high bias concerning the result.
F1	MS and/or MSD Recovery exceeds the control limits
J3	The associated batch QC was outside the established quality control range for precision.
J4	The associated batch QC was outside the established quality control range for accuracy.
J6	The sample matrix interfered with the ability to make any accurate determination; spike value is low.
O1	The analyte failed the method required serial dilution test and/or subsequent post-spike criteria. These failures indicate matrix interference.
P1	RPD value not applicable for sample concentrations less than 5 times the reporting limit.
T8	Sample(s) received past/too close to holding time expiration.
V	The sample concentration is too high to evaluate accurate spike recoveries.

MDH Human Health-Based Water Guidance Table

(1)	Value is representative of the lowest exposure duration published in the Minnesota Department of Health Human Health Advisory Table.
CR	Value represents the criteria for Chromium, hexavalent.
DCP	Value shown is 1,3-dichloropropene in the MDH criterion, however, the laboratory reports cis and trans isomers individually.
HBV20	Health Based Value 2020.
HBV22	Health Based Value 2022.
HRL09	Health Risk Limit 2009.
HRL13	Health Risk Limit 2013.
HRL15	Health Risk Limit 2015.
HRL18	Health Risk Limit 2018.
HRL23	Health Risk Limit 2023.
HRL93	Health Risk Limit 1993.
HRL94	Health Risk Limit 1994.
HRLMCL	Health Risk Limit; Maximum Contaminant Level.
ND	Not derived due to insufficient information.
RAA13	Risk Assessment Advice 2013.
RAA16	Risk Assessment Advice 2016.
RAA17	Risk Assessment Advice 2017.
XYL	Value shown is for the sum of the mixed o,m and p Xylene isomers.

Data Footnotes and Qualifiers

Barr Standard Footnotes and Qualifiers

--	Not analyzed/Not available.
U	The analyte was analyzed for, but was not detected.

Laboratory Qualifiers

B	The same analyte is found in the associated blank.
C3	The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.
J3	The associated batch QC was outside the established quality control range for precision.
J4	The associated batch QC was outside the established quality control range for accuracy.
Q	Sample was prepared and/or analyzed past holding time as defined in the method. Concentrations should be considered minimum values.
V	The sample concentration is too high to evaluate accurate spike recoveries.

MDH Human Health-Based Water Guidance Table

(1)	Value is representative of the lowest exposure duration published in the Minnesota Department of Health Human Health Advisory Table.
DCP	Value shown is 1,3-dichloropropene in the MDH criterion, however, the laboratory reports cis and trans isomers individually.
HRL09	Health Risk Limit 2009.
HRL13	Health Risk Limit 2013.
HRL15	Health Risk Limit 2015.
HRL18	Health Risk Limit 2018.
HRL23	Health Risk Limit 2023.
HRL93	Health Risk Limit 1993.
HRL94	Health Risk Limit 1994.
HRLMCL	Health Risk Limit; Maximum Contaminant Level.
ND	Not derived due to insufficient information.
RAA13	Risk Assessment Advice 2013.
RAA16	Risk Assessment Advice 2016.
RAA17	Risk Assessment Advice 2017.
XYL	Value shown is for the sum of the mixed o,m and p Xylene isomers.

B The same analyte is found in the associated blank

C5 The reported concentration is an estimate. The continuing calibration standard associated with this data responded high. Data is likely to show a high bias concerning the result.

F1 Sample filtration was performed in the laboratory.

H Recommended sample preservation, extraction or analysis holding time was exceeded.

J+ The result is an estimated quantity and may be biased high.

J3 The associated batch QC was outside the established quality control range for precision.

Q Sample was prepared and/or analyzed past holding time as defined in the method. Concentrations should beconsidered minimum values.

U The analyte was analyzed for, but was not detected.

> Greater than.

C3 The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.

C5 The reported concentration is an estimate. The continuing calibration standard associated with this data responded high. Data is likely to show a high bias concerning the result.

H Recommended sample preservation, extraction or analysis holding time was exceeded.

J Estimated detected value. Either certain QC criteria were not met or the concentration is between the laboratory's detection and quantitation limits.

J- The result is an estimated quantity and may be biased low.

J3 The associated batch QC was outside the established quality control range for precision.

J4 The associated batch QC was outside the established quality control range for accuracy.

L1 Analyte recovery in the laboratory control sample (LCS) was above QC limits. Results for this analyte in associated samples may be biased high.

N2 Analyte reported using a calibration and validation based on Azobenzene (CAS 103-33-3). 1,2-Diphenylhydrazine decomposes into Azobenzene during the analysis.

P RPD between the primary and confirmatory analysis exceeded 40%.

P1 RPD value not applicable for sample concentrations less than 5 times the reporting limit.

T8 Sample(s) received past/too close to holding time expiration.

U The analyte was analyzed for, but was not detected.

Notes and definitions:

[1] Minnesota unique well ID or MPCA EQuIS sys_loc_code.

[2] Sampling frequency listed in Sampling and Analysis Plan (SAP; Barr, 2024); pending update in 2025

[3] Per Permit SW-74; addnl monitoring may be conducted per other plans.

[4] Baseline monitoring to be completed 2025.

[5] Anticipated future annual sampling frequency in SAP shown.

[6] Former residential well at 22447 Tipton St. Disconnected from the house in September 2015.

[7] Listed as 11265 223rd Ave in Permit SW-74. Correct address shown above.

[8] Replacement well installed but not connected to house in 2023.

VOCs - Organic compounds; see Table A1 in SAP.

Inorganics - See Table A2 in SAP.

Status Key

In Network - monitoring well is incorporated into network (and included in SAP)

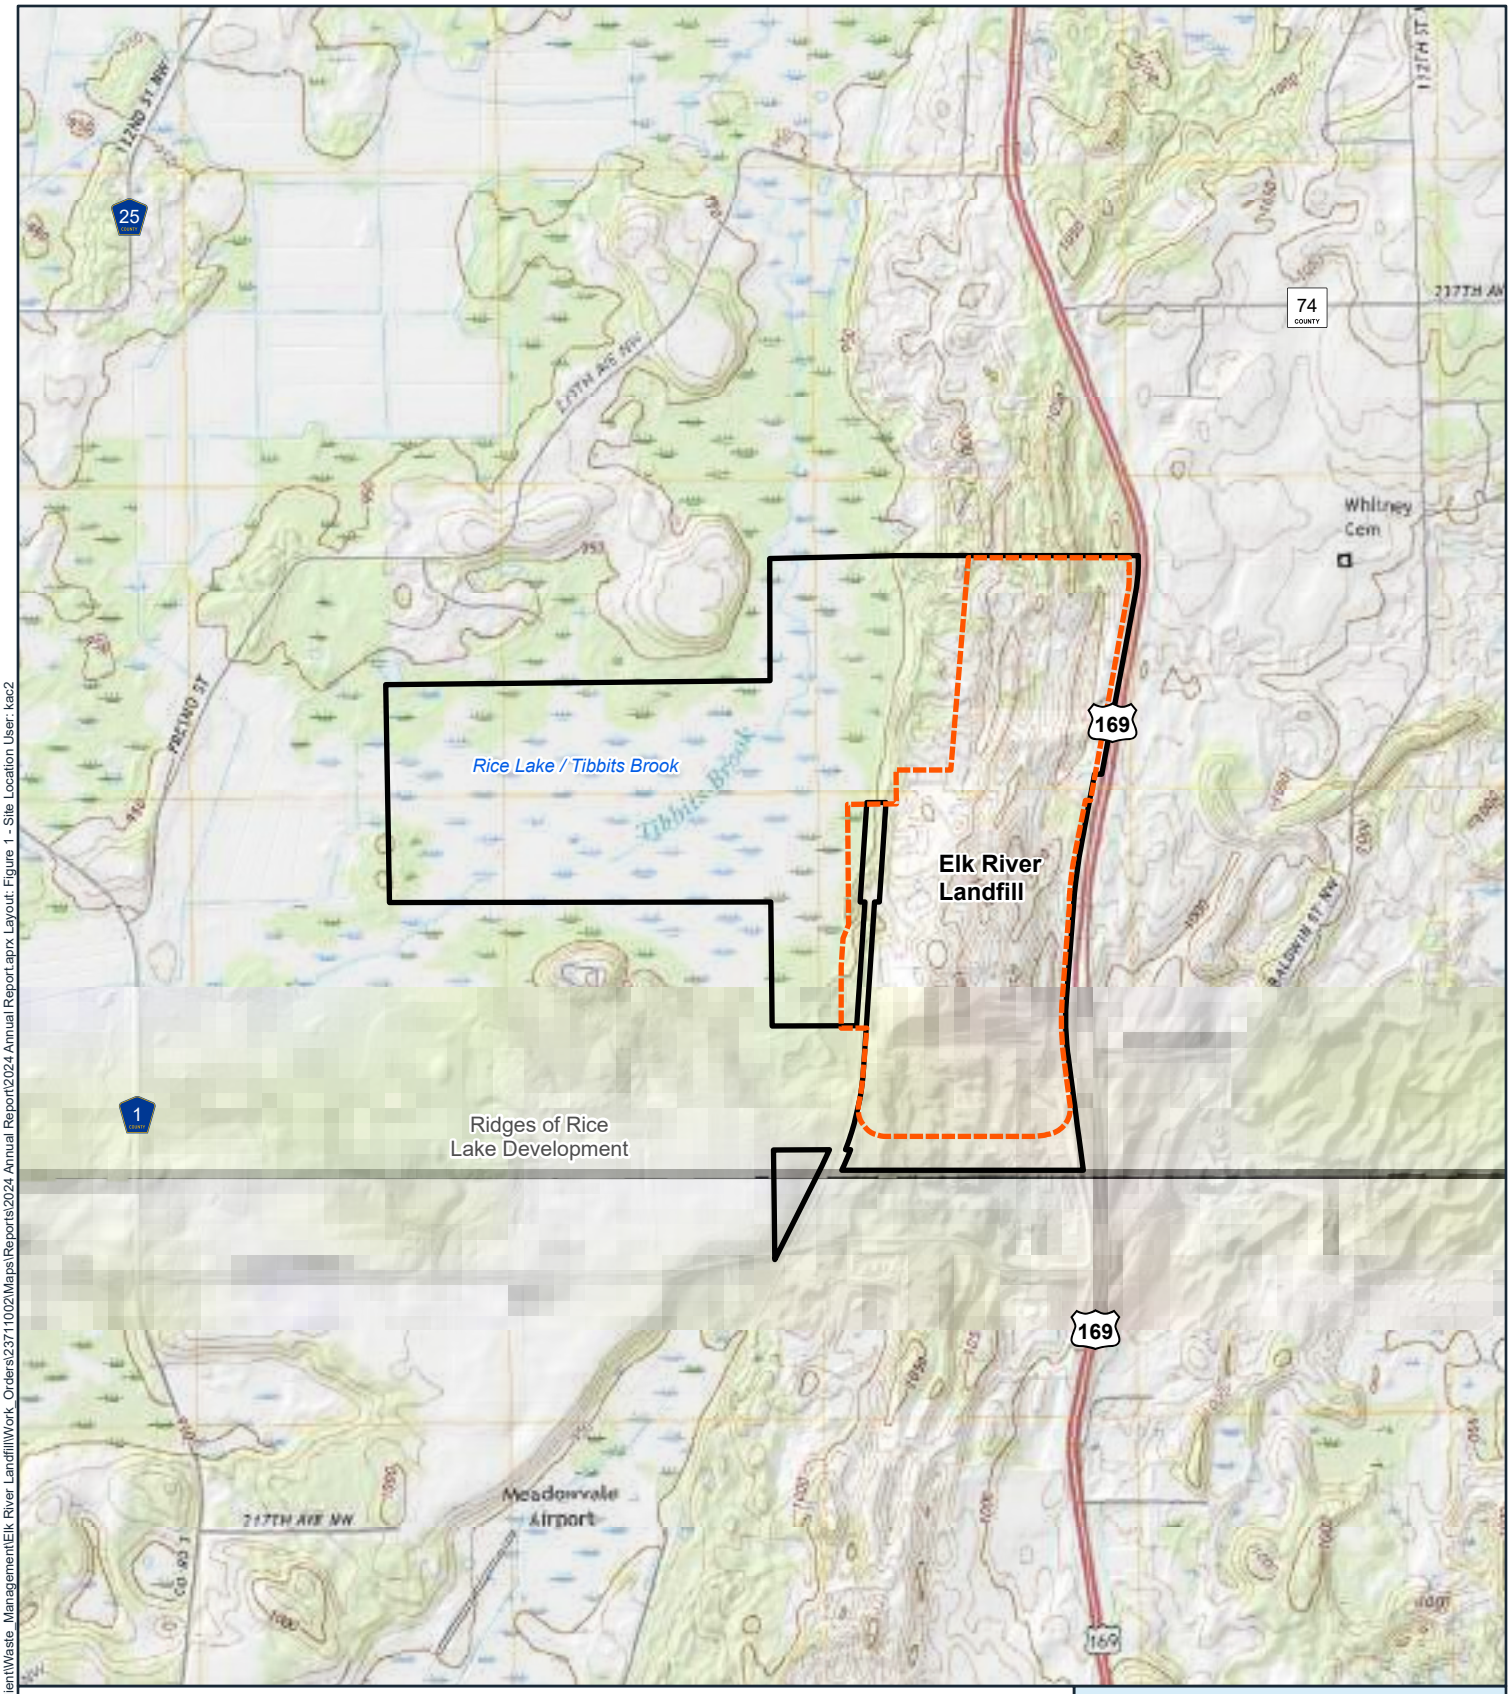
NC - Non-compliance monitoring well located within 200' of cell boundary

GWCAM - well is monitored to evaluate natural attenuation per GWCAWP (Apr. 2024)

GWCAS - well is monitored for sentinel monitoring purposes per the GWCAWP (Apr. 2024)

per Permit SW-74 - residential well is monitored per Solid Waste Permit SW-74

GWCAWP - residential well is monitored per the GWCAWP (Apr. 2024)



WL only - monitoring well is used for water level monitoring only per SAP and/or Permit SW-74

Well Screen Placement Key

WT - Well screen is constructed to intercept the water table

S - Monitoring well is constructed with a submerged screen

Methyl isobutyl ketone (MIBK)	ug/l	< 5.00 U	< 5.00 U	--	--	< 5.00 U	--	--
Methyl tertiary butyl ether (MTBE)	ug/l	< 1.00 U	< 1.00 U	--	--	< 1.00 U	--	--
Methylene chloride	ug/l	< 1.00 U	< 1.00 U	--	--	< 1.00 U	--	--
Naphthalene	ug/l	< 1.00 U	< 1.00 U	--	--	< 1.00 U	--	--
Propylbenzene	ug/l	< 1.00 U	< 1.00 U	--	--	< 1.00 U	--	--
Styrene	ug/l	< 1.00 U	< 1.00 U	--	--	< 1.00 U	--	--
Tetrachloroethylene	ug/l	< 1.00 U	< 1.00 U	--	--	< 1.00 U	--	--
Tetrahydrofuran	ug/l	< 5.00 U	< 5.00 U	--	--	< 5.00 U	--	--
Toluene	ug/l	< 1.00 U	< 1.00 U	--	--	< 1.00 U	--	--
Trichloroethylene (TCE)	ug/l	< 0.100 U	< 0.100 U	--	--	< 0.100 U	--	--
Trichlorofluoromethane (Freon-11)	ug/l	< 1.00 U	< 1.00 U	--	--	< 1.00 U	--	--
Trichlorotrifluoroethane (Freon 113)	ug/l	< 1.00 U	< 1.00 U	--	--	< 1.00 U	--	--
Vinyl chloride	ug/l	< 0.0500 U	< 0.0500 U	--	--	< 0.0500 U	--	--
Xylene, total	ug/l	< 2.00 U	< 2.00 U	--	--	< 2.00 U	--	--

Table A2
2023-2024 Groundwater Data for Upper Outwash/Shallow Wells
Elk River Landfill
Elk River, Minnesota

	Location	401-OWA	P-403C	P-403C	P-403C	408-OWA	408-OWA	408-OWA
	Date	4/20/2023	4/20/2023	10/23/2023	10/16/2024	4/20/2023	10/23/2023	10/16/2024
	Sample Type	N	N	N	N	N	N	N
Parameter	Units							
General Parameters								
Alkalinity, total, as CaCO3	mg/l	**359**	**254**	**374**	**323**	**246**	**278**	**297**
Anions	meq/l	**15.6**	**5.66**	**8.91**	**7.37**	**5.20**	**5.92**	**6.19**
Carbon, total organic	mg/l							
Cation-Anion balance	%	--	--	**-10.5**	**1.78**	--	**14.9**	**-1.05**
Cations	meq/l	**16.2**	**5.34**	**7.22**	**7.64**	**5.37**	**7.98**	**6.06**
Chloride	mg/l	**299**	**1.25 B**	**3.78**	**2.52**	**2.66**	**1.29**	**1.19**
Dissolved oxygen, field	mg/l	**9**	**1.7**	**1.5**	**1.6**	**8**	**6.2**	**2.4**
Ion Balance	%							
Iron, ferrous, FE II, field	mg/l							
Manganese II, field	mg/l							
Nitrogen, ammonia, as N	mg/l	< 0.100 U	< 0.100 U	< 0.100 U	< 0.100 U	< 0.100 U	< 0.100 U	< 0.100 U
Nitrogen, nitrate, as N	mg/l							
Nitrogen, nitrite, as N	mg/l							
Nitrogen, nitrate + nitrite, as N	mg/l							
Nitrogen, total kjeldahl (TKN)	mg/l							
pH, field	pH units	**6.86**	**7.15**	**7.25**	**7.05**	**7.14**	**7.38**	**7.19**
Redox (oxidation potential), field	mV	**24.8**	**31**	**19**	**100**	**66.7**	**25**	**150**
Solids, total dissolved	mg/l	**932**	**270**	**421**	**379**	**282**	**281**	**298**
Solids, total suspended	mg/l							
Specific conductance @ 25 ºC, field	umhos/cm	**1560**	**442**	**746**	**702**	**475**	**518**	**520**
Sulfate, as SO4	mg/l	**10.4**	**27.7**	**63.7**	**44.3**	**13.8**	**15.8**	**12.1**
Sulfide, as S^{2-}	mg/l							
Temperature, field	deg C	**9.7**	**7.7**	**8.8**	**9**	**10.7**	**10.9**	**11.4**
Turbidity, field	NTU	**24.6**	**90.6**	**77.7**	**34**	**0.6**	**1.5**	**1**
Dissolved Metals								
Arsenic	ug/l	< 1.00 U	< 1.00 U	< 2.00 U	< 2.00 U	< 1.00 U	< 2.00 U	< 2.00 U
Boron	ug/l	< 100 U	< 100 U	< 200 U	< 200 U	< 100 U	< 200 U	< 200 U
Cadmium	ug/l							
Calcium	mg/l	**145**	**50.5**	**96.5**	**81.7**	**65.3**	**73.1**	**75.7**
Chromium	ug/l	**8.96**	< 4.00 U	< 4.00 U	< 4.00 U	< 4.00 U	< 4.00 U	< 4.00 U
Copper	ug/l							
Iron	ug/l	< 100 U	< 100 U	< 100 U	< 100 U	< 100 U	< 100 U	< 100 U
Lead	ug/l							
Magnesium	mg/l	**40.9**	**29.1**	**24.6**	**39.3**	**22.6**	**49.3**	**24.6**
Manganese	ug/l							
Mercury	ug/l							
Potassium	mg/l	**3.33**	**3.45**	**1.58**	**1.36**	< 1 U	**1.05**	< 1 U
Sodium	mg/l	**127**	**7.89**	**7.79**	**6.87**	**5.26**	**5.83**	**5.44**
Zinc	ug/l	< 10.0 U	< 10.0 U	**16.1**	< 10.0 U	< 10.0 U	**15.4**	< 10.0 U

Monitored Natural Attenuation Evaluation

2024 Monitored Natural Attenuation Data Summary

The natural attenuation monitoring program is designed to collect the data needed to complete the assessment of relevant trends in key constituents as well as ascertain if the performance of monitored natural attenuation (MNA) is a suitable corrective action approach for chlorinated organics at ERL. Initial MNA performance monitoring began in 2021 per the Groundwater Corrective Action Work Plan (CAWP; Barr, 2021), and the Initial Performance Evaluation report was completed in 2024 per the CAWP (Barr, 2024). The 5-Year performance evaluation will be completed in the first quarter of 2027 (Q1 2027) to assess the corrective action protectiveness to human health and the environment (see Section 5.3 of the CAWP for additional details).

The following sections provide an overview of 2024 MNA monitoring activities, well network updates, a comparison of relevant groundwater quality results to the contingency action plan presented in the CAWP, an evaluation of vinyl chloride trends, an assessment of geochemical conditions, and updates to the MNA monitoring plan for 2025.

MNA Monitoring Activities

The 2024 through 2026 natural attenuation monitoring schedule and parameters are shown in Table 1 and Table 2, respectively. The 2024 natural attenuation monitoring was conducted in accordance with Table 1.

Monitoring Network Updates

ERL completed a vertical groundwater profiling boring (B2-342) and installed one additional monitoring well (P-342C) in February 2025 per the recommendations in the Initial Performance Evaluation report (Barr, 2024). The groundwater profiling data and well installation plan were provided to MPCA, Sherburne County, and the City of Elk River on February 13, 2025. No organics (including vinyl chloride) were detected in the vertical groundwater profiling samples. A report summarizing the investigation, initial well monitoring results, and baseline and future monitoring plans for well P-342C will be submitted later in 2025.

Contingency Summary

The groundwater corrective action contingency plan is summarized in Table 3. Scenarios that would trigger contingency actions include:

- Organic compound detection attributable to ERL in a water supply well sample; and
- Confirmed organic compound detection attributable to ERL in a sentinel well sample.

The 2024 water quality monitoring data collected from the MNA well network and sentinel wells is included in Table 4. Groundwater quality monitoring results did not trigger contingency actions in 2024.

Vinyl Chloride Extent and Concentration Trends

Plots of vinyl chloride concentrations are included on Figure 2 and shown spatially at ERL on Figure 3. A summary of the statistical evaluation of vinyl chloride concentration trends is provided in Table 5. The following observations are provided:

- The extent of the vinyl chloride plume downgradient of the landfill is delineated by the existing monitoring well network based on the 2024 (and previous) water quality monitoring results. Vinyl chloride (and other organics) have not been detected in samples collected from monitoring well

P-342L (or in groundwater profile samples collected there in early 2025 as mentioned above), or monitoring wells to the north (i.e., P-333L, P-329L, P-328L, P-340L, and P-327L), or monitoring wells to the south (i.e., P-335L, P-341L,).

- Vinyl chloride concentrations continue to decrease or have no trend (stable) below/near the Health Risk Limit [HRL] of 2 micrograms per liter [µg/L] in groundwater in the central and southern portions of the plume along the western edge of the landfill (Table 5; Figures 3 and 4). Vinyl chloride concentrations in groundwater at the nearest monitoring well located downgradient of the southern two-thirds of the plume (P-326L) are decreasing.
- In the northern third of the plume, along the western edge of the Pre-Subtitle D (unlined) portion of the landfill, vinyl chloride concentrations are increasing in groundwater at one well (P-302C) and stable at nearby wells P-29C and P-320C/320C2/320L. Vinyl chloride concentrations in groundwater downgradient of well P-302C are decreasing at P-321L and stable at P-325L (Table 5; Figures 3 and 4). Vinyl chloride concentrations are stable and below the HRL at well P-301C immediately north of this area.
- Vinyl chloride concentrations in groundwater at well P-321L, located upgradient of well P-325L, peaked around 2016 and have since decreased (Figure 2). The peak vinyl chloride concentration in groundwater occurred at well P-325L in 2022 and may be related to downgradient migration of peak concentrations in groundwater previously observed at P-321L.
- Vinyl chloride concentrations at monitoring wells P-334L, P-338L, and P694477, which are located closer to the middle and distal edge of the plume (Figure 3), have been increasing since approximately 2020 (Table 5; Figures 3 and 4). Based on historic organics concentration data at ERL and estimated groundwater flow velocities, it appears that the remnants of the slug of elevated organics concentrations observed at P-17C in 1994 may be reaching the distal portion of the plume. The slug of elevated organics was estimated to reach P-334L between approximately 2024 and 2033 (Barr, 2024). Water quality at monitoring well P-342L and recently installed well P-342C will continue to be monitored, and the data will be used to evaluate the extent of the vinyl chloride plume. The observed vinyl chloride concentration trends (i.e., increasing at wells P-334L/P-338L/P694477 and stable to decreasing at most wells located closer to the landfill) are consistent with the anticipated migration of peak vinyl chloride concentrations to the west and may be followed by decreasing concentrations in the future.
- Because vinyl chloride is a daughter product of cis-1,2-dichloroethylene (cDCE) dechlorination, the concentration and extent of vinyl chloride in groundwater can be directly related to where cDCE degrades to vinyl chloride along the flowpath. For example, 1 µg/L of cDCE will degrade to an equivalent micromolar mass of vinyl chloride with a concentration of 0.6 µg/L (the concentration is lower because the molecular weight of vinyl chloride is lower than cDCE); therefore, the low concentrations of cDCE that are observed in groundwater can degrade to vinyl chloride concentrations well above the reporting limit (0.05 µg/L). To further explore the relationship of cDCE to vinyl chloride downgradient of ERL, a low-level analysis of cDCE was

implemented for 2023-2024 to achieve a lower reporting limit (the reporting limit reduced from 1.0 µg/L to 0.1 µg/L). The low-level analysis results in 2023 and 2024 show that cDCE is present in groundwater at P-338L and absent at P-334L, where vinyl chloride concentrations currently demonstrate an increasing trend. As a result, it appears that the degradation of cDCE to vinyl chloride in the P-338L area is contributing to the vinyl chloride concentrations in the groundwater system, thereby extending the vinyl chloride plume downgradient (i.e., to well P-334L).

- The estimated mass flux of vinyl chloride in groundwater flowing from the western edge of the landfill was 0.017 pounds per year (lb/yr) in 2023, which is 82% less than the estimated mass flux in April 2010 (0.11 lb/yr) (Barr, 2024). The estimated overall mass of vinyl chloride in groundwater downgradient of the landfill is approximately one pound (Barr, 2020a).

Other Organics

Plots of vinyl chloride precursor compounds (e.g., trichloroethene (TCE), cDCE, etc.) concentrations are included on Figure 4, and plots of ethyl ether concentrations are included in Attachment A. The following observations are provided:

- Concentrations of vinyl chloride precursor compounds are generally consistent with previous years (Barr, 2020b).
- Ethyl ether concentration trends (Attachment A) are similar to vinyl chloride trends. Ethyl ether concentrations remain below the Intervention Limit (50 µg/L) at each well it is detected. A HRL has not been developed for ethyl ether.

Geochemical Conditions

Geochemical data (terminal electron acceptors, general indicator parameters) collected in 2024 were generally consistent with previous years.

This data shows that conditions are suitable for reductive dechlorination near the western edge of ERL, particularly in and downgradient of the P-17C Area (Barr, 2020b and 2024). The decrease in concentrations of chlorinated compounds over time in this area and the sparsity of vinyl chloride precursors in groundwater support this finding. The dominant reducing environment in the groundwater system downgradient of the landfill appears to be iron/manganese reduction (which is favorable for reductive dechlorination). It is also important to note that previous magnetic susceptibility testing demonstrated that abiotic pathways are also supporting the degradation of cDCE and VC.

Future Work

MNA monitoring will be conducted in 2025 (Table 1). Per the CAWP (Barr, 2021), a 5-Year performance evaluation will be conducted in the first quarter of 2027 (Q1 2027) to assess the corrective action protectiveness to human health and the environment. A report summarizing the vertical groundwater profiling results, well installation work, and initial groundwater monitoring results will be submitted within 60 days of receipt of the initial monitoring well sampling results from well P-342C.

Table 3
Groundwater Corrective Action Contingency Plan Summary
Elk River Landfill

Scenario	Description	Applicable Wells	Actions	Approximate Timing
1 Organics detection in a water supply well sample	A detection of an organic compound[1] in a sample from a downgradient water supply well will trigger data review and follow-up sampling[2] (to confirm/verify the initial result) and action to protect the health of the well users.	Downgradient monitored water supply wells.	Review the data to assess quality control/quality assurance results (including field and laboratory control sample) and potential of alternate sources[3].	As soon as feasible (but within two weeks of receiving sample results).
			Notify the owner/resident and MPCA (and others) and coordinate/collect/analyze a confirmation sample.	Within 48 hours of identifying the organics detection. Confirmation sample analysis will be expedited if possible.
			If the detected concentration is above Minnesota drinking water criteria, provide bottled water to the resident until the detection is resolved through confirmation sampling/analysis or addressed by further action.	Within 48 hours of identifying the organics detection.
			If confirmed[4], address the detected organic to prevent exposure to groundwater users[5].	As soon as feasible (after confirmation).
			Evaluate the need for additional or alternate correction action.	To be determined.
2 Organics detection at sentinel well	A first-time detection of an organic compound[1,4] at a concentration greater than the IL will trigger rapid notification (i.e., within 48 hours of identification) and resampling unless obvious sampling or laboratory QA/QC issues are evident.	Sentinel monitoring wells: P-327L, P-328L, P-329L, P-333L, P-335L, P-339L (contingent on final location), P-340L, and P-341L .	Notify the MPCA (and others) and coordinate/collect/analyze a verification sample.	Notify within 48 hours of identifying the organics detection above the IL. Verification resample will be conducted as soon as feasible.
			Review the evaluation criteria for nearby water supply wells in context of the detection (see Table 4) and determine if additional water supply well actions are appropriate.	Annual Water Quality Monitoring Report (or separate submittal).
			Review monitoring results from the following three triannual events and determine if additional investigation and/or well installation activities are appropriate.	Subsequent Annual Water Quality Monitoring Report.
			If appropriate, prepare plans for additional investigation activities and/or evaluate the need for additional or alternate corrective action.	To be determined.

Notes:

[1] Attributed to the landfill.

[2] Sampling and additional actions require permission of the well owner.

[3] Common sources of low level organics not attributed to the landfill include sample cross contamination (during sample collection, transport, or analysis), well disinfection byproducts (e.g., well disinfection), water pumping/transmission/storage system components, separate sources.

[4] A confirmed detection is defined as comparable detections for at least two consecutive sampling events that are not attributed to sampling, handling, or laboratory cross contamination.

[5] May include installation of a point of entry water treatment system, installation of a replacement water supply well, providing a long-term water delivery, or other options/combined approach

Notes
GWCAM - Groundwater Corrective Action Monitoring Well

Data Footnotes and Qualifiers

Barr Standard Footnotes and Qualifiers

U	The analyte was analyzed for, but was not detected.
H	Recommended sample preservation, extraction or analysis holding time was exceeded.

Laboratory Qualifiers

B	The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Data is likely to show a low bias concerning the result.
C3	The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.
C4	The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Data is likely to show a low bias concerning the result.
C5	The reported concentration is an estimate. The continuing calibration standard associated with this data responded high. Data is likely to show a high bias concerning the result.
J	The identification of the analyte is acceptable; the reported value is an estimate.
J3	The associated batch QC was outside the established quality control range for precision.
J4	The associated batch QC was outside the established quality control range for accuracy.
P1	P1 RPD value not applicable for sample concentrations less than 5 times the reporting limit.
Q	Sample was prepared and/or analyzed past holding time as defined in the method. Concentrations should be considered minimum values.
T8	Sample(s) received past/too close to holding time expiration.
V	The sample concentration is too high to evaluate accurate spike recoveries.

MDH Human Health-Based Water Guidance Table

(1)	Value is representative of the lowest exposure duration published in the Minnesota Department of Health Human Health Advisory Table.
CR	Value represents the criteria for Chromium, hexavalent.
DCP	Value shown is 1,3-dichloropropene in the MDH criterion, however, the laboratory reports cis and trans isomers individually.
HRL09	Health Risk Limit 2009
HRL13	Health Risk Limit 2013
HRL15	Health Risk Limit 2015
HRL18	Health Risk Limit 2018
HRL23	Health Risk Limit 2023
HRL93	Health Risk Limit 1993
HRL94	Health Risk Limit 1994
MCL	Maximum Contaminant Level.
ND	Not derived due to insufficient information.
RAA13	Risk Assessment Advice 2013.
RAA16	Risk Assessment Advice 2016.

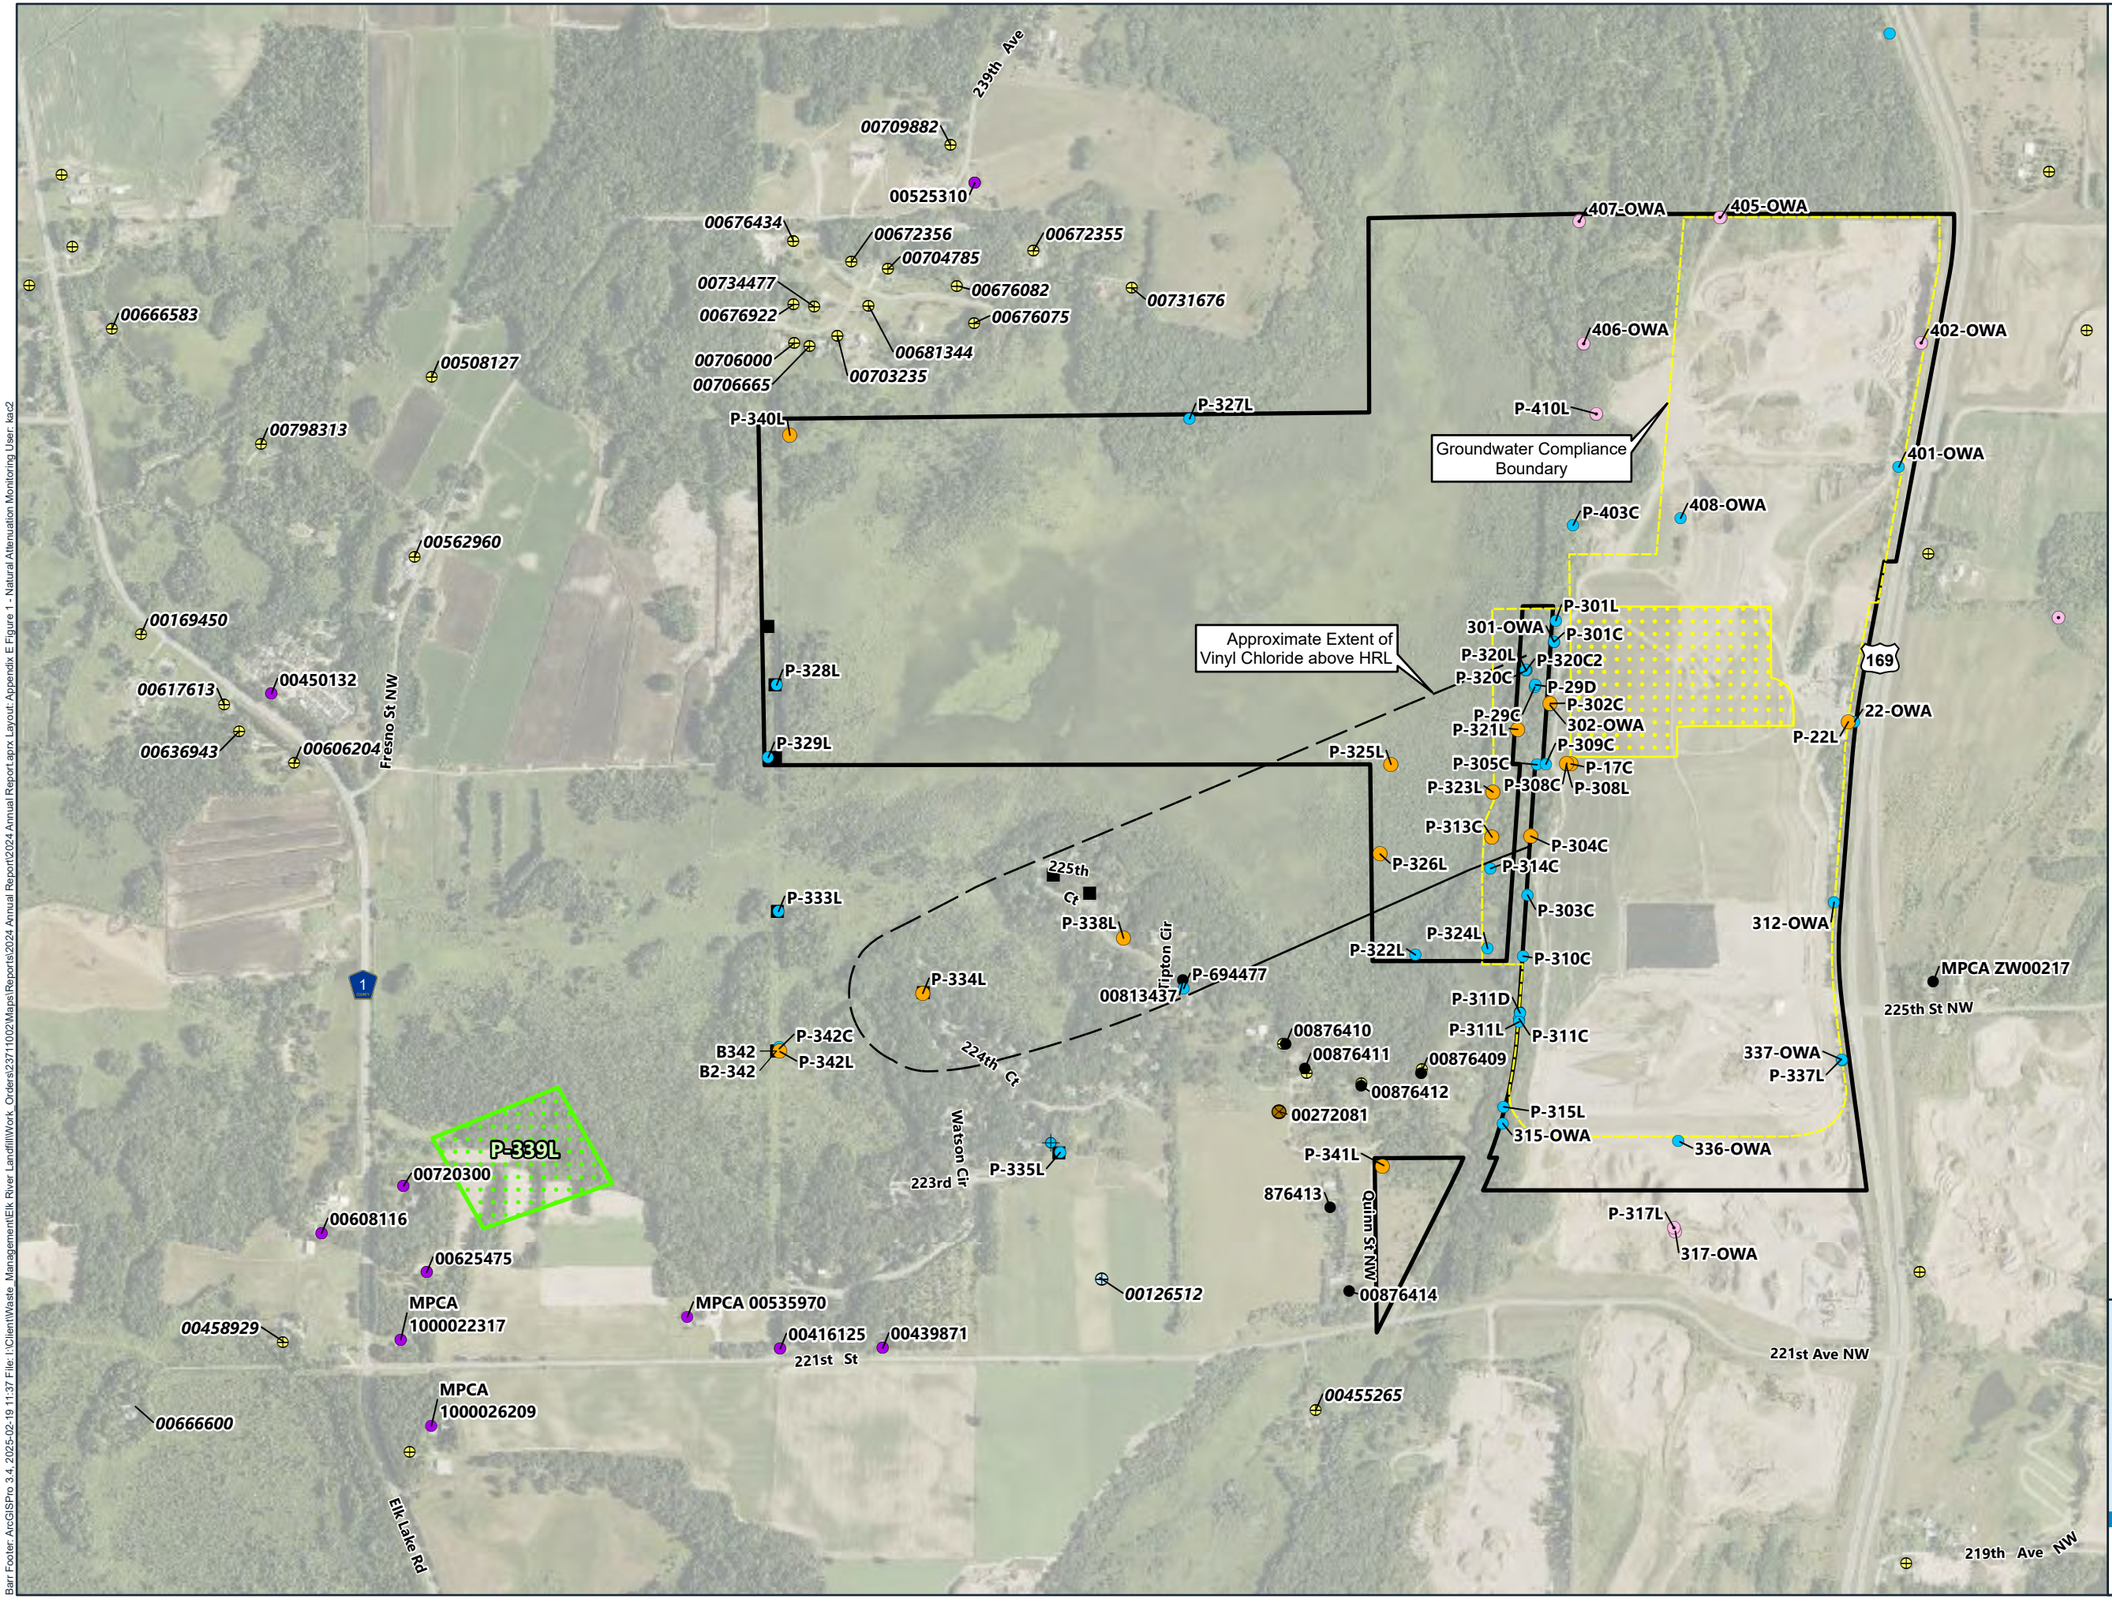
General Notes:

(1) For purposes of this trend analysis, all samples reported as non-detections were given the value of the reporting limit or detection limit unless otherwise noted. Mann-Kendall (MK) trend analyses were only considered if datasets had at least eight data points greater than or equal to the associated reporting or detection limit. To the extent possible, all data were used for trend analyses. Prior to completing the analyses, data were screened on a case-by-case basis to identify usable data within the time series and to remove ambiguities within the dataset (primarily as it relates to datasets with multiple detection limits). The following rules were used to screen data in a consistent manner:

(a) Time series with samples that have multiple detection limits were replaced with the highest detection limit value. Detections below the highest detection limit were replaced with the detection limit value. As long as the number of detections remains above eight, a trend analysis was run.

(b) To handle cases when analytical techniques improved over time and detection limits became lower, the period with the high detection limit(s) was excluded from the trend analysis, including both detections and non-detections. This removed ambiguity in the dataset caused by the prior non-detections.



(c) Under most circumstances, non-detections were not selectively exlcuded within a data series. However, there are instances where this is an appropriate practice in order to maintain the maximum amount of information. For example, singular non-detections at relatively high limits were excluded if there were at least 5 usable data points before and after a non-detection in question. This avoided the situation where the majority of a dataset would have been replaced by the highest non-detection value.

(2) Mean and standard deviations are reported for the data included in the trend analysis, not for the complete dataset. For data sets that included non-detects mean and standard deviation calculated using the Kaplan-Meier method.

(3) The direction of the trend (increasing or decreasing) is inferred based on the value of the Mann-Kendall (MK) test value, S. An S value that is greater than zero suggests an upward trend and an S value less than zero suggests a downward trend. Values that are close to zero suggest no net upward or downward trend. Statements concerning the statistical signifance of the trend are inferred based on the associated p-value.

(4) Trends with p-values that are less than or equal to 0.05 are considered statistically significant trends at the 95% confidence level. Trends with P-values greater than 0.05 and less than or equal to 0.1 are considered possible trends, but are not statistically significant. Trends with p-values greater than 0.1 do not have enough evidence to indicate an increasing or decreasing trend.

St. Paul, Minnesota, 55155-4194

Re: 2025 Spring Quarterly Report, Elk River Landfill

Dear Ms. Pugh:

On behalf of Elk River Landfill, Inc., enclosed please find the 2025 spring quarterly monitoring results for Elk River Landfill (ERL). The monitoring event was conducted April 14 through April 17, 2025, with field services provided by Alliance Technical Services (Alliance) of Circle Pines, Minnesota. Laboratory analyses were conducted by Pace Analytical National Center for Testing and Innovation in Mount Juliet, Tennessee (Pace National). The compliance monitoring locations, analytical parameters, sample collection methods, and data reporting were based on the Solid Waste Facility Operating Permit SW-74 dated July 23, 2015.

Tables summarizing the monitoring network, groundwater elevations, lysimeter purge volumes, and groundwater results are attached. Copies of the sample collection report and analytical reports are included in Appendices A and B, respectively. Electronic data deliverable packages consistent with the requirements of the Solid Waste Program Electronic Laboratory Data Submittal Manual have been submitted to the Minnesota Pollution Control Agency (MPCA) by the laboratories.

SITE MONITORING SYSTEM DESCRIPTION

The ERL is located on the border of the City of Elk River and Livonia Township, Sherburne County, Minnesota and is within Sections 3 and 4 of Township 33 North and Sections 33 and 34 of Township 33 North, Range 26 West (Figure 1). The network for the 2024 spring monitoring event included 32 monitoring wells located at or beyond the compliance boundary and 11 leak detection lysimeters. Table 1 lists the monitoring points in the monitoring network for this event. Locations of the monitoring points and leak detection lysimeters are shown on Figure 2.

Data collection efforts were conducted by Alliance. Alliance's Spring 2025 EMS Report on Groundwater Sample Collection at the Elk River Landfill Facility is included in Appendix A.

DATA COLLECTION

Prior to purging and sampling the monitoring wells, water levels were recorded to the nearest hundredth of a foot (Table 2). Groundwater parameters including pH, specific conductance, temperature, Eh, and dissolved oxygen were monitored to determine stabilization during well purging. The groundwater samples were analyzed for the parameters listed in the SAP and included low-level reporting for 1,1,2,2-tetrachloroethane; 1,1,2-trichloroethane; 1,2-dichoroethane; cis-1,3-dichloropropene; benzene; carbon

tetrachloride; hexachlorobutadiene; trichloroethylene; and vinyl chloride. The low-level analyses were performed using USEPA Method 8260D.

Modifications to the routine sampling program included the following:

- Monitoring well P-342C was installed in February 2025 as part of continued groundwater corrective action investigation, and was sampled for baseline monitoring parameters. The groundwater sample from this well was inadvertently analyzed for additional MNA parameters, including total organic carbon (TOC), ethane, ethene, and methane. This was the first baseline sampling event for this well. Organics were not detected in the sample from well P-342C. The baseline data are considered in and appended to this report (and will be included in the 2025 Annual Water Quality Monitoring Report).
- Lysimeters LYS-6S and LYS-10 were not monitored due to accumulated sediment (as reported previously). The second stage of the LYS-6S and LYS-10 Lysimeter Action Plan (dated April 22, 2022) has been implemented and the results will be provided under separate cover.
- Sherburne County collected split samples for organics analysis from the following monitoring wells: P-29C, P-301C, P-304C, P-302C, P-313C, P-320C2, P-320L, P-321L, P-323L, P-325L, P-326L P-334C, P-338C, P-342L, and P-694477. The County's data was reviewed and considered consistent with ERL's analytical results.[1]
- Sherburne County sampled wells P-334L, P-338L, and P-496677 for PFAS. ERL collected split groundwater samples with the County for PFAS analysis. The PFAS data will be reported under separate cover.
- The well casing and ground surface elevations were surveyed at the new monitoring well P-342C (and the adjacent P-342L because of suspected casing movement in the wetland) on June 16, 2025. The top-of-casing elevation for the new well and the revised elevation for P-342L are used to calculate groundwater elevations in this report (and future reports).

QUALITY ASSURANCE AND QUALITY CONTROL

Quality assurance and quality control (QA/QC) procedures implemented for the monitoring event included standard field and laboratory protocol for groundwater sample collection, labeling, preservation, chain-of-custody documentation, and sample check-in at the laboratory. Summaries of QA/QC findings are detailed case narrative sections of each analytical report. Pertinent findings are discussed below:

- Reporting limits for the following compounds exceeded groundwater-based Intervention Limits (ILs) in the Permit: 1,2,3-trichloropropane, 1,2-dibromo-3-chloropropane, and 1,2-dibromoethane. The ILs for these compounds are not achievable with current technology.

[1] ERL contacted Sherburne County in June 2025, to inform staff of inconsistencies with the County's sample identification number inconsistencies and a suspected switch of the County's samples from wells P-320L and P-320C2.

- One or more method blank samples had alkalinity, total, as $CaCO_3$, sulfate, as SO_4, chloride, nitrogen, nitrate + nitrite, as N, total organic carbon, toluene, chloroform, bromomethane, methylene chloride, 1,4-dichlorobenzene, 1,3-dichlorobenzene, 1,2-dichlorobenzene, chromium, and zinc detected between the method detection limit and the reporting limit. The laboratory did not qualify the associated sample results because the sample concentrations were either non-detect or were much higher than the method blank sample concentrations.
- The continuing calibration verification (CCV) was outside of the method specified limits for one or more organic compounds in eight USEPA Method 8260D batches. The associated organics results were qualified "C3 and C5" (estimated) by the laboratory.
- The laboratory control spike (LCS) and/or laboratory control spike duplicate (LCSD) sample percent recoveries and/or relative percent differences (RPDs) did not meet the established laboratory acceptance limits for one or more compounds in eight USEPA Method 8260D batches. The results were qualified "J3 or J4" (estimated) by the laboratory.
- The USEPA Method 8260D ethyl ether result associated with P-302C in report L1848860 was above the calibration range. The associated result was qualified "E" by the laboratory.
- The USEPA Method 6010D serial dilution test and/or subsequent post-spike criteria test did not pass for LYS-11 in report L1836539. The associated results were qualified "O1" (estimated due to matrix interference) by the laboratory.

EVALUATION OF ANALYTICAL RESULTS

Groundwater

The spring monitoring event included sampling and analysis of organic compounds from compliance monitoring wells completed in the lower outwash around the MSW portion of the landfill and organic and inorganic compounds from three compliance wells located around the C&D disposal cells in the North Development Area. Groundwater analytical results from compliance monitoring wells are compared to ILs included in Permit SW-74 and Health Risk Limits (HRLs) as appropriate below.

Table 3 provides a summary of results above the ILs and/or HRLs from wells with groundwater-based criteria. Vinyl chloride was detected above the HRL (0.2 micrograms per liter or µg/l) in samples from wells P-29C, P-302C, P-320C, P-320L, P-321L, P-323L, P-325L, P-338L, and P694477, and above the IL (0.05 µg/l) but below the HRL, at well P-314C, P-320C2, and P-326L. Trichloroethylene (TCE) was detected above the HRL (0.4 µg/l) in the sample from well P-323L, and above the IL (0.1 µg/l) but below the HRL at wells P-304C and P-313C. 1,2-dichloroethane was detected above the IL (0.25 µg/l) but below the HRL (1 µg/l) in samples from wells P-302C and P-323L. Dichlorofluoromethane (DCFM) was detected above the Risk Assessment Advice (RAA; 20 µg/l) in the sample from well P-334L, and above the IL but below the RAA at wells P-302C, P-323L, P-325L, P-338L, and P694477. cis-1,2-dichloroethylene was detected below the HRL but above the IL in samples from wells P-323L and P-325L. A HRL has not been established for DCFM. ERL is implementing groundwater corrective actions per the Groundwater Corrective Action Work Plan (Barr, 2021) and the Groundwater Corrective Action Report – Initial Performance Evaluation (Barr, 2024) to

address the organics in groundwater. Organics trends will be evaluated in the 2025 Annual Water Quality Monitoring Report.

Manganese was detected in the baseline groundwater sample collected from well P-342C at a concentration of 124 mg/l above the HRL (100 mg/l; Table 3). Manganese is a naturally occurring mineral that can be mobilized in groundwater under mildly reducing geochemical conditions. Manganese is not a routine monitoring parameter at the ERL because natural background manganese concentrations have been detected above the HRL upgradient and side gradient of the facility. Baseline groundwater quality data will be evaluated in the 2025 Annual Water Quality Monitoring Report.

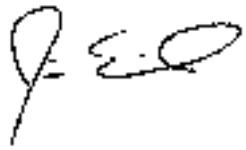
Table 4 provides a summary of results above the ILs and/or HRLs from wells with surface-water based criteria. Chloride was detected above the IL (57.5 mg/l) in the sample from well 401-OWA. Chloride concentrations in groundwater upgradient of the landfill have been detected an order of magnitude greater than typical natural background concentrations (≤5 mg/L) and are attributed to the application and infiltration of deicing agents along Highway 169 (Barr, 2015a). A HRL has not been established for chloride.

No organics were detected in bedrock monitoring wells P-29D and P-311D or in sentinel wells P-329L, P-333L, or P-335L.

Lysimeters

Table 5 provides a summary of lysimeter purge volumes. The purge volumes from each lysimeter were below 15 gallons (and the lysimeter threshold volumes in the SAP) so no samples were collected during the spring monitoring event.

Lysimeter LYS-6N, which was constructed below the northern portion of Cell 6 prior to the MPCA's promulgation of landfill design standards and the promulgation of Subtitle D of the Resource Conservation and Recovery Act (RCRA) and Minnesota Rule, is the subject of an ongoing automated pumping program. Liquid collected in LYS-6N is discharged to the leachate collection system by an automated pump installed at the base of the lysimeter. The LYS-6N totalizer registered 266 gallons purged by the automated pump between October 2024 and May 2025.



CONCLUSIONS/RECOMMENDATIONS

Monitoring was completed in accordance with the Permit with the exceptions noted in this report. Based on the data collected during the 2025 spring monitoring event, the following conclusions are drawn:

- Vinyl chloride was above the HRL in samples from nine downgradient monitoring wells, TCE was above the HRL in one downgradient monitoring well, and manganese was above the HRL in one groundwater well. ERL is implementing groundwater corrective actions (Barr, 2021 and 2024) to address the organics in groundwater.
- Lysimeter purge volumes were below the nominal threshold volumes.

Additional discussion of the spring monitoring data and recommendations for future monitoring at the ERL will be provided in the 2025 Annual Water Quality Monitoring Report.

If you have any questions, please contact me at 952-832-2763.

Table 2
Groundwater Elevations
Elk River Landfill
Elk River, Minnesota

Water level elevations in feet, Mean Sea Level (MSL)

Blank indicates no water level collected

S: Well has been sealed

BP: Below top of dedicated pump

**: Unusable/rejected measurement based on hydrograph evaluation

>: groundwater elevation is greater than elevation listed; formerly reported as "Flowing"

~: approximate elevation based on pressure gauge reading

! indicates reported water levels were measured during a routine monitoring event and not necessarily on the listed day

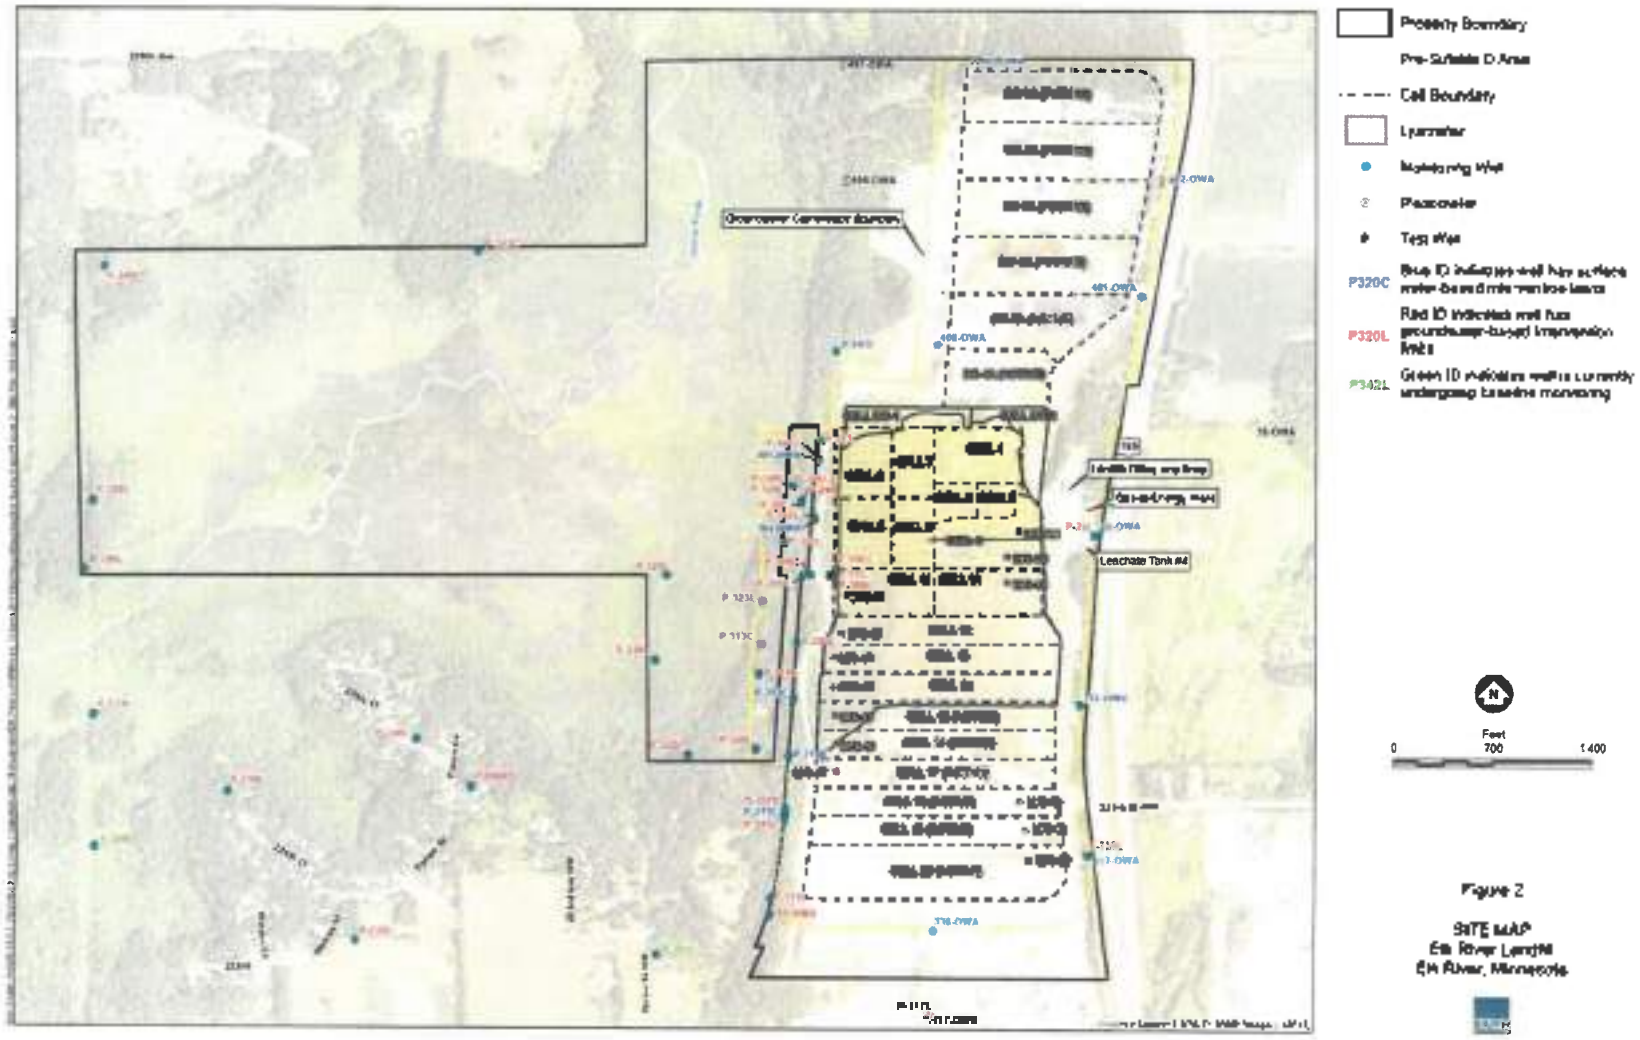
1 INTRODUCTION

ALLIANCE TECHNICAL GROUP submits this quarterly Environmental Monitoring System (EMS) report on ground and surface water sample collection at the Elk River Landfill Facility.

Thirty-two (32) ground water monitoring wells (Figure 1) were sampled during the April 15 – 18, 2025, groundwater sampling event at the Elk River Landfill Facility. These monitoring sites were identified as P-29C P-29D, P-301C, P-301L, P-302C, P-304C, P-305C, P-311D, P-311L, P-313C, P-314C, P-315L, P-320C, P-320C2, P-320L, P-321L, P-322L, P-323L, P-324L, P-325L, P-326L, P-329L, P-333L, P-334L, P-335L, P-339L, P-342C, P-342L, P-694477, 401-0WA, P-403C, and 408-0WA.



On May 19, 2025, six (6) lysimeters were purged (Lys-11, Lys-13, Lys-14, Lys, Lys-19 and Lys-20) and all yielded very little or no liquid so were therefore not sampled. The totalizer reading at lysimeter 6N was recorded and lysimeters 6S and 10 have no pumps in them.

The sampling was performed by Mike Hamer and Kenneth Smith of Alliance Technical Group in accordance in accordance with the Elk River Landfill Sampling and Analysis Plan (January 2021). This sampling guide was prepared by Jim Eidem of Barr Engineering and Waste Management, Inc.

The order of well stabilization/recovery or sample collection was as follows:

1. P-325L
2. P-326L
3. P-323L
4. P-321L
5. P-320L
6. P-320C2
7. P-320C
8. P-29D
9. P-694477
10. P-338L
11. P-334L
12. P-29C
13. P-305C
14. P-301C
15. P-311L
16. P-302C
17. P-311D
18. P-315L
19. P-313C
20. 401-OWA
21. P-304C
22. 408-OWA
23. P-342L
24. P-329L
25. P-322L
26. P-314C
27. P-324L

32. P-333L

Figure 1. Elk River Landfill Site Map.

2 SUMMARY

The groundwater monitoring wells at the Elk River Landfill were found locked and identified with a well number on the well riser. All samples were collected in a manner acknowledged to be acceptable to the MPCA.

Table 1. Results of Field Parameters

PURGE INFO

PURGE DATE (MM/DD/YY)	PURGE TIME (2400 H Clock)	ELAPSED HRS (hr:min)	WATER VOL IN CASING (Gallons)	ACTUAL VOL PURGED (Gallons)	WELL VOLS PURGED
10/15/25	0851				

Note: For Certain Sampling Applications Where Well is Going Dry and/Or Low Flow Purging/Sampling Flow Rate and Total Purge Volume Are Critical Data Points, Additional Purge Info May Be Recorded on Field Notes Only.

PURGE/SAMPLE EQUIPMENT

Purging and Sampling Equipment: Dedicated: (Y) or N

Filter Device: Y or N — 0.45 u or ____ u (circle or fill in)

Purging Device: A

A-Submersible Pump; B-Peristaltic Pump; C-QED Bladder Pump; D-Bailer; E-Piston Pump; F-Dipper/Bottle

Sampling Device: A

Filter Type: ____ A-In-line Disposable; B-Pressure; C-Vacuum; X-Other ____

X-Other: ____

Sample Tube Type: ____ A-Teflon; B-Stainless Steel; C-PVC; D-Polypropylene; X-Other ____

WELL DATA

Well Elevation (at TOC) ____ (ft msl)

Depth to Water (DTW) (from TOC) ____ (ft)

Groundwater Elevation (elev datum: from TOC) ____ (ft msl)

Total Well Depth (from TOC) ____ (ft)

Stick Up (from ground elevation) ____ (ft)

Casing ID ____ (in)

Casing Material ____

Note: Total Well Depth, Stick Up, Casing Id are optional and can be from Historical Data, unless required by Site/Permit. Well Elevation, DTW and Groundwater Elevation must be recorded.

STABILIZATION DATA (Optional)

Sample Time (2400 H Clock)	Rate/Unit	pH (std)	Conductance (SC/EC) (µmhos/cm @ 25°C)	Temp (°C)	Turbidity (NTU)	DO (mg/L, ppm)	eH/ORP (mV)	DTW (ft)
1 0845	1	1 6.43	1 1453	1 13		1 02		
2 0850	2	2 6.45	2 1457	2 12.6		2 01		
3 0855	3	3 6.47	3 1457	3 12.4		3 01		
4 0915	4	4 6.48	4 1460	4 12.0	03	4 1.72		

Suggested ranges for Tetratech readings at the Penn Hill location: +/- 0.2 | +/- 3% | - | - | +/- 10% | +/- 25 mV | Stabilize

Stabilization Data Fields are Optional (i.e. complete stabilization readings for parameters monitored in WM, Site, or State). These fields can be used where four (4) field measurements are required by State Permit/Site (i.e. flow cell or other discrete system is used, fill in field readings before and after each sample is collected). If none fields above are applicable, use comments section below.

FIELD DATA

SAMPLE DATE (MM/DD/YY)	pH (std)	CONDUCTANCE (umhos/cm @ 25°C)	TEMP. (°C)	TURBIDITY (ntu)	DO (mg/L-ppm)	eH/ORP (mV)	Other: ____ Units ____

Final Field Readings are required (i.e. normal field measurement from monitoring system sampling before sampling for all field parameters required by State/Permit/Site)

Sample Appearance: ____ Odor: NO Color: CL Other: ____

Weather Conditions (required daily, or as conditions change): Direction/Speed ____ Outlook ____ Precipitation: Y or N

Specific Comments (including purge/well volume calculations if required): ____

PURGE DATE (MM DD YY)	PURGE TIME (2400 Hr Clock)	ELAPSED HRS (decimal)	WATER VOL IN CASING (Gallons)	ACTUAL VOL PURGED (Gallons)	WELL VOLS PURGED
0 4 1 5 2 5	1 2 2 6				

Note: For Passive Sampling replace "Water Vol in Casing" and "Well Vols Purged" w/ Water Vol in Sampler(s) on Collected and Taking Forms. Do Not Purge, Must Assess Groundfield data Below

PURGE/SAMPLE EQUIPMENT

Purging and Sampling Equipment Dedicated? Y or N

Filter Device: Y or N (0.45 µ) or _____ (Circle or fill in)

Purging Device: C

Sampling Device: C

A-Submersible Pump D-Bailer
B-Peristaltic Pump E-Piston Pump
C-QED Bladder Pump F-Dipper/Bucket

Filter Type: _____

A-In-Line Disposable C-Vacuum
B-Pressure X-Other _____

X-Other _____

Sample Tube Type: _____

A-Teflon C-PVC X-Other: _____
B-Stainless Steel D-Polypropylene

WELL DATA

Well Elevation (at TOC): 9 7 2.5 6 (ft msl)

Depth to Water (DTW) (from TOC): 2 2.1 0 (ft)

Groundwater Elevation (abs datum, from TOC): 9 7 0 4.4 6 (ft msl)

Total Well Depth (from TOC): _____ (ft)

Stick Up (from ground elevation): _____ (ft)

Casing ID: _____ (in)

Casing Material: _____

Note: Total Well Depth, Stick Up, Casing ID are generally not to be from historical data, unless required by Site Permit. Well Elevation (TOC) and Groundwater Elevation are required.

STABILIZATION DATA (Optional)

Sample Time (2400 Hr Clock)	Rate (mL/min - LPM)	pH (std)	Conductance (SC/EC) (µmhos/cm @ 25 °C)	Temp. (°C)	Turbidity (ntu)	D.O. (mg/L - ppm)	eH/ORP (mV)	DTW (ft)
1 2 1 6	0.4	7.1 8	1 P 4 C	1 1.1		0 7		
1 2 1 9		7.1 6	1 P 3 C	1 1.3		0 6		
1 2 2 2		7.1 4	1 P 2 H	1 1.4		0 5		
1 2 2 5		7.1 3	1 P 3 2	1 1.5	E A	0 5 - 1 0 %		
Required range for 3 most readings per Permit, State requirement:		± 0.2	± 3%	±	±	+/- 10%	+/- 25 mV	± 0.01 ft

Stabilization Data Fields are Optional (i.e. complete stabilization readings for parameters required by WM, Site or State. These fields can be used whether (if) field measurements are required by Local/Protective (i.e. Data Logger or other Electronic) means and (if) actual readings below and other environmental parameters for Site. If none are needed, see remarks below.)

FIELD DATA

SAMPLE DATE (MM DD YY)	pH (std)	CONDUCTANCE (µmhos/cm @ 25°C)	TEMP. (°C)	TURBIDITY (ntu)	DO (mg/L - ppm)	eH/ORP (mV)	Other: _____ Units _____

Final Field Readings are required (i.e. record field measurements (final stabilized readings, passive sample readings) before sampling for all field parameters required by State/Permit/Site)

FIELD COMMENTS

Sample Appearance: _____ Odor: N _____ Color: N _____ Other _____

Weather Conditions (record daily, or as conditions change). Direction/Speed: _____ Outlook: _____ Precipitation: Y or N

Specific Comments (including purge/well volume calculations if required): _____

I certify that sampling procedures were in accordance with applicable EPA, State, and WM protocols (if none then use Samples, all should sign)

FIELD INFORMATION FORM

Site Name: ERL

Site No.:

Sample Point: P-3 (Sample ID)

This Waste Management Field Information Form is Required
This form is to be completed in addition to any State Forms. The Field Form is submitted along with the Chain of Custody Form that accompanies the sample containers (i.e. with the cooler when returned to the laboratory)

Laboratory Use Only/Lab ID

PURGE INFO

PURGE DATE (MM DD YY)	PURGE TIME (2400 Hr Clock)	ELAPSED HRS (minutes)	WATER VOL IN CASING (Gallons)	ACTUAL VOL PURGED (Gallons)	WELL VOLS PURGED
10 12 25	1315				

Note: For Ferrous Sampling replace "Water Level Casing" and "Well Depth" w/ "Water Level Tubing/Riser" and "Total Depth of Tubing/Riser". Call out Purged Above changes record/observations below.

PURGE/SAMPLE EQUIPMENT

Purging and Sampling Equipment: Dedicated? Y or N

Purging Device: A-Submersible Pump, B-Bailer, C-Peristaltic Pump, D-Piston Pump, E-QED Bladder Pump, F-Dipper/Bottle, X-Other

Sampling Device: 1

Filter Device: Y or N — 0.45 µ or ____ µ (circle or fill in)

Filter Type:

Sample Tube Type: A-Tefton, B-Stainless Steel, C-PVC, D-Polypropylene, X-Other

A-In line Disposable, B-Pressure, C-Vacuum, X-Other

WELL DATA

Well Elevation (at TOC): 611.77 (feet)

Depth to Water (DTW) (from TOC): 10.60 (ft)

Groundwater Elevation (elev. datum, from TOC): 601.17 (ft msl)

Total Well Depth (from TOC): ____ (ft)

Stick Up (ft +/- ground elevation): ____ (ft)

Casing ID: ____ (in)

Casing Material: ____

Note: Total Well Depth, Stick Up, Casing ID, etc. are optional and can be from historical data unless required by Site Permit. Well elevation, DTW, and Groundwater Elevation must be current.

STABILIZATION DATA (Optional)

Sample Time (2400 hr Clock)	Rate (mL/min)	pH (unit)	Conductance (SCOND) (µmhos/cm @ 25°C)	Temp (°C)	Turbidity (ntu)	D.O. (mg/L - ppm)	oHYORP (mV)	DTW (ft)
1120	200	7.22	1774	10.6		0.12		
1125		7.17	1810	10.7		0.11		
1130		7.16	1815	10.6		0.09		
1135		7.17	1815	10.6		0.09	-12	
Required ranges for 3 consec. readings or per Permit/Site requirements		+/- 0.1	+/- 3%	-	-	+/- 10%	+/- 25 mV	Minimum

Stabilization Data Fields are Optional for completion/collection readings for parameters required by WM, Site or State. These fields may be used when four (4) field measurements are required by Permit/Site. If a Data Logger or other Electronic Format is used for final readings below and retained on file; then reference to Site. If more fields/Note are needed, use Comment Sheet or Form

FIELD DATA

SAMPLE DATE (MM DD YY)	pH (std)	CONDUCTANCE (umhos/cm @ 25°C)	TEMP. (°C)	TURBIDITY (ntu)	DO (mg/L - ppm)	oHYORP (mV)	Other: Units

Final Field Readings are required for each parameter, final stabilized readings must be recorded before sampling for all field measurements required by Permit/Site.

FIELD COMMENTS

Sample Appearance: ____ Odor: ____ Color: ____ Other: ____

WELL DATA

Well Elevation (at TOC): 4132.13 (ft msl)

Depth to Water (DTW) (from TOC): 7667 (ft)

Groundwater Elevation (site datum, from TOC): 4465.13 (ft msl)

Tot. Well Depth (from TOC): (ft)

Stick Up (from ground elevation): (ft)

Casing ID: (in)

Casing Material:

Note: Total Well Depth, Stick Up, Casing Id are not required values by State Regulations, only required by SiteProtect. Well Elevation, DTW and Groundwater Elevation must be given.

STABILIZATION DATA (Optional)

Sample Time (2400 Hr Clock)	Rate/Unit	pH (std)	Conductance (SC/EC) (µmhos/cm @ 25°C)	Temp. (°C)	Turbidity (NTU)	D.O. (mg/L ppm)	eH/ORP (mV)	DTW (ft)
1116	0.5 1"	7.54 1"	4.51 1"	6.1 1"		10.6 1"		
1120	2"	7.56 2"	1.37 2"	6.1 2"		10.3 2"		
1124	1"	7.45 3"	2.40 3"	6.1 3"		10.2 3"		
1126	4"	7.45 4"	0.30 4"	6.1	2.5	10.1	-152	
Suggested range for 3 consec. readings or +/- Equip. Specs (see above)		+/- 0.1	+/- 3%			+/- 10%	+/- 25 mV	0.01 ft

Stabilization Data Fields are Optional (i.e. complete stabilization readings for parameters required by NJ, just as Optional). These fields can be used where four (4) field measurements are required by local Procedures. If a Data Logger is also being used, please record final stabilized reading below and submit electronic data separately as well. If more fields other than those included here are needed, use separate sheet or form.

FIELD DATA

SAMPLE DATE (MM DD YY)	pH (std)	CONDUCTANCE (µmhos/cm @ 25°C)	TEMP. (°C)	TURBIDITY (NTU)	DO (mg/L-ppm)	eH/ORP (mV)	Other: / Time:

Field Field Readings are required (i.e. record field measurements from stabilized readings just before sampling for all field parameters required by State Protocols).

Sample Appearance:

Odor: None

RE: Project: Elk River PFC Quarterly
Pace Project No.: 10720955

Dear Anna Schneider:

Enclosed are the analytical results for sample(s) received by the laboratory on January 14, 2025. The results relate only to the samples included in this report. Results reported herein conform to the applicable TNI/NELAC Standards and the laboratory's Quality Manual, where applicable, unless otherwise noted in the body of the report.

The test results provided in this final report were generated by each of the following laboratories within the Pace Network:

- Pace Analytical Services - Minneapolis

If you have any questions concerning this report, please feel free to contact me.

Sincerely,

Piper Gibbs

PROJECT NARRATIVE

Project: Elk River PFC Quarterly
Pace Project No.: 10720955

Method: **EPA 1633 DRAFT**
Description: EPA 1633 DRAFT Landfill Leach
Client: Waste Management National Services, Inc.
Date: January 29, 2025

General Information:
1 sample was analyzed for EPA 1633 DRAFT by Pace Analytical Services Minneapolis. All samples were received in acceptable condition with any exceptions noted below or on the chain-of custody and/or the sample condition upon receipt form (SCUR) attached at the end of this report.

Hold Time:
The samples were analyzed within the method required hold times with any exceptions noted below.

Sample Preparation:
The samples were prepared in accordance with EPA 1633 DRAFT with any exceptions noted below.

Initial Calibrations (including MS Tune as applicable):
All criteria were within method requirements with any exceptions noted below.

Continuing Calibration:
All criteria were within method requirements with any exceptions noted below.

Internal Standards:
All internal standards were within QC limits with any exceptions noted below.

Surrogates:
All surrogates were within QC limits with any exceptions noted below.

QC Batch: 989130

S0: Surrogate recovery outside laboratory control limits.

- SP-01 Leachate (Lab ID: 10720955001)
  - 13C2-PFTA (S)
  - 13C24:2FTS (S)
  - 13C4-PFBA (S)
  - 13C5-PFPeA (S)

Method Blank:
All analytes were below the report limit in the method blank, where applicable, with any exceptions noted below.

Laboratory Control Spike:
All laboratory control spike compounds were within QC limits with any exceptions noted below.

Matrix Spikes:
All percent recoveries and relative percent differences (RPDs) were within acceptance criteria with any exceptions noted below.

Additional Comments:

This data package has been reviewed for quality and completeness and is approved for release.

QUALIFIERS

Project: Elk River PFC Quarterly
Pace Project No.: 10720955

DEFINITIONS

DF - Dilution Factor, if reported, represents the factor applied to the reported data due to dilution of the sample aliquot.

ND - Not Detected at or above adjusted reporting limit.

TNTC - Too Numerous To Count

J - Estimated concentration above the adjusted method detection limit and below the adjusted reporting limit.

MDL - Adjusted Method Detection Limit.

PQL - Practical Quantitation Limit.

RL - Reporting Limit - The lowest concentration value that meets project requirements for quantitative data with known precision and bias for a specific analyte in a specific matrix.

S - Surrogate

1,2-Diphenylhydrazine decomposes to and cannot be separated from Azobenzene using Method 8270. The result for each analyte is a combined concentration.

Consistent with EPA guidelines, unrounded data are displayed and have been used to calculate % recovery and RPD values.

LCS(D) - Laboratory Control Sample (Duplicate)

MS(D) - Matrix Spike (Duplicate)

DUP - Sample Duplicate

RPD - Relative Percent Difference

NC - Not Calculable.

SG - Silica Gel - Clean-Up

U - Indicates the compound was analyzed for, but not detected.

N-Nitrosodiphenylamine decomposes and cannot be separated from Diphenylamine using Method 8270. The result reported for each analyte is a combined concentration.

Reported results are not rounded until the final step prior to reporting. Therefore, calculated parameters that are typically reported as "Total" may vary slightly from the sum of the reported component parameters.

Pace Analytical is TNI accredited. Contact your Pace PM for the current list of accredited analytes.

TNI - The NELAC Institute.

ANALYTE QUALIFIERS

S0	Surrogate recovery outside laboratory control limits.

RE: Project: Elk River PFC Quarterly-Revised Report
Pace Project No.: 10729533

Dear Anna Schneider:

Enclosed are the analytical results for sample(s) received by the laboratory on April 01, 2025. The results relate only to the samples included in this report. Results reported herein conform to the applicable TNI/NELAC Standards and the laboratory's Quality Manual, where applicable, unless otherwise noted in the body of the report.

The test results provided in this final report were generated by each of the following laboratories within the Pace Network:

- Pace Analytical Services - Minneapolis

This report was revised June 4, 2025, to include surrogate data associated with dilutions.

If you have any questions concerning this report, please feel free to contact me.

Sincerely,

Kirsten Hogberg for
Piper Gibbs

PROJECT NARRATIVE

Project: Elk River PFC Quarterly-Revised Report
Pace Project No.: 10729533

Method: **EPA 1633**
Description: EPA 1633 Landfill Leachate
Client: Waste Management National Services, Inc.
Date: June 04, 2025

General Information:
1 sample was analyzed for EPA 1633 by Pace Analytical Services Minneapolis. All samples were received in acceptable condition with any exceptions noted below or on the chain-of custody and/or the sample condition upon receipt form (SCUR) attached at the end of this report.

Hold Time:
The samples were analyzed within the method required hold times with any exceptions noted below.

Sample Preparation:
The samples were prepared in accordance with EPA 1633 with any exceptions noted below.

Initial Calibrations (including MS Tune as applicable):
All criteria were within method requirements with any exceptions noted below.

Continuing Calibration:
All criteria were within method requirements with any exceptions noted below.

Internal Standards:
All internal standards were within QC limits with any exceptions noted below.

Surrogates:
All surrogates were within QC limits with any exceptions noted below.

QC Batch: 1002017

S0: Surrogate recovery outside laboratory control limits.

- SP-01 (Lab ID: 10729533001)
  - 13C24:2FTS (S)
  - 13C26:2FTS (S)
  - 13C28:2FTS (S)
- SRM (Lab ID: 5225629)
  - d3-MeFOSAA (S)

Method Blank:
All analytes were below the report limit in the method blank, where applicable, with any exceptions noted below.

Laboratory Control Spike:
All laboratory control spike compounds were within QC limits with any exceptions noted below.

Matrix Spikes:
All percent recoveries and relative percent differences (RPDs) were within acceptance criteria with any exceptions noted below.

Additional Comments:

This data package has been reviewed for quality and completeness and is approved for release.

QUALIFIERS

Project: Elk River PFC Quarterly-Revised Report
Pace Project No.: 10729533

DEFINITIONS

DF - Dilution Factor, if reported, represents the factor applied to the reported data due to dilution of the sample aliquot.

ND - Not Detected at or above adjusted reporting limit.

TNTC - Too Numerous To Count

J - Estimated concentration above the adjusted method detection limit and below the adjusted reporting limit.

MDL - Adjusted Method Detection Limit.

PQL - Practical Quantitation Limit.

RL - Reporting Limit - The lowest concentration value that meets project requirements for quantitative data with known precision and bias for a specific analyte in a specific matrix.

S - Surrogate

1,2-Diphenylhydrazine decomposes to and cannot be separated from Azobenzene using Method 8270. The result for each analyte is a combined concentration.

Consistent with EPA guidelines, unrounded data are displayed and have been used to calculate % recovery and RPD values.

LCS(D) - Laboratory Control Sample (Duplicate)

MS(D) - Matrix Spike (Duplicate)

DUP - Sample Duplicate

RPD - Relative Percent Difference

NC - Not Calculable.

SG - Silica Gel - Clean-Up

U - Indicates the compound was analyzed for, but not detected.

N-Nitrosodiphenylamine decomposes and cannot be separated from Diphenylamine using Method 8270. The result reported for each analyte is a combined concentration.

Reported results are not rounded until the final step prior to reporting. Therefore, calculated parameters that are typically reported as "Total" may vary slightly from the sum of the reported component parameters.

Pace Analytical is TNI accredited. Contact your Pace PM for the current list of accredited analytes.

TNI - The NELAC Institute.

ANALYTE QUALIFIERS

S0	Surrogate recovery outside laboratory control limits.

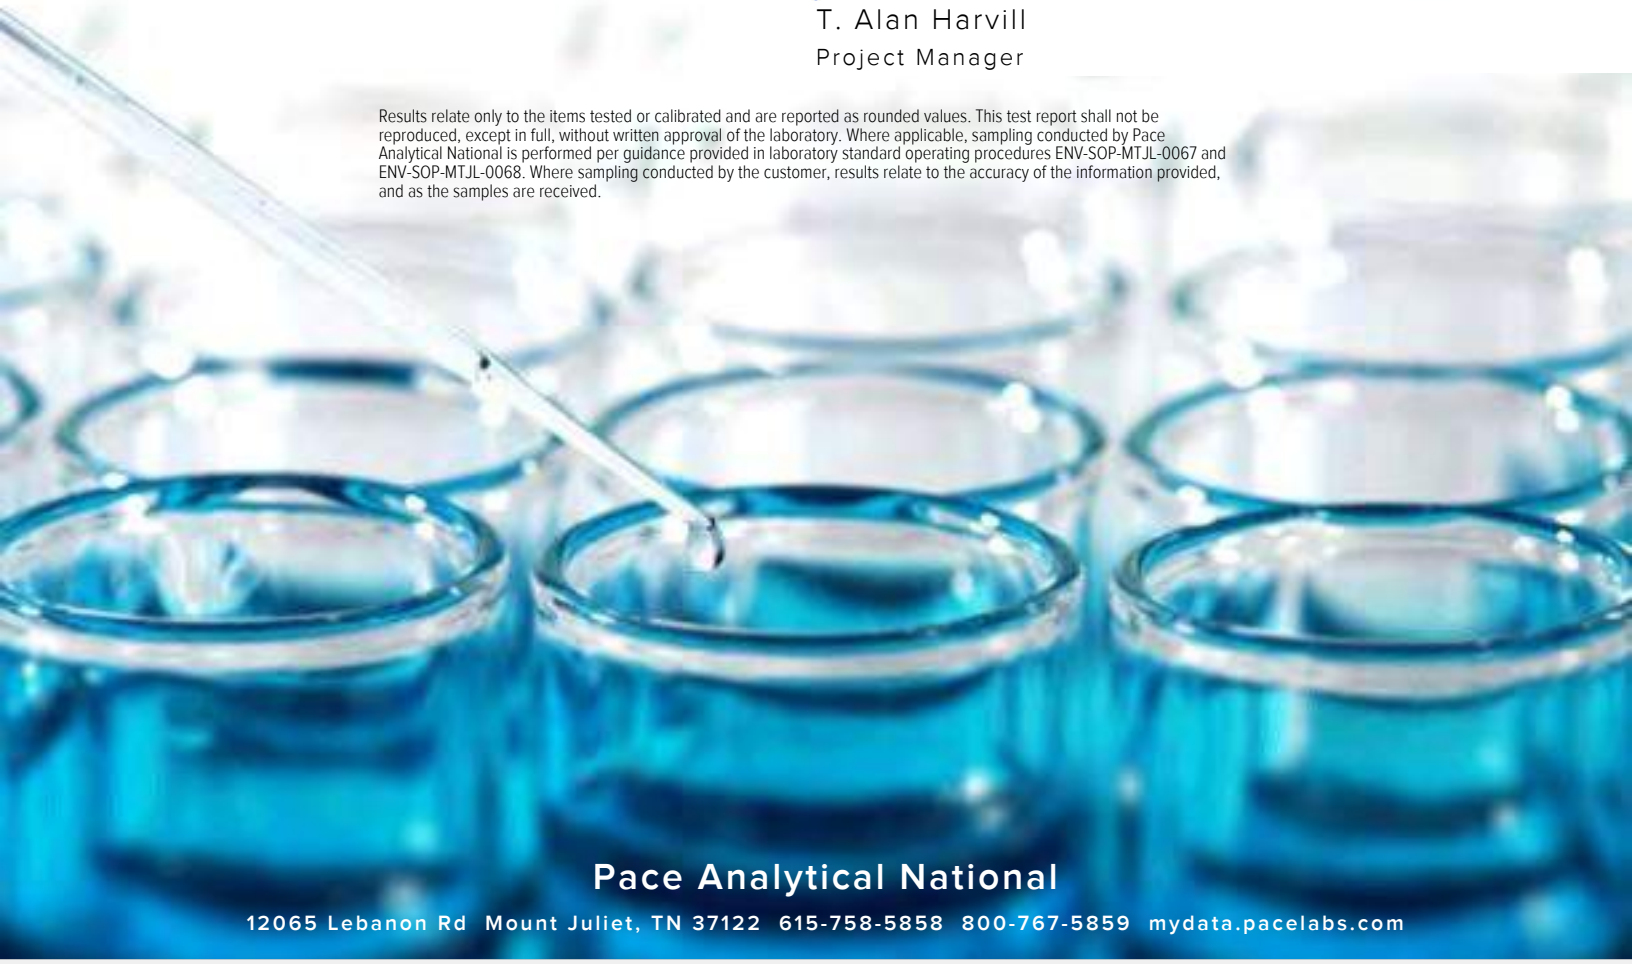
ANALYTICAL REPORT

January 29, 2025



Elk River Landfill

Sample Delivery Group:	L1816567
Samples Received:	01/14/2025
Project Number:	500
Description:	Elk River QTRLY Leachate(1,4,7,10)
Site:	MN02
Report To:	Jim Eidem 4300 MarketPoint Drive Suite 200 Minneapolis, MN 55435

Entire Report Reviewed By:

T. Alan Harvill
Project Manager

Results relate only to the items tested or calibrated and are reported as rounded values. This test report shall not be reproduced, except in full, without written approval of the laboratory. Where applicable, sampling conducted by Pace Analytical National is performed per guidance provided in laboratory standard operating procedures ENV-SOP-MTJL-0067 and ENV-SOP-MTJL-0068. Where sampling conducted by the customer, results relate to the accuracy of the information provided, and as the samples are received.

Unless qualified or notated within the narrative below, all sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

T. Alan Harvill
Project Manager

Project Comments

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

Bis(Chloro-methyl)Ether not identified as a TIC.

2,Propanol, 2-Chloroethyl vinyl ether, Acrolein will be reporting outside of seven day hold time. Sample aliquot was unpreserved due to 2-Chloroethyl vinyl ether being a target compound. HCL preservative destroys this compound, making collection in unpreserved container necessary. Initial in hold run was analyzed at 25x, however the matrix of the sample interfered with the internal standards resulting in unreportable data. The sample was analyzed again at 100x due to the matrix, however the hold time expired prior to this dilution being able to be run.

Sample Delivery Group (SDG) Narrative

Sample was prepared and/or analyzed past recommended holding time. Concentrations should be considered minimum values.

Batch	Method	Lab Sample ID
WG2436369	8260D	L1816567-01

The laboratory analysis was performed from an unpreserved, insufficiently or inadequately preserved sample.

Batch	Method	Lab Sample ID
WG2435006	245.1	L1816567-01
WG2435359	335.4	L1816567-01

The following samples were prepared and/or analyzed past recommended holding time. Concentrations should be considered minimum values.

Batch	Method	Lab Sample ID
WG2432906	4500H+ B-2011	L1816567-01

Gravimetric Analysis by Method 2540 D-2011

RPD value not applicable for sample concentrations less than 5 times the reporting limit.

Batch	Lab Sample ID	Analytes
WG2432967	(DUP) R4167139-3	Suspended Solids

Wet Chemistry by Method 300.0

The analyte concentration exceeds the upper limit of the calibration range of the instrument established by the initial calibration (ICAL).

Batch	Lab Sample ID	Analytes
WG2433526	(MS) R4167421-4	Chloride and Sulfate
WG2433526	(MSD) R4167421-5	Chloride and Sulfate

The sample matrix interfered with the ability to make any accurate determination; spike value is low.

Batch	Lab Sample ID	Analytes
WG2433526	(MS) R4167421-4, (MSD) R4167421-5	Chloride

The sample concentration is too high to evaluate accurate spike recoveries.

Batch	Lab Sample ID	Analytes
WG2433526	(MS) R4167421-4, (MSD) R4167421-5	Sulfate

Wet Chemistry by Method 335.4

RPD value not applicable for sample concentrations less than 5 times the reporting limit.

Batch	Lab Sample ID	Analytes
WG2435359	(DUP) R4168305-5	Cyanide

The sample matrix interfered with the ability to make any accurate determination; spike value is low.

Batch	Lab Sample ID	Analytes
WG2435359	(MS) R4168305-3, (MSD) R4168305-4	Cyanide

The associated batch QC was outside the established quality control range for precision.

Batch	Lab Sample ID	Analytes
WG2435359	(MSD) R4168305-4	Cyanide

Metals (ICP) by Method 200.7

The analyte concentration exceeds the upper limit of the calibration range of the instrument established by the initial calibration (ICAL).

Batch	Lab Sample ID	Analytes
WG2437479	(MS) R4169491-6	Sodium
WG2437479	(MSD) R4169491-7	Sodium

The sample concentration is too high to evaluate accurate spike recoveries.

Batch	Lab Sample ID	Analytes
WG2437479	(MS) R4169491-6, (MSD) R4169491-7	Sodium

Volatile Organic Compounds (GC/MS) by Method 8260D

The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.

Batch	Lab Sample ID	Analytes
WG2435218	L1816567-01	Bromomethane

Pesticides (GC) by Method EPA 608.3

RPD between the primary and confirmatory analysis exceeded 40%

Batch	Lab Sample ID	Analytes
WG2433414	(MS) R4167713-1	15 analytes
WG2433414	(MSD) R4167713-2	13 analytes

Pesticides (GC) by Method EPA 608.3

Surrogate recovery limits have been exceeded; values are outside lower control limits.

Batch	Analyte	Lab Sample ID
WG2433414	Decachlorobiphenyl	(MS) R4167713-1, (MSD) R4167713-2, L1816567-01
WG2433414	Tetrachloro-m-xylene	(MSD) R4167713-2

The sample matrix interfered with the ability to make any accurate determination; spike value is low.

Batch	Lab Sample ID	Analytes
WG2433414	(MS) R4167713-1, (MSD) R4167713-2	4,4-DDD, 4,4-DDE, 4,4-DDT, Aldrin, Endosulfan I, Endrin, Endrin aldehyde, Heptachlor and Heptachlor epoxide

The associated batch QC was outside the established quality control range for precision.

Batch	Lab Sample ID	Analytes
WG2433414	(MSD) R4167713-2	4,4-DDE

Polychlorinated Biphenyls (GC) by Method EPA-608.3

Surrogate recovery limits have been exceeded; values are outside lower control limits.

Batch	Analyte	Lab Sample ID
WG2434422	Decachlorobiphenyl	(MSD) R4167707-4, L1816567-01
WG2434422	Tetrachloro-m-xylene	L1816567-01

The sample matrix interfered with the ability to make any accurate determination; spike value is low.

Batch	Lab Sample ID	Analytes
WG2434422	(MS) R4167707-3, (MSD) R4167707-4	PCB 1016 and PCB 1260

Semi Volatile Organic Compounds (GC/MS) by Method 625.1

Analyte reported using a calibration and validation based on Azobenzene (CAS 103-33-3). 1,2-Diphenylhydrazine decomposes into Azobenzene during the analysis.

Batch	Analyte	Lab Sample ID
WG2432984	1,2-Diphenylhydrazine	(BLANK) R4167892-2, (LCS) R4167892-1, (MS) R4167892-3, (MSD) R4167892-4, L1816567-01

Surrogate recovery cannot be used for control limit evaluation due to dilution.

Batch	Analyte	Lab Sample ID
WG2432984	2,4,6-Tribromophenol	(MS) R4167892-3, (MSD) R4167892-4
WG2432984	2-Fluorobiphenyl	(MS) R4167892-3, (MSD) R4167892-4
WG2432984	2-Fluorophenol	(MS) R4167892-3, (MSD) R4167892-4
WG2432984	Nitrobenzene-d5	(MS) R4167892-3, (MSD) R4167892-4
WG2432984	Phenol-d5	(MS) R4167892-3, (MSD) R4167892-4
WG2432984	p-Terphenyl-d14	(MS) R4167892-3, (MSD) R4167892-4

Surrogate recovery limits have been exceeded; values are outside lower control limits.

Batch	Analyte	Lab Sample ID
WG2432984	p-Terphenyl-d14	L1816567-01

The sample matrix interfered with the ability to make any accurate determination; spike value is high.

Batch	Lab Sample ID	Analytes
WG2432984	(MS) R4167892-3, (MSD) R4167892-4	2,4-Dinitrophenol

The sample matrix interfered with the ability to make any accurate determination; spike value is low.

Batch	Lab Sample ID	Analytes
WG2432984	(MS) R4167892-3, (MSD) R4167892-4	2-Chloronaphthalene, Benzidine, Hexachlorocyclopentadiene and n-Nitrosodiphenylamine

The associated batch QC was outside the established quality control range for precision.

Batch	Lab Sample ID	Analytes
WG2432984	(MSD) R4167892-4	Hexachlorocyclopentadiene

GLOSSARY OF TERMS

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

Abbreviations and Definitions

MDL	Method Detection Limit.
ND	Not detected at the Reporting Limit (or MDL where applicable).
RDL	Reported Detection Limit.
Rec.	Recovery.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
(S)	Surrogate (Surrogate Standard) - Analytes added to every blank, sample, Laboratory Control Sample/Duplicate and Matrix Spike/Duplicate; used to evaluate analytical efficiency by measuring recovery. Surrogates are not expected to be detected in all environmental media.
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Original Sample	The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Uncertainty (Radiochemistry)	Confidence level of 2 sigma.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
C3	The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.
E	The analyte concentration exceeds the upper limit of the calibration range of the instrument established by the initial calibration (ICAL).
J	The identification of the analyte is acceptable; the reported value is an estimate.
J2	Surrogate recovery limits have been exceeded; values are outside lower control limits.
J3	The associated batch QC was outside the established quality control range for precision.
J5	The sample matrix interfered with the ability to make any accurate determination; spike value is high.
J6	The sample matrix interfered with the ability to make any accurate determination; spike value is low.
J7	Surrogate recovery cannot be used for control limit evaluation due to dilution.
N2	Analyte reported using a calibration and validation based on Azobenzene (CAS 103-33-3). 1,2-Diphenylhydrazine decomposes into Azobenzene during the analysis.
P	RPD between the primary and confirmatory analysis exceeded 40%.

GLOSSARY OF TERMS

Qualifier	Description
P1	RPD value not applicable for sample concentrations less than 5 times the reporting limit.
Q	Sample was prepared and/or analyzed past holding time as defined in the method. Concentrations should be considered minimum values.
T8	Sample(s) received past/too close to holding time expiration.
V	The sample concentration is too high to evaluate accurate spike recoveries.

T. Alan Harvill
Project Manager

Results relate only to the items tested or calibrated and are reported as rounded values. This test report shall not be reproduced, except in full, without written approval of the laboratory. Where applicable, sampling conducted by Pace Analytical National is performed per guidance provided in laboratory standard operating procedures ENV-SOP-MTJL-0067 and ENV-SOP-MTJL-0068. Where sampling conducted by the customer, results relate to the accuracy of the information provided, and as the samples are received.

Unless qualified or notated within the narrative below, all sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

T. Alan Harvill
Project Manager

Project Comments

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

Sample Delivery Group (SDG) Narrative

The laboratory analysis was performed from an unpreserved, insufficiently or inadequately preserved sample.

Batch	Method	Lab Sample ID
WG2449073	410.4	L1824935-01

The following samples were prepared and/or analyzed past recommended holding time. Concentrations should be considered minimum values.

Batch	Method	Lab Sample ID

GLOSSARY OF TERMS

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

Abbreviations and Definitions

MDL	Method Detection Limit.
ND	Not detected at the Reporting Limit (or MDL where applicable).
RDL	Reported Detection Limit.
Rec.	Recovery.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Original Sample	The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Uncertainty (Radiochemistry)	Confidence level of 2 sigma.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
T8	Sample(s) received past/too close to holding time expiration.

SAMPLE SUMMARY

SP-01_Leachate L1833771-01 WW

Collected by: Kenneth Smith
Collected date/time: 03/06/25 12:00
Received date/time: 03/07/25 09:00

Method	Batch	Dilution	Preparation date/time	Analysis date/time	Analyst	Location
Gravimetric Analysis by Method 2540 D-2011	WG2465249	1	03/08/25 18:19	03/09/25 21:44	BDC	Mt. Juliet, TN
Wet Chemistry by Method 410.4	WG2465179	5	03/08/25 15:00	03/08/25 18:50	JEG	Mt. Juliet, TN
Wet Chemistry by Method 4500H+ B-2011	WG2465885	1	03/10/25 12:30	03/10/25 12:30	BJM	Mt. Juliet, TN

Unless qualified or notated within the narrative below, all sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

T. Alan Harvill
Project Manager

Project Comments

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

Sample Delivery Group (SDG) Narrative

The following samples were prepared and/or analyzed past recommended holding time. Concentrations should be considered minimum values.

Batch	Method	Lab Sample ID
WG2465885	4500H+ B-2011	L1833771-01

Additional Information - Results for field analyses are not accredited to ISO 17025

GLOSSARY OF TERMS

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

Abbreviations and Definitions

MDL	Method Detection Limit.
ND	Not detected at the Reporting Limit (or MDL where applicable).
RDL	Reported Detection Limit.
Rec.	Recovery.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Original Sample	The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Uncertainty (Radiochemistry)	Confidence level of 2 sigma.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
T8	Sample(s) received past/too close to holding time expiration.

Unless qualified or notated within the narrative below, all sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

T. Alan Harvill
Project Manager

Project Comments

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

Wet Chemistry by Method 300.0

The sample matrix interfered with the ability to make any accurate determination; spike value is low.

Batch	Lab Sample ID	Analytes
WG2469652	(MS) R4189244-6, (MSD) R4189244-7	Chloride

Metals (ICP) by Method 6010D

Analysis was filtered in the laboratory.

Batch	Method	Lab Sample ID
WG2471374	6010D	L1836539-01, 02

The sample concentration is too high to evaluate accurate spike recoveries.

Batch	Lab Sample ID	Analytes
WG2471374	(MS) R4188516-4, (MSD) R4188516-5, L1836539-01	Calcium,Dissolved and Magnesium,Dissolved

The analyte failed the method required serial dilution test and/or subsequent post-spike criteria. These failures indicate matrix interference.

Batch	Lab Sample ID	Analytes
WG2471374	L1836539-01	Calcium,Dissolved, Magnesium,Dissolved, Potassium,Dissolved and Sodium,Dissolved

Volatile Organic Compounds (GC/MS) by Method 8260D

The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.

Batch	Lab Sample ID	Analytes
WG2472093	L1836539-01	1,1,2,2-Tetrachloroethane, 1,2,3-Trichloropropane, 1,4-Dichlorobenzene, 4-Chlorotoluene, Acetone, Naphthalene, n-Propylbenzene and Tetrahydrofuran
WG2472093	L1836539-02	1,1,2,2-Tetrachloroethane, 1,2,3-Trichloropropane, 1,4-Dichlorobenzene, 4-Chlorotoluene, Acetone, Naphthalene, n-Propylbenzene and Tetrahydrofuran

Volatile Organic Compounds (GC/MS) by Method 8260D

The associated batch QC was below the established quality control range for accuracy.

Batch	Lab Sample ID	Analytes
WG2472093	(LCS) R4188314-1, L1836539-01, 02	1,4-Dichlorobenzene

GLOSSARY OF TERMS

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

Abbreviations and Definitions

MDL	Method Detection Limit.
ND	Not detected at the Reporting Limit (or MDL where applicable).
RDL	Reported Detection Limit.
Rec.	Recovery.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
(S)	Surrogate (Surrogate Standard) - Analytes added to every blank, sample, Laboratory Control Sample/Duplicate and Matrix Spike/Duplicate; used to evaluate analytical efficiency by measuring recovery. Surrogates are not expected to be detected in all environmental media.
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Original Sample	The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Uncertainty (Radiochemistry)	Confidence level of 2 sigma.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
C3	The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.
J	The identification of the analyte is acceptable; the reported value is an estimate.
J4	The associated batch QC was outside the established quality control range for accuracy.
J6	The sample matrix interfered with the ability to make any accurate determination; spike value is low.
O1	The analyte failed the method required serial dilution test and/or subsequent post-spike criteria. These failures indicate matrix interference.
V	The sample concentration is too high to evaluate accurate spike recoveries.

Semi Volatile Organic Compounds (GC/MS) by Method 625.1	WG2482495	1.03	04/05/25 04:25	04/12/25 18:07	ADF	Mt. Juliet, TN
Semi Volatile Organic Compounds (GC/MS) by Method 625.1	WG2490619	1.09	04/15/25 18:35	04/18/25 06:15	JCH	Mt. Juliet, TN

Unless qualified or notated within the narrative below, all sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

T. Alan Harvill
Project Manager

Report Revision History

Level II Report - Version 1: 04/24/25 08:30

Project Comments

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory¿s PQL unless requested by the client.

Revised to include onsite data.

Sample Comments

L1842913-01	L1842913-01 -2-Propanol, 2-Chloroethylvinyl Ether, and Acrolein initially run within seven-day method hold time. The initial run had failing internal standards and surrogates due to a bad purge which was the result of the foamy matrix of this sample.

Sample Delivery Group (SDG) Narrative

pH outside of method requirement.

Batch	Method	Lab Sample ID
WG2487790	8260D	L1842913-01
WG2488192	8260D	L1842913-01
WG2490955	8260D	L1842913-01

Sample was prepared and/or analyzed past recommended holding time. Concentrations should be considered minimum values.

Batch	Method	Lab Sample ID
WG2487619	8260D	L1842913-01
WG2490588	8260D	L1842913-01
WG2490619	625.1	L1842913-01

The laboratory analysis was performed from an unpreserved, insufficiently or inadequately preserved sample.

Batch	Method	Lab Sample ID
WG2484529	200.7	L1842913-01
WG2484815	245.1	L1842913-01

The following samples were prepared and/or analyzed past recommended holding time. Concentrations should be considered minimum values.

Batch	Method	Lab Sample ID
WG2482289	4500H+ B-2011	L1842913-01

Analyzed from headspace vial.

Batch	Method	Lab Sample ID
WG2490955	8260D	L1842913-01

Gravimetric Analysis by Method 2540 D-2011

RPD value not applicable for sample concentrations less than 5 times the reporting limit.

Batch	Lab Sample ID	Analytes
WG2482974	(DUP) R4195878-3	Suspended Solids

Wet Chemistry by Method 335.4

The sample matrix interfered with the ability to make any accurate determination; spike value is low.

Batch	Lab Sample ID	Analytes
WG2485966	(MS) R4197388-5, (MSD) R4197388-6	Cyanide

The associated batch QC was outside the established quality control range for precision.

Batch	Lab Sample ID	Analytes
WG2485966	(MSD) R4197388-6	Cyanide

Metals (ICP) by Method 200.7

The sample concentration is too high to evaluate accurate spike recoveries.

Batch	Lab Sample ID	Analytes
WG2484529	(MS) R4196935-6, (MSD) R4196935-7	Sodium

Volatile Organic Compounds (GC/MS) by Method 8260D

The reported concentration is an estimate. The continuing calibration standard associated with this data responded high. Data is likely to show a high bias concerning the result.

Batch	Lab Sample ID	Analytes
WG2487790	L1842913-01	2-Butanone (MEK)

The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.

Batch	Lab Sample ID	Analytes
WG2487790	L1842913-01	4-Methyl-2-pentanone (MIBK), Acetone, Acrylonitrile, Chloromethane and Hexachloro-1,3-butadiene

The associated batch QC was above the established quality control range for accuracy.

Batch	Lab Sample ID	Analytes
WG2487619	(LCS) R4199482-1, (LCSD) R4199482-2, L1842913-01	Acrolein
WG2487790	(LCS) R4198196-1, L1842913-01	1,1,2-Trichloroethane, Bromomethane and Carbon tetrachloride

Pesticides (GC) by Method EPA 608.3

RPD between the primary and confirmatory analysis exceeded 40%

Batch	Lab Sample ID	Analytes
WG2484099	L1842913-01	Endosulfan I

Surrogate recovery limits have been exceeded; values are outside lower control limits.

Batch	Analyte	Lab Sample ID
WG2484099	Decachlorobiphenyl	L1842913-01
WG2484099	Tetrachloro-m-xylene	L1842913-01

Polychlorinated Biphenyls (GC) by Method EPA-608.3

Surrogate recovery limits have been exceeded; values are outside lower control limits.

Batch	Analyte	Lab Sample ID
WG2484099	Decachlorobiphenyl	L1842913-01

Semi Volatile Organic Compounds (GC/MS) by Method 625.1

Analyte reported using a calibration and validation based on Azobenzene (CAS 103-33-3). 1,2-Diphenylhydrazine decomposes into Azobenzene during the analysis.

Batch	Analyte	Lab Sample ID
WG2482495	1,2-Diphenylhydrazine	(BLANK) R4198313-3, (LCS) R4198313-1, (MS) R4199396-1, (MSD) R4199396-2, L1842913-01

Surrogate recovery limits have been exceeded; values are outside lower control limits.

Batch	Analyte	Lab Sample ID
WG2490619	p-Terphenyl-d14	L1842913-01

The associated batch QC was below the established quality control range for accuracy.

Batch	Lab Sample ID	Analytes
WG2482495	(LCS) R4198313-1, L1842913-01	1,2,4-Trichlorobenzene, 2-Chloronaphthalene, Fluorene and Hexachloroethane

The sample matrix interfered with the ability to make any accurate determination; spike value is low.

Batch	Lab Sample ID	Analytes
WG2482495	(MS) R4199396-1, (MSD) R4199396-2	11 analytes

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

Abbreviations and Definitions

MDL	Method Detection Limit.
ND	Not detected at the Reporting Limit (or MDL where applicable).
RDL	Reported Detection Limit.
Rec.	Recovery.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
(S)	Surrogate (Surrogate Standard) - Analytes added to every blank, sample, Laboratory Control Sample/Duplicate and Matrix Spike/Duplicate; used to evaluate analytical efficiency by measuring recovery. Surrogates are not expected to be detected in all environmental media.
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Original Sample	The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Uncertainty (Radiochemistry)	Confidence level of 2 sigma.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
C3	The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.
C5	The reported concentration is an estimate. The continuing calibration standard associated with this data responded high. Data is likely to show a high bias concerning the result.
J	The identification of the analyte is acceptable; the reported value is an estimate.
J2	Surrogate recovery limits have been exceeded; values are outside lower control limits.
J3	The associated batch QC was outside the established quality control range for precision.
J4	The associated batch QC was outside the established quality control range for accuracy.
J6	The sample matrix interfered with the ability to make any accurate determination; spike value is low.
N2	Analyte reported using a calibration and validation based on Azobenzene (CAS 103-33-3). 1,2-Diphenylhydrazine decomposes into Azobenzene during the analysis.
P	RPD between the primary and confirmatory analysis exceeded 40%.
P1	RPD value not applicable for sample concentrations less than 5 times the reporting limit.

GLOSSARY OF TERMS

Qualifier	Description
Q	Sample was prepared and/or analyzed past holding time as defined in the method. Concentrations should be considered minimum values.
T8	Sample(s) received past/too close to holding time expiration.
V	The sample concentration is too high to evaluate accurate spike recoveries.

Unless qualified or notated within the narrative below, all sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

T. Alan Harvill
Project Manager

Project Comments

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

Wet Chemistry by Method 300.0

The analyte concentration exceeds the upper limit of the calibration range of the instrument established by the initial calibration (ICAL).

Batch	Lab Sample ID	Analytes
WG2491881	(MS) R4201140-4	Nitrate
WG2491881	(MSD) R4201140-5	Nitrate

The sample matrix interfered with the ability to make any accurate determination; spike value is low.

Batch	Lab Sample ID	Analytes
WG2491881	(MS) R4201140-4, (MSD) R4201140-5	Chloride, Nitrate and Sulfate

Wet Chemistry by Method 9060A

RPD value not applicable for sample concentrations less than 5 times the reporting limit.

Batch	Lab Sample ID	Analytes
WG2492884	(DUP) R4201318-8	TOC

Volatile Organic Compounds (GC/MS) by Method 8260D

The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.

Batch	Lab Sample ID	Analytes
WG2493546	L1848209-01	1,2,3-Trichlorobenzene, 1,2-Dibromo-3-Chloropropane, 2,2-Dichloropropane, 2-Butanone (MEK), Acetone, Bromoform, Chloroethane, Naphthalene and Tetrahydrofuran
WG2493546	L1848209-02	1,2,3-Trichlorobenzene, 1,2-Dibromo-3-Chloropropane, 2,2-Dichloropropane, 2-Butanone (MEK), Acetone, Bromoform, Chloroethane, Naphthalene and Tetrahydrofuran
WG2493546	L1848209-03	1,2,3-Trichlorobenzene, 1,2-Dibromo-3-Chloropropane, 2,2-Dichloropropane, 2-Butanone (MEK), Acetone, Bromoform, Chloroethane, Naphthalene and Tetrahydrofuran
WG2493546	L1848209-04	1,2,3-Trichlorobenzene, 1,2-Dibromo-3-Chloropropane, 2,2-Dichloropropane, 2-Butanone (MEK), Acetone, Bromoform, Chloroethane, Naphthalene and Tetrahydrofuran

Volatile Organic Compounds (GC/MS) by Method 8260D

The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.

Batch	Lab Sample ID	Analytes
WG2493546	L1848209-05	1,2,3-Trichlorobenzene, 1,2-Dibromo-3-Chloropropane, 2,2-Dichloropropane, 2-Butanone (MEK), Acetone, Bromoform, Chloroethane, Naphthalene and Tetrahydrofuran

The associated batch QC was outside the established quality control range for precision.

Batch	Lab Sample ID	Analytes
WG2493546	(MSD) R4202903-5	1,1,2-Trichloro-1,2,2-trifluoroethane, Chloromethane, Dichlorodifluoromethane and Dichlorofluoromethane

Volatile Organic Compounds (GC/MS) by Method 8260D

GLOSSARY OF TERMS

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

Abbreviations and Definitions

MDL	Method Detection Limit.
ND	Not detected at the Reporting Limit (or MDL where applicable).
RDL	Reported Detection Limit.
Rec.	Recovery.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
(S)	Surrogate (Surrogate Standard) - Analytes added to every blank, sample, Laboratory Control Sample/Duplicate and Matrix Spike/Duplicate; used to evaluate analytical efficiency by measuring recovery. Surrogates are not expected to be detected in all environmental media.
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Original Sample	The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Uncertainty (Radiochemistry)	Confidence level of 2 sigma.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
C3	The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.
E	The analyte concentration exceeds the upper limit of the calibration range of the instrument established by the initial calibration (ICAL).
J	The identification of the analyte is acceptable; the reported value is an estimate.
J3	The associated batch QC was outside the established quality control range for precision.
J6	The sample matrix interfered with the ability to make any accurate determination; spike value is low.
P1	RPD value not applicable for sample concentrations less than 5 times the reporting limit.

FIELD INFORMATION FORM

WM WASTE MANAGEMENT

Site Name: ERL

Site No.: | | | | | Sample Point: P 3 2 1 L (Sample ID)

This Waste Management Field Information Form is Required
This form is to be completed, in addition to any State Forms. The Field Form is submitted along with the Chain of Custody Forms that accompany the sample containers (i.e. with the cooler that is returned to the laboratory).

Laboratory Use Only/Lab ID: LB48209

PURGE INFO

PURGE DATE (MM DD YY)	PURGE TIME (2400 Hr Clock)	ELAPSED HRS (hr:mn)	WATER VOL IN CASING (Gallons)	ACTUAL VOL PURGED (Gallons)	WELL VOLs PURGED
04 15 25	12:25				

Note: For Passive Sampling, replace "Water Vol in Casing" and "Well Vols Purged" w/ Water Vol in Tubing/Flow Cell and Tubing/Flow Cell Vols Purged. Mark changes, record field data, below.

PURGE/SAMPLE EQUIPMENT

Purging and Sampling Equipment ... Dedicated: (Y) or N

Filter Device: Y or (N) 0.45 µ or _____ µ (circle or fill in)

Purging Device: C
Sampling Device: C
X-Other: _____

A- Submersible Pump, B-Peristaltic Pump, C-QED Bladder Pump, D-Bailer, E-Piston Pump, F-Dipper/Bottle

Filter Type: _____

A-In-line Disposable, B-Pressure, C-Vacuum, X-Other _____

Sample Tube Type: _____

A-Teflon, B-Stainless Steel, C-PVC, D-Polypropylene, X-Other: _____

WELL DATA

Well Elevation (at TOC)	Depth to Water (DTW) (from TOC)	Groundwater Elevation (site datum, from TOC)
972.56 (ft/msl)	23.10 (ft)	949.56 (ft/msl)

Total Well Depth (from TOC): _____ (ft)
Stick Up (from ground elevation): _____ (ft)
Casing ID: _____ (in)
Casing Material: _____

Note: Total Well Depth, Stick Up, Casing Id, etc. are optional and can be from historical data, unless required by Site Permit. Well Elevation, DTW, and Groundwater Elevation must be current.

STABILIZATION DATA (Optional)

Sample Time (2400 Hr Clock)	Rate/Unit: LPM	pH (std)	Conductance (SC/EC) (µmhos/cm @ 25 °C)	Temp. (°C)	Turbidity (ntu)	D.O. (mg/L - ppm)	eH/ORP (mV)	DTW (ft)
12:30	0.4 1st	7.18 1st	940	11.1		0.2		
12:35	2nd	7.15 2nd	935	11.3		0.1		
12:40	3rd	7.14 3rd	934	11.6		0.0		
12:45	4th	7.13 4th	932	11.6	2.1	0.0	-106	
Suggested range for 3 consec. readings or note Permit/State requirements:		+/- 0.2	+/- 3%	-	-	+/- 10%	+/- 25 mV	Stabilize

Stabilization Data Fields are Optional *(i.e. complete stabilization readings for parameters required by WM, Site, or State). These fields can be used where four (4) field measurements are required by State/Permit/Site. If a Data Logger or other Electronic format is used, fill in final readings below and submit electronic data separately to Site. If more fields above are needed, use separate sheet or form.*

FIELD DATA

SAMPLE DATE (MM DD YY)	pH (std)	CONDUCTANCE (umhos/cm @ 25°C)	TEMP. (°C)	TURBIDITY (ntu)	DO (mg/L-ppm)	eH/ORP (mV)	Other: _____ Units

Final Field Readings are required *(i.e. record field measurements, final stabilized readings, passive sample readings, before sampling for all field parameters required by State/Permit/Site).*

FIELD COMMENTS

Sample Appearance: _____ Odor: None Color: None Other: _____

Weather Conditions (required daily, or as conditions change): Direction/Speed: _____ Outlook: _____ Precipitation: Y or N

Specific Comments (including purge/well volume calculations if required): _____

I certify that sampling procedures were in accordance with applicable EPA, State, and WM protocols (if more than one sampler, all should sign):

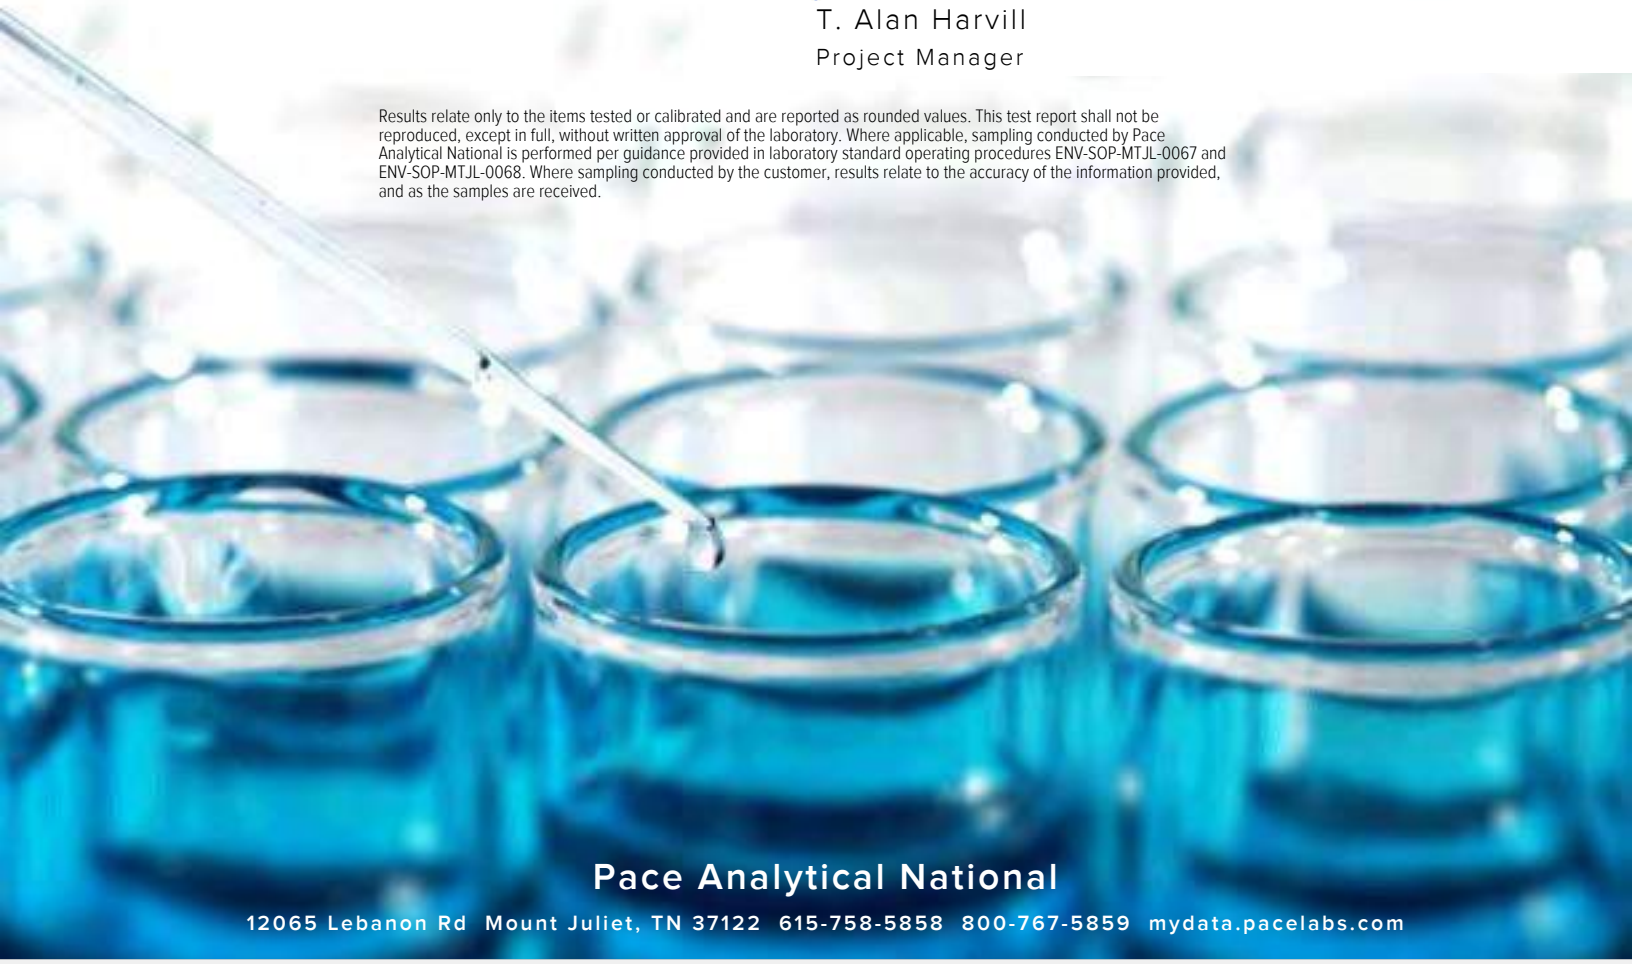
ANALYTICAL REPORT

May 07, 2025



Elk River Landfill

Sample Delivery Group:	L1848860
Samples Received:	04/17/2025
Project Number:	200
Description:	MNA Parameters
Site:	MN02
Report To:	Jim Eidem 4300 MarketPoint Drive Suite 200 Minneapolis, MN 55435

Entire Report Reviewed By:

T. Alan Harvill
Project Manager

Results relate only to the items tested or calibrated and are reported as rounded values. This test report shall not be reproduced, except in full, without written approval of the laboratory. Where applicable, sampling conducted by Pace Analytical National is performed per guidance provided in laboratory standard operating procedures ENV-SOP-MTJL-0067 and ENV-SOP-MTJL-0068. Where sampling conducted by the customer, results relate to the accuracy of the information provided, and as the samples are received.

Unless qualified or notated within the narrative below, all sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

T. Alan Harvill
Project Manager

Project Comments

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

Sample Delivery Group (SDG) Narrative

Analyzed from headspace vial.

Batch	Method	Lab Sample ID
WG2499929	8260D	L1848860-01

Wet Chemistry by Method 300.0

The analyte concentration exceeds the upper limit of the calibration range of the instrument established by the initial calibration (ICAL).

Batch	Lab Sample ID	Analytes
WG2493080	(MS) R4201978-6	Nitrate and Sulfate
WG2493080	(MSD) R4201978-7	Nitrate and Sulfate

RPD value not applicable for sample concentrations less than 5 times the reporting limit.

Batch	Lab Sample ID	Analytes
WG2493080	(DUP) R4201978-3	Sulfate

The sample matrix interfered with the ability to make any accurate determination; spike value is low.

Batch	Lab Sample ID	Analytes
WG2493080	(MS) R4201978-4, (MS) R4201978-6, (MSD) R4201978-7	Sulfate

Volatile Organic Compounds (GC/MS) by Method 8260D

Volatile Organic Compounds (GC/MS) by Method 8260D

The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.

Batch	Lab Sample ID	Analytes
WG2498825	L1848860-01	1,1,2,2-Tetrachloroethane, 2,2-Dichloropropane, 2-Butanone (MEK) and Chloromethane
WG2498825	L1848860-02	1,1,2,2-Tetrachloroethane, 2,2-Dichloropropane, 2-Butanone (MEK) and Chloromethane

WG2498825	L1848860-04	1,1,2,2-Tetrachloroethane, 2,2-Dichloropropane, 2-Butanone (MEK) and Chloromethane
WG2499929	L1848860-01	Tetrahydrofuran
WG2499929	L1848860-02	Tetrahydrofuran
WG2499929	L1848860-03	Tetrahydrofuran
WG2499929	L1848860-04	Tetrahydrofuran

The analyte concentration exceeds the upper limit of the calibration range of the instrument established by the initial calibration (ICAL).

Batch	Lab Sample ID	Analytes
WG2498825	L1848860-02	Ethyl ether

The associated batch QC was below the established quality control range for accuracy.

Batch	Lab Sample ID	Analytes
WG2498825	(LCS) R4205005-1, L1848860-01, 02, 03, 04	2,2-Dichloropropane

The associated batch QC was outside the established quality control range for precision.

Batch	Lab Sample ID	Analytes
WG2498825	(LCSD) R4205005-2, L1848860-01, 02, 03, 04	1,1-Dichloroethene, 2,2-Dichloropropane, Bromomethane, Chloroethane, Chloromethane, Dichlorodifluoromethane, Isopropylbenzene, Trichloroethene and Vinyl chloride

GLOSSARY OF TERMS

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

Abbreviations and Definitions

MDL	Method Detection Limit.
ND	Not detected at the Reporting Limit (or MDL where applicable).
RDL	Reported Detection Limit.
Rec.	Recovery.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
(S)	Surrogate (Surrogate Standard) - Analytes added to every blank, sample, Laboratory Control Sample/Duplicate and Matrix Spike/Duplicate; used to evaluate analytical efficiency by measuring recovery. Surrogates are not expected to be detected in all environmental media.
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Original Sample	The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Uncertainty (Radiochemistry)	Confidence level of 2 sigma.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
C3	The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.
E	The analyte concentration exceeds the upper limit of the calibration range of the instrument established by the initial calibration (ICAL).
J3	The associated batch QC was outside the established quality control range for precision.
J4	The associated batch QC was outside the established quality control range for accuracy.
J6	The sample matrix interfered with the ability to make any accurate determination; spike value is low.
P1	RPD value not applicable for sample concentrations less than 5 times the reporting limit.

FIELD INFORMATION FORM

WM WASTE MANAGEMENT

Site Name: ERL

Site No.:

Sample Point: P302C (Sample ID)

This Waste Management Field Information Form is Required
This form is to be completed, in addition to any State Forms. The Field Form is submitted along with the Chain of Custody Forms that accompany the sample containers (i.e. with the cooler that is returned to the laboratory).

Laboratory Use Only/Lab ID: L1845810

PURGE INFO

PURGE DATE (MM DD YY)	PURGE TIME (2400 Hr Clock)	ELAPSED HRS (hr:min)	WATER VOL IN CASING (Gallons)	ACTUAL VOL PURGED (Gallons)	WELL VOLs PURGED
04 16 25	13:55	:			

Note: For Passive Sampling, replace "Water Vol in Casing" and "Well Vols Purged" w/ Water Vol in Tubing/Flow Cell and Tubing/Flow Cell Vols Purged. Mark changes, record field data, below.

PURGE/SAMPLE EQUIPMENT

Purging and Sampling Equipment ... Dedicated: (Y) or N

Filter Device: Y or (O) 0.45 µ or _____ µ (circle or fill in)

Purging Device: C
Sampling Device: C
X-Other: _____

A- Submersible Pump, B-Peristaltic Pump, C-QED Bladder Pump, D-Bailer, E-Piston Pump, F-Dipper/Bottle

Filter Type:

A-In-line Disposable, B-Pressure, C-Vacuum, X-Other _____

Sample Tube Type:

A-Teflon, B-Stainless Steel, C-PVC, D-Polypropylene, X-Other _____

WELL DATA

Well Elevation (at TOC): 97063 (ft/msl)
Depth to Water (DTW) (from TOC): 21.10 (ft)
Groundwater Elevation (site datum, from TOC): 94953 (ft/msl)
Total Well Depth (from TOC): _____ (ft)
Stick Up (from ground elevation): _____ (ft)
Casing ID: _____ (in)
Casing Material: _____

Note: Total Well Depth, Stick Up, Casing Id, etc. are optional and can be from historical data, unless required by Site/Permit. Well Elevation, DTW, and Groundwater Elevation must be current.

STABILIZATION DATA (Optional)

Sample Time (2400 Hr Clock)	Rate/Unit L/M	pH (std)	Conductance (SC/EC) (µmhos/cm @ 25 °C)	Temp (°C)	Turbidity (ntu)	D.O. (mg/L - ppm)	eH/ORP (mV)	DTW (ft)
1410	0.4	7.30	1914	13.2		0.0		
1405		7.25	1882	12.9		0.0		
1410		7.19	1887	13.0		0.0		
1415		7.12	1893	13.3	25.1	0.0	-186	
Suggested range for 3 consec. readings or site Permit/State requirements:		+/- 0.2	+/- 3%	-	-	+/- 10%	+/- 25 mV	Bubble

Stabilization Data Fields are Optional *(i.e. sampling stabilization readings for parameters required by WM, Site, or State). These fields can be used where four (4) field measurements are required by State Permit/Site. If a Data Logger or other Electronic format is used, fill in final readings below and submit electronic data separately to Site. If more fields above are needed, use separate sheet or form.*

FIELD DATA

SAMPLE DATE (MM DD YY)	pH (std)	CONDUCTANCE (µmhos/cm @ 25°C)	TEMP. (°C)	TURBIDITY (ntu)	DO (mg/L-ppm)	eH/ORP (mV)	Other: Units

Final Field Readings are required *(i.e. record field measurements, final stabilized readings, passive sample readings before sampling for all field parameters required by State/Permit/Site).*

FIELD COMMENTS

Sample Appearance: _____ Odor: N Color: N Other: _____

Weather Conditions (required daily, or as conditions change): Direction/Speed: _____ Outlook: _____ Precipitation: Y or N

Specific Comments (including purge/well volume calculations if required): _____

I certify that sampling procedures were in accordance with applicable EPA, State, and WM protocols (if more than one sampler, all should sign):

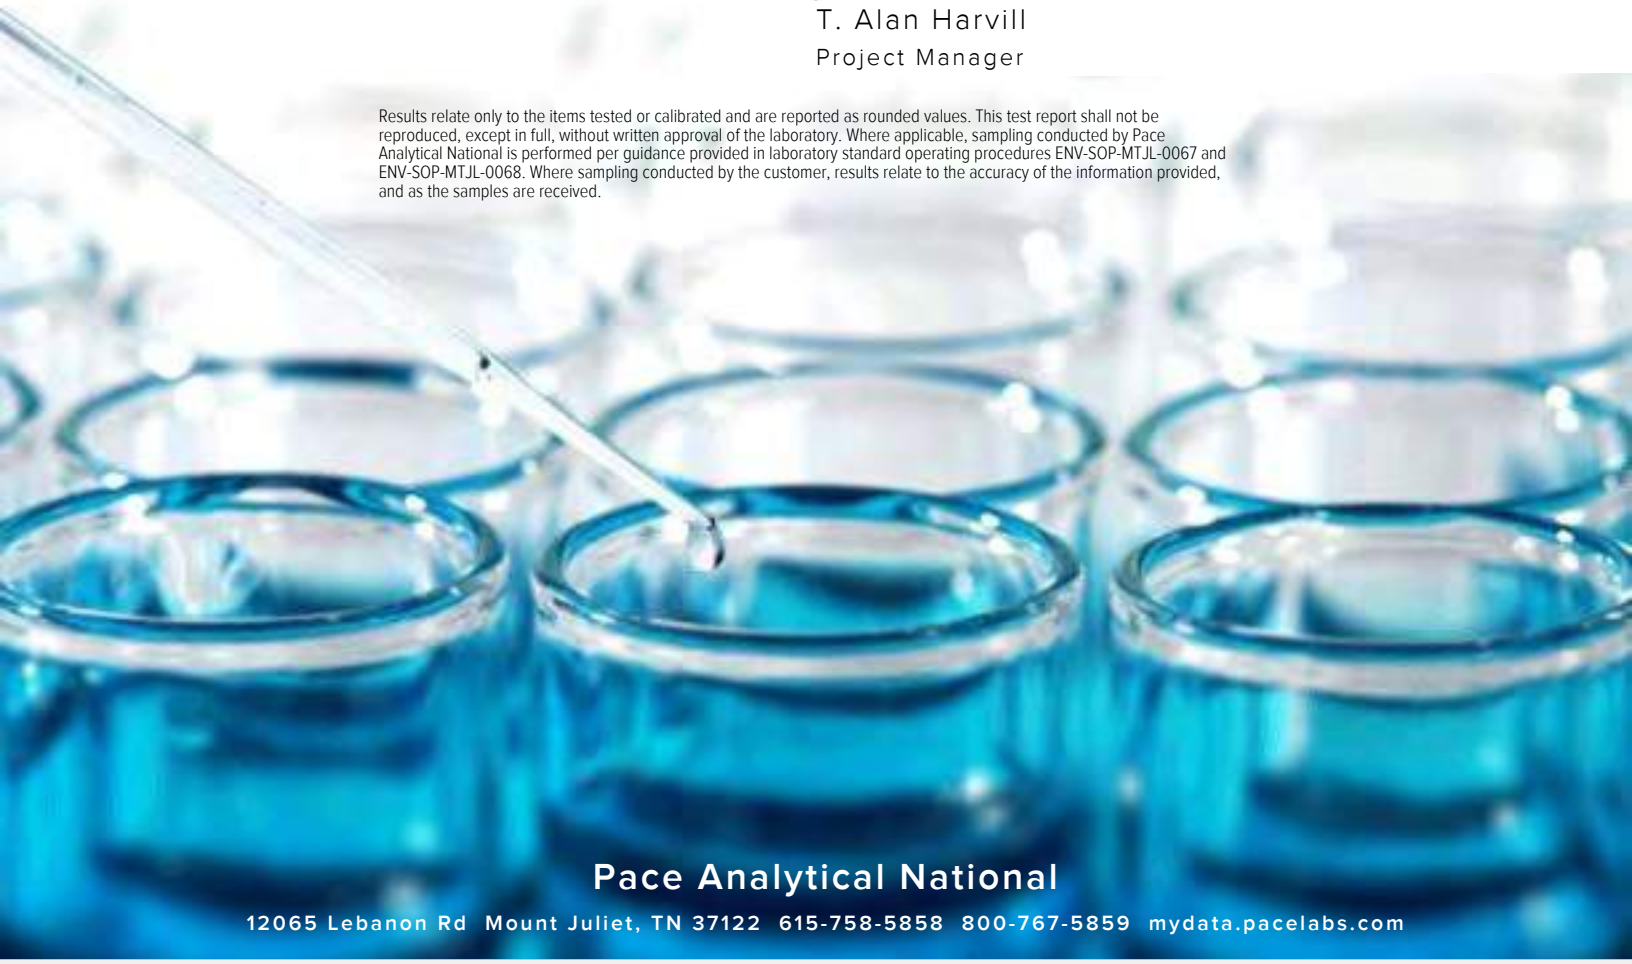
ANALYTICAL REPORT

May 13, 2025

Revised Report



Elk River Landfill

Sample Delivery Group:	L1849382
Samples Received:	04/18/2025
Project Number:	200
Description:	MNA Parameters
Site:	MN02
Report To:	Jim Eidem 4300 MarketPoint Drive Suite 200 Minneapolis, MN 55435

Entire Report Reviewed By:

T. Alan Harvill
Project Manager

Results relate only to the items tested or calibrated and are reported as rounded values. This test report shall not be reproduced, except in full, without written approval of the laboratory. Where applicable, sampling conducted by Pace Analytical National is performed per guidance provided in laboratory standard operating procedures ENV-SOP-MTJL-0067 and ENV-SOP-MTJL-0068. Where sampling conducted by the customer, results relate to the accuracy of the information provided, and as the samples are received.

Unless qualified or notated within the narrative below, all sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

T. Alan Harvill
Project Manager

Report Revision History

Level II Report - Version 1: 05/01/25 15:51

Project Comments

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

revised to include Field data.

Sample Delivery Group (SDG) Narrative

Analyzed from headspace vial.

Batch	Method	Lab Sample ID
WG2501712	8260D	L1849382-01

Wet Chemistry by Method 300.0

The analyte concentration exceeds the upper limit of the calibration range of the instrument established by the initial calibration (ICAL).

Batch	Lab Sample ID	Analytes
WG2493967	(MS) R4201985-4	Chloride
WG2493967	(MSD) R4201985-5	Chloride
WG2493967	(MS) R4201985-7	Chloride

The sample matrix interfered with the ability to make any accurate determination; spike value is low.

Batch	Lab Sample ID	Analytes
WG2493967	(MS) R4201985-4, (MSD) R4201985-5	Chloride and Sulfate

The sample concentration is too high to evaluate accurate spike recoveries.

Batch	Lab Sample ID	Analytes
WG2493967	(MS) R4201985-7	Chloride

Wet Chemistry by Method 9060A

RPD value not applicable for sample concentrations less than 5 times the reporting limit.

Batch	Lab Sample ID	Analytes
WG2495896	(DUP) R4202983-5	TOC

Volatile Organic Compounds (GC/MS) by Method 8260D

The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.

Batch	Lab Sample ID	Analytes
WG2498839	L1849382-01	1,1-Dichloroethene, 1,2-Dichloroethane, 2-Butanone (MEK), Bromomethane, Chloromethane, Dichlorodifluoromethane, Ethyl ether and Tetrahydrofuran
WG2498839	L1849382-02	1,1-Dichloroethene, 1,2-Dichloroethane, 2-Butanone (MEK), Bromomethane, Chloromethane, Dichlorodifluoromethane, Ethyl ether and Tetrahydrofuran
WG2498839	L1849382-03	1,1-Dichloroethene, 1,2-Dichloroethane, 2-Butanone (MEK), Bromomethane, Chloromethane, Dichlorodifluoromethane, Ethyl ether and Tetrahydrofuran
WG2498839	L1849382-04	1,1-Dichloroethene, 1,2-Dichloroethane, 2-Butanone (MEK), Bromomethane, Chloromethane, Dichlorodifluoromethane, Ethyl ether and Tetrahydrofuran

The associated batch QC was outside the established quality control range for precision.

Batch	Lab Sample ID	Analytes
WG2498839	(LCSD) R4206160-2, L1849382-01, 02, 03, 04	Bromomethane

Volatile Organic Compounds (GC/MS) by Method 8260D

GLOSSARY OF TERMS

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

Abbreviations and Definitions

MDL	Method Detection Limit.
ND	Not detected at the Reporting Limit (or MDL where applicable).
RDL	Reported Detection Limit.
Rec.	Recovery.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
(S)	Surrogate (Surrogate Standard) - Analytes added to every blank, sample, Laboratory Control Sample/Duplicate and Matrix Spike/Duplicate; used to evaluate analytical efficiency by measuring recovery. Surrogates are not expected to be detected in all environmental media.
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Original Sample	The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Uncertainty (Radiochemistry)	Confidence level of 2 sigma.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
C3	The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.
E	The analyte concentration exceeds the upper limit of the calibration range of the instrument established by the initial calibration (ICAL).
J3	The associated batch QC was outside the established quality control range for precision.
J6	The sample matrix interfered with the ability to make any accurate determination; spike value is low.
P1	RPD value not applicable for sample concentrations less than 5 times the reporting limit.
V	The sample concentration is too high to evaluate accurate spike recoveries.

FIELD INFORMATION FORM

WASTE MANAGEMENT

Site Name: ERL

Site No.: | | | | | Sample Point: P 3 1 3 4 (Sample ID)

This Waste Management Field Information Form is Required
This form is to be completed, in addition to any State Forms. The Field Form is submitted along with the Chain of Custody Forms that accompany the sample containers (i.e. with the cooler that is returned to the laboratory).

Laboratory Use Only Lab ID: C18040367

PURGE INFO

PURGE DATE (MM DD YY)	PURGE TIME (2400 Hr Clock)	ELAPSED HRS (hr:min)	WATER VOL IN CASING (Gallons)	ACTUAL VOL PURGED (Gallons)	WELL VOLs PURGED
04 17 25	08:20	:			

Note: For Passive Sampling, replace "Water Vol in Casing" and "Well Vols Purged" w/ Water Vol in Tubing Flow Cell and Tubing Flow Cell Vols Purged. Mark changes, record field data, below.

PURGE/SAMPLE EQUIPMENT

Purging and Sampling Equipment ... Dedicated: (Y) or N

Purging Device: C
Sampling Device: C
X-Other:

A- Submersible Pump, B-Peristaltic Pump, C-QED Bladder Pump, D-Bailer, E-Piston Pump, F-Dipper/Bottle

Filter Device: Y or (6) 0.45 µ or ____ µ (circle or fill in)

Filter Type: A-In-line Disposable, B-Pressure, C-Vacuum, X-Other ____

Sample Tube Type: A-Teflon, B-Stainless Steel, C-PVC, D-Polypropylene, X-Other: ____

WELL DATA

Well Elevation (at TOC) ____ (ft/msl)
Depth to Water (DTW) (from TOC) ____ (ft)
Groundwater Elevation (site datum, from TOC) ____ (ft/msl)
Total Well Depth (from TOC) ____ (ft)
Stick Up (from ground elevation) ____ (ft)
Casing ID ____ (in)
Casing Material ____

Note: Total Well Depth, Stick Up, Casing Id, etc. are optional and can be from historical data, unless required by Site/Permit. Well Elevation, DTW, and Groundwater Elev. must be current.

STABILIZATION DATA (Optional)

Sample Time (2400 Hr Clock)	Rate/Unit L/M	pH (std)	Conductance (SC/EC) (µmhos/cm @ 25 °C)	Temp. (°C)	Turbidity (ntu)	D.O. (mg/L - ppm)	eH/ORP (mV)	DTW (ft)
08:25	0.4 1"	7.38 1"	1329 1"	9.10		0.16		
08:30	2"	7.05 2"	1325 2"	9.0		0.1		
08:35	3"	6.97 3"	1318 3"	9.0		0.0		
08:40	4"	6.95 4"	1315 4"	9.0	5.0	0.0 -	1.17	
Suggested range for 3 consec. readings or state Permit/State requirements		+/- 0.2	+/- 3%	–	–	+/- 10%	+/- 25 mV	Stabilize

Stabilization Data Fields are Optional *(i.e. complete stabilization readings for parameters required by WM, Site, or State). These fields can be used where four (4) field measurements are required by State/Permit/Site. If a Data Logger or other Electronic format is used, fill in final readings below and submit electronic data separately to Site. If more fields above are needed, use separate sheet or form.*

FIELD DATA

SAMPLE DATE (MM DD YY)	pH (std)	CONDUCTANCE (µmhos/cm @ 25°C)	TEMP. (°C)	TURBIDITY (ntu)	DO (mg/L-ppm)	eH/ORP (mV)	Other: ____ Units ____

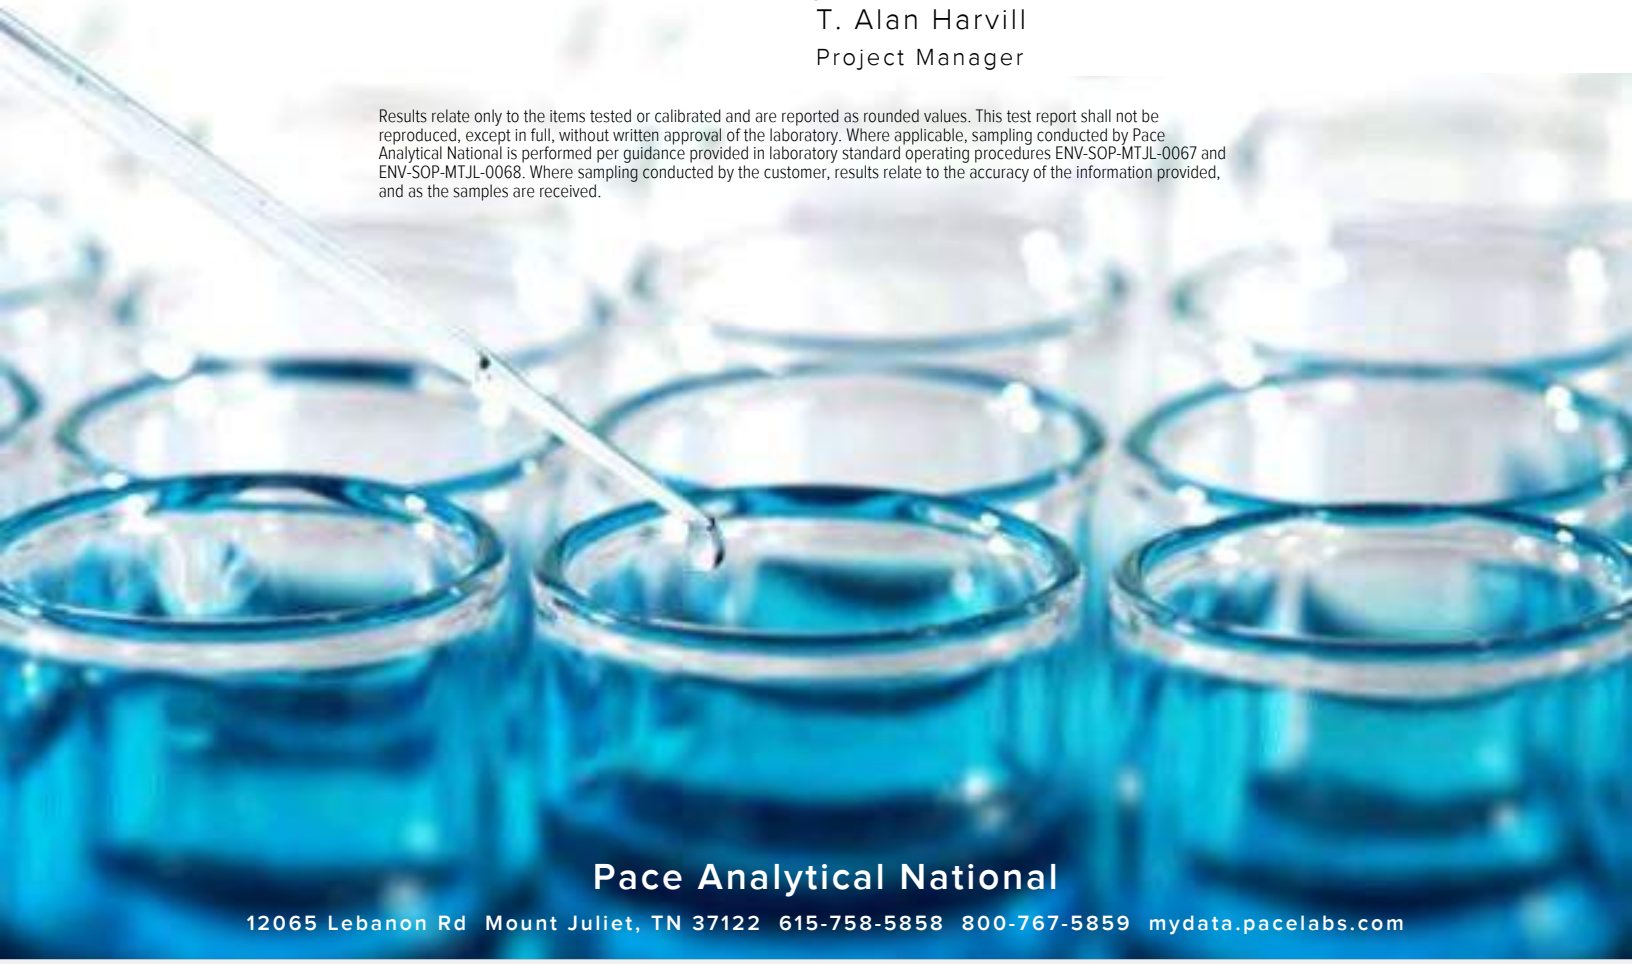
ANALYTICAL REPORT

May 21, 2025

Revised Report



Elk River Landfill

Sample Delivery Group:	L1849779
Samples Received:	04/18/2025
Project Number:	200
Description:	NDA Spring Sampling (4)
Site:	MN02
Report To:	Jim Eidem 4300 MarketPoint Drive Suite 200 Minneapolis, MN 55435

Entire Report Reviewed By:

T. Alan Harvill
Project Manager

Results relate only to the items tested or calibrated and are reported as rounded values. This test report shall not be reproduced, except in full, without written approval of the laboratory. Where applicable, sampling conducted by Pace Analytical National is performed per guidance provided in laboratory standard operating procedures ENV-SOP-MTJL-0067 and ENV-SOP-MTJL-0068. Where sampling conducted by the customer, results relate to the accuracy of the information provided, and as the samples are received.

Unless qualified or notated within the narrative below, all sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

T. Alan Harvill
Project Manager

Report Revision History

Level II Report - Version 1: 05/05/25 13:45

Project Comments

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

Revised to correct Total Anions

Wet Chemistry by Method 300.0

The analyte concentration exceeds the upper limit of the calibration range of the instrument established by the initial calibration (ICAL).

Batch	Lab Sample ID	Analytes
WG2494623	(MS) R4204453-4	Chloride
WG2494623	(MSD) R4204453-5	Chloride
WG2494623	(MS) R4204453-7	Chloride

The sample concentration is too high to evaluate accurate spike recoveries.

Batch	Lab Sample ID	Analytes
WG2494623	(MS) R4204453-4, (MS) R4204453-7, (MSD) R4204453-5	Chloride

The sample matrix interfered with the ability to make any accurate determination; spike value is low.

Batch	Lab Sample ID	Analytes
WG2494623	(MS) R4204453-4, (MS) R4204453-7, (MSD) R4204453-5	Sulfate

Metals (ICP) by Method 6010D

Analysis was filtered in the laboratory.

Batch	Method	Lab Sample ID
WG2499696	6010D	L1849779-01, 02, 04

Metals (ICPMS) by Method 6020

Analysis was filtered in the laboratory.

Batch	Method	Lab Sample ID
WG2496296	6020	L1849779-01, 02, 04

The sample concentration is too high to evaluate accurate spike recoveries.

Batch	Lab Sample ID	Analytes
WG2496296	(MS) R4204833-4	Magnesium,Dissolved

Volatile Organic Compounds (GC/MS) by Method 8260D

The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.

Batch	Lab Sample ID	Analytes
WG2498839	L1849779-01	1,1-Dichloroethene, 1,2-Dichloroethane, 2-Butanone (MEK), Bromomethane, Chloromethane, Dichlorodifluoromethane, Ethyl ether and Tetrahydrofuran
WG2498839	L1849779-02	1,1-Dichloroethene, 1,2-Dichloroethane, 2-Butanone (MEK), Bromomethane, Chloromethane, Dichlorodifluoromethane, Ethyl ether and Tetrahydrofuran
WG2498839	L1849779-03	1,1-Dichloroethene, 1,2-Dichloroethane, 2-Butanone (MEK), Bromomethane, Chloromethane, Dichlorodifluoromethane, Ethyl ether and Tetrahydrofuran
WG2502487	L1849779-04	Bromoform and Vinyl chloride

The associated batch QC was above the established quality control range for accuracy.

Batch	Lab Sample ID	Analytes
WG2502487	(LCS) R4207602-1, (LCSD) R4207602-2, L1849779-04	2-Butanone (MEK) and Acetone

The associated batch QC was outside the established quality control range for precision.

Batch	Lab Sample ID	Analytes
WG2498839	(LCSD) R4206160-2, L1849779-01, 02, 03	Bromomethane

Additional Information - Results for field analyses are not accredited to ISO 17025

GLOSSARY OF TERMS

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

Abbreviations and Definitions

MDL	Method Detection Limit.
ND	Not detected at the Reporting Limit (or MDL where applicable).
RDL	Reported Detection Limit.
Rec.	Recovery.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
(S)	Surrogate (Surrogate Standard) - Analytes added to every blank, sample, Laboratory Control Sample/Duplicate and Matrix Spike/Duplicate; used to evaluate analytical efficiency by measuring recovery. Surrogates are not expected to be detected in all environmental media.
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Original Sample	The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Uncertainty (Radiochemistry)	Confidence level of 2 sigma.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
C3	The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.
E	The analyte concentration exceeds the upper limit of the calibration range of the instrument established by the initial calibration (ICAL).
J3	The associated batch QC was outside the established quality control range for precision.
J4	The associated batch QC was outside the established quality control range for accuracy.
J6	The sample matrix interfered with the ability to make any accurate determination; spike value is low.
V	The sample concentration is too high to evaluate accurate spike recoveries.

Results relate only to the items tested or calibrated and are reported as rounded values. This test report shall not be reproduced, except in full, without written approval of the laboratory. Where applicable, sampling conducted by Pace Analytical National is performed per guidance provided in laboratory standard operating procedures ENV-SOP-MTJL-0067 and ENV-SOP-MTJL-0068. Where sampling conducted by the customer, results relate to the accuracy of the information provided, and as the samples are received.

Unless qualified or notated within the narrative below, all sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

T. Alan Harvill
Project Manager

Report Revision History

Level II Report - Version 1: 05/02/25 08:34
Level II Report - Version 2: 05/13/25 12:46

Project Comments

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

Revised report to change ID to P-342C per Barr Engineering

Gravimetric Analysis by Method 2540 D-2020

RPD value not applicable for sample concentrations less than 5 times the reporting limit.

Batch	Lab Sample ID	Analytes
WG2496890	(DUP) R4203897-5	Suspended Solids

Wet Chemistry by Method 300.0

The analyte concentration exceeds the upper limit of the calibration range of the instrument established by the initial calibration (ICAL).

Batch	Lab Sample ID	Analytes
WG2495099	(MS) R4204495-4	Chloride

The sample matrix interfered with the ability to make any accurate determination; spike value is low.

Batch	Lab Sample ID	Analytes
WG2495099	(MS) R4204495-4, (MS) R4204495-6, (MSD) R4204495-7	Chloride and Sulfate

Wet Chemistry by Method 353.2

The sample matrix interfered with the ability to make any accurate determination; spike value is high.

Batch	Lab Sample ID	Analytes
WG2496476	(MSD) R4206643-6	Nitrate-Nitrite

Mercury by Method 7470A

Analysis was filtered in the laboratory.

Batch	Method	Lab Sample ID
WG2495366	7470A	L1850102-01

Metals (ICP) by Method 6010D

Analysis was filtered in the laboratory.

Batch	Method	Lab Sample ID
WG2499701	6010D	L1850102-01

Metals (ICPMS) by Method 6020B

Analysis was filtered in the laboratory.

Batch	Method	Lab Sample ID
WG2499715	6020B	L1850102-01

The sample concentration is too high to evaluate accurate spike recoveries.

Batch	Lab Sample ID	Analytes
WG2499715	(MS) R4208233-4, (MSD) R4208233-5	Magnesium,Dissolved

Volatile Organic Compounds (GC/MS) by Method 8260D

The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.

Batch	Lab Sample ID	Analytes
WG2502097	L1850102-01	1,2,3-Trichlorobenzene, 1,2-Dibromo-3-Chloropropane, Hexachloro-1,3-butadiene and Naphthalene

The associated batch QC was above the established quality control range for accuracy.

Batch	Lab Sample ID	Analytes
WG2502097	(LCS) R4207086-1, L1850102-01	Bromomethane and Chloroethane

Additional Information - Results for field analyses are not accredited to ISO 17025

Analyte	Result	Units
pH (On Site)	7.5	su

GLOSSARY OF TERMS

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

Abbreviations and Definitions

MDL	Method Detection Limit.
ND	Not detected at the Reporting Limit (or MDL where applicable).
RDL	Reported Detection Limit.
Rec.	Recovery.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
(S)	Surrogate (Surrogate Standard) - Analytes added to every blank, sample, Laboratory Control Sample/Duplicate and Matrix Spike/Duplicate; used to evaluate analytical efficiency by measuring recovery. Surrogates are not expected to be detected in all environmental media.
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Original Sample	The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Uncertainty (Radiochemistry)	Confidence level of 2 sigma.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
C3	The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.
E	The analyte concentration exceeds the upper limit of the calibration range of the instrument established by the initial calibration (ICAL).
J	The identification of the analyte is acceptable; the reported value is an estimate.
J4	The associated batch QC was outside the established quality control range for accuracy.
J5	The sample matrix interfered with the ability to make any accurate determination; spike value is high.
J6	The sample matrix interfered with the ability to make any accurate determination; spike value is low.
P1	RPD value not applicable for sample concentrations less than 5 times the reporting limit.
V	The sample concentration is too high to evaluate accurate spike recoveries.

Unless qualified or notated within the narrative below, all sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

T. Alan Harvill
Project Manager

Report Revision History

Level II Report - Version 1: 05/02/25 08:25

Project Comments

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

Revised to correct onsite data.

Volatile Organic Compounds (GC/MS) by Method 8260D

The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.

GLOSSARY OF TERMS

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

Abbreviations and Definitions

MDL	Method Detection Limit.
ND	Not detected at the Reporting Limit (or MDL where applicable).
RDL	Reported Detection Limit.
Rec.	Recovery.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
(S)	Surrogate (Surrogate Standard) - Analytes added to every blank, sample, Laboratory Control Sample/Duplicate and Matrix Spike/Duplicate; used to evaluate analytical efficiency by measuring recovery. Surrogates are not expected to be detected in all environmental media.
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Uncertainty (Radiochemistry)	Confidence level of 2 sigma.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
C3	The reported concentration is an estimate. The continuing calibration standard associated with this data responded low. Method sensitivity check is acceptable.
C5	The reported concentration is an estimate. The continuing calibration standard associated with this data responded high. Data is likely to show a high bias concerning the result.
J	The identification of the analyte is acceptable; the reported value is an estimate.
J4	The associated batch QC was outside the established quality control range for accuracy.

FIELD INFORMATION FORM

Site Name: ERL

Site No.: | | | |

Sample Point: P644477 (Sample ID)

This Waste Management Field Information Form is Required
This form is to be completed, in addition to any State Forms. The Field Form is submitted along with the Chain of Custody Forms that accompany the sample containers (i.e. with the cooler that is returned to the laboratory).

Laboratory Use Only Lab ID: L1850104

PURGE INFO

PURGE DATE (MM DD YY)	PURGE TIME (2400 Hr Clock)	ELAPSED HRS (hr:min)	WATER VOL IN CASING (Gallons)	ACTUAL VOL PURGED (Gallons)	WELL VOLs PURGED
04/16/25	0830				

Note: For Passive Sampling, replace "Water Vol in Casing" and "Well Vols Purged" w/ Water Vol in Tubing/Flow Cell and Tubing/Flow Cell Vols Purged. Mark changes, record/field data below.

PURGE/SAMPLE EQUIPMENT

Purging and Sampling Equipment ... Dedicated: [Y] or [O]

Purging Device: A — Sampling Device: A — X-Other:

A- Submersible Pump; B-Peristaltic Pump; C-QED Bladder Pump; D-Bailer; E-Piston Pump; F-Dipper/Bottle

Filter Device: [Y] or [N] [0.45 µ] or [ ] µ (circle or fill in)

Filter Type: A-In-line Disposable; B-Pressure; C-Vacuum; X-Other

Sample Tube Type: A-Teflon; B-Stainless Steel; C-PVC; D-Polypropylene; X-Other:

WELL DATA

Well Elevation (at TOC)	Depth to Water (DTW) (from TOC)	Groundwater Elevation (site datum, from TOC)
98786 (ft/msl)	4156 (ft)	94636 (ft/msl)

Total Well Depth (from TOC)	Stick Up (from ground elevation)	Casing ID	Casing Material
(ft)	(ft)	(in)	

Note: Total Well Depth, Stick Up, Casing Id, etc. are optional and can be from historical data, unless required by Site Permit. Well Elevation, DTW, and Groundwater Elevation must be current.

STABILIZATION DATA (Optional)

Sample Time (2400 Hr Clock)	Rate (mL/min)	pH (std)	Conductance (SC/EC) (umhos/cm @ 25 °C)	Temp (°C)	Turbidity (ntu)	D.O. (mg/L - ppm)	eH/ORP (mV)	DTW (ft)
0850	3 1st	7.43 1st	795 1st	9.8		0.1		
0910	2nd	7.35 2nd	814 2nd	9.8		0.1		
0930	1st	7.31 3rd	834 3rd	9.7	0.2	0.0 - 2.03		
	4th	4th	4th					
Suggested range for 3 consec. readings or site Permit/State requirements		+/- 0.2	+/- 3%	-	-	+/- 10%	+/- 25 mV	Stabilize

Stabilization Data Fields are Optional *(i.e. complete stabilization readings for parameters required by WM, Site, or State). These fields can be used where four (4) field measurements are required by State/Permit/Site. If a Data Logger or other Electronic format is used, fill in final readings below and submit electronic data separately to Site. If more fields above are needed, use separate sheet or form.*

FIELD DATA

SAMPLE DATE (MM DD YY)	pH (std)	CONDUCTANCE (umhos/cm @ 25°C)	TEMP. (°C)	TURBIDITY (ntu)	DO (mg/L-ppm)	eH/ORP (mV)	Other: Units

Final Field Readings are required *(i.e. record field measurements, final stabilized readings, passive sample readings before sampling for all field parameters required by State/Permit/Site)*

FIELD COMMENTS

Sample Appearance: Odor: None Color: N-a Other:

Weather Conditions (required daily, or as conditions change): Direction/Speed: Outlook: Precipitation: Y or N

Specific Comments (including purge/well volume calculations if required):

I certify that sampling procedures were in accordance with applicable EPA, State, and WM protocols (if more than one sampler, all should sign):

WELL DATA

Well Elevation (at TOC): 943.72 (ft msl)
Depth to Water (DTW) (from TOC): 4.10 (ft)
Groundwater Elevation (site datum, from TOC): 939.62 (ft msl)
Total Well Depth (from TOC): [ ] (ft)
Stick Up (from ground elevation): [ ] (ft)
Casing ID: [ ] (in)
Casing Material: [ ]

Note: Total Well Depth, Stick Up, Casing Id, etc. are optional and can be from historical data, unless required by Site/Permit. Well Elevation, DTW, and Groundwater Elevation must be current.

STABILIZATION DATA (Optional)

Sample Time (2400 Hr Clock)	Purge Rate (LPM)	pH (std)	Conductance (SC/EC) (µmhos/cm @ 25 °C)	Temp (°C)	Turbidity (ntu)	D.O (mg/L - ppm)	eH/ORP (mV)	DTW (ft)
1115	0.2 1st	7.46 1st	3.66 1st	8.0		10.0		
1120	2nd	7.46 2nd	4.07 2nd	7.9		0.6		
1125	3rd	7.46 3rd	4.06 3rd	7.9		9.0		
1130	4th	7.45 4th	4.05 4th	8.0	1.0	9.0	-152	
Suggested range for 3 cons. readings or state Permit/State requirements:		+/- 0.2	+/- 3%	-	-	+/- 10%	+/- 25 mV	Stabilize

Stabilization Data Fields are Optional *(i.e. complete stabilization readings for parameters required by WM, Site, or State). These fields can be used where four (4) field measurements are required by State/Permit/Site. If a Data Logger or other Electronic format is used, fill in final readings below and submit electronic data separately to Site. If more fields above are needed, use separate sheet or form.*

FIELD DATA

SAMPLE DATE (MM DD YY)	pH (std)	CONDUCTANCE (umhos/cm @ 25°C)	TEMP. (°C)	TURBIDITY (ntu)	DO (mg/L-ppm)	eH/ORP (mV)	Other: / Units

Final Field Readings are required *(i.e. record field measurements, final stabilized readings, passive sample readings before sampling for all field parameters required by State/Permit/Site)*

FIELD COMMENTS

Sample Appearance: [ ] Odor: None Color: None Other: [ ]

Weather Conditions (required daily, or as conditions change): [ ] Direction/Speed: [ ] Outlook: [ ] Precipitation: Y or N

Specific Comments (including purge/well volume calculations if required): [ ]

I certify that sampling procedures were in accordance with applicable EPA, State, and WM protocols (if more than one sampler, all should sign):

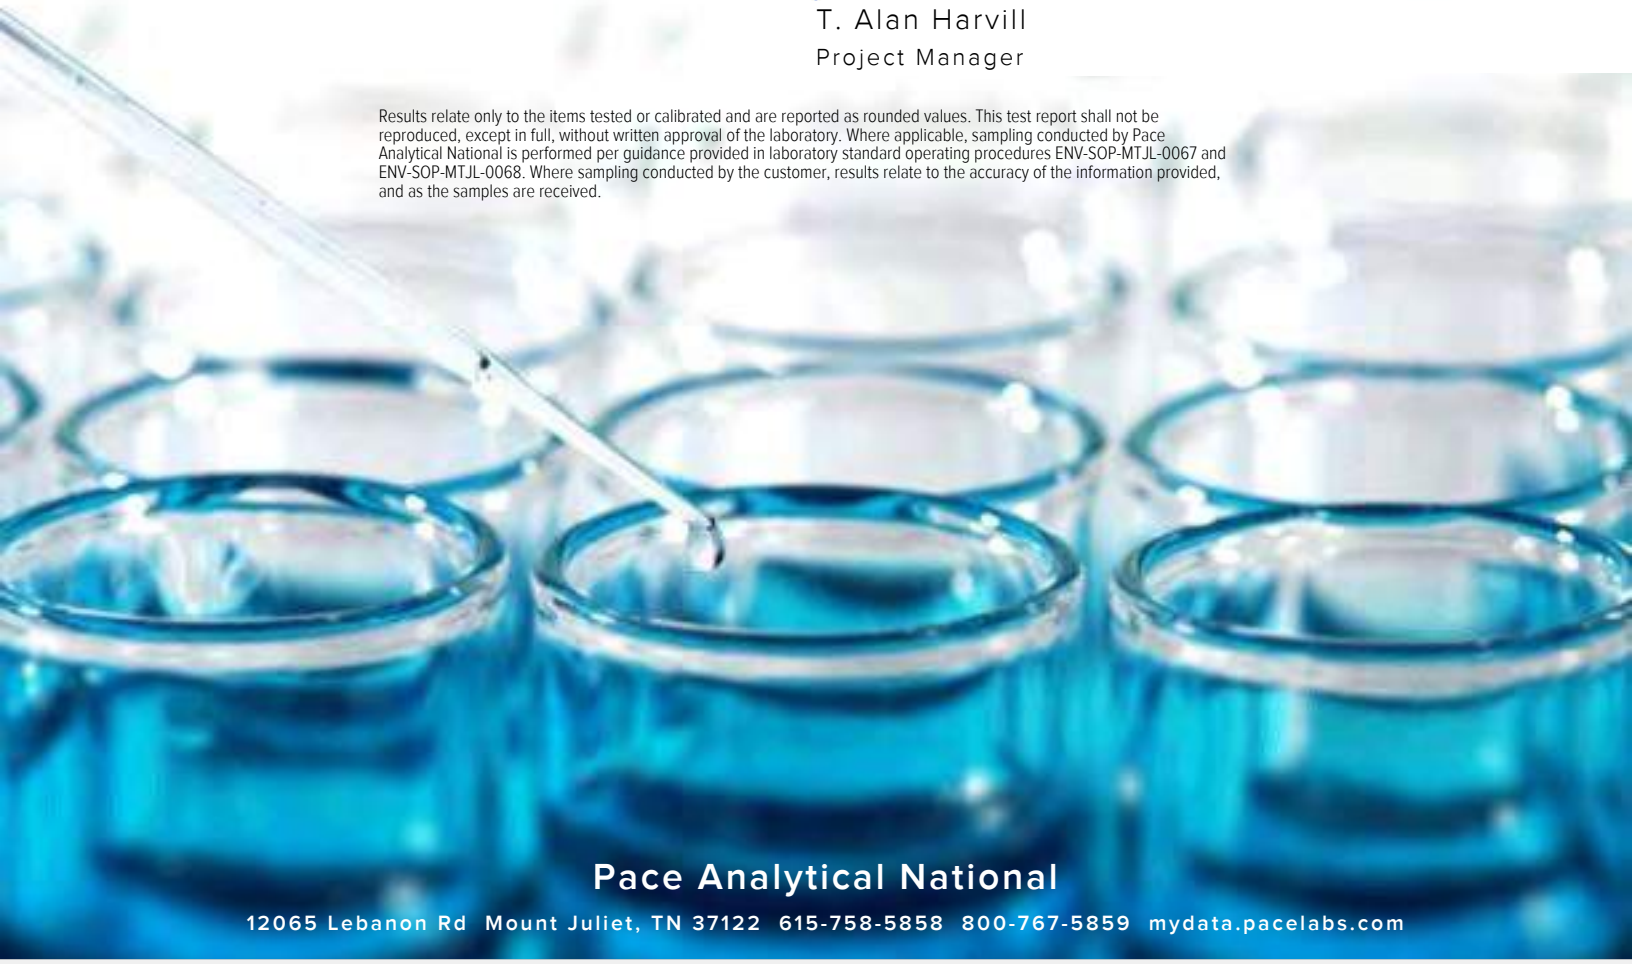
ANALYTICAL REPORT

May 13, 2025



Elk River Landfill

Sample Delivery Group:	L1857297
Samples Received:	05/09/2025
Project Number:	500
Description:	Elk River- Monthly Leachate
Site:	MN02
Report To:	Jim Eidem 4300 MarketPoint Drive Suite 200 Minneapolis, MN 55435

Entire Report Reviewed By:

T. Alan Harvill
Project Manager

Results relate only to the items tested or calibrated and are reported as rounded values. This test report shall not be reproduced, except in full, without written approval of the laboratory. Where applicable, sampling conducted by Pace Analytical National is performed per guidance provided in laboratory standard operating procedures ENV-SOP-MTJL-0067 and ENV-SOP-MTJL-0068. Where sampling conducted by the customer, results relate to the accuracy of the information provided, and as the samples are received.

Pace Analytical National
12065 Lebanon Rd Mount Juliet, TN 37122 615-758-5858 800-767-5859 mydata.pacelabs.com

SAMPLE SUMMARY

SP-01_Leachate L1857297-01

Collected by: Kenneth Smith
Collected date/time: 05/08/25 09:50
Received date/time: 05/09/25 08:45

Method	Batch	Dilution	Preparation date/time	Analysis date/time	Analyst	Location
Gravimetric Analysis by Method 2540 D-2011	WG2512963	1	05/12/25 11:43	05/12/25 18:24	AMG	Mt. Juliet, TN
Wet Chemistry by Method 410.4	WG2513499	5	05/13/25 08:07	05/13/25 14:08	DAM	Mt. Juliet, TN
Wet Chemistry by Method 4500H+ B-2011	WG2512219	1	05/10/25 22:30	05/10/25 22:30	KRB	Mt. Juliet, TN

Unless qualified or notated within the narrative below, all sample aliquots were received at the correct temperature, in the proper containers, with the appropriate preservatives, and within method specified holding times. Where applicable, all MDL (LOD) and RDL (LOQ) values reported for environmental samples have been corrected for the dilution factor used in the analysis. All Method and Batch Quality Control are within established criteria except where addressed in this case narrative, a non-conformance form or properly qualified within the sample results. By my digital signature below, I affirm to the best of my knowledge, all problems/anomalies observed by the laboratory as having the potential to affect the quality of the data have been identified by the laboratory, and no information or data have been knowingly withheld that would affect the quality of the data.

T. Alan Harvill
Project Manager

Project Comments

The requested project specific reporting limits may be less than laboratory standard quantitation limits (PQL) but will be greater than or equal to the laboratory method detection limits (MDL). It is noted that results reported below lab standard quantitation limits (PQLs) may result in false positive/false negative values that may require additional laboratory quality assurance review, if requested. Routine laboratory procedures do not initiate a data review process for detections below the laboratory's PQL unless requested by the client.

Sample Delivery Group (SDG) Narrative

The laboratory analysis was performed from an unpreserved, insufficiently or inadequately preserved sample.

Batch	Method	Lab Sample ID
WG2513499	410.4	L1857297-01

The following samples were prepared and/or analyzed past recommended holding time. Concentrations should be considered minimum values.

Batch	Method	Lab Sample ID
WG2512219	4500H+ B-2011	L1857297-01

Gravimetric Analysis by Method 2540 D-2011

GLOSSARY OF TERMS

Guide to Reading and Understanding Your Laboratory Report

The information below is designed to better explain the various terms used in your report of analytical results from the Laboratory. This is not intended as a comprehensive explanation, and if you have additional questions please contact your project representative.

Results Disclaimer - Information that may be provided by the customer, and contained within this report, include Permit Limits, Project Name, Sample ID, Sample Matrix, Sample Preservation, Field Blanks, Field Spikes, Field Duplicates, On-Site Data, Sampling Collection Dates/Times, and Sampling Location. Results relate to the accuracy of this information provided, and as the samples are received.

Abbreviations and Definitions

MDL	Method Detection Limit.
ND	Not detected at the Reporting Limit (or MDL where applicable).
RDL	Reported Detection Limit.
Rec.	Recovery.
RPD	Relative Percent Difference.
SDG	Sample Delivery Group.
Analyte	The name of the particular compound or analysis performed. Some Analyses and Methods will have multiple analytes reported.
Dilution	If the sample matrix contains an interfering material, the sample preparation volume or weight values differ from the standard, or if concentrations of analytes in the sample are higher than the highest limit of concentration that the laboratory can accurately report, the sample may be diluted for analysis. If a value different than 1 is used in this field, the result reported has already been corrected for this factor.
Limits	These are the target % recovery ranges or % difference value that the laboratory has historically determined as normal for the method and analyte being reported. Successful QC Sample analysis will target all analytes recovered or duplicated within these ranges.
Original Sample	The non-spiked sample in the prep batch used to determine the Relative Percent Difference (RPD) from a quality control sample. The Original Sample may not be included within the reported SDG.
Qualifier	This column provides a letter and/or number designation that corresponds to additional information concerning the result reported. If a Qualifier is present, a definition per Qualifier is provided within the Glossary and Definitions page and potentially a discussion of possible implications of the Qualifier in the Case Narrative if applicable.
Result	The actual analytical final result (corrected for any sample specific characteristics) reported for your sample. If there was no measurable result returned for a specific analyte, the result in this column may state “ND” (Not Detected) or “BDL” (Below Detectable Levels). The information in the results column should always be accompanied by either an MDL (Method Detection Limit) or RDL (Reporting Detection Limit) that defines the lowest value that the laboratory could detect or report for this analyte.
Uncertainty (Radiochemistry)	Confidence level of 2 sigma.
Case Narrative (Cn)	A brief discussion about the included sample results, including a discussion of any non-conformances to protocol observed either at sample receipt by the laboratory from the field or during the analytical process. If present, there will be a section in the Case Narrative to discuss the meaning of any data qualifiers used in the report.
Quality Control Summary (Qc)	This section of the report includes the results of the laboratory quality control analyses required by procedure or analytical methods to assist in evaluating the validity of the results reported for your samples. These analyses are not being performed on your samples typically, but on laboratory generated material.
Sample Chain of Custody (Sc)	This is the document created in the field when your samples were initially collected. This is used to verify the time and date of collection, the person collecting the samples, and the analyses that the laboratory is requested to perform. This chain of custody also documents all persons (excluding commercial shippers) that have had control or possession of the samples from the time of collection until delivery to the laboratory for analysis.
Sample Results (Sr)	This section of your report will provide the results of all testing performed on your samples. These results are provided by sample ID and are separated by the analyses performed on each sample. The header line of each analysis section for each sample will provide the name and method number for the analysis reported.
Sample Summary (Ss)	This section of the Analytical Report defines the specific analyses performed for each sample ID, including the dates and times of preparation and/or analysis.

Qualifier	Description
P1	RPD value not applicable for sample concentrations less than 5 times the reporting limit.
T8	Sample(s) received past/too close to holding time expiration.

1.0 Introduction

This Work Plan describes the planned 2014 groundwater monitoring network augmentation at the Elk River Landfill (ERL; Figure 1). The network augmentation will include installing two monitoring wells on ERL property at locations downgradient of existing monitoring wells.

The planned scope of work is based on the results of ERL's ongoing hydrogeologic investigation of Rice Lake/Tibbits Brook (RL/TB), routine groundwater monitoring results, and discussions/correspondence with the Minnesota Pollution Control Agency (MPCA), Sherburne County, and the City of Elk River.

The following sections of this Work Plan provide a summary of pertinent background information, a description of the approach used to site the planned wells and to determine well screen intervals, a description of the drilling and well installation methods, and the project schedule.

2.0 Background

A summary of pertinent groundwater investigations and routine groundwater monitoring results that were used to scope the monitoring network augmentation work is provided below.

2.1 Previous RL/TB Investigations

Previous groundwater investigations have included advancing direct-push soil borings in RL/TB and the installation of monitoring wells between the ERL and RL/TB. The locations of RL/TB soil borings and current monitoring wells are shown on Figure 2.

In 2004/2005, twelve soil borings and four piezometers were installed in RL/TB (Geomatrix, 2005). The results of these investigations confirmed the following:

- RL/TB is largely covered by floating bog vegetation and is over 30 feet deep in some locations.
- The geologic units beneath RL/TB include lake bottom muck, which is underlain by poorly graded sand (up to 14 feet thick), till (ranging from 4 to 15 feet thick), and the lower outwash (which is monitored by ERL monitoring wells)
- The till beneath RL/TB is softer/less dense and exhibits a more uniform thickness than the hard, over consolidated till that is present at the site. Based on these characteristics, the till beneath RL/TB is interpreted to be an ablation (melt-out) till (which is consistent with the Minnesota Geological Survey's interpretation that RL/TB is an ice-block lake; MGS, 2013).
- The hydraulic head in the lower outwash varied from approximately 8 to 11 feet above the RL/TB ground surface. The hydraulic head measurements equate to an approximate upward vertical gradient or 0.45 between the lower outwash and RL/TB.
- The horizontal hydraulic gradient between the three RL/TB piezometers installed in lower outwash had an easterly component (which contrasted with the westerly gradient consistently measured at the site).
- No volatile organic compounds (VOCs) were detected in groundwater samples collected from PZ3 and PZ6 in 2004. PZ3 and PZ6 were completed at the top of lower outwash unit.

After the 2005 investigation, relatively warm winter seasons prevented further drilling in RL/TB so the groundwater investigation focus shifted to the area between the ERL and RL/TB. In 2006/2007,

monitoring wells P320C, P320C2, and P320L (320 well nest) were installed for the purpose of monitoring vertical gradients and profiling groundwater quality in the lower outwash downgradient of the unlined (Pre-Subtitle D) portion of the landfill. Results from the 320 well nest included:

- Average vertical hydraulic gradients in the lower outwash based on 16 hydraulic head measurement events conducted between 2006 and 2013 (Barr, 2014) are provided in Table 1 and are summarized below:
    - Average vertical hydraulic gradients are upward between the top and middle portions and the top and bottom portions of the lower outwash (as measured by well pairs P320C/P320C2 and P320C/P320L, respectively).
    - Upward gradients were measured between the top and middle portions of the lower outwash during two-thirds of the monitoring events and between the top and bottom portions of the lower outwash during half of the monitoring events. Upward gradients were measured between the middle and bottom portions of the lower outwash during a quarter of the monitoring events.
- VOCs were detected in groundwater at the base of the lower outwash in monitoring well P320L. No VOCs were detected in groundwater at the top of the lower outwash in P320C.

Based on the water quality monitoring results at the 320 well nest, the ERL installed six additional L-series wells to monitor groundwater quality at the base of the lower outwash unit. The installation of the L-series wells provided substantial geologic and water quality data west of the landfill. Cross sections showing the lateral extent and thickness of the lower outwash along the west side of the ERL and beneath the RL/TB are included in Appendix A. Water quality monitoring results are discussed in the following section.

2.2 Routine Groundwater Monitoring Results

Routine groundwater monitoring has been performed in accordance with solid waste permit SW-74 and the permits and agreements with Sherburne County and the City of Elk River since the mid-1980s. Monitoring results are reported in triannual monitoring reports and are evaluated in annual water quality monitoring reports. The details of the current groundwater monitoring program are provided in the Sampling and Analysis Plan (SAP; Barr, 2011).

Below are summaries of 2012 and 2013 HRL exceedences from selected locations downgradient of the ERL.

- **320 Well Nest (including P-29C):** No VOCs were detected above the HRL in the 320 well nest area except for one vinyl chloride detection in the spring 2012 groundwater sample from P320L. No VOCs were detected in groundwater from P320C. Total VOC concentrations in P29C and P320L have decreased from past results (see Appendix F in Barr, 2013).
- **P-321L and P-323L:** Vinyl chloride was detected above the HRL in groundwater at P-321L in 2012 and 2013 and in groundwater at P-323L in 2013.
- **P-304C area:** Vinyl chloride was detected above the HRL in groundwater at P313C and P314C during the three 2012 routine monitoring events and in only one groundwater sample collected from P314C during 2013. Total VOC concentrations in P313C and P314C have demonstrated stabile to decreasing trends over recent years (see Appendix F in Barr, 2013).
- **P-301L, P-322/P324L:** No VOCs have been detected above HRLs in groundwater at P-301L, P-322L, or P-324L. These well delineate the northern and southern extent of groundwater impacts west of the ERL.

3.0 Technical Approach

The planned monitoring wells will be used to define the extent of VOC-impacted groundwater and provide sentinel groundwater monitoring data west of the ERL. The technical approaches for well location and screen placement selection are discussed below.

3.1 Well Locations

The planned well locations are shown on Figure 2. Monitoring wells P-325L and P-326L are located downgradient of monitoring wells P-321L, P-323L, and P-314C (i.e., where VOCs have recently been detected above HRLs).

- Monitoring well P325L will provide groundwater monitoring data west of P-321L and the P-17C area. This location was selected based on the westerly groundwater flow directions inferred from hydraulic head data from the ERL monitoring well network (Barr, 2013).
- Monitoring well P326L will provide groundwater monitoring data southwest of P-321L/P-323L and west of P-313C/P314C. This location was selected based on the southwesterly groundwater flow direction inferred from hydraulic head data from the L-series monitoring wells which are completed at the base of the lower outwash (Appendix B).

The new monitoring wells will provide sentinel groundwater monitoring data that will be used to define the extent of VOC-impacted groundwater downgradient of the ERL.

3.2 Well Screen Placement

The thickness of the lower outwash and the elevation of the underlying bedrock are not fully known at the proposed well locations. The elevation of the top of bedrock (or the top of till directly overlying bedrock) at the L-series well east of the RL/TB ranges from approximately 840 to 860 feet MSL (which equates to 80 to 100 feet below the surface of RL/TB). Due to the uncertainty of the thickness of the lower outwash unit at the proposed well locations, specific well screen intervals will be determined in the field during drilling. However, the following general rationale for well screen interval selection will be employed:

- If the lower outwash is 30 or less feet thick, the bottom of the monitoring well screen will be placed at the base of the lower outwash. The well screen will be no longer than 15 feet. This scenario will result in a monitoring well that is screened in the stratigraphic interval

monitored by wells P-321L and P-323L (and similar to P313C and P314C) where vinyl chloride has been detected above the HRL.

- If the lower outwash is greater than 30 feet thick, well screens may be adjusted and set to the approximate center elevation of the L series wells (P-321L and P-323L). Nested monitoring wells may also be considered but it is noted that achieving a proper well seal given the high hydraulic head differential expected is critical. Nested wells further reduce the likelihood that a proper well seal can be achieved; so nested wells will only be considered if deemed crucial. If nested wells are installed, the lower monitoring well may be set at the base of the lower outwash and the upper nested well will be screened at the elevation of the L-series well located to the east (i.e., the upper well at P-325L will be screened at an elevation consistent with P321L and the upper well P-326L will be screened at an elevation consistent with P323L).

It is important to note that the well screen placement strategy outlined above will insure monitoring in the same screen interval of known groundwater detections at wells P321L, P323L, and P314C. If no significant discharge is occurring to RL/TB then this interval should be ideal for detection monitoring. If discharge is occurring to RL/TB then no detections or very low levels may be evident. In either case this work will result in important information concerning nature and extent VOC-impacted groundwater as well as informing potential corrective actions.

4.0 Methods

The monitoring wells will be constructed in accordance with State of Minnesota Well code by a licensed well contractor. The wells will likely be constructed using rotasonic drilling or equivalent driven casing methods. Geologic samples will be collected and logged by Barr staff. One of the key advantages of driven casing techniques is the improved odds of maintaining a well seal through the relatively thin ablation till that is present beneath RL/TB.

4.1 Well Construction, Development, and Surveying

The boreholes for monitoring wells P325L and P326L will likely be constructed using double-cased well installation methods. At each location, 6-inch inner diameter, permanent steel casing will be set into the till above the lower outwash and grouted in-place. After the grout sets, the borehole will be advanced through the permanent casing to total depth and the monitoring wells will be constructed with 2-inch diameter stainless steel well screens and low carbon steel risers. If feasible, filter pack sand will be placed from the bottom of the borehole to two feet above the top of the well screen and the remainder of the borehole annulus will be sealed with neat cement grout. Based upon previous experience with well construction in RL/TB, strong upward gradients are expected as well as heaving sands. These conditions challenge well construction and especially seal placement. If the upward gradient/flowing conditions prevent the placement of filter pack sand, a natural sand pack (i.e., lower outwash) will be used and the remainder of the borehole annulus will be sealed with neat cement grout. Each monitoring well will be water tight and completed above grade with a lockable well cover.

The wells will be developed after construction to remove fines from the screened interval and to ensure a good hydraulic connection between the screen and the surrounding geologic media.

A licensed land surveyor will survey the horizontal location, ground surface elevation, and top of casing elevation.

4.2 Background Monitoring

The monitoring wells will be sampled for background parameters in accordance with the Sampling and Analysis Plan (SAP; Barr, 2011) during the 2014 routine monitoring events. Background monitoring data will be submitted in quarterly monitoring reports and summarized in the 2014 Annual Water Quality Report. The ERL will provide a recommendation regarding the inclusion of

P325L and P326L in the groundwater monitoring network in the 2014 Annual Water Quality Monitoring Report.

5.0 Schedule

The monitoring well installation work is planned for as soon as ice road conditions allow safe access (anticipated to be February 2014) and is anticipated to take approximately 4 weeks.

Please note, the RL/TB is covered by floating bog vegetation and winter ice conditions have been variable in the past due to apparent water upwelling. The implementation of this work plan is contingent on the driller's verification that conditions are sufficient to safely support the drill rig, ancillary equipment, and the crew. If unforeseen circumstances that could jeopardize the safety of the crew arise, work will be stopped.

Executive Summary

On behalf of Elk River Landfill, Inc., Barr Engineering Co. has prepared this Corrective Action Evaluation Report to evaluate options for addressing groundwater quality downgradient of the unlined (Pre-Subtitle D) portion of the Elk River Landfill (ERL or Site). The evaluation has been prepared in accordance with Minnesota Pollution Control Agency's (MPCA) process for implementing corrective actions at solid waste facilities. The report appendices include supporting documentation and preliminary estimates of natural attenuation rates and feasibility-study level cost estimates for alternatives comparison purposes.

ERL has developed an extensive groundwater monitoring network that is based on numerous hydrogeologic investigations and groundwater quality monitoring activities that have taken place over the last 40+ years. These investigations have included the installation/placement of approximately 277 monitoring wells and borings at and around the Site (Appendix B, B-5; Barr, 2018 and 2015a). ERL placed final cover over the unlined portion of the landfill and installed an active gas extraction system in the early to mid-1990s as part of groundwater corrective actions that stemmed from the detection of a leachate (slug) release from the Pre-Subtitle D portion of the landfill. Since then, groundwater investigations have included the evaluation of hydrogeologic conditions and water quality in the areas north, south, and west of the landfill to better understand the fate and transport of organics in groundwater. ERL incorporated low level reporting methods for vinyl chloride in 2015 and for other organics in 2017. Results attained from the low level reporting methods led to ERL completing a remedial investigation in 2018 that largely defined the extent and concentration of vinyl chloride in groundwater at, and downgradient of, the Site (Barr, 2018). Vinyl chloride has been detected in groundwater samples at concentrations above Minnesota Department of Health (MDH) groundwater criteria known as Health Risk Limits (HRLs) in wells located approximately 1,100 feet from the unlined portion of the landfill and sporadically at lesser concentrations in samples collected from a distal monitoring well located approximately 4,600 feet from the unlined portion of the landfill. Based on groundwater monitoring data and delineation results, the estimated mass of vinyl chloride in the groundwater downgradient of ERL is approximately 1 pound (lb) and the estimated vinyl chloride flux from the landfill at present is 0.07 lbs/year (Appendix C).

This report builds on prior alternatives and natural attenuation screening reports (Barr, 2019 and 2020b, respectively) and evaluates the feasibility, costs, risks / benefits of the following corrective action alternatives designed to address vinyl chloride in groundwater at and downgradient of the ERL:

- Alternative #1, Monitored Natural Attenuation (MNA) and Residential Water Supply Replacement
- Alternative #2, Groundwater Extraction and Treatment with Focused MNA and Residential Water Supply Replacement
- Alternative #3, Pre-Subtitle D Landfill Excavation and Placement on Liner
- Alternative #4, Groundwater Extraction (on and off-site) and Treatment

Each of the alternatives described below is considered protective of human health and the environment and are judged potentially capable of meeting applicable groundwater criteria[1].

Alternative #1 – Monitored Natural Attenuation and Residential Water Supply Replacement

This alternative includes the development of a monitored natural attenuation (MNA) program to evaluate and document the natural attenuation of organics. Additional monitoring wells would be established on privately-owned land (contingent on access) to provide further definition of organics and data necessary to better understand attenuation processes, rates and organics migration over time. The MNA approach has on-site and off-site components based on the refined natural attenuation analysis appended to this report. This alternative also includes replacing the lower outwash water supply wells that are located downgradient or near sidegradient of the projected migration pathway of organics with deeper wells screened in the Mt. Simon aquifer to eliminate the risk of exposure to downgradient residents. Alternatives to well replacement are also discussed should residents prefer a different option. The estimated total cost (capital plus 30 year operation and maintenance, Net Present Value [NPV]) for this alternative ranges from $590,000 to $1,300,000.

Alternative #2 – Groundwater Extraction and Treatment with Focused MNA and Residential Water Supply Replacement

This alternative includes the construction and operation of a groundwater extraction system along the west side of the landfill, treating and discharging the extracted groundwater at the Site, development of a focused MNA program, and replacing residential water supply wells. Under this alternative, extracted groundwater would be treated for organics and re-infiltrated at the Site. Groundwater extraction systems present unique challenges to the attainment of groundwater criteria, result in the withdrawal of significant volumes of groundwater to remove little mass, and require the long-term management of extracted groundwater. The MNA component would focus on documenting the efficacy of MNA in areas along the west side of the landfill where applicable. Residential water supply replacement would be consistent with Alternative #1. The estimated total cost (NPV) for this alternative ranges from $3,400,000 to $7,000,000.

Alternative #3 – Pre-Subtitle D Landfill Excavation/Placement on Liner

This alternative evaluated at the request of MPCA and includes excavation of the unlined pre-Subtitle D landfill and placement on new liner at ERL. This alternative would include the excavation of approximately 4.9 million cubic yards (MCY) of in-place waste, including volumes in overlying lined phases and adjoining lined cells, and approximately 1 MCY of excavated (non-waste) fill as needed. This alternative would require an expansion of the ERL to accommodate the

[1] MPCA requested the alternatives consider meeting Intervention Limits (ILs) at the ERL groundwater compliance boundary. The application of ILs are unique to the solid waste program in Minnesota and are intended to trigger assessment monitoring and/or corrective actions. ERL has moved to corrective action, therefore, ILs are not applicable. The subject release is from the Pre-Subtitle D portion of the landfill which, in accordance with Minnesota Rule 7035.2815 Subpart 4 (H)(2), may necessitate the establishment of appropriate groundwater criteria.

excavated Pre-Subtitle D waste. Identification and feasibility planning for significant construction, geotechnical, interim leachate management, oxygen intrusion, odor/landfill gas management, unknown/restricted waste management, and other issues related to implementing this alternative is beyond the scope of this document. Operation of a groundwater extraction/treatment system and replacement of residential water supply wells would be required to mitigate risk to downgradient residents and control releases to the groundwater system as a result of waste excavation activities. The preliminary estimated total cost for this alternative is based on an estimated feasibility-study level cost estimate from a similar project at a non-operating facility in the Twin Cities area and ranges from $63,000,000 to $140,000,000.

Alternative #4 – Groundwater Extraction (on and off-site) and Treatment

This alternative was evaluated at the request of MPCA and includes constructing and operating a groundwater extraction system along the west side of the landfill and a second groundwater extraction system on private property (contingent upon access), near the downgradient end of the vinyl chloride plume. The combined flow from both systems would be treated and discharged at ERL. This alternative would require the installation and ongoing operation and maintenance of a groundwater extraction system on privately-owned land west of ERL. Challenges to this alternative include the lack of ownership of the property where the off-site system would be implemented and the long distance that groundwater forcemain piping would need to be installed for extracted groundwater conveyance. The preliminary estimated total cost for this alternative ranges from $6,400,000 to $14,000,000.

The corrective action alternatives were evaluated against seven criteria that are based on Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) guidance (USEPA, 1988). Consistent with the National Oil and Hazardous Substances Pollution Contingency Plan (NCP), the selected alternative must meet two threshold criteria and achieve the best balance of trade-offs with respect to the balancing criteria (long-term effectiveness and permanence; reduction of toxicity, mobility, or volume through treatment; short-term effectiveness; implementability; and cost) in a cost-effective manner. The NCP says, "a remedy shall be cost-effective if its costs are proportional to its overall effectiveness."

Alternative #1, MNA and Residential Water Supply Replacement achieves the threshold criteria and is the most cost-effective alternative that achieves the best balance of the evaluation criteria, assuming further evaluation demonstrates MNA is occurring sufficiently and applicable alternative groundwater requirements are met. Based on the refined preliminary analysis presented here, MNA is anticipated to sufficiently reduce the toxicity, mobility, and volume of vinyl chloride via natural processes and protectiveness to human health would be addressed with water supply well replacements. Alternative #1 would be equally protective in the short-term and long-term, reasonably implementable, and is the lowest cost alternative evaluated in this report. Alternative #1 is consistent with the MPCA Closed Landfill Program strategy for understanding if there is risk to human health and addressing it using a risk based approaches (MPCA, 2020).

Alternative #2, Groundwater Extraction and Treatment with Focused MNA and Residential Water Supply Replacement is equally protective to downgradient residents as Alternative #1 but is not a cost-effective

alternative due to the operation of the groundwater extraction and treatment system. Alternative #2 provides a means to make progress towards achieve groundwater criteria at the compliance boundary (above and beyond natural processes) by intercepting the migration of groundwater with vinyl chloride along the west side of the landfill, however, preliminary estimates suggest that, on an annual basis, an extraction system would remove approximately 0.2 pounds (lbs) of vinyl chloride from approximately 21,000,000 gallons of extracted groundwater on an annual basis. This alternative could be considered in the future if MNA is not demonstrated to be protective.

Alternative #3, Pre-Subtitle D Landfill Excavation/Placement on Liner best addresses long-term effectiveness and permanence but is not cost effective. This alternative is not feasible because lined waste is present in cells adjacent to and overlying the Pre-Subtitle D area and capacity does not exist to accommodate the excavated waste. The alternative is not judged to be effective in the short-term due to the long lead time required to plan and implement it and because excavation of the unlined waste will require removing the landfill cap, resulting increased contaminant flux to the groundwater system. Incomplete waste removal and/or residual impacts below the closed Pre-Subtitle D area would require long-term operation of a groundwater treatment system and residential water supply well replacements would be needed to protect the downgradient residents to the same extent in Alternatives #1 and #2.

Alternative #4, Groundwater Extraction (on and off-site) and Treatment is equally protective of downgradient residents as Alternatives #1 and #2 but offers less certainty than residential water supply well replacement. Implementation of this alternative is considered difficult given the need to negotiate access to construct, operate, and maintain a groundwater extraction system on privately-owned land. This alternative will also entail extracting groundwater with low vinyl chloride concentrations (e.g., at or below the reporting limit), pumping the groundwater to ERL for treatment, and discharging at the Site. The estimated range of combined flows from the two extraction systems would also be challenging to discharge at the Site. Preliminary estimates suggest that, on an annual basis, the removal of approximately 0.21 lbs of vinyl chloride from approximately 42,000,000 gallons of extracted groundwater (assuming a rate of 80 gallons per minute [gpm]).

Upon receiving concurrence with MPCA on Alternative #1, a work plan including implementation steps and schedule will be submitted under separate cover to MPCA for review and approval. Implementation would prioritize the installation of replacement water supply wells and the installation of additional MNA monitoring network points downgradient of the ERL.

1.0 Introduction

On behalf of Elk River Landfill, Inc., Barr Engineering Co. has prepared this Corrective Action Evaluation Report to evaluate options for addressing groundwater quality downgradient of the unlined (Pre-Subtitle D) portion of the Elk River Landfill (ERL or Site; Figure 1). The content of this report is based on Minnesota Solid Waste Rules; a corrective action alternatives screening report (Barr, 2019); an informational report assessing groundwater natural attenuation conditions at the Site (Barr, 2020b); feedback from MPCA, Sherburne County, and City of Elk River staff; Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) guidance (USEPA, 1988) and MPCA Closed Landfill Program's strategy for understanding and addressing groundwater impacts (MPCA, 2020). The following sections summarize background information, describe the contemplated corrective action technologies and approaches, and evaluate corrective action alternatives to address groundwater quality at and downgradient of the ERL. The report appendices include supporting documentation and preliminary estimates of natural attenuation rates (based on comments received on prior submittals) and feasibility-study level cost estimates for alternatives comparison purposes.

2.0 Background

2.1 Facility Description

ERL is authorized for operation as a solid waste disposal facility by the MPCA under Solid Waste Permit SW-74 and licenses and permits from Sherburne County and the City of Elk River. The ERL was initially permitted for waste disposal in 1972. A portion of the landfill, including landfill cells 1 through 5, 7, 9, and the northern portion of cell 6 (6N) was constructed prior to the effective date of Resource Conservation and Recovery Act (RCRA) Subtitle D regulations. Landfill cells 1 through 5, 7, and 9 are unlined and capped (closed) with final cover (or covered with lined construction and demolition debris disposal cells DC-1 through DC-3). Cell 6N was constructed with a Pre-Subtitle D liner consisting of 80-millimeter-thick, high-density polyethylene and a leachate collection system. The other landfill cells, including construction and demolition debris disposal cells DC-4A and DC-5A, were constructed with composite liners and leachate collection systems. The leachate collected from the lined cells is disposed off-site at a publicly owned treatment facility. Figure 2 shows the Site layout and groundwater monitoring locations. MPCA Permit SW-74 provides additional details on the ERL's construction and operating history.

2.2 Site Hydrogeology

The geology at the ERL includes 100 to 200 feet of glacial deposits overlying Paleozoic bedrock. The predominant glacial deposits include two outwash units, referred to as the upper and lower outwash that are separated by sandy-silt textured till deposited from ice advances from the northeast (predominantly Cromwell and older Pre-Wisconsinan tills) (Barr, 2015a). The till is inferred to be discontinuous or leaky in the Pre-Subtitle D area based on downward migration of organics and the presence of organics in the lower outwash downgradient of the landfill (Barr, 2015b). The lower outwash, which is present from approximately 60 to 100+ feet below ground surface (bgs) west of the landfill, is laterally continuous beneath the ERL and Rice Lake/Tibbits Brook (RL/TB) (Barr, 2018) and is the focus of contemplated corrective actions based on the presence of organics in groundwater. Along the west side of the landfill, the lower outwash grades from fine/medium sand at the top of the unit to coarse sand with discontinuous gravel lenses near the base of the unit. The coarsest intervals of lower outwash have been observed near the base of the unit at wells P-325L and P-326L in RL/TB and at well P334L. The lower outwash is confined along the west side of the landfill by till of the Late-Wisconsinan, Cromwell Formation (Barr, 2015a).

The lower outwash extends to the west across the investigation area at/around elevation 860 feet MSL. The thickness of the lower outwash varies from approximately 60 feet thick west of the Pre-Subtitle D portion of the landfill to approximately 25± feet west and southwest of the landfill (Barr, 2018). Recent investigations have shown the lower outwash is continuous beneath and beyond RL/TB with the exception of one boring location south of well P-333L (Barr, 2018). RL/TB, the large wetland complex located west of the landfill, is with covered with floating bog vegetation with the exception of small areas of open water. The floating bog makes for difficult/unsafe access, especially to equipment traffic. The RL/TB is underlain with loose organic silt/clay (i.e., lake sediments). Water and mucky lake sediment depths near 30 feet have been encountered during past drilling operations in RL/TB.

The groundwater flow direction in the lower outwash unit is to the west beneath the Pre-Subtitle D portion of the Site and west-southwest beneath RL/TB (Figure 3). The groundwater velocity at the lower outwash unit (where organics mass transport is predominantly occurring west of ERL) is estimated to be between 60 and 112 feet/year, based on aquifer parameter estimates (Barr, 2020b) and the observed extent of organics downgradient of the landfill. Groundwater velocity may be higher in portions of the lower outwash unit due to heterogeneity, particularly beneath RL/TB.

The Eau Claire Formation, a regional confining unit, is the uppermost continuous bedrock unit at the Site. The Eau Claire Formation forms a local bedrock high in the southwestern portion of the Site and, in places, is capped by clayey, Pre-Wisconsinan till and/or a thin mantle of fine sandstone/siltstone from the basal Wonewoc Formation (Barr, 2015a). The Mt. Simon Sandstone is the uppermost bedrock aquifer in the area and is underlain by crystalline Pre-Cambrian bedrock. Prior groundwater investigation has shown the Mt. Simon does not contain modern (i.e., tritiated) water (Geomatrix, 1998), indicating that it does not receive recharge at or near the Site.

2.3 Groundwater Quality

ERL is committed to preventing exposure to organic compounds from the landfill in nearby water supply wells. ERL has developed an extensive groundwater monitoring network that is based on numerous hydrogeologic investigations that have been conducted over the past 20+ years (Barr, 2015a, 2018). The 2019 groundwater monitoring network included 39 monitoring wells and 11 piezometers (Figure 2). Additional monitoring network information is provided in the 2019 Annual Water Quality Monitoring Report (Barr, 2020a).

Routine monitoring includes sampling and analysis of organic and inorganic compounds including metals and general chemistry parameters. ERL began low level reporting for vinyl chloride in 2015 and for nine other organic compounds (including trichloroethylene [TCE]) in 2017.

A summary of the 2018 through 2020 (April) data is included in Appendix A and vinyl chloride concentration trend plots are included in Appendix B. No organics have been detected above their respective HRL in wells located off of ERL Property[2]. On ERL property, no organics have been detected above their respective HRL in wells located at or beyond the groundwater compliance boundary except for vinyl chloride and TCE. Vinyl chloride was detected above the HRL (0.2 µg/L) in twelve monitoring wells (and above the Intervention Limit [IL] of 0.050 µg/L in five additional monitoring wells). TCE was detected above the HRL (0.4 µg/L) in one monitoring well (P-323L) (and above the IL in two other monitoring wells). The highest vinyl chloride concentration detected in groundwater in 2019 was at non-compliance well P-308L (1.9 µg/L) located approximately 20 feet from the western edge of the fill. The highest detected TCE concentration in 2019 was at well P-323L (1.3 µg/L). Vinyl chloride concentrations are typically not detected in leachate samples, although reporting limits usually elevated due to sample matrix effects.

[2] Vinyl chloride was detected in one sample collected from investigation borings B330 and B331 in 2016 (Barr, 2018). These data are considered in the vinyl chloride delineation included in this report.

Other confirmed organics detections in groundwater at concentrations below HRLs (if established) in monitoring wells located at or beyond the compliance boundary included cis-1,2-dichloroethylene (cDCE), 1,1-dichloroethane, 1,2-dichloroethane, chloroethane, dichlorodifluoromethane (Freon-12), dichlorofluoromethane (Freon-21), ethyl ether, and tetrahydrofuran (Appendix A). Of these, only 1,2-dichloroethane was detected above the IL (and was in the presence of vinyl chloride). Organic compounds (other than vinyl chloride) in groundwater at distal wells P-334L and P-694477 include 1,1-dichloroethane (unconfirmed), dichlorodifluoromethane, dichlorofluoromethane, and ethyl ether. The 2019 groundwater quality data are described in more detail in the 2019 Annual Water Quality Monitoring Report (Barr, 2020a).

Vinyl chloride and TCE are the constituents of concern (COCs) and the drivers for consideration of corrective actions at the Site.

2.4 Vinyl Chloride Extent and Mass in Groundwater

Recent groundwater investigations have focused on defining the extent of COCs in the groundwater at and downgradient of the ERL (Barr, 2016 and 2018). Because TCE was detected above the HRL in only one well (P-323L), the following discussion focuses on vinyl chloride.

The estimated width of the vinyl chloride plume above the HRL on the west side of the landfill (i.e., roughly transverse to the groundwater flow direction) is approximately 1,500 feet and is defined by wells P-301L and P-324L, respectively (Figure 4). Farther west, the plume is defined to the south by wells P-322L, P-324L, and P-335L. The southern edge of the vinyl chloride plume is located near monitoring well P-694477 based on the initial detection of vinyl chloride slightly above the IL (0.05 µg/L) but below the HRL in September and December 2019. The northern extent of vinyl chloride has been defined approximately by past sampling of well P-327L (non-detect). The maximum extent of vinyl chloride at concentrations at or above the IL shown on Figure 4 is based on an evaluation of lower outwash groundwater contours from 2014 through 2019.

The western extent of vinyl chloride is depicted on Figure 4 and is estimated to be near well P-334L based on detections at or slightly above the IL (but below the HRL). Vinyl chloride was not detected in April 2020 sample from well P-334L (Appendix A). This western (leading) edge of vinyl chloride is approximately 3,500 feet from the nearest downgradient residential well located farther west/southwest (Figure 5). Based on the estimated of groundwater flow rate (112 feet per year), the travel time from well P-334L to the nearest residential well is estimated to be between 25 to 35 years based on advective transport using recent monitoring results; however, uncertainties regarding outwash heterogeneities make it difficult to develop a prediction with a high degree of certainty.

Vinyl chloride can be produced as a daughter product via reductive dechlorination from cDCE. Since the 1990s, the reductive dechlorination pathway of chlorinated compounds has been well studied. The sequential dechlorination pathway (stepwise removal of a chlorine atom and replacement with hydrogen atom), that includes cDCE and vinyl chloride, is commonly from more highly chlorinated compounds tetrachloroethylene (PCE) and TCE:

PCE → TCE → cDCE → VC → Ethene

Because vinyl chloride is a daughter product of cDCE dechlorination, the extent of vinyl chloride in groundwater is directly related to where cDCE degrades to vinyl chloride along the flowpath. For example, 1 µg/L of cDCE degrades to an equivalent micromolar mass of vinyl chloride with a concentration 0.6 µg/L (lower concentration because molecular weight of vinyl chloride is lower than cDCE); therefore, the low concentrations of cDCE that are observed in groundwater can degrade to vinyl chloride concentrations well above the reporting limit (0.05 µg/L). This process masks the overall magnitude of vinyl chloride degradation along the flowpath and gives the false appearance of more tempered vinyl chloride degradation because the cDCE plume overlaps the vinyl chloride plume.

As shown on Figure 4, cDCE is present in groundwater at wells P-325L and P-326L and not present in groundwater at P-334L. The limited extent of cDCE, coupled with decreasing vinyl chloride concentrations with distance, provides evidence that degradation is occurring and that the extent of vinyl chloride may be extended downgradient due to sequential dechlorination reactions and not from limited degradation of vinyl chloride. TCE in groundwater at wells located along the compliance boundary and upgradient of P-325L and P-326L and not in downgradient wells also supports evidence of degradation and may further add to the downgradient extent of cDCE and vinyl chloride.

Routine monitoring and prior groundwater investigation that included vertical water quality profiling showed that the vertical extent of vinyl chloride is limited to the lower outwash (Barr, 2020a and 2018; Figures 6, 7, and 8). Vinyl chloride is present in groundwater in the lower outwash downgradient of the Site and not detected in groundwater samples from in the upper outwash or the Mt. Simon sandstone (beneath the Eau Claire Formation). West of the landfill, near vertical aquifer profile borings B-330 and B-331, vinyl chloride was detected in the lower outwash and not detected in the outwash deposits that were encountered above (i.e., shallower than) or below (i.e., deeper than) the lower outwash or in the underlying Eau Claire Formation (uppermost bedrock) (Figure 8; Barr, 2018).

Based on groundwater monitoring data and estimated flow rates, the total mass of vinyl chloride present in the lower outwash unit west of the landfill is calculated to be approximately 1 lb. The estimated current mass flux of vinyl chloride from ERL through the cross sectional plane represented in Figure 8 is 0.07 lbs/year, which is approximately 42% lower that the estimates vinyl chloride mass flux from April 2010 (Appendix C). These low total mass and mass flux estimates reflect the relatively low vinyl chloride concentrations in groundwater downgradient of ERL. The vinyl chloride mass estimates/calculation details are included in Appendix C.

2.5 Area Water Supply

The ERL and surrounding area are not serviced by public utilities (i.e., no City water or sewer). Water at the ERL office is provided by a 360-foot well (unique ID #420558) referred to as the ERL Shop Well (Barr, 2020a). Downgradient of the Site, with the exception of the Ridges of Rice Lake Development community supply well (unique well ID #626766) and the water supply well at 22447 Tipton Street (unique ID #813437), residences have individual domestic water supply wells that are known or assumed to be

completed in the lower outwash unit. The Ridges of Rice Lake well is completed in an outwash near the base of buried bedrock valley between 294 and 325 feet bgs (approximate elevations 699-668 feet relative to mean sea level [MSL]) and the 22447 Tipton Street well is completed in the Mt. Simon Aquifer between depths of 254 and 300 (elevations 732 and 686 feet MSL). The nearby residential wells are routinely monitored per ERL permits and licenses and no organics have been detected in the existing residential wells. Appendix D includes a summary of the water supply wells located west of the Site and past residential water well monitoring data.

The ERL routinely samples 11 nearby water supply wells, including nine domestic wells, one community water supply well (Ridges of Rice Lake development), and the ERL Shop well per Permit SW-74. Nine additional residential wells have been sampled as part of recent hydrogeologic investigations (Barr, 2018). The locations of the monitored residential wells are shown on Figure 5.

2.6 Prior Corrective Actions

In response to increased concentrations of organics in groundwater, ERL completed a Corrective Action Investigation (Camp, Dresser, & McKee, 1994) and a series of groundwater investigations to investigate the organics source and extent (Geomatrix, 1998, 1999, and 2000). A spike in organics loading to groundwater at the top of the lower outwash unit was demonstrated near the southwest corner of the Pre-subtitle D portion of the landfill in 1991. Total organics concentrations at monitoring well P-17C increased from less than 1 to more than 24 milligrams per liter (mg/L) between 1992 and 1994, subsequently concentrations rapidly decreased to less than 1 mg/L by 1997 (Barr, 2015a). In this same timeframe, other wells located southeast of P-17C (i.e., beneath the future landfill footprint), such as P-43B, also had relatively high concentrations of organics in groundwater (Appendix B, Chart and Figure B-5) (e.g., vinyl chloride at 12 µg/L; Camp, Dresser, & McKee, 1994; Barr, 2015b). A

These organic detections and trends prompted the enactment of facility improvements designed to mitigate organics in groundwater and consisted of final cover installation and active gas extraction. ERL placed final cover over much of the unlined portion of the landfill, starting with cell 2 (which is adjacent to well P17C); by 1997 over cells 1, 3, 4, 5, and 7 were also covered. The active landfill gas extraction system was installed and became operational in March 1996 and was augmented in 1997 and 2001 specifically to address organics in groundwater at the landfill. Vinyl chloride concentrations in landfill gas samples collected from 2008 to 2010 ranged from 220 to 670 part per billion by volume which equates to approximately 30 to 90 lbs of vinyl chloride removal annually via landfill gas extraction applying the average LFG extraction volume between 2015 and 2019.

Groundwater investigations and isotopic sample analysis concluded that the organics spike in the P-17C Area was the result of leachate from the Pre-subtitle D portion of the landfill (Geomatrix, 1998). Due to the elevated reporting limits and sample matrix interference issues, the concentrations of chlorinated ethylene compounds (such as vinyl chloride and trichloroethylene) were largely reported as non-detect in leachate samples and from well P-17C. Despite the elevated reporting limits, based on total organics concentrations of up to 24 mg/L, it is reasonable to assume that the chlorinated ethylene inputs to groundwater from the unlined portion of the landfill were higher at that time. As discussed in this report,

vinyl chloride and TCE are the only organics detected in groundwater above their respective HRLs at ERL, concentrations of both these parameters have been low (i.e., non-detect to approximately 2 micrograms per liter [µg/L]) or decreasing since the implementation of prior corrective actions, and the extent of TCE is limited compared to vinyl chloride. In response to the slug of leachate affected groundwater observed at P-17C, an oxygen diffusive system was installed in the P-17C area to deliver oxygen to groundwater at the top of the lower outwash to spur the rapid degradation of the targeted compounds (e.g., methyl ethyl ketone, acetone, etc.) via a cometabolic degradation. The system was operated from 2003 to 2008 and, during monitoring data collected demonstrated that the operation of the system increased dissolved oxygen and decreased organics concentrations in groundwater in the P-17C area. System operation was discontinued to allow groundwater to return to reducing conditions and the target compound concentrations remained low.

2.7 Conceptual Release Model

The evidence points to both leachate and landfill gas from the pre subtitle D fill area as the source area for organic impacts to groundwater at the ERL (Barr, 2015a; Geomatrix, 1998). The pre subtitle D unlined area consists of 28.1 acres and approximately 5 million cubic yards of waste that was placed from 1972 to approximately 1990. Waste Management acquired the site in late 1995 after unlined filling had ceased. Evidence for the release of leachate to groundwater is described in the above Section 2.6. Gas migration is also attributed to be a source of impacts to groundwater (Barr, 2015; Geomatrix, 1998; Camp, Dresser & McKee, 1994) based on the fact that vinyl chloride is a relatively more common constituent of landfill gas than leachate. Since Minnesota Rules require the separation between waste and groundwater of at least 5 feet and sand exists under the liner, a potential unsaturated conduit exists between the composite liner system and groundwater. These conditions may trap landfill gas that potentially migrates from the Pre-subtitle D area allowing it to partition into groundwater.

Releases of leachate and landfill gas from the unlined waste have resulted in organics concentrations beneath, upgradient, and south of the Pre-Subtitle D area at ERL (Barr, 2015a and 2015b). A leachate (slug) release was well documented in the P-17C Area and was characterized by high concentrations of non-chlorinated organics that masked the concentrations of chlorinated organics. Elevated chlorinated organics concentrations were quantified southeast of P-17C Area prior to the construction of landfill cells 13 and 14 at monitoring well P-43B (e.g., vinyl chloride concentrations of 12 µg/L in 1996; See Appendix B, Figure B-5 for historical trend charts for wells P-17C, P-43B, P-304C, P-313C, and P-326L) (Camp, Dresser & McKee, 1994; Barr, 2015b). These chlorinated (and other) organics have migrated west (downgradient) with groundwater and have decreased in concentrations due to natural attenuation processes; however, the attenuation processes have not occurred at a rate sufficient to meet applicable regulatory criteria in areas along the compliance boundary.

Past corrective actions including final cover placement and the installation of an active gas extraction system appear to have significantly reduced the magnitude of the release from the Pre-Subtitle D, and the high concentrations at documented at P-17C and P-43B in the early to mid-1990s are no longer present in groundwater along the western side of the landfill (Barr, 2020a). Currently, organic concentration trends along the west side of the landfill include predominantly decreasing trends south of the P-17C Area and a

mix of stable, increasing, and decreasing trends to the north. Concentrations of chlorinated ethenes along the centerline of the plume evidence attenuation by reductive dechlorination with distance from the Pre-Subtitle D area (Appendix B). The current vinyl chloride concentration trends and related projections may underestimate the degree and rate of attenuation with distance (or time) due to the reductive dechlorination reactions that transform parent compounds TCE and, more prominently, cDCE to vinyl chloride.

Water quality data from 2019 and early 2020 indicate the fringe of the vinyl chloride plume is present near monitoring wells P-334L and P-694477. The first time detections of vinyl chloride in samples from these wells in 2019, coupled with some non-detect results, suggest more data is needed to determine whether the vinyl chloride plume is migrating or stable. Based on Site history the leading edge of the plume is anticipated to result from higher vinyl chloride concentration flux from the 1990s (or prior) and current vinyl chloride flux appear to be substantially lower, likely as a result of past groundwater corrective actions (i.e., final cover and active gas extraction). Based on the estimated vinyl chloride mass flux, the plume is anticipated to be stable or shrink in the future as a result of natural attenuation processes; however, additional wells and data collect are needed to substantiate this model and document the mass/concentration decreases.

3.0 Corrective Action Objectives

This section presents groundwater corrective action objectives for ERL.

3.1 Corrective Action Goals

The primary and near-term goal for implementing corrective action at the ERL is to protect human health by preventing exposure to of organic compounds in water supply wells[3]. Recent residential water supply well monitoring data indicate that this goal is being achieved under current/natural conditions; however, ERL is committed to proactively protect residential water wells by taking appropriate actions to improve future protectiveness.

The secondary, longer-term corrective action goal is to increase the certainty of protectiveness to nearby water supply wells by meeting appropriate groundwater criteria. ERL is addressing impacts related to the closed, Pre-Subtitle D portion of the landfill, so the establishment of alternative limits under Minnesota Rule 7035.2815, Subpart (H)(2) may be appropriate (see Section 5.1).

It should be noted, that achieving corrective action objective #1 satisfies a risk-based remedial approach and additional effort beyond verifying that corrective action objective #1 is achieved and risk to human health is mitigated is unwarranted from a technical standpoint.

3.2 Constituents of Concern

As described in Section 2.4 of this report, vinyl chloride and TCE are the COCs at the Site.

3.3 Potential Exposure Pathways and Receptors

The potential exposure pathway for COCs in groundwater at ERL is ingestion by a water well user. Municipal water is not available near ERL so nearby residents use groundwater as their water supply. Based on a search of the Minnesota Well Index, approximately 23 residential water supply wells are located within 8,500 feet of the ERL in the southwest/west direction. With a few exceptions, these wells are known or assumed to be completed in unconsolidated outwash that correlates to the lower outwash unit at the Site (Figure 5; Appendix D).

ERL has routinely collected and analyzed water samples from the residential water supply wells nearest to the landfill (Appendix D). Water samples from an extended residential well network were collected and analyzed between 2015 and 2017 as part of past groundwater investigations (Barr, 2018). Organics attributed to the landfill have not been detected in samples from water supply wells near the ERL with one

[3] This corrective action objective includes the COCs and other organic compounds in groundwater attributable to the ERL.

exception that was addressed by ERL in 2014[4]. ERL has also developed a monitoring well network to provide early warning detection upgradient of nearby water well users.

Groundwater discharge to RL/TB is possible given the upward hydraulic gradients between the lower outwash and the surface water elevation. However, organics concentrations are generally below surface-water criteria established by the MPCA (see Permit SW-74) and, based on the lateral extent of vinyl chloride and the vertical extent of vinyl chloride (Barr, 2018), groundwater discharge to RL/TB from the lower outwash does not appear to be significant.

[4] ERL arranged for the installation of a point-of-entry water treatment system at a Tipton Street residence in late 2014 as a result of a confirmed organic compound detection (at a concentration below the HRL) and arranged for the installation of a deeper replacement water supply well in 2015.

4.0 Corrective Action Technologies

The following sections describe corrective action technologies identified as potentially viable in the Groundwater Corrective Actions Alternatives Screening Report (CAAR; Barr, 2019):

1) Alternate Residential Water Supply
2) Monitored Natural Attenuation
3) Groundwater Extraction and Treatment
4) In-Situ Groundwater Treatment

At the request of MPCA, evaluation of the excavation and relining of Pre-Subtitle D portion of the landfill and off-site groundwater extraction are also included in this report. No additional action and air sparging technologies were previously screened out in the CAAR (Barr, 2019) and are not considered in this evaluation. Specific correction action alternatives for the ERL are described in Section 5 of this report.

4.1 Alternate Residential Water Supply

Eliminating the groundwater pathway between the landfill and residential water supply wells will eliminate the risk of vinyl chloride (and other organics) exposure to residents (i.e., groundwater users) and will achieve the primary and near-term goal of protecting human health by preventing the migration of organic compounds to water supply wells.

Alternative water supply options include the installation of point-of-entry treatment (POET) systems that treat groundwater at individual residences upstream of use or replacing existing individual water supply wells completed in the lower outwash and located downgradient of the plume with individual water supply wells screened in deeper geologic units. POET systems are commonly deployed in private residences and the treatment media / technology is selected based on specific treatment needs. POETs require ongoing maintenance for effective long-term treatment and the installation/maintenance requires work inside individual residences. The installation of replacement water supply wells for use at residences downgradient of the existing organics detections is an option given that organics are limited to the lower outwash and the Mt. Simon is accessible. The use of deeper wells is preferred by ERL (compared to POETs) provided water quality standards are met in the deeper units.

The installation of deeper replacement wells (or POETs) require owner permission to access, install, connect, and test the installations. ERL has a successful track record for open communication and developing mutually acceptable access agreements with individuals (without complaint to State, County, or City).

4.2 Monitored Natural Attenuation

Natural attenuation includes destructive processes (biodegradation and abiotic degradation) and nondestructive processes (e.g., dispersion, diffusion, and sorption) that affect the fate and transport of organic compounds in groundwater systems (USEPA, 1998). The application of a monitored natural

attenuation (MNA) remedy to address organics in groundwater, in whole or as part of a combined remedy, is common at groundwater sites in Minnesota and throughout the United States.

The Groundwater Natural Attenuation Report (Barr, 2020b) provided an updated screening evaluation of geochemical conditions in the lower outwash at the ERL to inform the potential application of natural attenuation as a corrective action strategy and an evaluation of geochemical conditions, terminal electron acceptors, distance-concentration plots, and estimates of degradation rates downgradient of the landfill. These evaluations showed that conditions in the P-17C area provide evidence that reductive dechlorination of chlorinated compounds is occurring. Farther downgradient (near and beyond the ERL property boundary) prevailing geochemical conditions are iron-reducing (which is suitable for the natural attenuation of vinyl chloride through other destructive and nondestructive processes).

Recent data have shown sporadic detections of low concentrations of vinyl chloride at monitoring wells P-334L and P-694477. Vinyl chloride concentrations in µg/L at well P-334L between the 2019 and 2020 spring sampling events have been 0.050 h, <0.050, 0.050, 0.10, and <0.050. Over this same period, vinyl chloride concentrations (in µg/L) at well P-694477 have been <0.050, <0.050, 0.10, 0.075, and <0.23. These data demonstrate that both wells are located near the fringe of the vinyl chloride plume. Further monitoring and new MNA monitoring locations upgradient and downgradient of P-334L would provide insight on vinyl chloride plume stability and attenuation rates downgradient of the landfill.

In effort to provide additional context and address feedback from the MPCA and others, additional/refined evaluation of vinyl chloride natural attenuation is provided in Appendix C. The evaluation is based on existing data through 2019 and is based on the assumption that the plume is stable. Specifically, Appendix C presents:

- Refined velocities for groundwater flow and vinyl chloride migration.
- Vinyl chloride attenuation rates based on data from individual wells and the resulting estimated timeframes to achieve the ILs at those wells - well specific attenuation rates ranged from 0.081 (at P-326L) to 0.269 (at P-314C) and projected timeframes to achieve groundwater criteria ranged from approximately 4 years (at P-314C) to 28 years (at P-326L).
- Bulk vinyl chloride attenuation rates based on vinyl chloride data and total molar concentrations (which incorporate vinyl chloride parent products) - bulk vinyl chloride attenuation rates varied from 0.045 to 0.145/yr.
- Estimated vinyl chloride concentrations that are projected to attenuate between the compliance boundary and the nearest residential well downgradient of monitoring well P-334L - 7 µg/L (average) with a range of 1 to 90 µg/L.
- Estimated ranges of vinyl chloride concentrations that are projected to attenuate between monitoring well P-334L and the nearest downgradient residential well - 0.54 µg/L (average) with a range of 0.21 to 1.8 µg/L.

- Estimated distance vinyl chloride is projected to travel downgradient from the compliance boundary - 5,400 feet (average) with a range of 3,500 to 9,000 feet.
- Estimated vinyl chloride mass and mass flux downgradient of ERL – estimated vinyl chloride mass is approximately 1 lb and the estimated vinyl chloride mass flux is 0.07 lbs/yr.

The 2019 and April 2020 vinyl chloride concentrations in groundwater along the compliance boundary and at monitoring wells P-334L and P-694477 are less than the estimated range of concentrations expected to attenuate before reaching the nearest down gradient residential well, suggesting vinyl chloride at these wells will attenuate before reaching downgradient receptors. It should be noted, however, that peak vinyl chloride concentrations are projected to reach well P-334L between 2026 and 2034 due to the leachate slug that was released in the P-17C area in the early to mid-1990s.

Based on this refined analysis, natural attenuation in the lower outwash at and downgradient of the landfill appears to be sufficient to eliminate the risk to nearby residents and can achieve the primary and near-term goal of protecting human health by preventing the migration of vinyl chloride to water supply wells; however, the given the uncertainty of plume stability, the presence of other organics at P-334L and P694477 (prior to vinyl chloride), and the lack of additional monitoring wells downgradient of P-334L, ERL does not intend to propose MNA as a standalone remedy.

In regard to natural attenuation being capable of meeting the longer-term goal of increasing protectiveness to nearby water supply wells by meeting appropriate groundwater criteria, data are mixed. The three southernmost wells located along the compliance boundary within the organics plume (P-314C, P-313C, and P-323L) have shown decreasing vinyl chloride concentration trends since 2011 (Appendix B; Barr, 2020b) and the refined analysis indicates that criteria may be achieved in these wells within 11 years; however, the presence of parent compound cDCE at these wells (and TCE at P-323L) adds a degree of uncertainty to these projections. In areas in the northern portion of the delineated organics area, projections for natural attenuation to achieve groundwater criteria were not made due to mixed vinyl chloride concentration trends (including decreasing trends at wells P-320L/P320C2, stable/no-trends in the other wells located closest to the groundwater compliance boundary, and closer to the landfill at the top of the lower outwash increasing trend is present at wells P-301C and P-302C) (Appendix B).

4.3 Groundwater Extraction and Treatment

Groundwater extraction and treatment is a corrective approach that has been applied to intercept the migration of groundwater constituents and provide treatment with physical, chemical, or biological processes. Applications include the installation and operation of a groundwater extraction well(s) to remove impacted groundwater from the subsurface for discharge with or without treatment depending on a number of site-specific factors. The application details and ultimate effectiveness of a groundwater extraction approach is a function of site hydrogeologic conditions (e.g., unconfined vs. confined groundwater conditions, etc.), placement and construction of extraction wells relative to the source, operation of the system (e.g., steady pumping vs. pulsing), and the requirements for treating and discharging the extracted groundwater. Groundwater extraction physically removes groundwater around and upgradient of the extraction well(s) and lowers the hydraulic head/potentiometric surface in the

vicinity of pumping which in turn reduces the gradient and groundwater velocity and/or can result in localized flow stagnation on the downgradient side of the extraction system. The performance of a groundwater system is primarily a function of the hydrogeologic properties of the targeted and overlying/underlying geologic units, subsurface/geologic unit heterogeneities, and physical and chemical processes in the geologic unit and extraction wells (e.g., COC back diffusion from the aquifer matrix, well fouling, etc.). For these reasons, reliable estimates of achieving groundwater criteria are difficult (or not feasible) to make and are typically made either by reviewing multiple years of water chemistry monitoring data after groundwater extraction has been occurring or grossly with the assistance of a calibrated groundwater flow model and simplifying assumptions.

Although the concept of extracting groundwater to remove COCs is straightforward, groundwater extraction systems present unique challenges in the attainment of groundwater performance standards due to asymptotic COC response as a result of physical and chemical processes in the subsurface and result in a significant withdrawal of groundwater volume that may affect surrounding groundwater users or surface water habitats while producing a steady stream of effluent that requires management (typically under a discharge permit). Furthermore, the efficiency of COC removal on a mass per volume of water basis is often low and can decrease with continued pumping. At ERL, assuming a groundwater extraction system is implemented west of the Pre-Subtitle D area, it is estimated that the current annual flux of vinyl chloride (0.2 lbs) will be removed via treatment of 21,000,000 gallons (at an average withdrawal rate of 40 gpm) of groundwater in one year.

Given the hydrogeologic conditions and nature of the Pre-Subtitle D source, groundwater extraction is an option that could be employed to help achieve the secondary corrective action objective (meeting applicable groundwater criteria) by using a groundwater extraction well(s) located along the western edge of the landfill for the targeted removal of groundwater from the lower outwash unit. The lower outwash unit is confined unit which may be favorable for gradient control purposes but can present unique geochemical challenges. Existing wells P-308L (6-inch dia.), P-321L or P-324L (4-inch dia.) may be viable options. The preliminary estimated total pumping rate along the western side of the landfill ranges from 20 to 60 gallons per minute (gpm). Groundwater extraction in this range will require groundwater appropriations permitting with the Minnesota Department of Natural Resources (MDNR).

Options for managing the extracted groundwater include treatment via an on-site water treatment system with discharge to and infiltration system or into RL/TB. Both options require permitting, design, pilot testing, construction, start-up, and long-term system operation and maintenance. Discharge to a publicly owned treatment works (POTW) is not considered in this report due to the high disposal costs and concerns regarding long-term viability of discharge of impacted groundwater.

At MPCA's request, a corrective action alternative involving the construction of an off-site groundwater extraction is also evaluated in Section 5 of this report.

4.4 In-Situ Treatment

In-situ treatments involve the introduction of amendments that are intended to foster or enhance the attenuation, fixation, or destruction of COCs in the subsurface. In-situ treatment agents are applied to the

subsurface to contact/interact with COCs and have the benefit of not generating waste streams that require ongoing management.

The hydrogeologic conditions (heaving sands), vinyl chloride plume size and depth, and the size and nature of the source limits the practicality of in-situ treatment at ERL to targeted applications of injections via appropriately spaced permanent wells, injection via soil borings, or diffusive technologies. Implementation of in-situ remedies downgradient of the ERL (off-site) to address low COC concentrations is inefficient and presents several challenges including access to privately-owned land and safety concerns with working in RL/TB. For these reasons, in-situ treatment is not evaluated as a plume-wide treatment in this report; however, two in-situ treatment approaches, enhanced natural attenuation and permeable reactive barrier, could be considered in the future to help achieve the second corrective action objective in targeted areas under an Adaptive Site Management strategy. Overviews of conceptual approaches for each option are described below:

Enhanced natural attenuation can promote the increased biodegradation of vinyl chloride via the addition of electron donors, nutrients, and microbes to the aquifer. Vinyl chloride can attenuate under aerobic and anaerobic conditions and the rate and efficiency of the attenuation processes can be enhanced by carefully altering geochemical conditions in the aquifer through in-situ delivery of treatment agents or dissolved gases. General and proprietary treatment agents can be used to stimulate the microbial community in the aquifer and promote conditions to support aerobic or anaerobic biodegradation. These or other commonly available products may be used individually, or in combination, to enhance biodegradation rates at some sites provided field and aquifer conditions are suitable.

Permeable Reactive Barriers (PRBs) are installations of reactive materials that can attenuate dissolved phase contaminants in groundwater by sorption or transformation as they flow through the reactive zone under a natural or induced gradient. Various materials (e.g., zero-valent iron or carbon-based products) can be used. The effectiveness of the injection media in addressing vinyl chloride is highly dependent on direct contact, geochemical conditions, small scale hydraulic properties (e.g., hydraulic conductivities), and uniform placement of the media.

Permitting through the Minnesota Department of Health and U.S. Environmental Protection Agency may be required for the use of inject treatment agents.

4.5 Pre-Subtitle D Landfill Excavation and Placement on Liner

This technology is included in this report at the request of MPCA. The legacy waste in the unlined, Pre-Subtitle D closed portion of the landfill is the source of organics in leachate-impacted groundwater at the ERL. Waste removal from the unlined portion of the landfill and placement in a lined cell would eliminate the original source of organics in groundwater; however, the flux of remaining impacted groundwater, leaching from residual source material, back diffusion of organics sorbed onto geologic units, or leaching from unlined wastes that may not feasibly be excavated is expected to continue after excavation and relining is completed. The flux of impacted groundwater from the residual/remaining source materials would end significantly sooner if the area was excavated but would likely require groundwater corrective action downgradient of the landfill during and after implementation as leachate leakage rates to the

groundwater system would likely increase as a result of increased infiltration and disturbance of the unlined waste.

The ERL has approximately 4 million cubic yards (MCY) of remaining permitted airspace. The Pre-Subtitle D waste (approx. 4.9 MCY of waste) would be excavated to the extent feasible and would require transport to another lined cell for which there is not sufficient capacity. Safe excavation would require removal of significant volumes of wastes that are currently on lined areas to provide adequate factor of safety for slope stability. This approach would also require existing, overlying, or abutting lined cells (DC-1, DC-2, 6S, 10, and 11) to be partially excavated for access to the unlined legacy waste plus the excavation of an estimate 1 MCY of non-waste soils. Identification and planning for significant construction, geotechnical, interim leachate management, oxygen intrusion, odor/landfill gas management, unknown/restricted waste management, and other issues associated with implementation of this option is beyond the scope of this document.

5.0 Corrective Action Alternatives Evaluation

The following corrective action alternatives for organics in groundwater at and downgradient of the ERL are evaluated below:

- Alternative #1: Monitoring Natural Attenuation and Residential Water Supply Replacement
- Alternative #2: Groundwater Extraction and Treatment with Focused MNA and Residential Water Supply Replacement
- Alternative #3: Pre-subtitle D Landfill Excavation and Placement on Liner
- Alternative #4: Groundwater Extraction (on and off-site) and Treatment

Each corrective action alternative is evaluated individually against the corrective action objectives and additional criteria based on CERCLA guidance (USEPA, 1988) below and a summary is provided in Table 1.

5.1 Alternative #1: Monitored Natural Attenuation and Residential Water Supply Replacement

Alternative #1 would involve preventing exposure to downgradient residents by replacing residential water supply wells and the development of a groundwater monitoring network and program to evaluate and document the effects of natural attenuation. Under this alternative, ERL would replace lower outwash water supply wells that are located downgradient or near sidegradient of the projected migration pathway of organics with deeper wells completed in a hydraulically separated unit (assuming Mt. Simon aquifer for the purposes of this report). Subject to the owner's acceptance, at no cost to the resident, ERL would arrange for the permitting, drilling, installation, and well development. In addition, ERL would sample the well to evaluate groundwater quality. If the water is free of organics and analyte concentrations meet HRLs and USEPA Maximum Contaminant Levels, a new submersible pump would be installed and the well would be connected to the house and put into service. The former residential well would be sealed. The work would be conducted under an access agreement with the owner and performed by a licensed well contractor with knowledge of the area.

This alternative assumes that ten replacement wells will be installed. If a resident does not accept the well replacement offer, the installation POET system or, if feasible, installation and monitoring of a sentinel well on their property will be offered. If a resident insists on a "no action until organics detected approach," a response that includes follow-up actions (e.g., providing bottled drinking water, expedited verification resampling, communications, and an anticipated timeframe for establishing an alternate water supply) will be prepared and implemented.

The MNA component would include installing additional monitoring wells, determining the status of the organics plume (in terms of stability), estimating the organics mass reductions that are occurring as a result of natural attenuation processes, refining the estimates of point-specific and bulk attenuation rates (and related projections) with additional data, and documenting changes in organics concentrations

versus time at locations in the plume. A monitoring plan would be developed and monitoring wells would routinely be analyzed for MNA parameters.

MNA would have on-site and off-site components that build on the details described in Appendix C. The on-site component involves tracking vinyl chloride concentration trends and monitoring geochemical conditions for changes in wells near the compliance boundary. The off-site (distal) component includes the installation and monitoring of monitoring wells up and downgradient of well P-334L to allow better understanding of attenuation and plume stability over time, evaluation of geochemical conditions, and evaluating vinyl chloride and parent compound ratios and concentration trends versus time and distance.

Overall Protection of Human Health and the Environment

Alternative #1 provides the highest degree of protectiveness to the health of nearby residents (i.e., groundwater users) by replacing lower outwash supply wells with deeper water supply wells. Eliminating the groundwater pathway between the landfill and the water supply wells will eliminate the risk of exposure to vinyl chloride (and other organics). Based on prior vertical delineation efforts, completing wells in the Mt. Simon provides a high degree of confidence that the pathway will be incomplete. Using a licensed well contractor, requiring well construction materials and methods that comply with the State well code, sealing the former wells, and conducting periodic monitoring will also support the protectiveness of this alternative.

In regards to MNA, the refined analyses presented in this report adds to the weight of evidence that natural attenuation processes are occurring to a degree that supports further evaluation of this alternative to demonstrate its future protectiveness. Recent evaluations have utilized existing wells to update screening evaluations and generate the preliminary estimates of attenuation rates and vinyl chloride travel distances. Additional monitoring points along the plume centerline and additional data to better evaluate trends and parent compound concentrations will help to better evaluate, demonstrate, and document the effectiveness of natural attenuation downgradient of the landfill.

Meeting Applicable Requirements

The primary goal of the corrective action objectives evaluated in this report is to protect human health and the environment and the secondary goal is to meet applicable groundwater criteria to improve the protectiveness of the implemented corrective action. ERL will request the MPCA establish alternative limits for the Pre-Subtitle D portion of the landfill per Minnesota Rule 7035.2815 Subp. 4 (H)(2). The request will be submitted under separate cover and will provide the proposed approach and technical basis for development of the alternative limits. The envisioned approach includes completing the MNA evaluation and, if appropriate, applying technically sound natural attenuation rates to back calculate protective alternative limits to apply at the Site. This approach is consistent with MPCA Closed Landfill Program's consideration of risk to human health, evaluation of plume stability, and strategy to collect necessary data to if environmental response actions are needed to further reduce risk (MPCA, 2020).

Alternative #1 relies on the natural processes that affect water quality at and downgradient of ERL. Given the weight of evidence that natural attenuation processes are occurring, the projections in this report

suggest natural attenuation may be a feasible approach to develop and meet alternate limits that are established under Minnesota solid waste rules.

Reduction of Toxicity, Mobility, or Volume through Treatment

Alternative #1 relies on the natural processes that are occurring at and downgradient of the ERL for the reduction of toxicity, mobility, or volume of vinyl chloride. The reduction in toxicity of vinyl chloride occurs as a result of sequential dechlorination or via other destructive attenuation reactions (Barr, 2019) which, when completed, results in non-toxic daughter products. Other organics detected in groundwater downgradient of the landfill are below HRLs, indicating the concentrations are considered non-toxic. The mobility and volume of vinyl chloride and other organics would be the subject of the MNA evaluation effort; however, recent water quality data demonstrate that distal wells P-334L and P-694477 are located near the fringe of the vinyl chloride plume and increasing concentration trends are not confirmed[5]. Additional data would be required to further refine the calculation of the mobility and volume of vinyl chloride in groundwater downgradient of ERL.

Under this alternative, organics would remain in groundwater in the lower outwash until attenuating via destructive or non-destructive processes. The migration of these organics are not anticipated to pose a threat to human health or the environment.

Short-Term and Long-Term Effectiveness

Alternative #1 provides a high degree of both short-term and long-term effectiveness/permanence for protecting human health by eliminating the exposure pathway with water supply well replacements. The vinyl chloride and other organics in the lower outwash unit are anticipated to continue to decrease in concentration with distance from the landfill as a result of destructive and non-destructive natural attenuation processes. Preliminary projections suggest vinyl chloride may migrate through the lower outwash from 5,400 to 9,000 feet from the unlined portion of the landfill (Appendix C); however, risk to groundwater receptors will be mitigated with deeper replacement wells and routine monitoring. Replacement wells provide long-term protection and would be installed within 2 to 3 years, including access coordination and agreement finalization, which is considerably sooner than the estimated time of travel to the downgradient residences.

The long-term effectiveness may be bolstered with the establishment of institutional controls preventing the future installation of water supply wells in the lower outwash the area downgradient from the landfill; however, prior conversation with Minnesota Department of Health staff suggest conditions do not warrant a Special Well and Boring Construction Area (i.e., well advisory). Nevertheless, local communities may consider adopting ordinance restricting well installation for consumptive use.

[5] Preliminary projections suggest peak organics concentrations are anticipated to reach well P-334L between 2026 and 2034 due to higher organics inputs at the landfill in the early 1990s (Appendix C).

Implementability

Alternative #1 is considered highly implementable. The installation of deeper water supply wells is highly implementable from the construction and permitting standpoints. Domestic well construction is allowed in the Mt. Simon aquifer in Sherburne County and water quality is anticipated to be suitable for consumption without treatment provided concentrations of naturally occurring elements or compounds unrelated to the landfill are below drinking water criteria. ERL has a successful track record for open communication with area neighbors and developing mutually acceptable access agreements with individuals (without complaint to State, County, or City).

Scoping and implementing a natural attenuation evaluation is also considered highly implementable. MNA applications are widely accepted in Minnesota and throughout the United States and guidance from State, Federal, and non-governmental organizations is readily available. ERL has access to both internal and external technical expertise capable of developing an MNA evaluation and the MPCA has the expertise to review and comment on plans and evaluation results. The locations of new monitoring wells would require the development of an agreement(s) to access to private property for the installation and subsequent monitoring.

Cost

The primary Alternative #1 cost components include capital costs for replacement well/pump installation, connection, and sealing the existing well. There are no operation and maintenance costs associated with Alternative #1 because the residents will assume ownership of the new wells and pumps (which are low maintenance items). The primary MNA cost components include monitoring well installations and long-term monitoring and evaluation costs. The estimated total cost (30 Year, Net Present Value [NPV]) for Alternative 1 – MNA and Residential Water Supply Replacement ranges from $590,000 to $1,300,000 (Table 1). Cost estimate details are included as Appendix E.

5.2 Alternative #2: Groundwater Extraction and Treatment with Focused MNA and Residential Water Supply Replacement

Alternative #2 includes constructing and operating a groundwater extraction system along the west side of the landfill, in the northern portion of the vinyl chloride plume, and on-site water treatment and discharge, in addition to a focused MNA evaluation and replacement of residential water supply wells (as detailed in Alternative #1). Alternative #2 assumes that three extraction wells would be installed, equipped with submersible pumps, and connected to groundwater forcemains to transmit groundwater to an on-site system for organics treatment and discharge to an infiltration basin located on the east side of the landfill in the extraction system capture zone. For the purpose of this report, the groundwater treatment is assumed to include pre-filtration and air stripping/carbon fixation depending on discharge requirements. Seasonal discharge to RL/TB may be a viable alternative if groundwater extraction is focused between the compliance boundary and property boundary.

Based on the challenges presented by the hydrogeologic conditions, the depth of the organics plume, and the nature of the release from the closed Pre-Subtitle D area, the implementation of this alternative would utilize an observational approach to evaluate performance and Adaptive Site Management

principles that allow for adjustments over the Site's life cycle as new site information and technologies become available (ITRC, 2017). This flexible approach would allow for a more expedient start up to groundwater extraction compared to a 30%/60%/90% design progression and would allow flexibility for ERL to propose modifications to the corrective action approach, adjust the treatment technologies or discharge locations, or to incorporate an alternate corrective action approach as performance data is reviewed and new information or technologies become available. This type of flexible approach is inherent to managing large, ongoing remediation projects and is compatible with the existing reporting cycle.

The replacement of residential water supply wells (as described in Alternative #1) is critical to the protectiveness of this alternative, and would be the initial priority for implementation. The MNA component would be focused on the southern portion of the vinyl chloride plume where decreasing concentrations are present along the compliance boundary (Appendix B).

Overall Protection of Human Health and the Environment

Alternative #2 provides an equally high degree of protectiveness to the health of nearby residents (i.e., groundwater users) and confidence that the groundwater pathway from the landfill to residential wells will be incomplete due to the replacement of water supply wells. Discharge of treated water to RL/TB would potentially affect ground conditions/stability of the floating bog in the discharge area and exacerbate health and safety issues related to accessing the area for monitoring, maintenance, or other reasons (including trespassers).

Meeting Applicable Requirements

Alternative #2 would provide additional means to meet applicable groundwater criteria along the compliance boundary by intercepting and/or stagnating impacted groundwater migrating from the Pre-Subtitle D area. The extraction well(s) zone of influence would extend upgradient (beneath the Pre-Subtitle D portion of the landfill) and to the west to a lesser degree. Long-term operation of the extraction system will remove impacted groundwater and allow for fresh groundwater to in fill west of the extraction area. As previously discussed, the timeframe to meet applicable groundwater criteria is based on many factors and may take decades.

Reduction of Toxicity, Mobility, or Volume through Treatment

Alternative #2 will provide reduction of toxicity, mobility, or volume with a combination of engineered groundwater extraction/treatment system and natural attenuation processes. South and west of the extraction system, the toxicity, mobility, and volume of vinyl chloride would be reduced by either destructive or non-destructive natural attenuation processes that are occurring in the subsurface. The toxicity of the vinyl chloride (and other organics) in the extracted groundwater would be addressed by a phase change to vapor which would transfer the organics to the air at very low concentrations or by being bound to a carbon media which would be disposed of or thermally regenerated. The mobility of organics in groundwater upgradient of the extraction system would be reduced by intercepting the migration pathway between the unlined portion of the landfill and either the compliance boundary or property boundary. The operation of the groundwater extraction and treatment system would provide a minimal

reduction of the volume of vinyl chloride in the groundwater system. Preliminary annual estimates using existing data and applying an average pumping rate of 40 gpm, approximately 0.2 lbs of vinyl chloride would be treated from approximately 21,000,000 gallons of groundwater. For comparison purposes, the current active gas extraction system is estimated to remove approximately 60 lbs of vinyl chloride from the landfill annually.

Under Alternative #2, the organics in groundwater downgradient of the extraction system would remain in groundwater in the lower outwash until attenuating via destructive or non-destructive processes. The migration of these organics is not anticipated to pose a threat to human health or the environment.

Short-Term and Long-Term Effectiveness

Alternative #2 provides a high degree of short-term and long-term effectiveness/permanence for protecting human health due to the residential well replacements. Alternative #2 is expected to achieve applicable groundwater criteria in the southern portion of the vinyl chloride plume along the landfill via natural attenuation and in the northern portion of the vinyl chloride plume along the landfill via groundwater extraction. For the reasons explained in Section 4.3, providing a reliable timeframe for achieving groundwater criteria at wells along the northern portion of the landfill is not appropriate at this time. In general terms, the anticipated timeframe for achieving criteria may be decades and, should groundwater extraction be maintained as the long-term corrective action approach, it is anticipated to continue until either the source is depleted, another approach or technology is employed using Adaptive Site Management principles, or natural attenuation is demonstrated to be a protective corrective action approach.

Implementability

Alternative #2 is considered moderate to low in terms of implementability based on anticipated challenges regarding discharge of the extracted groundwater and permitting. Pumping along the west side of the landfill would extract groundwater with elevated concentrations of certain compounds that may require a waiver to discharge limits or a higher degree of treatment which would increase the treatment system costs and/or operation and maintenance needs. On-site discharge would also require the construction of an appropriately sized infiltration basin or other infrastructure (e.g., injection wells) to discharge the treated groundwater.

Pumping in RL/TB near the landfill could be conducted seasonally. Pumping would be achieved using the natural hydraulic heads in the lower outwash beneath RL/TB. The concentration of inorganic compounds would not be as high as those encountered closer to the landfill (at least at start-up) but would also likely require a wavier for discharge. Further, discharge of a constant flow of water in RL/TB may adversely affect ground/floating bog conditions in the discharge area and further complicate access.

An engineered onsite groundwater treatment system would require permitting, design, pilot testing, construction, start-up, and long-term system operation and maintenance. Prior to start-up of the groundwater extraction system, discharge to an infiltration basin would likely require National Pollutant Discharge Elimination System (NPDES) permitting with the MPCA. Direct discharge to RL/TB may require a

waiver for certain inorganic constituents, permitting with the MDNR and the U.S. Army Corps of Engineers (401 Certification and 404 Discharge of Fill to Wetlands).

Cost

The primary cost components of Alternative #2 (in addition to those detailed in Alternative #1) include capital costs for installing and connecting the groundwater extraction, conveyance, and treatment system infrastructure and piloting/start-up activities. Operation and maintenance costs include regular well and forcemain maintenance activities; long term monitoring costs; and components previously described in Alternative #2. The estimated total cost (30 Year, NPV) for Alternative #2 – Groundwater Extraction and Treatment with Focused MNA and Residential Water Supply Replacement ranges from $3,400,000 to $7,000,000 (Table 1). Cost estimate details are included as Appendix E.

5.3 Alternative #3: Pre-subtitle D Landfill Excavation and Placement on Liner

Alternative #3 is being evaluated at the request of the MPCA and includes excavation of the unlined pre-Subtitle D landfill and abutting waste followed by placement on new liner at ERL. This scenario would include the excavation of approximately 4.9 MCY of in-place waste and 1 MCY non-waste soils.

For protectiveness purposes, this alternative would also include the installation and operation of an on-site groundwater extraction/treatment system to manage the anticipated increased leachate flux rate to groundwater during the excavation project and the replacement of residential water supply wells to be protective to downgradient residents because excavating the Pre-Subtitle D portion of the landfill is not expected to improve downgradient water quality in the foreseeable future.

Overall Protection of Human Health and the Environment

Alternative #3 provides an equally high degree of protectiveness to the health of nearby residents (i.e., groundwater users) and confidence that the groundwater pathway from the landfill to residential wells will be incomplete due to the replacement of water supply wells. The excavation of the unlined Pre-Subtitle D portion of the landfill and placement on a lined landfill cell at ERL adds to the high degree of overall protection in the long-tern by eliminating the source of organics; however, the introduction and migration of organics in groundwater would likely be increased in the short-term due to removing the final cover and increased leakage during excavation. Longer-term sources to groundwater would include leaching from residual source materials, residual impacts beneath the landfill, and back diffusion from the organics that are sorbed to the aquifer matrix.

Meeting Applicable Requirements

Alternative #3 would provide additional means to meet applicable groundwater criteria along the compliance boundary by intercepting and/or stagnating impacted groundwater migrating from the excavated Pre-Subtitle D area via operation of the groundwater extraction/treatment. The groundwater extraction/treatment system operation would be similar to that in Alternative #2 but would likely not need to be operated as long and the mass of vinyl chloride removed would be anticipated to be higher.

Reduction of Toxicity, Mobility, or Volume through Treatment

Alternative #3 will not result in a reduction of toxicity because the waste not being treated. A temporary but sustained increase of organics mobility and volume in the groundwater system would be expected during and for some time after waste excavation activities were completed. In the long-term (likely decades), the mobility of organics from the source would be eliminated or greatly reduced by removal of unlined waste.

Under Alternative #3, the organics in groundwater downgradient of the extraction system would remain in groundwater in the lower outwash until attenuating via destructive or non-destructive processes. The migration of these organics is not anticipated to pose a threat to human health or the environment.

Short-Term and Long-Term Effectiveness

Alternative #3 provides a low degree of short-term effectiveness and a high degree of long-term effectiveness/permanence for protecting human health due to the residential well replacements. Alternative #3 is expected to result in moderate to low short-term effectiveness as a result of the long lead time it would take to plan and construct and high degree of long-term effectiveness/permanence due to unlined waste removal.

Implementability

The excavation of the Pre-Subtitle D portion of the landfill is presently infeasible given that space does not exist in the currently permitted landfill for the excavated waste. In addition, lined landfill cells are built over and adjacent to the unlined waste. Removal of material in the unlined landfill must either be limited to maintain the integrity of the adjacent lined portions or include the excavation of the neighboring lined waste for purposes of stability. If a portion of the unlined waste remains in place, it will remain as source material and long-term groundwater corrective actions may be required. Additional implementability challenges may include: odors and emissions during excavation, increased levels of dust and noise; prolonged exposure of waste to the environment which would lead to generation of additional leachate and landfill gas emissions; and disruption of neighboring lined landfill cells.

Cost

The unit rates used for the cost estimate are based on feasibility study costs for a similar project involving the excavation and relining of a different landfill in the Twin Cities area. It is noted that the excavation at ERL is considered more challenging due to overlying lined phases and adjoining lined waste areas. This cost may underestimate the actual cost, however, detailed cost estimated for this alternative is beyond the scope of this report.

Primary capital costs items include the constructing a new lined footprint to accept the Pre-Subtitle D waste and associated infrastructure to accept the unlined waste, construction costs to excavate and place the waste on liner, increased leachate management, etc. The estimated total cost (30 Year, NPV) for Alternative #4: Pre-subtitle D Landfill Excavation and Placement on Liner ranges from $64,000,000 to $140,000,000 (Table 1). Cost estimate details are included as Appendix E. However, again it is important to

note that the ERL does not have enough remaining capacity for MSW waste to accommodate waste from this exhumation.

5.4 Alternative #4: Groundwater Extraction (on and off-site) and Treatment

Alternative #4 is being evaluated at the request of the MPCA and includes constructing and operating an on-site groundwater extraction system, an off-site groundwater extraction system, and a water treatment discharge structure at ERL. This alternative assumes that, in addition to the system discussed in Alternative #2, two extraction wells are installed downgradient of well P-334L and utilized for groundwater extraction. These extraction wells would be equipped with submersible pumps and connected to a groundwater forcemain that conveys water back to the landfill for treatment and discharge at ERL. For the purpose of this report, it is estimated that a combined pumping rate of 80 gpm would be sufficient. Conveying groundwater to the ERL for discharge is considered more implementable than permitting, constructing, operating, and discharging from a groundwater treatment system on privately owned property.

Because the groundwater extraction system is operating downgradient of well P-334L and upgradient of residential wells, replacement residential water supply wells and documenting natural attenuation downgradient of well P-334L would not be included in this alternative. Groundwater extraction at the Site would be required to achieve applicable groundwater criteria.

Overall Protection of Human Health and the Environment

Alternative #4 provides a high to moderate degree of protectiveness to the health of nearby residents (i.e., groundwater users) with less certainty that the groundwater pathway from the landfill to residential wells will be incomplete as compared to Alternative #1.

Meeting Applicable Requirements

Alternative #4 will improve water quality at monitoring wells located along the compliance boundary by intercepting and/or stagnating leachate-impacted groundwater migrating from the northern portion of vinyl chloride plume along the west side of the ERL. The capture zone for the extraction wells will extend upgradient (beneath the Pre-Subtitle D portion of the landfill) and to the west to a lesser degree. Long-term operation of the extraction system will remove leachate-impacted groundwater and allow for fresh groundwater to in fill west of the groundwater extraction area. As previously discussed, the timeframe to meet applicable groundwater criteria is based on many factors and may take decades.

Reduction of Toxicity, Mobility, or Volume through Treatment

Alternative #4 will provide reduction of toxicity, mobility, or volume in addition to the natural processes already occurring. The mobility and volume/mass of organics in the groundwater system will be reduced by cutting off the pathway both downgradient of the landfill and between well P-334L and the residential wells. Toxicity of organic compounds is addressed through treatment. Preliminary estimates using existing data and applying an average annual pumping rate of 80 gpm, approximately 0.2 lbs of vinyl chloride from approximately 42,000,000 gallons of groundwater.

Alternative #4, is intended to remove the organics in groundwater downgradient of the landfill.

Short-Term and Long-Term Effectiveness

Alternative #4 will provide a moderate degree of short-term effectiveness and a high long-term effectiveness/permanence protecting human health. Alternative #4 has a moderate degree of short-term effectiveness because the implementation timeframe is anticipated to be longer than Alternative #1 due to the need to design and pilot test such a system, negotiate access agreements for installing and operating remedial system components and the time it will take to implement well and forcemain construction activities on privately-owned property. Alternative #4 is expected to achieve applicable groundwater criteria in the long-term.

Implementability

Off-site groundwater extraction with off-site treatment has a low degree of implementability due to the lack of ownership of the property where the alternative would be implemented, the long distance that groundwater forcemain piping would need to be installed for extracted groundwater conveyance, and permitting. The groundwater extraction approach is reliable and effective in the long term if target pumping rates are continuously achieved in a well-maintained and monitored system. After the groundwater extraction system is established, modifications to pumping schemes will be employed to optimize recovery, however the combined flow of the on-site and off-site extraction systems may present unique challenges.

Cost

Major cost components of Alternative #4 (in addition to those detailed associated with on-site groundwater extraction and treatment in Alternative #2) include capital costs for installing and connecting the groundwater extraction and conveyance system to infrastructure from the off-site groundwater extraction wells to the ERL. Significant operation and maintenance costs include third-party treatment fees for the combined flow of the on-site and off-site systems; regular well and forcemain maintenance activities; and long term monitoring costs. The estimated total cost (30 Year, NPV) for Alternative #4 – Groundwater Extraction (on and off-site) and Treatment i ranges from $6,400,000 to $14,000,000 (Table 1). Cost estimate details are included as Appendix E.

6.0 Comparison of Alternatives

This section presents a relative comparison of the corrective action alternatives described in Section 5.

The alternatives were evaluated against seven evaluation criteria that are based on CERCLA guidance (USEPA, 1988). Consistent with the NCP, the selected alternative must meet two threshold criteria and achieve the best balance of trade-offs with respect to the balancing criteria (long-term effectiveness and permanence; reduction of toxicity, mobility, or volume through treatment; short-term effectiveness; implementability; and cost) in a cost-effective manner. The NCP says, "a remedy shall be cost-effective if its costs are proportional to its overall effectiveness."

Alternative #1, MNA and Residential Water Supply Replacement achieves the threshold criteria and is judged to be the most cost-effective alternative that achieves the best balance of the evaluation criteria assuming that further evaluation demonstrates MNA is occurring sufficiently and applicable groundwater requirements are met. Based on the refined preliminary analysis presented herein, MNA is anticipated to sufficiently reduce the toxicity, mobility, and volume of vinyl chloride via natural processes and protectiveness to human health would be addressed with water supply well replacements. Alternative #1 would be equally protective in the short-term and long-term, reasonably implementable, and is the lowest cost alternative evaluated in this report.

Alternative #2, Groundwater Extraction and Treatment with MNA and Residential Water Supply Replacement is equally protective as Alternative #1 but is not a cost-effective alternative due to the operation of the groundwater extraction and treatment system. Alternative #2 provides a means to make progress towards achieving groundwater criteria at the compliance boundary (above and beyond natural processes) by intercepting the migration of groundwater with vinyl chloride along the west side of the landfill, however, preliminary estimates suggest that, on an annual basis, removal of 0.2 lbs of vinyl chloride from approximately 21,000,000 gallons of extracted groundwater. This alternative could be considered in the future if MNA is not demonstrated to be protective.

Alternative #3, Pre-Subtitle D Landfill Excavation/Placement on Liner best addresses long-term effectiveness and permanence but is not cost effective. This alternative is not feasible because lined waste is present in cells adjacent to and overlying the Pre-Subtitle D area and capacity does not exist to accommodate the excavated waste.

This alternative is not judged to be effective in the short-term due to the long lead time required to plan and implement it and because excavation of the unlined waste will require removing the landfill cap, resulting in increased contaminant flux to the groundwater system. Incomplete waste removal and/or residual impacts below the closed Pre-Subtitle D area would require long-term operation of a groundwater treatment system and residential water supply well replacements would be needed to protect the downgradient residents to the same extent in Alternatives #1 and #2.

Alternative #4, Groundwater Extraction (on and off-site) and Treatment is equally protective of Alternatives #1 and #2 but offers less certainty than residential water supply well replacement. Implementation of this alternative is considered difficult given the need to negotiate access to construct, operate, and maintain a groundwater extraction system on privately-owned land. This alternative will also entail extracting groundwater with low vinyl chloride concentrations (e.g., at or below the reporting limit), pumping the groundwater to ERL for treatment, and discharge at the Site. The estimated range of combined flows from the two extraction systems would also be challenging to discharge at the Site. Preliminary estimates suggest that, on an annual basis, the removal of approximately 0.21 lbs of vinyl chloride from approximately 42,000,000 gallons of extracted groundwater (assuming a rate of 80 gpm).

All four alternatives meet the threshold criteria of protecting human health and the environment and have the ability to meet appropriate groundwater criteria at the ERL. Alternative #1, MNA and Residential Water Supply Replacement, is judged to achieve the best balance of the other criteria in a cost-effective manner. The components of Alternative #1 are discussed below:

- Residential water supply replacement: replacing lower outwash supply wells with deeper wells will eliminate the exposure pathway and be protective of downgradient receptors. This component is critical to Alternative #1, provides the greatest value for the cost because it will mitigate risk to downgradient residents (i.e., groundwater users) with a high degree of certainty. Replacement of water supply wells would be the initial priority for implementation for this alternative.

- Monitored natural attenuation (on-site): the results of the evaluation in Appendix C project that the groundwater criteria may be achieved in areas along the west side of the landfill in a reasonable timeframe via naturally occurring attenuation processes. One of these areas is southern portion of the vinyl chloride plume in the vicinity of monitoring wells P-314C, P-313C, and P-323L. The focus along the west side of the landfill would include collecting additional data to track vinyl chloride trends and continue to assess geochemical conditions on a regular basis.

- Monitored natural attenuation (off-site): the focus of this compound would be to conduct additional evaluation of MNA to build on the recent screening update (Barr, 2020b). The off-site evaluation would focus on the areas up and downgradient of well P-334L, including installation of additional MNA monitoring points and collecting additional data to evaluate the stability of the vinyl chloride plume, assess daughter-parent compound relationships, and to refine the attenuation rate estimates and the preliminary projections presented in Appendix C of this report. Provided MNA proves to be a fully appropriate corrective action alternative, the data will be used to support a proposal for the establishment of appropriate alternative groundwater criteria for the Pre-Subtitle D portion of the landfill consistent with Minnesota Solid Waste Rules.

7.0 Summary and Next Steps

This report summarizes four corrective action alternatives identified to address vinyl chloride in groundwater at and downgradient of the ERL. Alternative #1, MNA and Residential Water Supply Replacement meets the threshold criteria and is judged to achieve the best balance of the other criteria in a cost-effective manner. Upon receiving concurrence with MPCA on Alternative #1, a work plan including implementation steps and schedule will be submitted under separate cover to MPCA review and approval. Implementation would prioritize the installation of replacement water supply wells and the installation of additional MNA monitoring network points downgradient of the ERL.

Table 1
Corrective Action Evaluation Summary
Elk River Landfill

CERLCA Criteria		Threshold Criteria	Threshold Criteria	Balancing Criteria	Balancing Criteria	Balancing Criteria	Balancing Criteria	Balancing Criteria	Comments
Alternatives		Overall Protection of Human Health and the Environment	Meeting Applicable Requirements[1]	Reduction of Toxicity, Mobility, or Volume through Treatment	Short-Term Effectiveness	Long-Term Effectiveness and Permanence	Implementability	Cost Range (Capital + 30 Year NPV for O&M, +50% / -30%)	
		(CAO #1 - Priority/Initial Objective)	(CAO #2 - Long Term Objective)						
#1	Monitored Natural Attenuation + Residential Water Supply Replacment	Provides the highest degree of protectiveness for human health based on the replacement of water supply wells. Preliminary evaluation / weight of evidence suggest MNA is a protective approach.	Based on preliminary evaluation, this alternative is anticipated to meet applicable alternate groundwater criteria established under MN Rules.	Based on preliminary evaluation, this alternative is anticipated to reduce toxicity and volume of organics upgradient of groundwater users via destructive and non-destructive natural attenuation processes. Relies on natural processes occurring the subsurface for reductions of toxicity, mobility, or volume.	High degree of short-term effectiveness and permanence in protecting human health with well replacements implemented within 2 to 3 years. Provides additional monitoring locations upgradient of residential wells. Provides data required to evaluate plume stability, refine estimate, verify geochemical conditions, and document mass destruction.	High degree of long-term effectiveness and permanence in protecting human health. Provides additional monitoring locations upgradient of residential wells. Provides data required to evaluate plume stability, refine estimate, and verify geochemical conditions. Documents mass reductions via natural attenuation using methods developed by, applied, and accepted by regulatory agencies.	Residential well replacements are highly implementable with owner acceptance and alternatives to well replacements are available. Natural attenuation evaluation and implementation is highly implementable. Preliminary data / weight of evidence suggest MNA is a protective approach.	$ 590,000 to $1,300,000	This approach achieves the threshold criteria as discussed in the report, is cost-effective, and is judged to achieve the best balance of the evaluation criteria. If MNA evaluation does not prove to be adequate, additional measures can be considered in the future.
#2	Groundwater Extraction with Treatment with Focused MNA and Residential Water Supply Replacement	Same degree of protectiveness to downgradient residents as Alt. #1 due to replacement of water supply wells. If discharge occurs to RL/TB, the volume of water may affect the ground conditions in the discharge area (e.g., ponding water) and exacerbate health and safety issues relating to access for monitoring, maintenance, and/or trespassers.	This alternative provides additional means to achieve alternate groundwater criteria. The timeframe to meet criteria and may be on the order of decades (but would be better understood after the system is installed and performance data and water quality trend data is generated).	In addition to Alt. #1, vinyl chloride mobility would be reduced at the landfill via groundwater extraction. Toxicity of organic compounds would be reduced by treatment. The operation of the extraction system is estimated to marginally reduce volume of vinyl chloride in the groundwater system. Treatment system wastes (if generated) would require disposal/management.	Permitting, extraction and treatment system design, construction, and start-up would be required prior to starting the extraction and treatment system operations. Well replacement and MNA implementation would be the same as Alt. #1.	Same as Alt. #1 with regard to protecting human health. If MNA proves to be effective, long term (>30 years) pumping and treating would not increase effectiveness and permanence.	Moderately implementable due to water discharge challenges. Infiltration east of landfill may be hindered due to space needed for infiltration basin. Discharge to RL/TB could be conducted seasonally if permitted but access may become problematic. Groundwater extraction along the west side of the landfill would be anticipated to extract groundwater with high inorganic compound concentrations. These concentrations may necessitate discharge waivers or a higher degree of treatment which would substantially increase costs and/or operation and maintenance needs.	$ 3,400,000 to $7,000,000	This approach is not cost effective and does not provide additional protection to human health or the environment to a degree greater than Alternative #1. Using an average groundwater extraction rate of 40 gpm, approximately 21,000,000 gallons of groundwater would be extracted annuallyand treatment would remove approximately 0.2 pounds/year of vinyl chloride.

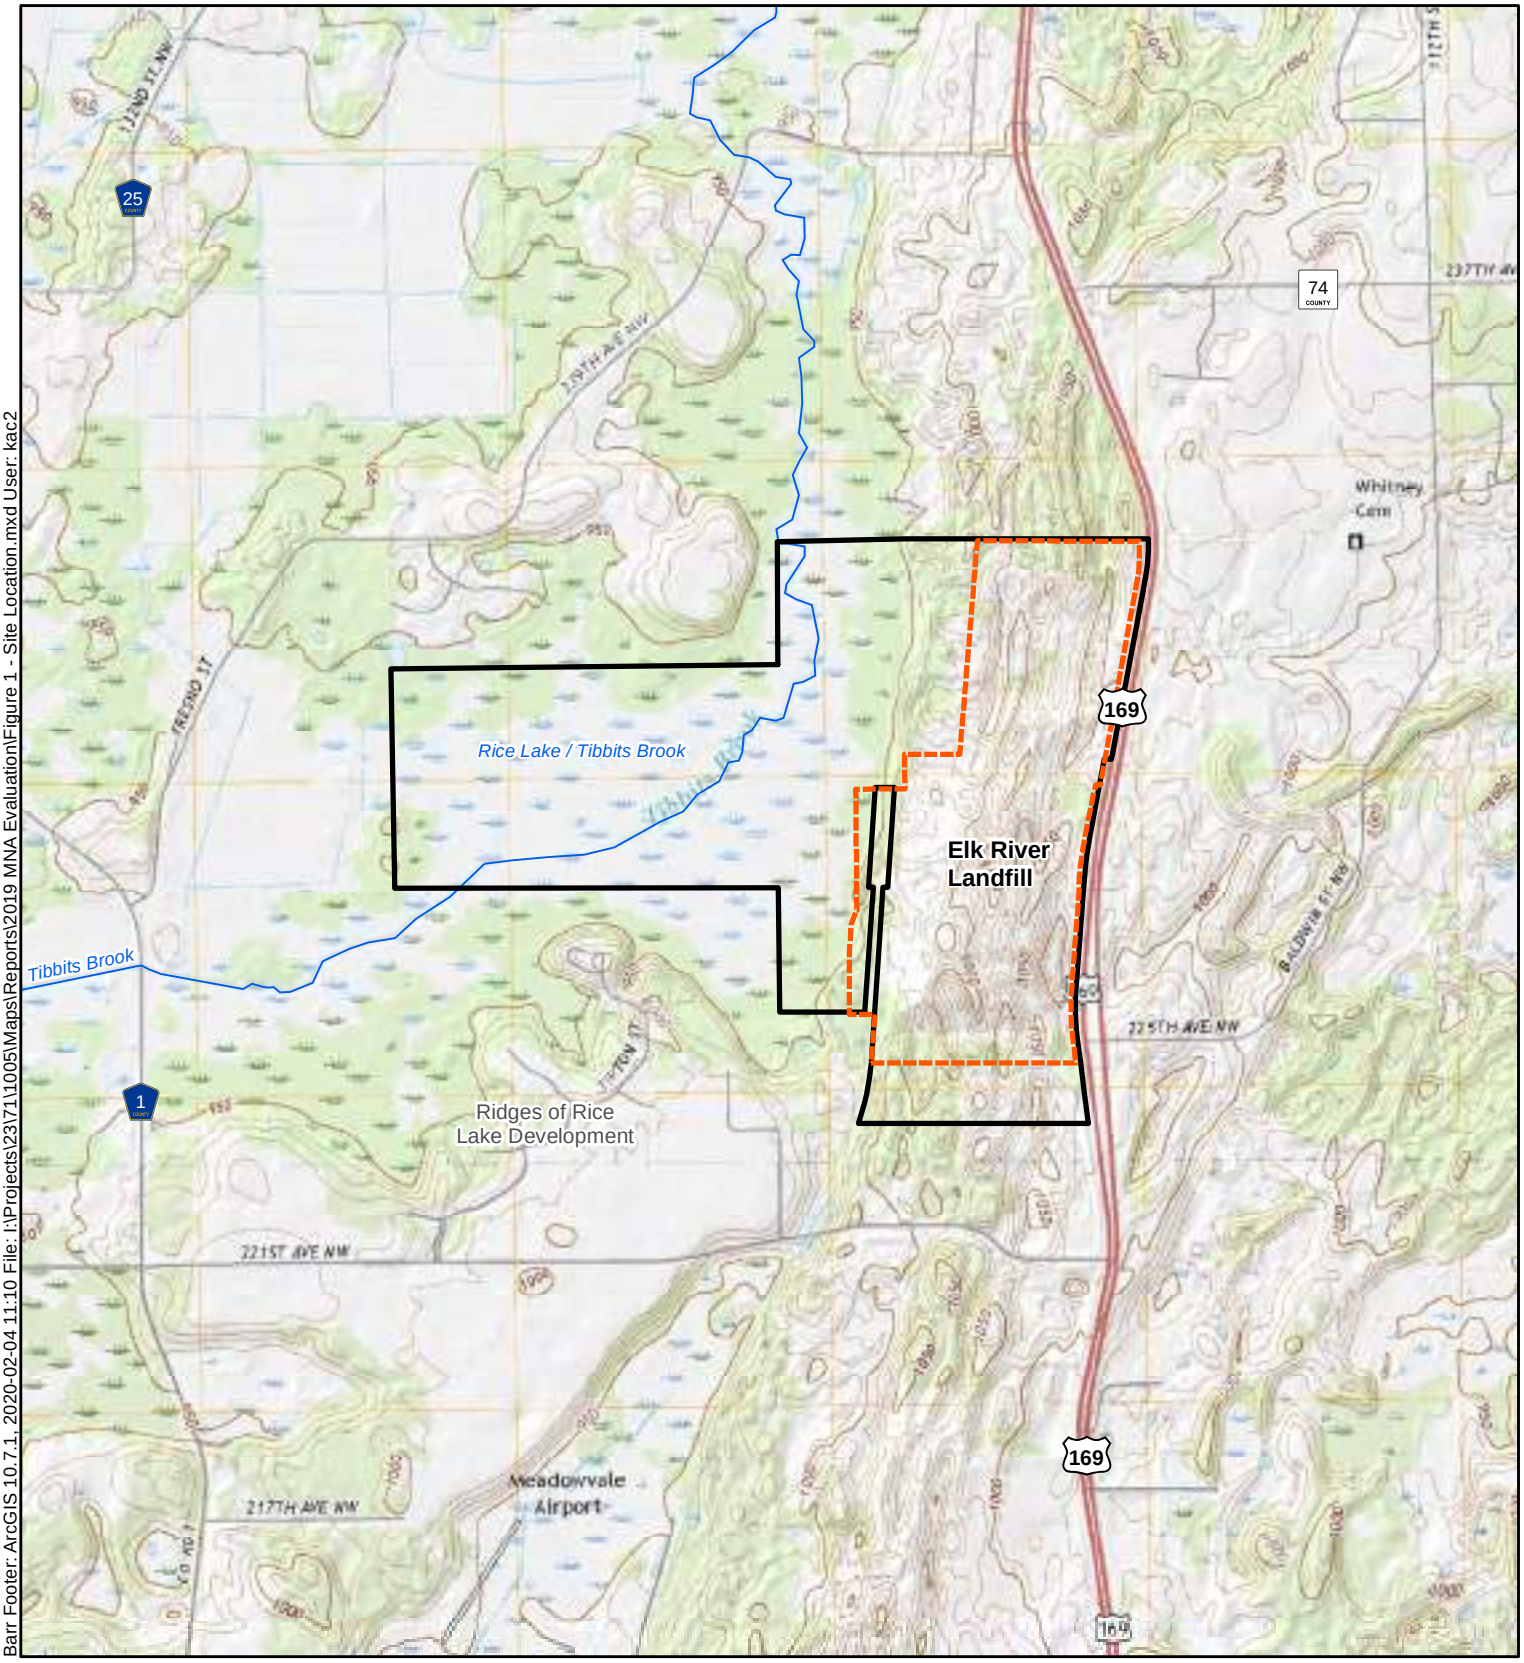
CERLCA Criteria		Threshold Criteria	Threshold Criteria	Balancing Criteria	Balancing Criteria	Balancing Criteria	Balancing Criteria	Balancing Criteria	Comments
Alternatives		Overall Protection of Human Health and the Environment	Meeting Applicable Requirements[1]	Reduction of Toxicity, Mobility, or Volume through Treatment	Short-Term Effectiveness	Long-Term Effectiveness and Permanence	Implementability	Cost Range (Capital + 30 Year NPV for O&M, +50% / -30%)	
		(CAO #1 - Priority/Initial Objective)	(CAO #2 - Long Term Objective)						
#3	Pre-subtitle D Landfill Excavation and Placement on Liner	Same degree of protectiveness to downgradient residents as Alt. #1 due to replacement of water supply wells. Provides the highest degree of overall protection of human health in the long-term due to removal of unlined waste.	Expected to meet alternate groundwater criteria in the long term but not likely in the foreseeable future due to a long lead time for planning/implementation, increased organics flux during implementation. The possibility of incomplete waste removal or continued organics flux from residual impacts (in addition to increased organics flux during implementation) requires the addition of additional groundwater corrective actions (i.e. gw extraction) for the foreseeable future. The timeframe to meet applicable groundwater criteria would be dependent on completeness of source removal (i.e., waste and residuals) and physical processes (e.g., advective transport, matrix rebound, etc.).	Anticipated to increase mobility in the short-term / foreseeable future due to waste disturbance, increased infiltration, cover removal, etc. (generation of leachate and LFG emissions). Increased mobility would require additional groundwater corrective measures (i.e., gw extraction).	Timeline for planning and implementation would be protracted due to magnitude of the project and need to permit and construct new lined area. High degree of short-term effectiveness and permanence in protecting human health with well replacements implemented within 2 to 3 years.	Provides highest degree of long term effectiveness / permanence. Excavation of the unlined pre-Subtitle D landfill and placement on a lined landfill cell is reliable and effective in the long term provided the entire source is removed.	Infeasible given space for the excavated waste does not exist in the currently permitted landfill. Difficult implementation due to lined phases with leachate collection are built over and adjacent to the Pre-Subtitle D area. Difficulties in removing all off the unlined waste, managing leachate and contact water, managing landfill gas/odors/emmission and dust are anticipated.	$ 63,000,000 to $ 140,000,000	This alternative is not not feasible given sufficient permitted air space is not available at ERL to accept excavated waste. This alternative is not considered to be cost effective. The detailed estimation of costs for this alternative and consideration of the are beyond the scope of this evaluation. This alternative would require implementation of groundwater extraction/treatment and water supply replacement to manage anticipated increase in flux to groundwater from implementation. The operation of a groundwater extraction/treatment system (or an alternate technology would be expected to be shorter than without waste removal.
#4	Groundwater Extraction (on and off-site) and Treatment	Provides high degree of protectiveness for human health but less certainty than residential well replacements.	Same as Alt. #2.	Vinyl chloride mobility would be reduced at and downgradient of the landfill via groundwater extraction. Toxicity of organic compounds at and downgradient of the landfill would be reduced by treatment.	Timing based on negotiating access agreements with private property owners. Negotiating access for an active system that would require regular operation and routine maintenance is anticipated to be more difficult than access for monitoring. High degree of short-term effectiveness in protecting human health assuming full plume interception.	If MNA proves to be effective, long term (>30 years) pumping and treating would not increase effectiveness and permanence. Long-term operation would require long-term access agreement with private land owner.	Judged to have low degree of implementability due private property ownership by others, permitting, rate of discharge required, and issues of operating and maintaining a system in RL/TB. Moderate to low implementability assuming seasonal extraction/ treatment/discharge is permitted in RL/TB on ERL property. Infiltration east of landfill may be hindered due to space needed for infiltration basin.	$ 6,400,000 to $ 14,000,000	This approach is not cost effective and does not provide additional protection to human health or the environment to a degree greater than Alternative #1. Using an average groundwater extraction rate of 80 gpm , approximately 42,000,000 gallons of groundwater would be extracted annually and treatment would remove approximately 0.2 pounds/year of vinyl chloride.



Notes:

[1] MPCA requested the evaluation to consider meeting Intervention Limits at the Compliance Boundary. ERL is addressing impacts related to the Pre-Subtitle D portion of the site which may necessitate the establishment of alternate limits under 7035.2815 Subpart 4 (H) (2).

Color Key for this chart is provided to indicate relative degree of achieving listed criteria and/or relative ranking of favorability. Gradient color fills indicate uncertainty.

- Favorable / High
- Neutral / Moderate
- Less Favorable / Low

Data Footnotes and Qualifiers

Barr Standard Footnotes and Qualifiers

--	Not analyzed/Not available.
U	The analyte was analyzed for, but was not detected.
*	Estimated value, QA/QC criteria not met.
h	EPA recommended sample preservation, extraction or analysis holding time was exceeded.

TestAmerica Qualifiers

*	LCS or LCSD is outside acceptance limits.
^	ICV,CCV,ICB,CCB, ISA, ISB, CRI, CRA, DLCK or MRL standard: Instrument related QC is outside acceptance limits.
F1	MS and/or MSD Recovery is outside acceptance limits.
H	Sample was prepped or analyzed beyond the specified holding time
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Pace Qualifiers - 2020

J0	The identification of the analyte is acceptable, but the reported concentration is an estimate. The calibration met method criteria.
J4	The associated batch QC was outside the established quality control range for accuracy.
Q	Sample was prepared and/or analyzed past holding time as defined in the method. Concentrations should be considered minimum values.

MDH Human Health-Based Water Guidance Table

CR	Value represents the criteria for Chromium, hexavalent.
DCP	Value shown is 1,3-dichloropropene in the MDH criterion, however, the laboratory reports cis and trans isomers individually.
(1)	Health Based Value 2014; Value is representative of the lowest exposure duration published in the Minnesota Department of Health Human Health Advisory Table.
HBV14	Health Based Value 2014.
HBV17	Health Based Value 2017.
HBV18	Health Based Value 2018.
HBV19	Health Base Value 2019.
HRL09	Health Risk Limit 2009.

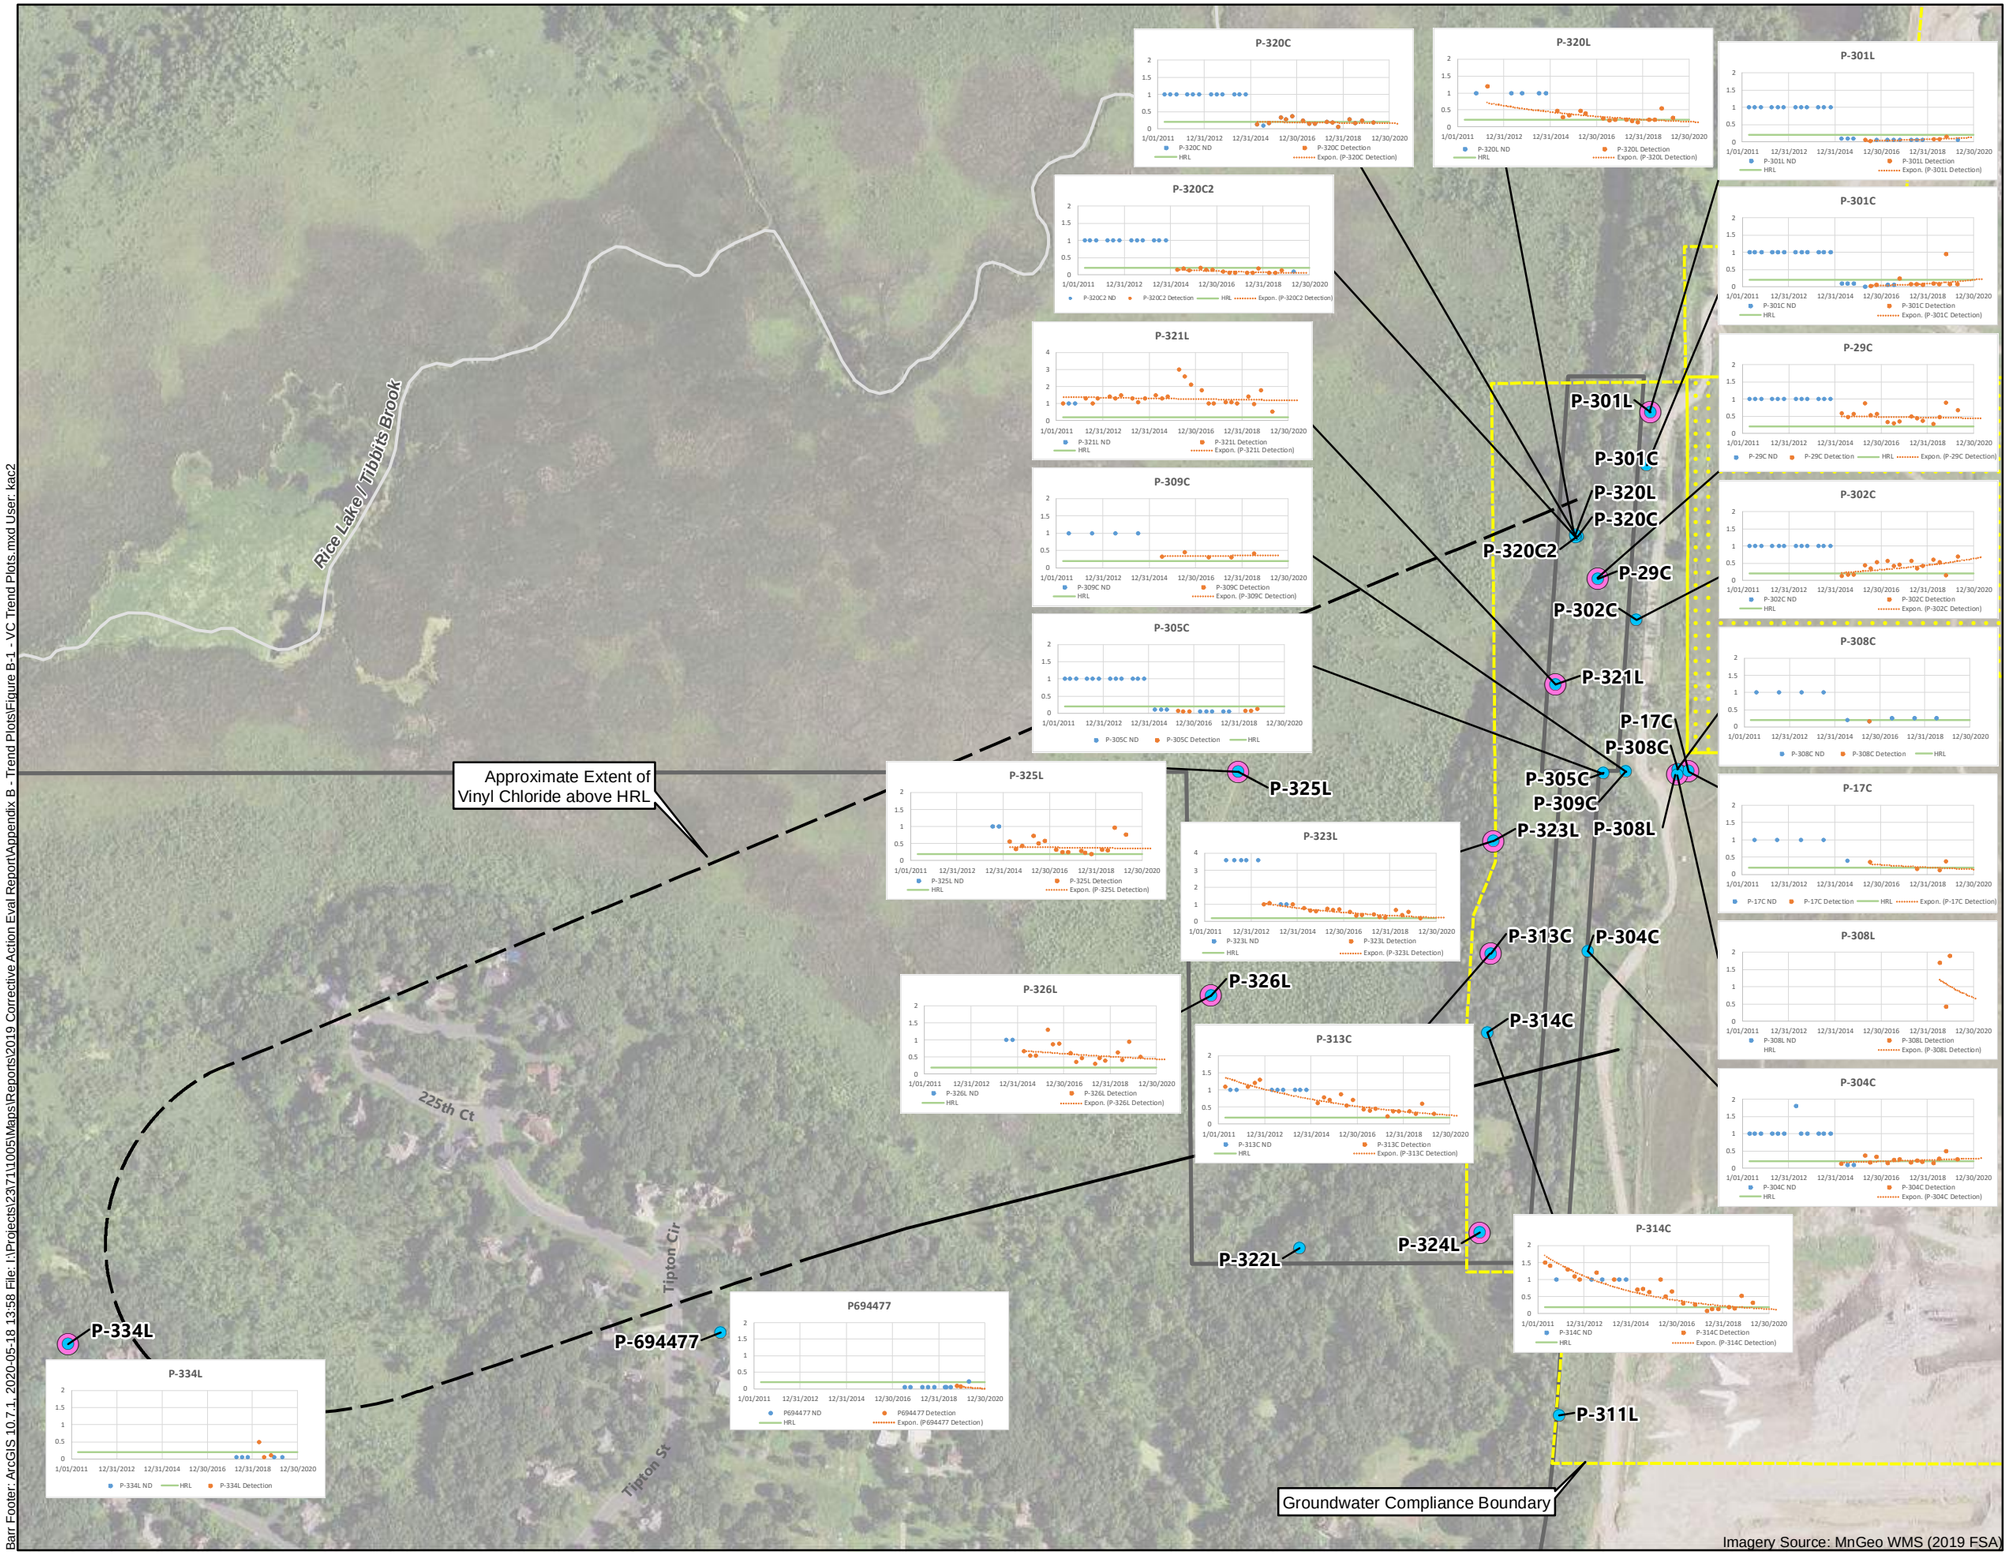
HRL15	Health Risk Limit 2015
HRL18	Health Risk Limit 2018.
HRL20	Health Risk Limit 2020.
HRL93	Health Risk Limit 1993.
HRL94	Health Risk Limit 1994.
***	Dual guidance applies: See Dual Guidance for Drinking Water (https://www.health.state.mn.us/communities/environment/risk/guidance/dualguidance.html)
HRLMCL	Health Risk Limit; Maximum Contaminant Level.
ND	Not derived due to insufficient information.
RAA13	Risk Assessment Advice 2013.
RAA16	Risk Assessment Advice 2016.
RAA17	Risk Assessment Advice 2008.
XYL	Value shown is for the sum of the mixed o,m and p Xylene isomers.

Appendix B

Concentrations Trend Plots



Appendix B
Trend Plots – Overall Summary

This appendix shows vinyl chloride and parent compound concentration trends since 2011 at wells where vinyl chloride has recently been detected. Data from the April 2020 sampling event are included in the plots and are subject to quality assurance review presented in the spring 2020 quarterly monitoring report. The trends for the displayed wells indicate the following:

1. The central and southern portion of vinyl chloride extents nearing the Compliance Boundary (P-313C, P-314C, P-323L) is attenuating steadily over time. The reductive dechlorination progression from TCE to vinyl chloride is evident in this area.
2. Limited attenuation is occurring in the northern portion of vinyl chloride extents near the landfill and Compliance Boundary. Wells P-321L and P-302C have shown stable to increasing trends, respectively. Precursor compounds TCE and cis-DCE are not typically observed in this area.
3. In general, an uptick in vinyl chloride concentrations were observed in 2019 but draft April 2020 data indicate concentrations have returned to levels observed prior to 2019.
4. Vinyl chloride was detected for the first time at distal wells P-334L and P-694477 in 2019. Draft April 2020 vinyl chloride data for these locations are non-detect, although the reporting limit for the P-694477 sample was elevated.
5. Concentrations of chlorinated compounds down the centerline of the plume show attenuation of these compounds with distance from the source area. Vinyl chloride plots alone do not encapsulate the entirety of attenuation with distance (or time) due to the reductive dechlorination process transforming TCE and, more prominently cDCE, to vinyl chloride.
6. Based on theoretical molar mass transformations via a reductive dechlorination pathway, 1 µg/L of cDCE is estimated to produce approximately 0.6 µg/L of vinyl chloride. As shown on Figure 4 of the report, cDCE is present in groundwater at wells P-325L and P-326L and not present in groundwater at P-334L. The limited extent of cDCE, coupled with decreasing vinyl chloride concentrations with distance, suggest that natural attenuation is occurring and that the extent of vinyl chloride may be extended downgradient due to sequential dechlorination reactions producing vinyl chloride via the degradation of cDCE.
7. Vinyl chloride concentrations have dramatically decreased in concentration downgradient of former well P-43B. See attached historic trend plots (and map showing well locations).

Appendix C

Preliminary Attenuation Rate Calculations

Appendix C
Estimated Attenuation Rates and Projections

This appendix documents the inputs, assumptions, and methodology for developing A) estimated groundwater flow velocity, B) attenuation rates and resulting projections of vinyl chloride concentrations (and travel distance) downgradient of ERL, and C) vinyl chloride mass and input (flux) from the western edge of ERL into the groundwater system.

A) Vinyl Chloride Transport Velocity and Approximated Arrival Times at Downgradient Monitoring Wells

The vinyl chloride transport velocity (V_{VC}) the lower outwash aquifer (where organics mass transport is predominantly occurring west of ERL) is estimated to be approximately 106 feet/year (Equation 1). The 106 feet/year value is based on the observed extent of vinyl chloride downgradient of the facility at P-334L (detected for the first time at this location in 2019) and the beginning of landfill operations (estimated to be 1972).

Applying a retardation factor (R) of 1.052 for vinyl chloride (Equation 2), the groundwater flow velocity (V_{GW}) is calculated to be approximately 112 feet/year (Equation 3). This calculated V_{GW} is approximately twice the calculated velocity from an aquifer test at P-308L performed in 2019 (Equation 4). This discrepancy is attributed to the heterogeneity in the lower outwash (e.g., coarse gravel was more abundant at wells P-325L and P-326L than at the wells along the west side of the landfill).

Note that the vinyl chloride transport velocity would be higher if the release did not occur for years after landfill operations began. In the estimates provided in this Appendix, a +25% multiplier is applied to represent an alternative higher end estimate for vinyl chloride transport velocity ($V_{VC,HI}$ = 133 ft/yr) and groundwater flow velocity ($V_{GW,HI}$ = 140 ft/yr) to account for this uncertainty.

Using these velocity values, the estimated arrival times for the slug of elevated organics concentrations (observed at P-17C in 1994) to arrive at downgradient monitoring points was calculated (See Table C1). Based on this estimation, the slug of elevated organics concentrations is predicted to have reached the borings B-330/B-331 in the period of 2017 to 2023 and is projected to reach well P-334L between 2026 and 2034. Vinyl chloride was detected in groundwater from one sample interval at a concentration of 0.43 micrograms per liter (µg/L) at B-331 in 2016.

B) Attenuation Rates

Location-specific (k_{POINT}) and bulk overall attenuation rates (k_{BULK}) and were calculated to further assess attenuation and develop projections based on existing data. Location-specific attenuation rates provide a gauge of the degree of attenuation is occurring at the evaluated location. For example, a value of 0.07/year represents a half-life of approximately 10 years. Bulk overall attenuation rates provide an overall assessment of attenuation across the entire length of a plume. Details are provided below.

Location-Specific Attenuation Rates (k_{POINT})

Location-specific vinyl chloride attenuation rates are useful in assessing trends and projecting time until concentrations reach a certain level (i.e. Intervention Limits) at well locations. This evaluation was only applied to vinyl chloride in the central and southern portions of the plume (where decreasing vinyl chloride trends are occurring near the Compliance Boundary) and not the northern half of the plume (i.e., well P-321L and northward) due to mixed trends. See Appendix B for trend data. Attenuation rates were also not calculated for locations P-334L and P694477 due to too few detections at these locations.

Appendix C
Estimated Attenuation Rates and Projections

This approach should not be used to make projections across an entire plume (Newell & Rifai et. al, 2002).

Vinyl chloride concentration data from 2011 to 2019 was reviewed to calculate k_{POINT} values (Newell & Rifai et. al, 2002) for six wells located near (P-313C, P-314C, P-321L, P-323l), and beyond (P-325L, P-326L) the Compliance Boundary (see Equation 6).

Calculated k_{POINT} values ranged from 0.081 (P-326L) to 0.269 (P-314C). These values indicate the following:

- Attenuation is occurring at a greater rate near the Compliance Boundary compared to the downgradient Property boundary.
- In recent years, the central and southern areas of the vinyl chloride extents near the landfill are naturally attenuating over time and attenuation near P-321L is more stagnant.

Note that the location-specific attenuation rates may be biased low as they do not account for conversion of precursor compounds (PCE, TCE, and DCE) to vinyl chloride. Using first order kinetics and k_{POINT} values, projections for when each of these wells may approach Intervention Limits (ILs) were calculated. These projections range from approximately 4 (i.e., 2024 at P-314C) to 28 years (i.e., 2048 at P-326L) and are shown in Table C2.

Bulk Attenuation Rates (k_{BULK})

Bulk attenuation rates describe the behavior of the entire plume at one point in time and can be useful to project how far along a flow path a plume will expand (Newell & Rifai et. al, 2002).

Overall bulk attenuation rates (k_{BULK}) were estimated using trend line analysis methods outlined in MPCA guidance (MPCA, 2006). A primary assumption in applying this method is that vinyl chloride and other organics have achieved steady state (i.e., not expanding). Late 2019 monitoring results showed first-time confirmed detections of vinyl chloride in samples from monitoring wells P-334L and P-694477. Vinyl chloride was not detected in the spring 2020 samples at wells P-334L (<0.05 µg/L) or P-694477 (<0. 231; i.e., the reporting limit was elevated). The sporadic detections at concentrations near the reporting limit and non-detections suggest these wells are located near the plume fringe and that further monitoring is necessary to assess the overall stability of the organics downgradient of the ERL. Note that if the extents of vinyl chloride are expanding, the attenuation rates presented below are overestimated.

Three approaches were applied to develop a range of potential overall attenuation rates along the plume centerline (P-308L, P-323L, P-326L, and P-334L) using the trend line analysis method. July and October 2019 datasets were used in the review for the first two approaches with the objective of including both wells P-308L (installed in 2019) and P-334L (installed in 2018).

1) July and October 2019 datasets (vinyl chloride only). This approach likely represents a low estimate of attenuation rates as conversion from precursor compounds (PCE, TCE, DCE) to vinyl chloride are not considered.
2) July and October 2019 datasets (total molar concentration of vinyl chloride and precursor compounds PCE, TCE, DCE). This approach includes precursor compounds to capture transformation to vinyl chloride and likely represents a high estimate of attenuation rates as

precursor compounds are present at several locations and generally attenuate more rapidly than vinyl chloride.

3) Maximum reported concentrations at each well since 2015 (vinyl chloride only). This approach estimates rates at the highest reported concentrations at each well since 2015 when reporting limits were lowered to current standards.

Based on these varying approaches (Equation 5), estimated overall attenuation rates are summarized in the following table:

	Bulk Overall Att. Rate at V_{GW} = 112 ft/yr		***Bulk Overall Att. Rate at V_{GW} = 145 ft/yr***	
Method	**$K_{BULK,JULY}$ (/yr)**	**$K_{BULK,OCT}$ (/yr)**	***$K_{BULK,JULY,HI}$ (/yr)***	***$K_{BULK,OCT,HI}$ (/yr)***
1. Vinyl chloride (2019)	0.078	0.045	*0.102*	*0.058*
2. Molar (2019)	0.112	0.067	*0.145*	*0.087*
3. Vinyl chloride (max since 2015)	0.067		*0.087*	
4. Overall average	0.074		*0.096*	

The estimated vinyl chloride travel velocities and k_{BULK} are applied to evaluate the following scenarios. See Table C2 for details.

A) Scenario A: What is the estimated highest vinyl concentration at the Compliance Boundary that would naturally attenuate before reaching nearest residential water supply user in the direct downgradient flowpath of the mapped vinyl chloride extent.
   a. Range: 1 to 90 µg/l
   b. Average: 7 µg/l

   This scenario suggests that, on average, vinyl chloride concentrations at or below 7 µg/l at the Compliance Boundary will attenuate before reaching the nearest residential well downgradient of P-334L.

B) Scenario B: What is the estimated highest vinyl chloride concentration at monitoring well P-334L that would naturally attenuate below the IL or detection limit (0.05 µg/l) before reaching nearest residential water supply user in the direct downgradient flow path of the mapped vinyl chloride extent.
   a. Range: 0.21 to 1.8 µg/l
   b. Average: 0.54 µg/l)

   This scenario suggests that, on average, vinyl chloride concentrations at or below 0.54 µg/l in groundwater at well P-334L will attenuate before reaching the nearest residential well downgradient of P-334L.

C) Scenario C: How far is vinyl chloride projected to travel downgradient of the Compliance Boundary considering peak 2019 concentrations reported near Compliance Boundary (*1.8 ug/l at P-321L*)?
   a. Range: 3,500 to 9,000 feet
   b. Average: 5,400 feet

This scenario suggests that, on average, the vinyl chloride detected in groundwater at well P-321L will travel a distance of 5,400 feet. For context the nearest residential water supply user in the direct downgradient flow path of the mapped vinyl chloride extent is approximately 7,500 feet downgradient of the Compliance Boundary.

C) Mass Estimates of Vinyl Chloride

The change in vinyl chloride inputs from western edge of the landfill into the groundwater system over time were estimated using a mass flux approach that applies principles of Darcy's Law. The Approximate Extent of Vinyl Chloride Above Intervention Limits shown on Cross Section A-A' (Figure 8 of the Report) represents the evaluated transect of flow. This transect of flow was evaluated using datasets from April 2010 and 2019. The April 2010 dataset was selected as it represents the passage of approximately 10 years. Data inputs, assumptions, and calculated values are included in Table C4.

Using the mass flux approach, in 2019, vinyl chloride flowed from the western edge of ERL (represented by Cross Section A-A') into the downgradient groundwater system at a rate of 0.065 lb/yr. This is a 42% reduction compared to April 2010 (0.11 lb/yr). Consistent with the k_{POINT} values, the zones showing the greatest decrease in mass flux over that time period were in the central and southern areas while the northern area remained similar over that time period.

For context, the estimated total mass of vinyl chloride in the plume downgradient of the unlined area is estimated to be approximately 1 lb. Data inputs and calculated values are included in Table C5.

Summary

The estimates above suggest that natural attenuation to meet ILs in the short term along the southern portion of the organics plume is plausible and less likely in the northern area. Assuming the plume is stable, vinyl chloride concentrations along the Compliance Boundary from are anticipated to attenuate under natural conditions before reaching the nearest residential well downgradient of well P-334L (using average k_{BULK} value).

Mass flux calculations show the overall input of vinyl chloride into the downgradient groundwater system is declining over time. This reduction of inputs is expected to result in lower downgradient concentrations and have a positive effect on the overall plume extents in coming years.

Reliance on Rates and Projections

The attenuation rates and the resulting projections above should be considered as approximations based on existing data (at this time) and the stated assumptions (i.e., not definitive estimates). Further long-term monitoring at current vinyl chloride reporting limits and at wells installed in the last decade are necessary to improve confidence in and refine these estimates as appropriate. This variability and need for additional data is further emphasized by the variability in the values derived using k_{BULK}.

Vinyl Chloride Transport Velocity and Attenuation Rate Estimates

Elk River Landfill

1) **Vinyl Chloride Velocity Estimate → $V_{VC}=x/t_{LF}$**

Variable	Value	Units	Source/Comment			
x	5000	ft	Estimated distance vinyl chloride has traveled from source			
t_{LF}	47	years	Years from beginning of landfill operations (est. 1972) to detection of vinyl chloride at P-334L in 2019.			
V_{VC}	106	ft/yr	Vinyl chloride velocity	$V_{VC,HI}$	133 ft/yr	+25% higher end estimate

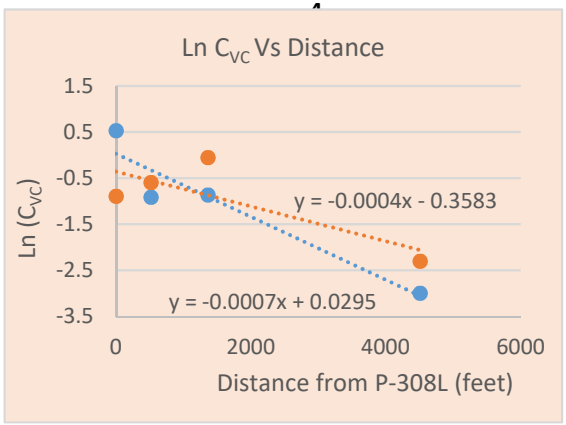
2) **Retardation Factor → $R=1+r_b k_d/n$**

Variable	Value	Units	Source/Comment
r_s	2.65	kg/L	Quartz solids density
r_b	1.9875	kg/L	Bulk Density → $r_b=r_s(1-n)$
f_{oc}	0.00035		Fractional organic carbon - https://www.itrcweb.org/DNAPL-ISC_tools-selection/Content/Appendix%20I.%20Foc%20Tables.htm
k_{oc}	18.6	L/kg	MPCA Risk-Based Buidance for Soil Leaching Pathway, Working Draft Guidelines (1998)
k_d	0.00651	L/kg	Soil Distribution Coefficient → $k_d=f_{oc}k_{oc}$
n	0.25		2015 Hydro Report (Barr)
R	1.052		Retardation Factor - Vinyl chloride 5.2% retarded

3) **Groundwater Velocity → $V_{GW}=V_{VC}R$**

Variable	Value	Units	Source/Comment			
V_{GW}	112	ft/yr	Velocity of Groundwater at Base of Lower Outwash Unit	$V_{GW,HI}$	140	+25% higher end estimate

4) **ALTERATE Groundwater Velocity → $V_{GW}=Ki/n$**



Variable	Value	Units	Source/Comment
K	41.99	ft/day	P-308L Step Test (2019) ALTERNATE IS 5.67 ft/d (0.002 cm/s from 2015 Hydro Report)
n	0.25		2015 Hydro Report
$x_{P323L-P334L}$	3990	ft	Distance from P-323L to P-334L
i	0.00097	ft/ft	Avg water Levels 2018-2019 (P-323L, P-334L), Distance between the locations (3990 ft)
V_{GW}	59.7	ft/yr	Not utilized for attenuation rate calculations as it does not align with vinyl chloride presence at well P-334L

Table C1
Organics Plug Travel Projections

Projections/Estimated timing of when the 1992 organics slug arrived/will arrive downgradient of ERL

Location	Distance from P-17C (feet)	Est. Year (using V_{VC})	Est. Year (using $V_{VC,HI}$)	Observed Maximum Vinyl Chloride Concentration (ug/l)	Observed Maximum Vinyl Chloride Concentration Date	Notes
P-325L	1175	**2003**	**2001**	0.97	10/22/2019	P-325L was installed in 2014.
P-326L	1375	**2005**	**2002**	1.3	4/22/2016	P-326L was installed in 2014.
B-330 / B-331	3300	**2023**	**2017**	0.43	5/2/2016	Temporary boring B-331 was completed in 2016.
P-334L	4500	**2034**	**2026**	0.10	10/23/2019	P-334L was installed in 2018.

Inputs

V_{VC}	106	ft/yr	Vinyl Chloride Travel Velocity (estimated)
$V_{VC,HI}$	133	ft/yr	Vinyl Chloride Travel Velocity (high estimate)
Year	1992		Starting Year of Organics Concentration Spike at P-17C (1992-1994)

Table C2
Projecting Time to Achieve ILs at Wells

Well	k_{POINT}	C_0	C_0 Date	C_{IL}	Projected Year C_{IL} Achieved
P-313C	0.161	1.1	4/19/2011	0.05	2031
P-314C	0.269	1.5	4/19/2011	0.05	2024
P-321L	NA (not decreasing)	1.0	4/19/2011	0.05	
P-323L	0.183	1.0	7/17/2013	0.05	2030
P-325L	0.086	0.56	4/14/2015	0.05	2044
P-326L	0.081	0.67	4/14/2015	0.05	2048

Notes: -Projected Year C_{IL} Achieved is based on application of first order kinetics using calculated overall attenuation rate and dataset shown in attached calculations.
-Locations nearest to the Compliance Boundary and Property Boundary are shown.

Variables

$C_{IL} = C_0 e^{-kt}$

t = time (years)

k_{POINT} = Calculated overall attenuation rate at well (/year)

x = distance

C_{IL} = Vinyl chloride intevention limit (0.05 ug/l)

V_{VC} = Vinyl chloride velocity (ft/year)

C_0 = Vinyl chloride concentration at date listed. Listed date based on first detections at well since 2011 (or installation date)

Table C3
Bulk Attenuation Projections

ID	Description	Guiding Equation	Overall Attenuation Rate		Vinyl Chloride Travel Distance, Velocity, and Time					Vinyl Chloride Concentration	
			Variable	Overall Attenuation Rate (/yr)	Start Point	End Point	Distance (feet)	V_{GW} (ft / year)	Travel Time (years)	C_{IL} (ug/l)	C_{CB} (ug/l)
A	Calculate the maximum vinyl chloride concentration at the Compliance Boundary that would naturally attenuate below ILs before reaching nearest residential water supply user downgradient of mapped extent?	$C_{CB} = \frac{C_{IL}}{e^{-k\frac{x}{V_{GW}}}}$	$k_{JUL, VC}$	0.078	Compliance Boundary	Nearest Directly Downgardient Residential Water Supply User	7500	112	67	0.05	**10**

			$k_{MAX,VC}$	0.067							**4.5**
			k_{AVG}	0.074							**<u>7.1</u>**
B	Calculate the maximum vinyl chloride concentration at P-334L that would naturally attenuate before reaching nearest residential water supply user downgradient of mapped extent (C. Thompson)?	$C_{P-334L} = \frac{C_{IL}}{e^{-k\frac{x}{V_{GW}}}}$	$k_{JUL, VC}$	0.078	P-334L	Nearest Directly Downgardient Residential Water Supply User	3600	112	34	0.05	**0.62**
			$k_{OCT, VC}$	0.045							**0.21**
			$k_{JUL, MOL}$	0.112							**1.8**
			$k_{OCT, MOL}$	0.067							**0.43**
			$k_{MAX,VC}$	0.067							**0.43**
			k_{AVG}	0.074							**<u>0.54</u>**
C	How far is vinyl chloride projected to travel downgradient of the Compliance Boundary considering peak 2019 concentrations reported near Compliance Boundary *(1.8 ug/l at P-321L)* ?	$x = \left(\frac{ln\frac{C_{IL}}{C_{CB}}}{-k}\right)V_{GW}$	$k_{JUL, VC}$	0.078	Compliance Boundary	NA	**5124**	112	46	0.05	1.8
			$k_{OCT, VC}$	0.045			**8968**		80		
			$k_{JUL, MOL}$	0.112			**3587**		32		
			$k_{OCT, MOL}$	0.067			**5978**		53		
			$k_{MAX,VC}$	0.067			**5978**		53		
			k_{AVG}	0.074			**<u>5435</u>**		49		

<u>Assumptions/Notes:</u>

-Overall attenuation rates may be conservatively biased low due to observed presence of parent compounds to vinyl chloride upgradient of P-334L.
-The extent of vinyl chloride is stable and no longer expanding.
-First order kinetics applied, i.e. $C_x=C_0e^{-kt}$
-The higher end groundwater velocities (+25%) do not yield different results than what is shown above. A change in groundwater velocities yields a proportional change in attenuation rates. This results in no change to results in bolded text above.
NA = Not applicable or not analyzed
Inputs in Standard Text
Results in Bolded Text
<u>Value calculated using average attenuation rate, or estimated groundwater velocity, is underlined.</u>

<u>Variables</u>

C_{CB} = Vinyl chloride concentration at Compliance Boundary.
t = time
k = overall attenuation rate
x = distance
C_{IL} = Vinyl chloride intevention limit (0.05 ug/l)
V_{VC} = Vinyl chloride velocity
C_{P334L} = Vinyl chloride concentration at P-334L

									Decrease in VC flux in 2019 compared to April 2010:		**42%**

Notes:

Mass flux estimated using transect/box model method by application of Darcy's Law.

Estimated areas are based on Approximate Extent of Vinyl Chloride above IL on Figure 8 of CAER.

Hydraulic conductivity (K) data based on P-308L step test (2019)

Wells P-29C, P-320C, P-320C2, and P-321L included in Box E. Wells P-301C and P-301L included in Box F.

2019 groundwater elevations/horizontal gradient (i) are based on 952 ft MSL (u/g) and 951 ft MSL (d/g) contours on Figure 3 of CAER.

For consistency, the 2010 groundwater elevations/horizontal gradient (i) were kept consistent with 2019. The current downgradient well network was not yet established.

2019 Average Vinyl Chloride and Total Organics concentrations are average values from wells located in each "box".

2010 Average Vinyl Chloride concentrations are from the April 2010 monitoring event from wells located in each "box". For locations with no data or where non-detect values were reported due to higher reporting limits, data from the nearest date where a detection was reported is applied. These data points are *italicized* .

Technical Memorandum

To: File
From: Jim Eidem
Subject: 2020 Well Search Update
Date: May 2020
Project: Elk River Landfill

This technical memorandum summarizes the 2014 update to the Elk River Landfill (ERL) well search. The following subsections describe the well search update methods and results.

Methods

The Minnesota Well Index (MWI) was queried to identify water wells located in the vicinity of ERL (Figure D1). Well records from the MWI are attached.

Results

The construction details for the wells located west of the landfill are summarized in Table D1. Table D1 also summarizes the years the residential wells were sampled dating back to 2011. Data are included in Table D2. No organics have been detected.

Attachments:

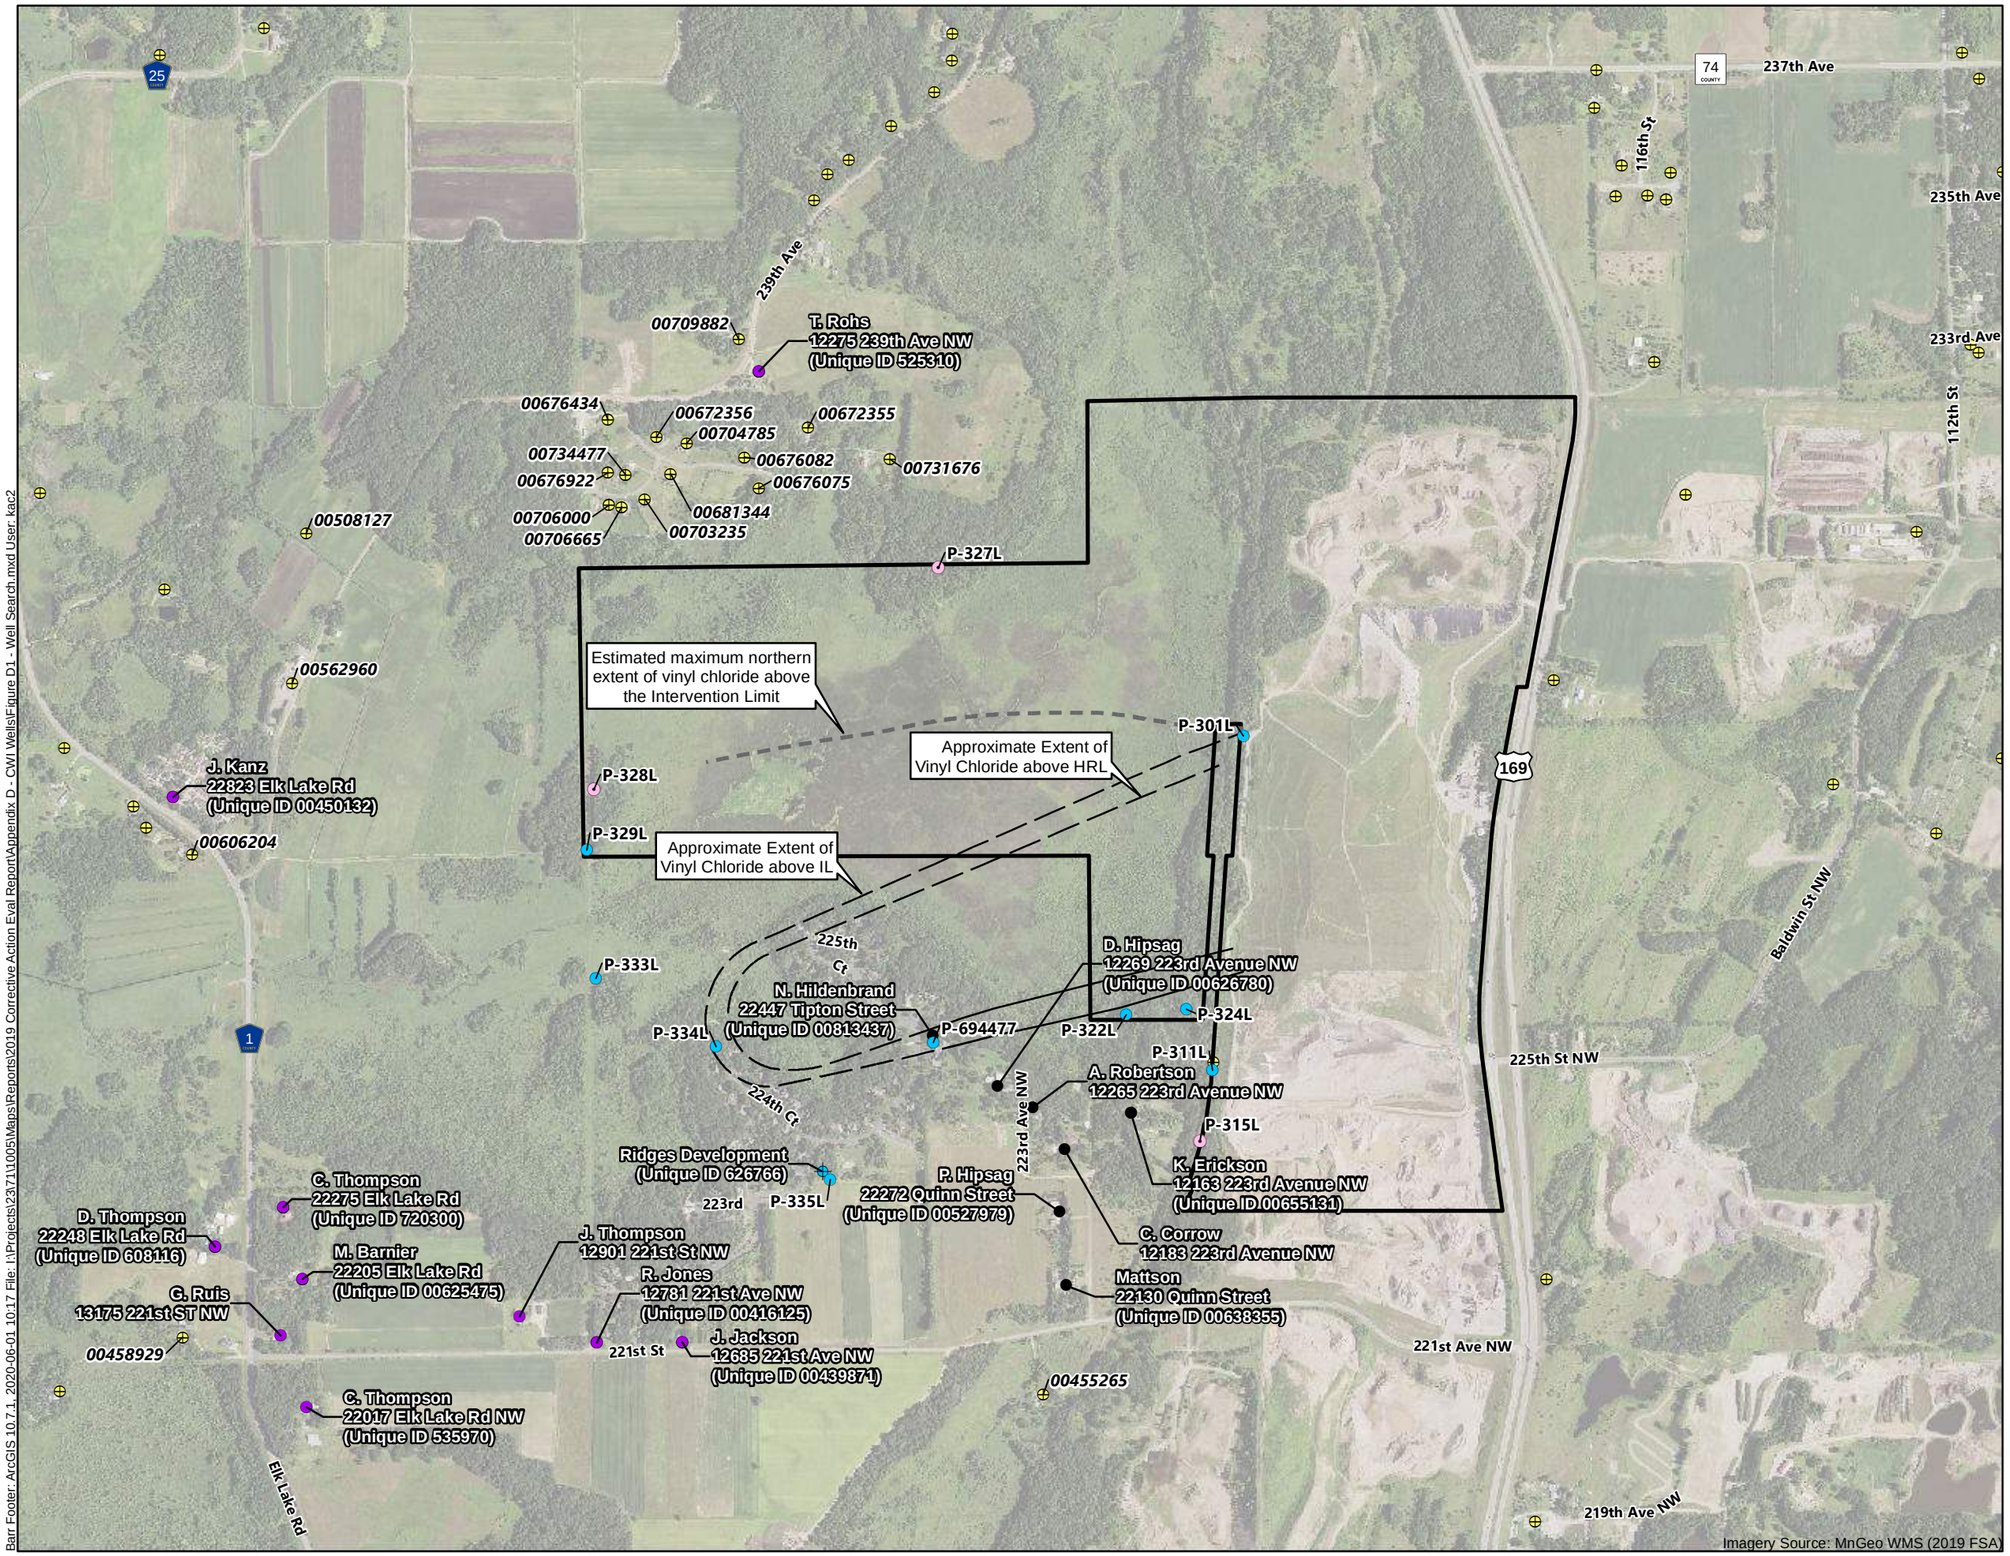
Data Footnotes and Qualifiers

Barr Standard Footnotes and Qualifiers



--	Not analyzed/Not available.
*	Estimated value, QA/QC criteria not met.
[1]	Well 12265 223rd was incorrectly listed as 11265 223rd in Permit SW-74
[2]	Upgradient well located east of Hwy 169 NW

TestAmerica Qualifiers

*	LCS or LCSD is outside acceptance limits.
^	ICV,CCV,ICB,CCB, ISA, ISB, CRI, CRA, DLCK or MRL standard: Instrument related QC is outside acceptance limits.
4	MS, MSD: The analyte present in the original sample is greater than 4 times the matrix spike concentration; therefore, control limits are not applicable.
B	Compound was found in the blank and sample.
F1	MS and/or MSD Recovery is outside acceptance limits.

MDH Human Health-Based Water Guidance Table

DCP	Value shown is 1,3-dichloropropene in the MDH criterion, however, the laboratory reports cis and trans isomers individually.
(1)	Value is representative of the lowest exposure duration published in the Minnesota Department of Health Human Health Advisory Table.
HBV14	Health Based Value 2014
HBV17	Health Based Value 2017
HBV18	Health Based Value 2018
HBV19	Health Base Value 2019.
HRL09	Health Risk Limit 2009
HRL13	Health Risk Limit 2013.
HRL15	Health Risk Limit 2015
HRL18	Health Risk Limit 2018.
HRL20	Health Risk Limit 2020
HRL93	Health Risk Limit 1993.
HRL94	Health Risk Limit 1994.
***	Dual guidance applies: See Dual Guidance for Drinking Water (https://www.health.state.mn.us/communities/environment/risk/guidance/dualguidance.html)
HRLMCL	Health Risk Limit; Maximum Contaminant Level.
ND	Not derived due to insufficient information.
RAA13	Risk Assessment Advice 2013
RAA16	Risk Assessment Advice 2016
RAA17	Risk Assessment Advice 2017.
XYL	Value shown is for the sum of the mixed o,m and p Xylene isomers.

Cost Estimate Details

Cost Estimate Summary
Corrective Action Evaluation Report

ID	Alternative	Capital Cost	O&M (30 Year NPV)	Total Estimated Cost (2020 NPV)	Low Range (-30%)	High Range (+50%)
1	Residential Water Supply Replacement + Monitored Natural Attenuation	$ 690,000	$ 150,000	$ 840,000	$ 590,000	$ 1,300,000
2	Groundwater Extraction (ERL Property) with Onsite Treatment + Residential Water Supply + MNA	$ 2,100,000	$ 2,700,000	$ 4,800,000	$ 3,400,000	$ 7,000,000
3	Pre-subtitle D Landfill Excavation and Placement on Liner	$ 84,000,000	$ 6,000,000	$ 90,000,000	$ 63,000,000	$ 140,000,000
4	Groundwater Extraction (on-site & off-site) and Treatment (on-site)	$ 2,900,000	$ 6,200,000	$ 9,100,000	$ 6,400,000	$ 14,000,000

The opinion of probable remedial action cost is made on the basis of Barr's experience and qualifications and represents our best judgment as experienced and qualified professionals familiar with the project. The cost opinion is based on project-related information available to Barr at this time and includes a Detailed Analysis of Alternatives level of project definition. The opinion of cost may change as more information becomes available and regulatory negotiations proceed. In addition, since we have no control over the cost of labor, materials, equipment, or services furnished by others, or over the contractor's methods of determining prices, or over competitive bidding or market conditions, Barr cannot and does not guarantee that proposals, bids, or actual remedial action costs will not vary from the opinion of probable remedial action cost prepared by Barr.

Alt 1

Monitored Natural Attenuation + Residential Water Supply Replacement

Corrective Action Evaluation Report

No.	Item	Quantity	Unit	Unit Cost	Cost
1	Mobilization / Demobilization	1	LS	$ 32,000	$ 32,000
2	Drinking Water Well Installation & Connection	10	Ea	$ 20,000	$ 200,000
3	Drinking Water Quality Testing	10	Ea	$ 1,000	$ 10,000
4	Monitoring Well Site Preparation	1	LS	$ 30,000	$ 30,000
5	Monitoring Well Installation	2	Ea	$ 40,000	$ 80,000
6	Construction Contingency			25%	$ 88,000
Construction Cost Subtotal					$ 440,000
7	Well Installation Coordination with Residents	10	Ea	$ 10,000	$ 100,000
8	Engineering and Construction Administration			33%	$ 150,000
Engineering Cost Subtotal					$ 150,000
Estimated Capital Cost					**$ 690,000**
Operation and Maintenance		1	ANNUAL	$ 10,000	**$ 150,000**
				ESTIMATED TOTAL	**$ 840,000**
				High Range (+50%)	$ 1,260,000
				Low Range (-30%)	$ 590,000

Primary Assumptions:

-Engineering and construction administration based on A Guide to Developing and Documenting Cost Estimates During

-Assumes two distal monitoring wells to be installed in the wetland area.

-Assumes ten wells have increased analytical monitoring for continued tracking of natural attenuation processes.

-Total well completion depth will be approximately 300 feet below ground surface in Mt. Simon Aquifer

-Costs shown do not include any additive alternatives (i.e. Alternate Water Supply)

Alt 2

Groundwater Extraction and Treatment with Focused MNA and Residential Water Supply Replacement

High Range (+50%)	$	14,000,000
Low Range (-30%)	$	6,400,000

Primary Assumptions:

-Engineering and construction administration based on A Guide to Developing and Documenting Cost Estimates During the Feasibility Study (EPA 540-R-00-002)

-Five extraction wells will operate to achieve remedial goals.

-Lump sum construction unit costs scaled up from Alt 2 by 66% to account for extra wells, flow, and infrastructure.

-Total depth of extraction wells and piezometers will average 90 feet below ground surface.

Appendix F

Monitoring Well Network Considerations

Appendix F
Monitoring Well Network Considerations

The ERL monitoring network includes 39 monitoring wells, of which 25 are sampled three times per year. Monitoring network considerations are provided below based on the corrective action evaluation and feedback from MPCA and others:

- P-301L area – vinyl chloride concentrations were above the IL in sample from monitoring well P-301L during the three triannual sampling events in 2019 and not detected (<0.050 µg/L) in the April 2020 sample (Appendix A). This suggests well P-301L remains on the northern fringe of the vinyl chloride plume. Vinyl chloride concentrations at P-301L will be watched, and if necessary, an additional lower outwash monitoring well will be considered.

- P-694477 area - vinyl chloride was detected and confirmed in monitoring well P-694477 in October and December 2019 and was not detected (at an elevated reporting limit) in the April 2020 sample (Appendix A). As part of the corrective action implementation, unique well #626780 (which is sidegradient to the organics) is a candidate for replacement and conversion of the existing supply well to a lower outwash monitoring well that will provide monitoring data southeast of well P-694477.

- Northern Rice Lake/Tibbits Brook (RL/TB) - the County has suggested the installation of a monitoring well north of well P-325L in RL/TB. The installation of a well(s) in this area is a significant undertaking during installation and raises safety concerns for the individuals responsible for preparing the area for drilling, drilling and installing the well, and samplers who monitor the wells. ERL will provide access to the County to install the well (at the County's risk) if requested. Please contact Mr. Terry Johnson if you would like to schedule a site visit to conduct a site walk in RL/TB for reconnaissance purposes or to discuss our experience with creating access, drilling in RL/TB and a similar wetlands in Minnesota, and safety concerns.

  ERL will consider incorporating monitoring wells P-327L and P-328L to the monitoring network for sampling on an annual basis.

- Upgradient Lower Outwash Well – ERL will provide a plan to establish additional upgradient monitoring under separate cover.

EXHIBIT 16

Natural Wild Rice In Minnesota

A Wild Rice Study document submitted to the Minnesota Legislature by the Minnesota Department of Natural Resources February 15, 2008

Fiscal Disclosure

Pursuant to Minnesota Statutes, Section 3.197, we estimate that it cost approximately $72,614 to produce this report. This includes Minnesota Department of Natural Resources (MNDNR) staff time for conducting the inventory, attending meetings, drafting and reviewing the report and compiling comments and recommendations ($45,159) and meeting expenses, including travel, for consultation with the Technical and Partnership Teams ($1,772). In addition, costs accrued to other agencies and individuals participating on the Technical Team are $22,618 for time and $3,065 for travel. These costs do not include the costs of preceding research and public participation efforts conducted by the MNDNR or Team members prior to the requirement that this report be prepared.

Executive Summary

Introduction

This report fulfills the requirements of Session Law 2007, Chapter 57, Article 1, Section 163 requiring the Commissioner of Natural Resources to prepare a study for natural wild rice that includes: (1) the current location and estimated acreage and area of natural stands; (2) potential threats to natural stands, including, but not limited to, development pressure, water levels, pollution, invasive species, and genetically engineered strains; and (3) recommendations to the house and senate committees with jurisdiction over natural resources on protecting and increasing natural wild rice stands in the state.

In fulfilling these requirements, the Minnesota Department of Natural Resources (MNDNR) established a Technical Team of wild rice experts from State, Tribal, and Federal governments, as well as academia and the private sector. The MNDNR also established a Partnership Team representing major stakeholders.

Importance of Natural Wild Rice

Nowhere has natural wild rice been more important, nor had a richer history, than in Minnesota. No other native Minnesota plant approaches the level of cultural, ecological, and economic values embodied by this species. Natural wild rice has been hand harvested as a source of food in the Great Lakes region for thousands of years.

The Ojibwe people have a special cultural and spiritual tie to natural wild rice. Known to their people as Manoomin, it is revered as a special gift from the Creator. In addition many immigrants to Minnesota adopted hand harvesting of natural wild rice as an annual ritual. Annual sales of state licenses for wild rice harvesting peaked in 1968 at over 16,000. In recent years, annual sales have averaged fewer than 1500. In many instances, though, tribal harvesters are not required to buy state licenses. It is thought that more than 3000 tribal members participate in wild rice harvesting, providing a statewide total (tribal and nontribal) of 4000-5000 individuals annually.

The value of natural wild rice to wildlife has been long appreciated by American Indians and was marveled at by early European explorers. Research since then has documented that wild rice provides food and shelter for many fish and wildlife species. It is one of the most important foods for waterfowl in North America. More than 17 species of wildlife listed in the MNDNR's Comprehensive Wildlife Conservation Strategy as "species of greatest conservation need" use wild rice lakes as habitat for reproduction or foraging.

Wild rice harvest has provided important economic benefits to local economies. As with other commodities, the price paid for unprocessed natural wild rice can vary considerably. Although pricing is mainly determined by supply, marketing also plays a role. During the past 70 years, the price of one pound of unprocessed wild rice has ranged from $0.10 in 1940 to $2.17 in 1966. Adjusted for inflation these prices in today's dollars are equivalent to $0.75 and $13 per pound, respectively. As an example, the 1966 harvest of 924,000 lbs would have been worth over $12 million today.

Prior to 1970, Minnesota provided half of the global market supply of wild rice. Most of this rice was from hand harvested natural stands. By 1990, the large-scale production of cultivated wild rice had expanded, and natural wild rice accounted for less than 10% of the global market supply. The total annual yield of cultivated and hand harvested wild rice in Minnesota today ranges from four to eight million pounds. A recent MNDNR survey found the average annual hand harvest of natural stands to be 430 pounds per individual.

Background

Although stands of natural wild rice occur most commonly in central and north-central Minnesota, the historic range of wild rice included all of the state. Based on the inventory conducted for this report, the range of natural wild rice today includes 55 counties in Minnesota. Stands of natural wild rice were present or occurred in recent history on approximately 1286 lakes and river/stream segments. These areas support a minimum of 64,328 acres of natural wild rice when growing conditions are favorable.

The greatest concentration of lakes supporting natural wild rice is in Aitkin (4,859 acres), Cass (8,323 acres), Crow Wing (3,751 acres), Itasca (8,448 acres), and St. Louis (8,939 acres) counties. These counties contain over 60% of the inventoried natural wild rice acreage in Minnesota. These counties also account for over 70% of the harvesting trips for natural wild rice.

Natural wild rice generally requires some moving water, with rivers, flowages, and lakes with inlets and outlets being optimal areas for growth. Wild rice grows well at depths of 0.5 to 3 feet of water, although some plants may be found in deeper waters. As an annual plant, natural wild rice develops each spring from seeds that fell into the water during a previous fall. Germination requires a dormancy period of three to four months of cold, nearly freezing water (35° F or colder). Seeds are unlikely to survive prolonged dry conditions.

The entire process, from germination of a new plant to dropping of mature seeds, requires about 110 to 130 days, depending on temperature and other environmental factors. Seeds begin ripening at the top of the stem and then ripen over several days on an individual plant. Plants within a stand ripen at different times because of genetic, developmental, and environmental variation. This staggered maturation process means that ripe seeds may be available within individual stands for several weeks, and across the entire range of natural wild rice in Minnesota for a month or longer.

The earliest laws and regulations concerning wild rice in Minnesota focused on wild rice harvest and date back more than 75 years. Today, there is a complex mix of tribal, federal, state, and local laws and regulations. These are associated with the formal recognition of the significance of natural wild rice and its protection, management, and harvest. The application of regulations varies by jurisdiction (i.e., tribal versus state) and geography (i.e., on-reservation versus off-reservation, or within various ceded territories). Regulatory authority governing different aspects of wild rice management occurs within several state agencies yet within state statutes there is no unifying policy to provide overall guidance in implementation.

Threats

Despite its rich history and abundance in Minnesota, natural wild rice faces many current and potential threats in this region. In general, any factor that can affect water quality, seasonal water levels, lakebed conditions, regional climate, aquatic vegetation, or the natural genetic diversity of wild rice could potentially threaten natural stands. These threats may work in concert or individually to damage wild rice stands.

Important threats that impact local stands of natural wild rice include changes in local hydrology due to dams and channelization, water-based recreation and shoreland development, and mining and other industrial activities. Although the impacts are to local stands, the cumulative effect of these threats can have statewide implications. Hydrological impacts and shoreland development are particularly important.

On a statewide and regional scale, the most important threats are the potential loss of genetic integrity, invasive species, and climate change. Nearly all of the concern expressed about wild rice genetics focuses on the potential of genetic engineering. Invasive species are an ongoing statewide issue impacting aquatic systems in general. Climate change has the potential for the greatest long-term impacts on natural wild rice.

As citizens become more distant from positive experiences with natural wild rice through harvesting, hunting, trapping, or wildlife watching, they are less likely to recognize the very real impacts that the previously noted threats could have on natural wild rice in Minnesota. This loss of appreciation, while not a direct threat to the wild rice resource, nevertheless increases the risks because the level of resource protection and management is often based on the perceived value of a resource.

Unfortunately wild rice harvesters are relatively few in number and have experienced a long-term decline, although the number of tribal harvesters has rebounded in recent years. Only about 4000-5000 people participate in hand harvesting natural stands of wild rice annually.

The future of natural wild rice in Minnesota will depend in large part on its protection and management by state and tribal natural resource agencies. The role of the agencies is complicated by the limitations of their authority and the challenges posed by multiple jurisdictions, annual variability of wild rice crops due to weather and other factors, and lack of information concerning the natural ecology of wild rice, historical losses, trends in abundance and distribution, threats to its future, and a better understanding of wild rice harvesters.

Recommendations

The following recommendations were developed with valuable input and discussion from the members of the Wild Rice Study Technical Team and Partnership Team. However, the MNDNR assumes sole responsibility for these recommendations as written and presented here.

MNDNR recognizes the importance of protecting natural wild rice beds from genetic modification and agrees with wild rice stakeholders that this protection is critical to the future of this resource. We strongly support the Minnesota Environmental Quality Board in adopting rules

that require an Environmental Impact Statement for a proposed release of genetically engineered wild rice (MS 116C.94 Subd.1b).

Recommendation 1

Recodify current wild rice harvest statutes and rules to remove duplication and inconsistencies.

Rationale: The state's wild rice statutes and rules have been developed and modified piecemeal over a long period of time. As a result they contain a number of inconsistencies and duplication.

Recommendation 2

Establish statutory policy guidance on wild rice and its management.

Rationale: Within state statutes there is no unifying policy that provides direction to agencies responsible for some aspect of wild rice management.

Recommendation 3

The MNDNR will convene an interagency workgroup in 2008 to identify desired statutory updates in harvest regulations.

Rationale: Harvest regulations and license fee structure should be reviewed by an interagency work group for suggested changes.

Recommendation 4

The MNDNR will designate and publish a list of important natural wild rice areas.

Rationale: Recognizing important wild rice areas and publishing the list would call attention to the importance of these areas, indicate management priorities, and provide a formal list that may prove useful for local units of government that are considering zoning and surface use restrictions.

Recommendation 5

The MNDNR will convene a standing interagency wild rice workgroup to share information and develop recommendations for inventory methodology and trend assessments, education and information outreach, lake planning and management, harvester recruitment and retention, and other management issues as they arise.

Rationale: Comprehensive protection and management of wild rice involves multiple agencies. Management needs include better inventory information including consistent methodology for trend analysis, documenting natural genetic diversity, and establishing long-term case studies on identified lakes.

Recommendation 6

Increase intensive natural wild rice lake management efforts and accelerate the restoration of wild rice stands within its historic range.

Rationale: Protecting and managing natural wild rice resources on many lakes requires active annual management activities to maintain free flowing outlets. Active management is also required to restore wild rice to wildlife habitat areas within its historic range. These efforts should be accelerated as funding, time, and opportunity permit.

Sacred Food and Medicine

Wild rice, or manoomin, is a sacred food and medicine integral to the religion, culture, livelihood, and identity of the Anishinaabeg. According to our sacred migration story, in the long ago a prophet at the third of seven fires beheld a vision from the Creator calling the Anishinaabe to move west (to a land previously occupied long ago) until they found the place "where food grows on the water." The Anishinaabeg of the upper Mississippi and western Great Lakes have for generations understood their connection to anishinaabe akiing (the land of the people) in terms of the presence of this plant as a gift from the Creator. In the words of White Earth's Tribal Historian, Andy Favorite, "Wild rice is part of our prophecy, our process of being human, our process of being Anishinaabe … we are here because of the wild rice. We are living a prophecy fulfilled."

In our Ojibwe language, manoomin is animate, grammatically referred to as "him/her" not "it," a non-human being, not just an inanimate "resource." It is both difficult and of utmost importance to adequately translate and appreciate this worldview in the language of mainstream culture and society with its scientific advisory boards for the study of humans and animals but not plants. According to Anishinaabe author, Basil Johnson, "…in essence each plant ... was a composite being, possessing an incorporeal substance, its own unique soul-spirit. It was the vitalizing substance that gave to its physical form growth, and self-healing." The Anishinaabeg believe that wild rice will always grow where they live. Menominee chief Chieg Nio'pet said his people did not need to sow rice because it would follow them wherever they went. He told of how Shawano Lake never had manoomin until the Menominee moved there. Similarly when they were banned from Lake Winnebago, the rice that had been plentiful there all but disappeared. Whatever happens to the land and to manooomin happens to the Anishinaabe.

Our ceremonies and aadizookanag -sacred stories- also tell of our people's relations with this plant. White Earth Anishinaabe, Joe LaGarde, notes that wild rice and water are the only two things required at every ceremony. Manoomin accompanies our celebrations, mourning, initiations, and feasts, as both a food and a spiritual presence. It holds special significance in traditional stories, which are only told during ricing time or when the ground is frozen. "In these stories, wild rice is a crucial element in the realm of the supernaturals and in their interactions with animals and humans; these legends explain the origin of wild rice and recount its discovery…" by Wenabozhoo, or Nanabozho, the principal manidoo or spirit in our sacred aadizookanag.

Manoomin is just as central to our future survival as our past. While we try to overcome tremendous obstacles to our collective health, the sacred food of manoomin is both food and medicine. "Wild rice is consequently a very special gift, with medicinal as well as nutritional values—belief reflected in the Ojibwe use of wild rice as a food to promote recovery from sickness as well as for ceremonial purposes." (Vennum 62). Manoomin is inextricably bound to the religion and identity of the Anishinaabeg. This is why these threats are potentially so devastating and why it is essential that the sanctity and integrity of this plant be preserved. If artificially produced or engineered varieties of wild rice were to compromise the wild manoomin that has existed in the lakes for thousands of years, it will compromise the Anishinaabe people and our way of life. Joe LaGarde puts it plainly, "If we lose our rice, we won't exist as a people for long. We'll be done too."

Erma Vizenor, Tribal Chairwoman, White Earth Nation
With the participation of Carlton College Students.

Introduction

This report fulfills the requirements of Session Law 2007, Chapter 57, Article 1, Section 163:

By February 15, 2008, the commissioner of natural resources must prepare a study for natural wild rice that includes: (1) the current location and estimated acreage and area of natural stands; (2) potential threats to natural stands, including, but not limited to, development pressure, water levels, pollution, invasive species, and genetically engineered strains; and (3) recommendations to the house and senate committees with jurisdiction over natural resources on protecting and increasing natural wild rice stands in the state.

In developing the study, the commissioner must contact and ask for comments from the state's wild rice industry, the commissioner of agriculture, local officials with significant areas of wild rice within their jurisdictions, tribal leaders within affected federally recognized tribes, and interested citizens.

In fulfilling these requirements, the Minnesota Department of Natural Resources (MNDNR) established a Technical Team of wild rice experts from State, Tribal, and Federal governments; the Minnesota cultivated wild rice industry; Ducks Unlimited; Save Our Rice Alliance (SORA), an organization of interested citizens who hand harvest natural wild rice; White Earth Land Recovery Project; the University of Minnesota; and the University of Wisconsin (Appendix A). The MNDNR also established a Partnership Team representing the Minnesota wild rice industry, the state commissioner of agriculture, the Association of Minnesota Counties, tribal leaders within affected federally recognized tribes, the United States Fish and Wildlife Service, Ducks Unlimited, Minnesota Waterfowl Association, and SORA (Appendix A).

The Technical Team, working with MNDNR staff, developed drafts of the wild rice study document for review by the Partnership Team. The collaboration of these two teams was instrumental in producing this document for MNDNR review and approval. The MNDNR is indebted to team members for their contributions of time, expertise, and hard work. It should be clear, however, that the MNDNR assumes sole responsibility for the content and recommendations of this document.

The wild rice study document and its appendices are intended to provide the reader with a thorough background on the importance of natural wild rice to Minnesota, its natural ecology and distribution, threats to its future, challenges in managing the resource, and recommendations to insure its abundance for future generations.

Importance of Natural Wild Rice in Minnesota

As directed by the legislature, the wild rice study document focuses on natural wild rice. For this study, we define natural wild rice as native species of wild rice (*Zizania*) that are growing in public waters and are not subject to cultivation. The simplest description of natural wild rice in Minnesota is that it is an annual aquatic grass that produces an edible grain.

This simple description, of course, does not do justice to this unique and valuable plant. History is replete with examples of its importance to wildlife and value to humans both nutritionally and culturally. Wild rice (manoomin to the Ojibwe) is a spiritually significant resource for Native Americans in the Great Lakes region, and it has been for centuries. Nowhere has this grain been more important, nor had a richer history, than in Minnesota. No state harbors more acres of natural wild rice than Minnesota (Moyle and Krueger 1964). No other native Minnesota plant approaches the level of cultural, ecological, and economic values embodied by natural wild rice.

Cultural Importance

Natural wild rice has been hand harvested as a source of food in the Great Lakes region for thousands of years. Evidence of its human use dates back to the Late Archaic and Early Woodland periods, more than 2000 years ago (Valppu 2000). Archeological evidence indicates that from the 1600s to the 1800s wild rice was a staple food for the Algonquian and Dakota peoples throughout the area now known as Minnesota. It has been important historically for gifting and trading, as well. For example, when Dakota Chief Wabasha hosted Zebulon Pike in 1805 he offered gifts of wild rice to the explorer (Vennum 1988).

The Ojibwe people have a special cultural and spiritual tie to natural wild rice. Their Migration Story describes how they undertook a westward migration from the eastern coast of North America. Tribal prophets had foretold that this migration would continue until the Ojibwe people found "the food that grows on water" (Benton-Banai 1988). That food was wild rice, known as manoomin, and is revered to this day by the Ojibwe as a special gift from the Creator (Ackley 2000; Schlender 2000).

Early European explorers and fur traders were impressed with the availability and nutritional quality of wild rice, and attempts were made to import it to Europe as early as 1790 (Oelke 2007). Many immigrants to Minnesota adopted hand harvesting of natural wild rice as an annual ritual. The importance of this harvest to European settlers lessened only when cultivated non-native grains became more readily available.

The tradition of hand harvesting natural wild rice continues to this day among both tribal and nontribal cultures. This tradition has been preserved through tribal code and state regulations that reflect traditional methods of harvesting. State statutes in Minnesota include regulations that restrict the maximum length (18 feet) and width (36 inches) of the harvesting boat, as well as the maximum weight (1 pound) and length (30 inches) of hand flails. The regulations also require that push poles have forks 12 inches or less in length. The use of any machine or mechanical device to harvest natural wild rice is generally prohibited.

Annual sales of state licenses for wild rice harvesting peaked in 1968 at over 16,000. In recent years, annual sales have averaged fewer than 1500. However, because in many instances tribal harvesters are not required to buy state licenses, state numbers do not adequately reflect the numbers of individuals participating in wild rice harvesting. It is thought that more than 3000 tribal members participate in wild rice harvesting providing the statewide total (tribal and nontribal) of 4,000 to 5,000 individuals.

Annual harvests can vary greatly. Rice productivity, weather, and harvester participation are all important factors. The MNDNR survey of state licensees from 2004 to 2006 found the average annual harvest to be 430 pounds per individual (MNDNR 2007). Aitkin, Cass, Crow Wing, Itasca, and St. Louis counties accounted for over 70% of the harvesting trips for natural wild rice. Estimates of annual harvest of natural stands in Minnesota between 1940 and 1972 ranged from 20 thousand to nearly 4 million pounds of unprocessed grain (Oelke et al. 1973).

Another aspect of the cultural importance of wild rice is its nutritional value. Noted for its importance as a whole grain, wild rice is an excellent source of complex carbohydrates, vitamins, minerals, fiber and protein. It is a particularly good source of potassium, zinc and riboflavin (Oelke 2007). Access to traditional foods is felt to be an important element of restoring individual and community health of the Ojibwe people (W. LaDuke, personal communication). Natural wild rice is one of the mainstays of traditional foods for the Ojibwe community.

Concerns for the preservation of hand harvesting traditions and related issues led to the formation in 2007 of a tribal and nontribal partnership called Save Our Rice Alliance (SORA). The stated mission of SORA is “To preserve and enhance the culture, economy, and sustainability of native wild rice” (A. Drewes, personal communication).

Ecological Importance

The value of natural wild rice to wildlife has been long appreciated by American Indians and was marveled at by early European explorers (Jenks 1900). Jonathan Carver traveled through eastern portions of North America in the 1760s and observed of wild rice that “the sweetness and nutritious quality of it attracts an infinite number of wild fowl of every kind which flock from distant climes to enjoy this rare repast, and by it become inexpressively fat and delicious” (Stoddard 1957).

Both migrating and resident wildlife rely on the nutritious and abundant seeds of natural wild rice. One acre of natural wild rice can produce more than 500 pounds of seed. These seeds have long been recognized as an important source of food during fall migrations (McAtee 1917). Martin and Uhler (1939) listed wild rice as the ninth most important source of food for ducks throughout the United States and Canada, and the third most important source of food for ducks in the eastern portions of the continent. Research conducted on the Chippewa National Forest found that natural wild rice was the most important food for mallards during the fall (Stoudt 1944). Although the value of wild rice to mallards, wood ducks, and ring-necked ducks is most commonly recognized, other ducks such as black ducks, pintail, teal, wigeon, redheads, and lesser scaup also use stands of wild rice (Rossman et al. 1982, Huseby 1997).

The stems of wild rice provide nesting material for such species as common loons, red-necked grebes, and muskrats; and critical brood cover for waterfowl. The entire wild rice plant provides food during the summer for herbivores such as Canada geese, trumpeter swans, muskrats, beaver, white-tailed deer, and moose (Martin et al.1951, Tester 1995). In addition, rice worms and other insect larvae feed heavily on natural wild rice. These, in turn, provide a rich source of food for blackbirds, bobolinks, rails, and wrens. In the spring, decaying rice straw supports a diverse community of invertebrates and thus provides an important source of food for a variety of wetland wildlife including birds, small fish, and amphibians. Indeed, every stage of growth of natural wild rice provides food for wildlife (McAtee 1917, Stoudt 1944).

As a result, wild rice lakes and streams are breeding and nesting areas for many species. More than 17 species of wildlife listed in the MNDNR's Comprehensive Wildlife Conservation Strategy (2006) as "species of greatest conservation need" use wild rice lakes as habitat for reproduction or foraging (Henderson 1980, Martin et al.1951). Listed bird species can be found in Table 1.

Table 1. Minnesota birds that utilize wild rice habitat and are listed in *Tomorrow's Habitat for the Wild and Rare* as species of special concern.

Birds of Special Concern	Life Cycle Stage
American Black Duck	Breeding and migration
Lesser Scaup	Migrant
Northern Pintail	Migration, Rare Breeder
Trumpeter Swan	Breeding and migration
American Bittern	Breeding and migration
Least Bittern	Breeding and migration
Red-necked Grebe	Breeding and migration
Common Loon	Breeding and migration
Sora Rail	Breeding and migration
King Rail	Casual migrant
Virginia Rail	Breeding and migration
Yellow Rail	Breeding and migration
Black Tern	Breeding and migration
Bobolink	Foraging and migration
Rusty Blackbird	Foraging and migration
Sedge Wren	Breeding and migration
Bald Eagle	Foraging and migration

Natural wild rice has other ecological values as well. Emergent aquatic plants such as wild rice, bulrush, and cattails protect shorelines and provide habitat for fish (Radomski and Goeman 2001). Dense stands of wild rice stabilize loose soils and form natural windbreaks that can limit the mixing of soil nutrients into the water column (Meeker 2000). In addition, natural wild rice has relatively high requirements for nutrients such as phosphorus and nitrogen (Oelke et al. 2000). During periods of rapid growth, which occurs in spring and summer, the plants sequester

these nutrients. Thus stands of natural wild rice counter the effects of nutrient loading and the potential increases in algal growth and lake turbidity.

Economic Importance

Prior to European settlement of Minnesota, natural wild rice was the most important grain available to native peoples, early explorers, and fur traders (Vennum1988). Properly dried, and stored in clean, dry conditions, uncooked wild rice has an estimated shelf life of up to 10 years. One pound yields up to ten and a half cups of cooked wild rice (Oelke 2007). As a dietary staple that was so easily stored and used, wild rice had considerable economic value. With the influx of immigrant settlers and the agricultural production of non-native grains, the overall economic value of wild rice waned. Nevertheless, harvest of natural wild rice continued to be popular in Minnesota. During the 1960s, sales of state licenses averaged over 10,000 per year.

The economic value of wild rice is reflected in the efforts of many to expand its occurrence into new waters. Native peoples have long sown wild rice to create additional sources of grain (Vennum 1988). Waterfowl hunters have commonly planted wild rice to attract ducks. The demand for seed of wild rice and other aquatic wildlife foods presumably fostered the establishment of Wildlife Nurseries, Inc. in Oshkosh, Wisconsin in 1898 (Oelke 2007). This firm continues selling wild rice for planting today. Conservation agencies have long participated in planting efforts as well, working to establish new stands of wild rice and perpetuate traditional areas (Moyle 1944b).

David Owens noted the potential benefits of cultivating wild rice as early as 1852 (Vennum 1988). In 1853, Oliver H. Kelley published an article discussing the merits of wild rice cultivation. Albert E. Jenks discussed wild rice cultivation as part of "agricultural development" in 1901. Yet not until 50 years later did James and Gerald Godward pioneer the first real efforts. They began production of cultivated wild rice in central Minnesota, near Merrifield, in 1950 (Oelke 2007).

The 1950s and 1960s may well have been the peak of modern hand harvesting of wild rice. From 1957 to 1963 the state of Minnesota sold an average of 10,012 wild rice harvest licenses (Table 2). The average annual harvest of unprocessed wild rice exceeded 2 million pounds or about 227 pounds per picker per year (Moyle and Krueger 1964).

Table 2. Hand harvesting of natural wild rice 1957-1963.

Year	Licenses sold	Harvest *
1957	7,535	1,057,000
1958	9,702	3,224,000
1959	9,332	2,067,000
1960	9,664	2,301,000
1961	14,660	2,772,000
1962	6,709	1,292,000
1963	12,482	3,212,000

*Harvest is in unprocessed pounds

As with other commodities, the price paid for unprocessed natural wild rice can vary considerably. Although pricing is mainly determined by supply, marketing also plays a role. During the past 70 years, the price of one pound of unprocessed wild rice has ranged from $0.10 in 1940 to $2.17 in 1966 (Oelke 2007). Adjusted for inflation these prices in today's dollars are equivalent to $0.75 and $13 per pound, respectively. The 1966 harvest of 924,000 lbs would have been worth over $12 million today. Since 1990, the price paid for unprocessed rice from the Leech Lake Reservation has varied between $1.00 and $1.50 per pound (R. Robinson,

Jr., personal communication). Sales during this period ranged from approximately 7,400 to 280,000 pounds.

Prior to 1970, Minnesota provided half of the global market supply of wild rice. Most of this rice was from hand harvested natural stands. By 1990, the large-scale production of cultivated wild rice had expanded, and natural wild rice accounted for less than 10% of the global market supply. Cultivated wild rice from Minnesota provided 40% of the market and California provided 50% (Lee 2000). California still leads the cultivated wild rice industry. The total annual yield of cultivated and hand harvested wild rice in Minnesota today ranges from four to eight million pounds.

Although cultivated rice dominates these production numbers, hand harvested natural wild rice remains a vital component of tribal and local economies in Minnesota. The MNDNR survey of 2004 – 2006 state license buyers found an average annual individual harvest of 430 pounds. In 2007, nearly 300,000 pounds of unprocessed rice were purchased from LLBO-licensed harvesters. At $1.50 per pound, this harvest generated more than $400,000 of income for tribal members (R. Robinson, Jr., personal communication).

Wild Rice Background

Taxonomy

Native North American wild rice is classified as a grass in the family *Poaceae* and the genus *Zizania*. The most common species throughout Minnesota is northern wild rice, or *Zizania palustris* L. (Ownbey and Morley, 1991). Two varieties of natural wild rice occur in this region and in other parts of the Upper Midwest: Z. *palustris* var. *palustris* and Z. *palustris* var. *interior* (Gleason and Cronquist, 1991; Flora of North America, 1993+).

A more southern and eastern species, *Zizania aquatica* L., is uncommon but thought by many to occur in Minnesota as well. The precise distribution of *Z. aquatica* is unclear because of differences in taxonomic interpretations and potentially overlapping ranges. *Z. aquatica* is physically larger than *Z. palustris* but its grain is more slender and difficult to harvest. Both of these species are native only to North America.

Distribution and Abundance

Minnesota historically harbored more acres of natural wild rice than any other state (Moyle and Krueger 1964). Despite losses of wild rice habitat, the importance of Minnesota as a center of natural wild rice abundance has actually increased as wild rice acreage has declined elsewhere in the United States. For thousands of years, wild rice thrived in shallow lakes, rivers, and streams left behind by melting glaciers. Although stands of natural wild rice occur most commonly in areas of glacial moraines, such as in central and north-central Minnesota, the historic range of wild rice included all of Minnesota (Moyle 1944b).

Its range also extended westward into the present-day Dakotas and eastward to the Atlantic coast. While not distributed evenly, wild rice likely occurred in many places where its ecological requirements were met. Because wild rice also was planted in areas where it did not occur naturally, it is sometimes difficult today to distinguish between historically natural stands and successfully seeded stands (Vennum 1988).

An updated inventory of the distribution and abundance of natural wild rice was compiled for this study by selected members of the Technical Team and the MNDNR (Appendix B). Data are from lake-habitat surveys, reported observations, and interviews with field personnel of state, federal, and tribal agencies. Although this inventory provides a marked improvement in our understanding of natural wild rice distribution in Minnesota, it should be considered a minimum estimate. The data for many wild rice lakes, streams and rivers is incomplete or totally lacking.

Based on this inventory, the range of natural wild rice today includes 55 counties in Minnesota (Figure 1). The only Minnesota counties without significant populations of natural wild rice are along the western and southwestern boundaries of the state. It should be noted, however, that historical records of wild rice include herbarium specimens that were collected in several western counties not documented by the current inventory. These counties include Pipestone, Cottonwood, Chippewa, Swift, Clay, and western Polk (Moyle 1939, Ownbey and Morley, 1991).

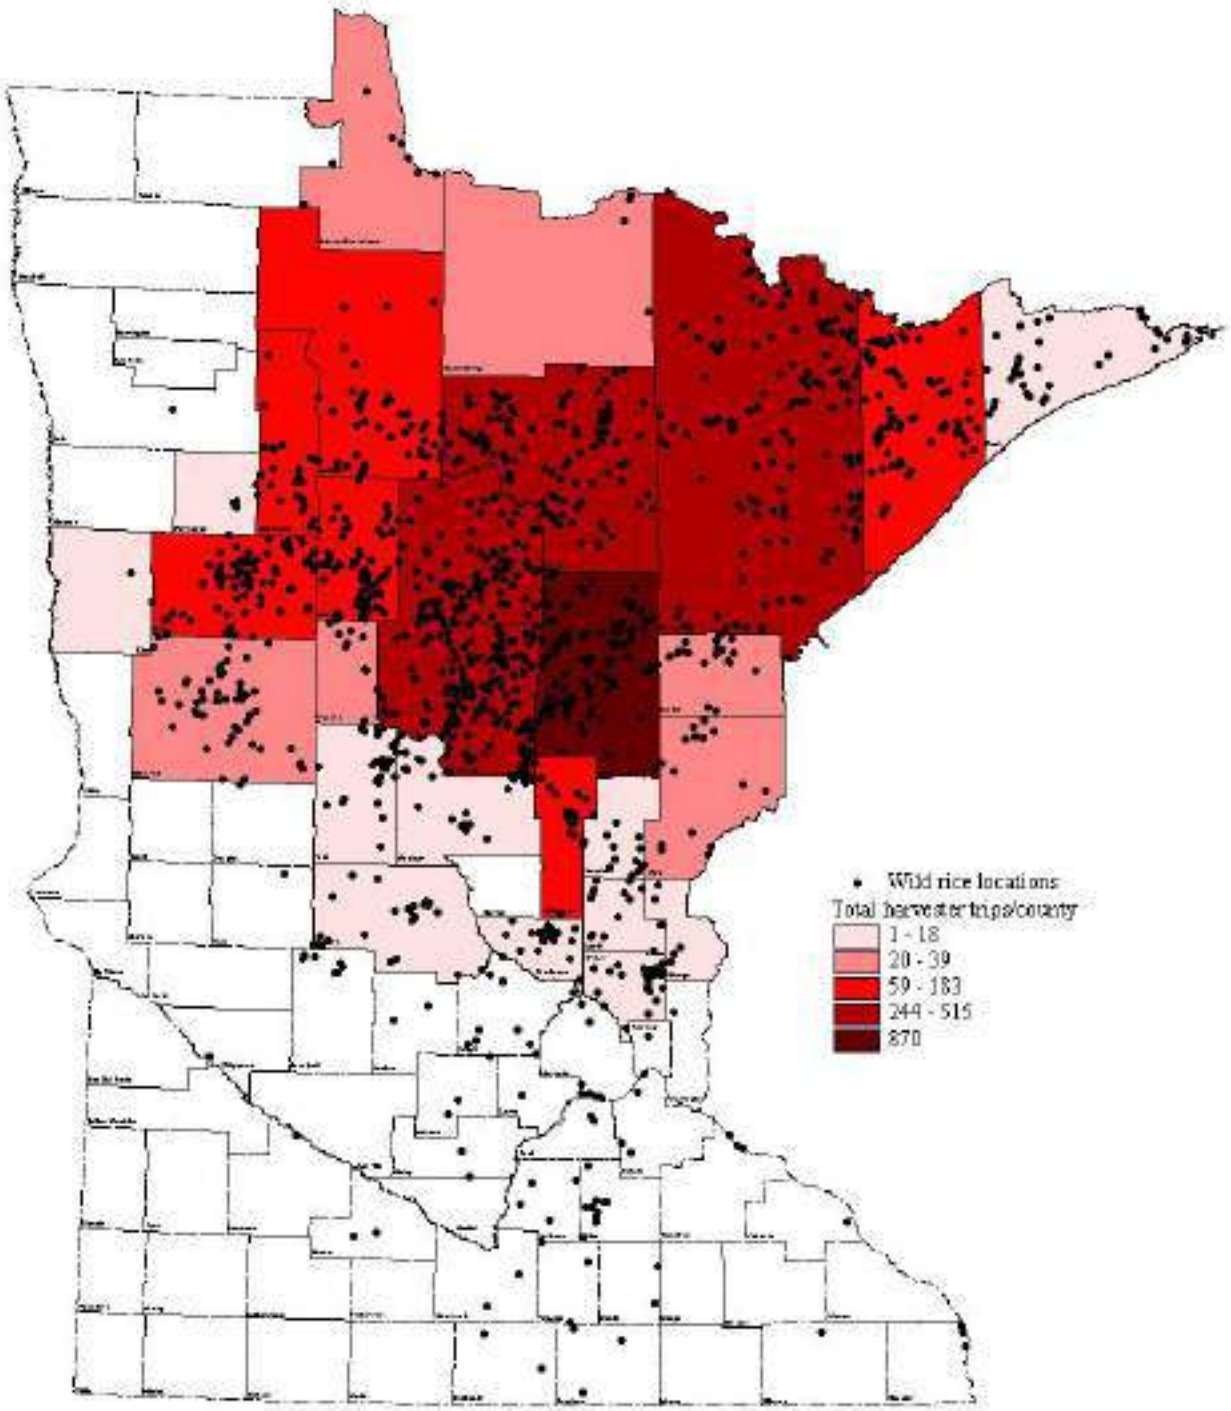

Figure 1. Distribution of wild rice lakes and wild rice harvesting pressure in Minnesota.

Stands of natural wild rice were present or occurred in recent history on approximately 1,286 lakes and river/stream segments (Figure 1). These areas support a minimum of 64,328 acres of natural wild rice when growing conditions are favorable. These areas vary from large, shallow lakes dominated by natural wild rice stands (i.e. Nature's Lake in Cass County) to significant bays within large fish lakes (i.e. Leech Lake) to a narrow fringe along lake/river shorelines. The greatest concentrations of lakes that support natural wild rice are in Aitkin (4,859 acres), Cass (8,323 acres), Crow Wing (3,751 acres), Itasca (8,448 acres), and St. Louis (8,939 acres) counties. These counties contain over 60% of the inventoried natural wild rice acreage in Minnesota. These counties also account for over 70% of the harvesting trips for natural wild rice (MNDNR 2006 harvest survey, Appendix C).

The abundance of natural wild rice in Minnesota today is largely due to abundant suitable habitat, favorable climate, and natural genetic variability that allows for environmental selection of traits that perform well under varying conditions. Studies in Wisconsin found sufficient genetic diversity between geographically separated stands of wild rice to potentially identify regional populations. Within-stand diversity also varied greatly, with larger and denser stands having greater genetic diversity (Waller et al. 2000).

Life History

While the historical range of natural wild rice illustrates its broad distribution, its specific occurrence and abundance is in large part dependent on local environmental conditions. For example, clear to moderately colored (stained) water is preferred, as darkly stained water can limit sunlight and may hinder early plant development.

Wild rice grows within a wide range of chemical parameters (i.e. alkalinity, salinity, pH, and iron; Meeker 2000). However, productivity is highest in water with a pH of 6.0 to 8.0 and alkalinity greater than 40 ppm. While researchers have observed that natural wild rice stands are relatively nutrient rich, excess levels of some nutrients, especially phosphorus, can have significant adverse effects on productivity (Persell and Swan 1986).

Natural wild rice generally requires some moving water, with rivers, flowages, and lakes with inlets and outlets being optimal areas for growth. Seasonal water depth is critical, however. Water levels that are relatively stable or decline gradually during the growing season are preferred. In particular, abrupt increases during the early growing season can uproot plants. Wild rice grows well at depths of 0.5 to 3 feet of water, although some plants may be found in deeper waters (M. McDowell, J. Persell personal communication).

Shallower sites can allow strong competition from perennial emergent plant species, while deeper sites can stress wild rice plants and limit seed production. Although wild rice may occur in a variety of lake bottoms, the most consistently productive stands are those with soft, organic sediment (Lee 1986). Nitrogen and phosphorus are limiting nutrients for wild rice (Carson 2002).

As an annual plant, natural wild rice develops each spring from seeds that fell into the water and settled into the sediment during a previous fall. Germination requires a dormancy period of three

to four months of cold, nearly freezing water (35° F or colder). Seeds are unlikely to survive prolonged dry conditions.

Seed germination typically occurs when the substrate and surrounding water temperatures reach about 40° F. Depending on water depth, latitude, and the progression of spring weather, wild rice germinates in Minnesota sometime in April, well ahead of most but not all perennial plants. Within three weeks, the seedlings develop roots and submerged leaves.

The emergent stage begins with the development of one or two floating leaves and continues with the development of several aerial leaves two to three weeks later. The floating leaves appear in late May to mid June in Minnesota, again dependent on water depth, latitude, and weather. Because of the natural buoyancy of the plant, it is at this stage of growth that wild rice is most susceptible to uprooting by rapidly rising water levels. Plants can be significantly stressed even when they remain rooted.

Natural wild rice begins to flower in mid to late July in Minnesota. Flowering times are dependent on both day length and temperature. Flowers are produced in a branching panicle. Female flowers (pistillate or seed-producing) occur at the top of the panicle on appressed branches. Male flowers (staminate or pollen-producing) occur on the lower portion of the panicle on nearly horizontal branches. Natural wild rice is primarily pollinated by wind. High temperatures and low humidity can negatively affect fertilization rates.

Cross-pollination is typical in natural wild rice stands because female flowers develop, become receptive, and are pollinated before male flowers on the same plant shed pollen. Cross-pollination is further enhanced by plant-to-plant variation in flowering times within stands. This cross-pollination within and among wild rice populations helps to preserve the genetic variability and thus biologic potential for wild rice to adapt to changing conditions such as the highly variable climate of the Great Lakes region.

The genetic variability that exists today in natural wild rice may be a critical determinant of whether stands of wild rice can adapt to long-term changes in regional climate. Studies in northern Wisconsin found sufficient genetic diversity among geographically distinct stands of natural wild rice to identify four regional populations. The degree of diversity within stands varied widely as well, with larger and denser stands having greater diversity (Waller et al. 2000).

Wild rice seeds are visible two weeks after fertilization, and they mature in four to five weeks. Immature seeds have a green outer layer that typically turns purplish black as the seed reaches maturity. Seeds begin ripening at the top of the stem and then ripen over several days on an individual plant. Plants within a stand ripen at different times because of genetic and developmental variation. In general, natural wild rice in rivers ripens earlier than that in lakes, rice in shallow waters earlier than that in deeper waters, and rice in northern Minnesota earlier than that in more southerly stands.

This staggered maturation process means that ripe seeds may be available within individual stands for several weeks, and across the entire range of natural wild rice in Minnesota for a month or longer. This extended period of “shattering”, or dropping of ripened seed, is an

important mechanism to ensure that some seeds will survive environmental conditions and perpetuate the natural stand. The entire process, from germination of a new plant to dropping of mature seeds, requires about 110 to 130 days, depending on water and air temperatures and other environmental factors.

Not all wild rice seeds germinate the following year. Seeds may remain dormant in the bottom sediment for many years to several decades if conditions are not suitable for germination. This mechanism allows wild rice populations to survive through years of high water levels or storms that reduce or eliminate productivity. Moreover, natural wild rice can germinate and re-colonize sites after other species have been reduced or eliminated by environmental disturbance (Meeker 2000).

Even under ideal growing conditions, populations of natural wild rice undergo approximately three to five year cycles in which productivity can vary greatly (Jenks 1900, Moyle 1944b, Pastor and Durkee Walker 2006, Durkee Walker et al. 2006). Highly productive years are frequently followed by a year of low productivity, that is then followed by a gradual recovery in wild rice yield (Moyle 1944b, Grava and Raisanen 1978, Atkins 1986, Lee 1986, Aiken et al. 1988, Archibold et al. 1989).

Recent studies suggest that oscillations in wild rice productivity may be caused in part by the accumulation of old straw from previous growth that inhibits plant growth and seed production (Pastor and Durkee Walker 2006, Durkee Walker et al. 2006). In particular, the amount of wild rice straw, its stage of decay, and its tissue chemistry likely affect nutrient availability, influence wild rice productivity, and thus drive cycling of wild rice populations (Durkee Walker, Ph.D. thesis 2008).

Legal Considerations

The earliest laws and regulations concerning wild rice in Minnesota date back more than 75 years. While some harvesting regulations existed through earlier session laws and statutes, comprehensive state regulation of the wild rice harvest was apparently first codified in 1939. These regulations controlled methods and locations of harvest to reduce damage to natural beds and to distribute the harvest.

Today, there is a complex mix of tribal, federal, state, and local laws and regulations. These are associated with the formal recognition of the significance of natural wild rice and its protection, management, and harvest. It is difficult to capture all the important details that exist within these myriad regulations in a summary overview. The application of regulations varies by jurisdiction (i.e., tribal versus state) and geography (i.e., on-reservation versus off-reservation, or within various ceded territories). In addition, some regulations may be changed over time.

The following discussion is not intended to provide a complete legal brief of the law as it relates to natural wild rice. Rather the intent is to indicate the complexity of this law and to make clear the multiple jurisdictions that have recognized legal interests in Minnesota wild rice.

Treaties and Tribal Regulations

Tribal regulations of the harvest and protection of wild rice within reservation boundaries vary from tribe to tribe. Therefore individual tribal governments or their natural resource departments should be contacted for details.

In addition to tribal regulations, treaties and other agreements with the U.S. government reserved off-reservation harvesting rights for some tribes. For example, the Ojibwe tribes that co-signed the Treaty of 1837 reserved the right to gather wild rice from the lands ceded in that treaty. These include an area that eventually became part of east-central Minnesota. The standing of these off-reservation rights was upheld by the U.S. Supreme Court in 1999. [1,2,3]

Similar off-reservation rights are reserved for other Ojibwe tribes in the 1854 ceded territory, in northeastern Minnesota. Rights of traditional tribal harvesting have also been preserved through other agreements between tribes and the U.S. government. For example, in the early 1900s the U.S. began buying lands adjacent to wild rice stands on Minnesota lakes. These were stands that had traditionally been harvested or lands that were to be used as rice camps by the Minnesota Chippewa Tribe (MCT). Lands were purchased and placed into trust status on Swamp, Mallard and Minnewawa Lakes in Aitkin County; on Basswood Lake in Becker County; on Leech, Mud, and Laura Lakes in Cass County; on Lower Dean Lake in Crow Wing County; on Sugar and Bowstring Lakes in Itasca County; on Onamia and Ogechie Lakes in Mille Lacs County; and on Star Lake in Ottertail County.

MCT members can harvest wild rice on these lakes with a tribal identification card issued under the sovereign authority of their respective tribal governments and current Minnesota statute (MS 84.10). Similarly, local tribal members can harvest wild rice on Rice Lake National Wildlife Refuge and on Tamarack National Wildlife Refuge under the 1936 Collier agreement between the U.S. Bureau of Indian Affairs and Bureau of Biological Survey (predecessor to the U.S. Fish and Wildlife Service).

This Wild Rice Study document is not intended to provide an indepth analysis of treaties and subsequent agreements affecting tribal harvest of wild rice in Minnesota. Tribal governments have sovereignty over the harvest of wild rice within the boundaries of their reservations. Some tribal governments also have the authority to regulate harvest by tribal members within certain ceded lands, while other tribal rights exist for specific off-reservation waters. The state of Minnesota has jurisdiction over the wild rice harvest by nontribal harvesters within ceded territories and over all off-reservation wild rice harvest outside of the ceded lands.

[1,2,3][Minnesota, et al., Petitioners v. Mille Lacs Band of Chippewa Indians et al. [No. 97-1337].

[2] See McClurken et al., 2003: 30 for a map of ceded lands in Minnesota under this and subsequent treaties.

[3] See McClurken et al., 2003: 486 for exact treaty language pertaining to cession of land and gathering wild rice.

State and Local Regulations

State laws addressing issues of wild rice in Minnesota date back to 1929 or perhaps earlier. These statutes state that wild rice and other aquatic vegetation is owned by the state and that a person may not acquire a property interest in or destroy wild rice except as allowed by law (MS 84.091). State statutes also regulate the harvest of natural wild rice with the exceptions of tribal jurisdictions and regulations, as noted above (MS 84.10, 84.15, 84.027, 84.28). State regulations address the methods and timing of natural wild rice harvest (MS 84.105, 84.111, and 84.152). In addition, several Agency rules also govern the harvest of wild rice in Minnesota (Minnesota Rules 6284.0300 to 6284.0700).

Because State statutes and rules affecting wild rice in Minnesota have been developed and modified over many years, they contain inconsistencies and duplications. These laws could be clarified and made more concise through recodification.

A long-standing tradition of tribal governments and the state of Minnesota involved posting of "closed" signage on selected individual lakes until the wild rice was deemed ripe for harvest. In 1996, after years of criticism from harvesters about particular decisions to open or close wild rice stands, a state law was passed that would open the ricing season on July 15 each year (MS 84.105). The new law also made it illegal to pick wild rice that is not ripe. Wild rice usually ripens in Minnesota between the third week of August and the second week of September, thus the new law was intended to employ a "pick when ripe" philosophy. The opening date was set early enough so that it would always precede the ripening of the rice, and it would also help avoid opening day rushes that can potentially damage rice stands.

One of the rationales behind the new state law was that most other plant products harvested from the wild are picked when the harvester judges them as ready for food, decorative, or medicinal use. Harvesting wild rice before it is ripe produces a product that has no value as a food or cash crop. The new law reduced the need for extensive MNDNR staff time and subjective judgments. It also helps avoid the opening day "stampede" that seems to be associated with all "opening days", which are often perceived as the best day based on "first-come, first-served".

Most of the treaties, agreements, and statutes discussed above are concerned with the harvest of the wild rice grain rather than with protection or enhancement of natural wild rice ecosystems. Harvest issues are moot if the wild rice resource is lost due to damage of natural stands. The viability of these stands often depends on active management.

For example, more than 200 wild rice lakes benefit annually from removal of beaver dams. These dams block the outlets of significant wild rice lakes, and their removal allows the outlets to flow freely; reducing the threat of excessive flooding of wild rice stands. The authority to remove beaver, beaver dams, and beaver lodges is found in MS 97A.045 Subd.1; 97A.401 Subd. 5; and 97B.655, Subd. 2. Without these statutes the current management efforts of the DNR and its partners (i.e., Ducks Unlimited) would be significantly restricted.

Wild rice and other aquatic plants are protected from unauthorized removal under the MNDNR Aquatic Plant Management Program (MS 103G.615). Guidelines prohibit the removal of

emergent aquatic plants, including wild rice, without an approved permit. Notable exceptions involve the building of duck hunting blinds and gaining access to open water from shorelines. Removal of aquatic plants is allowed for such access though removal is limited to an area 15 feet or less in width.

Less direct, although important, protection is also provided through shoreland protection laws and regulations (MS 103F.201 through 103F.221). This protection is based on a system of classification for lakes and rivers that applies different zoning regulations depending on classification. Classifications include three for lakes and six for rivers. These regulations are implemented by local units of government within a statewide statutory framework that dictates minimum standards. These standards address issues of shoreland development and uses such as sewage treatment, storm water management, minimum lot size and water frontage, building and septic system setbacks, building heights, subdivisions, and alterations of land and vegetation close to the shore.

The stakeholders group for a pilot project in the five-county north-central lakes area surrounding Brainerd raised concerns about increased shoreline development potentially threatening water quality and the traditional use of individual lakes. One result was the development of alternative shoreland management standards through an advisory committee. The alternative standards provide options for local governments to address specific shoreland issues identified in the five-county area. Subsequently, local governments outside the pilot area began considering elements of these alternative standards for use in their own shoreland ordinances.

In 2005, for example, Beltrami County initiated a review of all of their Natural Environment Lakes in cooperation with the MNDNR and Minnesota Pollution Control Agency (PCA). The MNDNR Section of Wildlife and Division of Ecological Resources procured funding to hire two 2-person crews to conduct site visits to inventory these lakes. Surveys were completed with additional funding from the MNDNR Section of Wildlife in 2006. As a result of this work and the input from a Citizen Advisory Committee, Beltrami County rewrote their shoreland ordinance and reclassified their Natural Environment Lakes. They created one additional lake class, Sensitive Area, with protection criteria intermediate between Natural Environment and the more protective Special Protection. The new Beltrami County Shoreland Ordinance was voted on and approved by the Beltrami County Board in December 2006 (R. Gorham personal communication).

Alternative shoreland management standards may include the promotion of conservation subdivisions over conventional subdivisions (i.e., lot and block); multiple classifications on a single lake (i.e. Natural Environment bay within a General Development lake); districts designated as Sensitive Areas for lakeshore segments so that development standards follow Natural Environment Lake class standards; and a new classification of Special Protection for lakes that have considerable wetland fringe, shallow depth, or unique fish and wildlife habitat.

While these alternative standards can provide protection for natural wild rice habitat, local governments too often lack information on the locations of significant stands of natural wild rice. An updated inventory of wild rice stands in Minnesota would help provide this information.

Further regulation of wild rice occurs through the Minnesota Department of Agriculture (MDA). The MDA has approval authority over the permit-regulated release of genetically modified organisms (GMO), which would include genetically engineered wild rice, under MS Chapter 18. MS Chapter 18 also provides for the issuance of export certificates for the international sale of wild rice. In addition, the MDA inspects and certifies that wild rice seed is free of weed contamination and meets germination standards, and that the labeling of packaged wild rice is truthful and accurate (MS Chapter 21).

The 2006 Minnesota Legislature provided the state Environmental Quality Board (EQB) additional authority over issues related to natural wild rice. The EQB is now required to notify interested parties if a permit to release genetically engineered wild rice is issued anywhere in the United States (MS 116C.92, Subd. 2). The 2006 legislation also requires that EQB adopt rules requiring an Environmental Impact Statement (EIS) for any proposed release and a permit for an actual release of genetically engineered wild rice (MS 116C.94 Subd.1b).

While two other State statutes further signify the importance of natural wild rice in Minnesota, they do not provide additional protection for the resource. One statute, adopted in 1977, recognizes wild rice as the State Grain of Minnesota (MS 1.148). This law needs to be amended, however, to accommodate revised scientific nomenclature.

Another important State statute is the labeling law for packaged wild rice (MS 30.49). This was adopted in 1989 following a joint effort between tribal governments and the Minnesota Cultivated Wild Rice Council. Consumers of wild rice benefit from this law in that it distinguishes among natural lake or river wild rice that is hand-harvested, wild rice that is machine-harvested, and wild rice that is cultivated. This legislation further distinguishes between wild rice that is grown in Minnesota and that which is grown outside of the state.

Threats to Natural Wild Rice in Minnesota

Despite its rich history and abundance in Minnesota, natural wild rice faces many current and potential threats in this region. In general, any factor that can affect water quality, seasonal water levels, lakebed conditions, regional climate, aquatic vegetation, or wild rice's natural genetic makeup could potentially threaten stands of natural wild rice. These threats may work in concert or individually to damage wild rice stands. The order in which the threats are presented in this report is not intended to portray or imply the significance of the threat. Instead these threats are divided into stand level or statewide level categories.

Stand-Level Threats

Hydrologic Changes

Wild rice is by its very nature a shallow water plant and sensitive to changes in water levels. The status of natural wild rice in Minnesota was particularly threatened in the late 1800s and 1900s by installations of dams to increase water levels for navigation, logging, flood control and power production. Although wild rice may persist at depths greater than three feet, these plants typically have poor or no seed production. Over time the plants will decline in numbers and density (Engel 1994). Although some aquatic plants will readily migrate to newly created shallow waters, wild rice apparently does so much less frequently. This may be due to limitations on its rate of seed dispersal.

Even when the normal runout elevation of a lake remains steady, heavy precipitation can cause an abrupt though temporary change in water level that can uproot aquatic plants. Natural wild rice is particularly susceptible to uprooting during its floating-leaf stage, which occurs in early summer. At this stage, any rapid increase in water level can cause damage to natural stands. Changes in lake outlets that reduce flow capacity can also significantly impact wild rice by increasing the frequency and severity of these temporary flood events. For example, permanent dams, beaver dams, culverts, and debris such as mats of vegetation can reduce outlet flow capacity and impact wild rice habitat (Ustipak 1983).

These factors can work in concert to produce cumulative effects. For example, culverts can attract beaver because the culvert is a much more restricted area than the creek or riverbed which channels through it. The roadbed often associated with culverts acts as a ready made dike that further contributes to the ease of blockage. As another example, dams and other outlets can be plugged by vegetation such as floating bogs that break loose in high winds. The effect of the dam in reducing outflows is compounded by the blockage raising water levels and increasing the probability of additional bog breaking off.

Changes in upstream watersheds can also reduce the productivity of natural wild rice stands. Drainage ditches and tiles, pumps, and channelization can increase the quantity and speed of waters moving downstream. The resulting peaks in water levels can produce the same effects as reduced outlet capacity by creating abrupt "bounces" or rapid increases in water depth. Increased sedimentation caused by drainage and channelization can also bury seeds and reduce germination.

Increased sedimentation can also increase the height of runout elevations and reduce outlet capacity. These changes can cause long-term damage to natural wild rice stands. The situation is acerbated by the installation of artificial dams. Removing the natural flushing action at outlets causes sediment to accumulate more readily (R. Ustipak, personal communication).

Dams that maintain stable water levels can have long-term deleterious effects on natural wild rice, as well. Water levels that are held stable year after year can create conditions that favor perennial vegetation and shoreline encroachments that impair wild rice habitat.

Recreational Water Use and Shoreland Development

Natural wild rice represents different things to different people. While some consider this native aquatic grass to be a nuisance, others value it greatly as a spiritual entity or as prime habitat for fish and wildlife.

Minnesota is a national leader in numbers of recreational boaters and anglers, with approximately 862,937 registrations for recreational watercraft. Although wild rice provides habitat for spawning fish and their offspring, stands of wild rice can be very frustrating for anglers to fish. Recreational boaters often consider wild rice to be a nuisance because it can be difficult to motor through. The strong stems of erect plants are easily tangled in propellers and may require removal by hand, often by forcibly cutting the tightly wrapped stems.

As a result, wild rice plants are often removed by boaters near docks, in navigational channels, and in other high-use areas. Removal can be direct or incidental due to cutting by propellers or dislodging by excessive wave action (Asplund 2000, Tynan 2000).

As the human population increases, so will the number of boaters. Predictions of demographic changes in Minnesota suggest that the areas of greatest population increases over the next 20

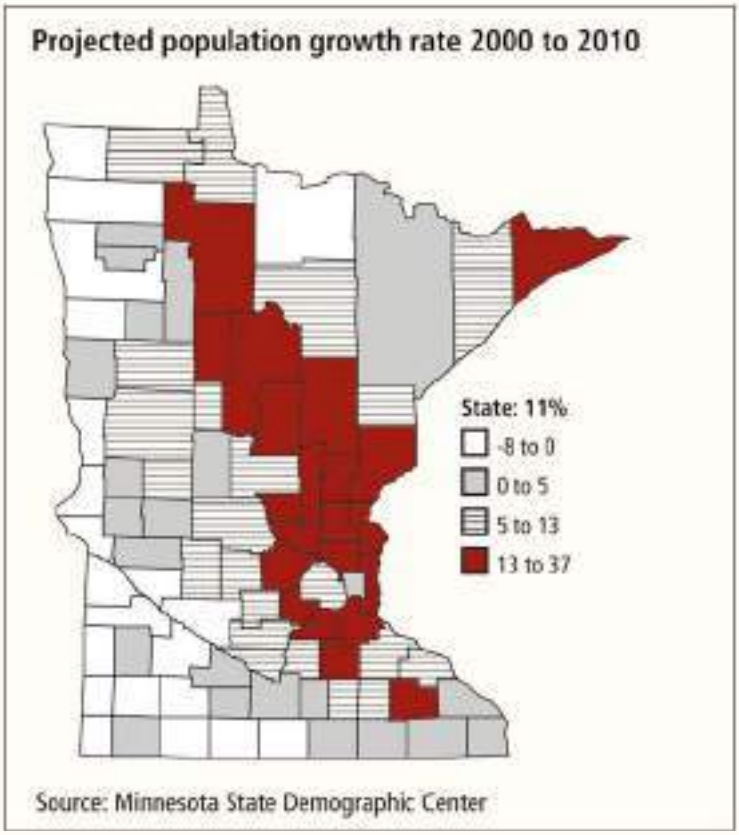

Figure 2. Greatest predicted population growth will occur within the primary range of wild rice in Minnesota.

years will include those counties that currently have the highest occurrence of natural wild rice (Figure 2, Minnesota Department of Administration 2007).

The damming of lakes to enhance recreational water use often corresponds with the increased development of shorelands. Shoreland development has increased dramatically in Minnesota, especially in those counties that include the greatest amount of habitat for natural wild rice. This development is often associated with installations of docks, removal of aquatic vegetation, and increases in nutrient-rich runoff.

Seasonal housing across the lake country of the upper Midwest jumped 500% during the past twenty years (United States Forest Service 2007). As lands bordering deeper lakes become more fully developed, prospective lakeshore buyers are increasingly considering lakes that are shallower, often well-vegetated, and more likely to support wild rice habitat.

The changing pattern of forestland ownership in Minnesota is adding to development pressure. Internationally-owned timber corporations are increasingly divesting of their land holdings as part of their fiscal management strategy. These lands have previously been managed somewhat as public lands and have been protected from development. However, as market values increase for shorelands and riparian areas, corporate stockholders are increasingly interested in selling these parcels. About seven million acres of forestland in Minnesota is privately owned, and predictions are that about one million of these acres may be sold for development (Myers 2006).

Such development often accompanies major changes in shorelines and near-shore vegetation (Radomski and Goeman 2001). Natural wild rice is often viewed only as a nuisance to boaters and other lakeshore users. Few shoreland owners consider the cumulative impacts of docks, vegetation removal, dredging, and runoff.

Although known violations of MNDNR Aquatic Plant Management permits do not always indicate which vegetative species were removed, wild rice is a common target where it occurs. A recent permit violation included the removal of 600 feet of natural wild rice from the shoreline of Upper Whitefish Lake in Crow Wing County. The violator was a new landowner who explained that the plants were an “eyesore”.

Wildlife Activity

Natural stands of wild rice provide excellent habitat for wildlife such as waterfowl and aquatic furbearers. The activities of these animals generally have minimal impact on wild rice stands. Although animals use plant stems for building overwater bird nests and muskrat houses, this activity usually affects only small areas. Moreover, wildlife activity often enhances overall aquatic habitat by creating stand diversity.

An exception to this is when beaver use wild rice stems and other vegetation to plug outlets. The resulting dam increases overall water levels and the probability of damage to natural stands by uprooting wild rice plants.

Birds generally have little impact on natural wild rice. For example, blackbirds, waterfowl and other birds can consume most of the ripening wild rice grain yet still leave more than 200 seeds per square foot (Haramis and Kearns 2004). Canada geese, though, can seriously damage stands of wild rice by grazing on emerging stems. For example, researchers monitored tidal marshes along the Patuxent River in Maryland and documented the loss of existing stands of wild rice due to season-long grazing by the geese (Haramis and Kearns 2004).

Although currently not common in Minnesota, some damage to rice stands has been attributed to Canada geese. High concentrations of geese on small lakes or impoundments have eliminated wild rice crops in some years through overgrazing of the emerging stems (R. Naplin and D. Rhode, personal communication). However, ongoing management of resident populations of Canada geese in Minnesota can limit this type of depredation through increased harvest levels . By contrast, shoreline development that converts communities of native vegetation to managed lawns can result in locally concentrated populations of geese that then may overgraze adjacent wild rice stands.

The effect of trumpeter swans on natural stands of wild rice is less clear. Populations of these native birds are slowly recovering after extirpation in the 1800s from most of their range. Anecdotal reports suggest that swans can damage natural stands of wild rice in particular areas (P. David and R. Naplin, personal communication). Nevertheless, low numbers of trumpeter swans combined with a preference for submergent vegetation suggest that these birds pose a minimal threat to natural wild rice (LaMontagne 2000, Norrgard 2006).

Some non-native species of wildlife do threaten stands of wild rice. These will be discussed below (Non-native Invasive Species section).

Plant Competition

Natural wild rice must compete for space, light, and nutrients with other aquatic plants, particularly perennial species (Rogosin 1951). Competitive species include submerged pondweeds (primarily *Potamogeton* L. spp.), floating leaved plants such as waterlilies (*Nuphar* J.E. Smith and *Nymphaea* L. spp.), and emergents such as cattail (*Typha* L. spp.) and pickerelweed (*Pontederia cordata* L.). Seasonal water levels play an important role in this competition (Meeker 2000). Natural wild rice may be favored at depths of one to two feet.

Pickerelweed may be an exception in at least three locations in Minnesota where ongoing management to benefit wild rice also found pickerelweed increasing significantly (N. Hansel-Welch, personal communication). Promising management responses have included lowering water levels in winter to freeze and desiccate pickerelweed roots, and cutting competitive species during spring and summer using airboats (McDowell, 2006) or harvesting machines (T. Howes, personal communication). However, maintaining stable water levels over many years may favor other species (D. Vogt, personal communication). Perennial species such as pickerelweed can establish footholds and thus gain the advantage in lakes that are maintained at constant levels. .

The seeds of natural wild rice can remain dormant for years until conditions are more favorable for germination. This trait allows rice to maintain long-term viability through years of low

productivity. Natural wild rice is well-adapted to annual fluctuations in water levels, while other species may be less suited to such changes.

Strong competition among native aquatic plants appears to be localized and specific to individual stands. It does not appear to be a significant factor limiting the distribution or abundance of natural wild rice in Minnesota (Meeker 2000, Norrgard 2006).

Mining and Other Industrial Activity

Mining and industrial activities can potentially adversely affect stands of natural wild rice. For example, this can occur when hydrology is altered in watersheds that support natural wild rice. Alterations can result from the pumping and dewatering of sites. This increases downstream flows (discussed earlier in Hydrologic Changes section) and subsequent depressions in groundwater in surrounding areas. The potential effects of groundwater depression are not well understood. Water levels in basins with higher gradients could be sufficiently lowered to cause shallow areas inhabited by wild rice to dry out.

Other adverse effects can result from the release of chemicals such as sulfate from mine pits and tailings. These chemicals can negatively affect wild rice as well as other plant and animal species in the area. Seepages from tailings can exceed the state established water quality criteria of 10 mg/L for wild rice waters. For example, sulfate has been measured at 1,000 mg/L in these seepages (Udd 2007). State agencies are working with mining companies to decrease sulfate concentrations in discharge waters. Tribal governments express strong concern over the cumulative impacts of the many historic, currently operational, and planned mines in northeastern Minnesota.

Statewide Threats

Loss of Natural Genetic Characteristics

The cultural, ecological, and economic value of natural wild rice distinguishes it as a unique natural resource in Minnesota. There is strong agreement among stakeholders that it is critically important to maintain the natural genetic diversity of natural stands of wild rice (Porter et al. 2000, LaDuke and Carlson 2003). This importance reflects an understanding of spiritual and cultural values, biological and ecological principles, and agricultural and economic realities.

Natural population diversity provides wild rice the ability to adapt to changing environmental conditions such as annual variations in temperature and precipitation. Maintaining natural genetic diversity provides the best chance for any species to survive variations related to global warming, for example (BSU-CRI 2007). Ongoing analyses continue to support the position that managing for high biodiversity will best insure the survival of plant and animal communities that have characterized the Great Lakes region for thousands of years.

The flower structure and timing of maturation of wild rice promotes cross-pollination within and among stands. Wind pollination further insures genetic diversity. Genetic variability allows for the natural selection of traits that perform best under different environmental conditions. Studies

in Wisconsin found sufficient genetic diversity between distinct stands of natural wild rice to identify potentially distinct regional populations. The degree of diversity within the stands also varied widely, with larger and denser stands being most diverse (Lu et al. 2005, Waller et al., 2000). The degree of genetic variability within and among natural stands of wild rice in Minnesota is not known. Thus our ability to recognize changes in the genetics of natural wild rice in this region is limited.

Although some studies of wild rice pollen travel have been conducted (Cregan 2004), more research is needed to understand the potential for genetic transfer among natural and cultivated stands. Drift of wild rice pollen may exceed that of other cultivated crops due to the small size of the pollen and its relatively slow settling rate (P. Bloom, personal communication). In addition, a study in Canada has provided evidence that wild geese, and perhaps ducks, can be important transporters of pollen to lake sediments (McAndrews et al. 2007). This raises the possibility that waterfowl may also serve as transporters of viable pollen.

Another means of introducing new genotypes into local populations is the intentional seeding of wild rice to restore historical sites or to develop new stands. Such plantings have a long history in Minnesota. For example, the demand for seeds of wild rice and other native plants helped to establish businesses such as Wildlife Nurseries, Inc. in 1898, in Oshkosh, Wisconsin (Oelke 2007). However, the risks associated with introducing nonlocal genes into local native gene pools are of increasing concern to many scientists (Maki and Galatowitsch 2004).

Plant breeding programs have developed strains of wild rice suitable for commercial production (Oelke 2007). Consistency in plant morphology, control of shattering, and disease resistance have been important objectives of these programs. Because wild rice pollen is airborne, some have expressed concerns about unplanned cross-pollination between cultivated stands and natural stands. At this point in time, however, traditional wild rice breeding programs are not thought to pose a threat to natural stands since the cultivated varieties reflect the selection of genes from within the naturally occurring gene pool (R. Porter, personal communication).

There have been concerns expressed about the potential impact of transgenic engineering. The dramatic increase in use of this technique to alter food crops has been followed by questions concerning its safety, economic losses, potential impact on the natural environment, regulatory framework and compliance, and the ability to mediate unplanned releases. One of the driving forces behind these concerns is evidence that current gene containment practices cannot achieve absolute protection from unwanted pollination (Thai 2005). The unplanned cross-pollination between cultivated crops such as creeping bentgrass and wild relatives has fueled the concerns of both environmentalists and agricultural producers (Haygood et al. 2003, Weiss 2006).

These concerns are evident in the international guidelines for sustainable forest management developed by the Forest Stewardship Council (FSC). The state of Minnesota has actively sought certification of its public forestlands under the Regional Forest Stewardship Standards published by the council. These standards specifically prohibit the use of genetically modified organisms within certified forests (Minnesota Forest Resource Council 2004).

While there are no known research programs in any country to produce transgenic varieties of wild rice (R. Phillips, personal communication), DNA of wild rice has been transferred to white rice (Abedinia et al., 2000). The very possibility of transgenic engineering wild rice generates deep cultural, economic, and ecologic concerns. These include issues surrounding Native American rights, food safety and nutritional value, protection of economic markets, patenting of species, and protection of natural resources that already face significant threats (LaDuke and Carlson 2003).

This controversy ultimately relates to differing worldviews and the valuation of risk and consequences. For some stakeholders, there is no level of acceptable risk. For others, the potential benefits of genetically engineered wild rice may be worth the possible consequences of escaped transgenic traits. A thorough analysis of the cultural, economic, and ecological consequences of genetic contamination of natural wild rice in Minnesota is required to assess potential impacts.

Transgenic alterations of some U.S. crops will likely continue for the foreseeable future. Traditional plant breeding will also continue. A better understanding of the natural genetic variability of wild rice in Minnesota would increase our understanding of the potential impacts of these activities. Efforts to restore native wild rice to its historical range should be encouraged. Studies of the natural variability and ecological requirements of natural wild rice in this region would enhance these efforts.

Non-native Invasive Species

Non-native invasive species impact every aspect of natural resource management in Minnesota. Protecting and managing natural stands of wild rice is no exception. The movement of watercraft from one wild rice lake to another creates the potential for transfer of invasive animals and plants.

The common carp (*Cyprinus carpio*) leads the way in historical presence and impact. Common carp feed primarily on invertebrates in bottom soils. Their feeding action dislodges plants and suspends fine particles into the water column. The increased turbidity, caused both by disturbed sediments and by algae stimulated by the phosphorus released from disturbed sediments, shades out aquatic plants. Turbidity then increases as non-vegetated lake bottoms are disturbed by wind. The reduction in aquatic vegetation also allows for increased boat traffic and wave action that can further dislodge plants such as wild rice (Pillsbury and Bergey 2000).

Natural stands of wild rice are negatively impacted by turbid conditions during early stages of growth and by disturbances to bottom soils and boat traffic in later stages. The common carp is primarily a problem today in southern Minnesota, where the species occurs in high densities. Carp likely contributed to the loss of natural wild rice from its historic range in this region (Norrgard, 2006). If the predicted changes in climate in northern Minnesota result in warmer waters, carp could achieve higher densities in that region and cause significant damage within the core of prime habitat for natural wild rice.

The non-native rusty crayfish (*Orconectes rusticus*) can directly impact wild rice by cutting stems of the plant. Although the extent of this depredation in Minnesota is not known, significant impacts of native crayfish on cultivated wild rice have been documented (Richards et al. 1995). Native to parts of some states in the Great Lakes region, rusty crayfish have invaded portions of Minnesota, Wisconsin, and Ontario, including areas that are important for wild rice. Rusty crayfish frequently displace the native crayfish, reduce the diversity and abundance of aquatic plants and invertebrates, and reduce some fish populations (MNDNR 2007).

Rusty crayfish were first documented in Minnesota in 1967, at Otter Creek in southern Minnesota. Twenty years later, a statewide survey documented their presence in many areas (Helgen 1990). To date, rusty crayfish have been found in 31 lakes and streams in 11 counties. They prefer areas where rocks, logs, or other debris provide cover. Preferred sediment types include clay, silt, sand, gravel, and rock. The soft organic sediments usually favored by wild rice do not seem to be favored by rusty crayfish and may help minimize their impact.

The non-native mute swan (*Cygnus olor*) can seriously threaten the sustainability of natural wild rice stands (P. Wilson, personal communication). To date, Minnesota has limited the number of these birds to only a few that are held in captivity. With continued efforts to identify free-ranging non-native swans and to respond rapidly with control measures, their impact on natural wild rice in Minnesota could be minimal.

Invasive plants such as purple loosestrife (*Lythrum salicaria* L.), curlyleaf pondweed (*Potamogeton crispus* L.), and Eurasian water milfoil (*Myriophyllum spicatum* L.) occur throughout much of the range of natural wild rice. Although these species may prefer water depths that do not favor wild rice, more research is needed to better understand the potential for competition. It is known that these invasive species can disrupt local aquatic ecosystems and lower habitat quality overall. However, it is also important to monitor the mechanisms of control to insure that these do not have unintended effects on natural wild rice.

Hybrid cattail (*Typha* x *glauca*), a cross of native and non-native cattail (*Typha latifolia* L. and *Typha angustifolia* L., respectively), competes directly with natural wild rice for shallow-water habitat. These plants aggressively form thick mats of roots that can float as water levels fluctuate. The bog-like mats expand across areas of shallow water and can plug lake outlets when broken off and blown by high winds.

Native sedge bogs often border wild rice lakes in northern regions. These bogs are increasingly being invaded and eventually dominated by hybrid cattails. High infestations of hybrid or non-native cattails near lake outlets can increase rates of sedimentation. This, in turn, can combine with the additional plant material to further decrease outlet capacity (R. Ustipak, personal communication).

A relatively new threat to natural stands of wild rice is the non-native flowering rush (*Butomus umbellatus* L.). Found in similar habitats as native bulrush (*Scirpus* L. spp.), which it resembles, flowering rush can persist in either emergent or submergent forms. Though its distribution in Minnesota is limited, its range is expanding. Flowering rush spreads primarily through

rootstalks. At a site in Idaho, flowering rush was documented to be out-competing other plants such as willow (*Salix* L. spp.) and cattail (MNDNR 2007).

Another potential threat to natural wild rice in Minnesota is the non-native form of phragmites, or common reed [*Phragmites australis* (Cav.) Trin.]. While phragmites appears in fossil records for North America as early as 40,000 years ago, the non-native form was likely introduced in the late 1700s in ship ballast from Europe. Common reed has since dominated Atlantic coastal marshes and migrated landward, particularly during the 1900s. To date, the non-native form of common reed has invaded natural areas in 18 states including Wisconsin and other Great Lakes states. Although it is still rare in Minnesota, this exotic has been observed in a few disturbed sites in the Minneapolis-St. Paul area and in Duluth harbor (L. Skinner, personal communication).

Although phragmites can spread by seed, the most aggressive growth occurs through rhizomes. Non-native phragmites forms a dense network of roots that can reach several feet in depth. It spreads horizontally by sending out rhizome runners that can grow ten or more feet in a single season if conditions are favorable. Very dense stands are formed, that include live stems as well as standing dead stems from the previous year. The stems of non-native phragmites often reach 15 feet in height along the Atlantic coast.

In a recent study of phragmites in wetlands at Long Point, Lake Erie, researchers found that the occurrence of phragmites increased exponentially in the late 1990s. Of the 31 stands analyzed, 28 (90%) were dominated by the non-native strain (Wilcox et al. 2003). Part of the rapid expansion of the non-native form may be related to its ability to weaken the root structure of adjacent plants through the secretion of gallic acid, which attacks a structural protein (tubulin) in the roots of competing plants (Murray 2007).

Climate Change

The warming of the earth is now evident from measurements and observations. These include increases in average global air and ocean temperatures, widespread melting of snow and ice, and rising global sea levels. The average surface temperature of Earth has risen by about 1.3° F since 1850. The Fourth Assessment Report (AR4) of the Intergovernmental Panel on Climate Change (IPCC), published in 2007, projects that the average global surface temperature is likely to further increase by 3 to 7° F by the year 2100. This projection assumes a moderate level of action to reduce anthropogenic emissions of greenhouse gases.

According to the IPCC, the lower end of this range (i.e., a further warming of 3° F) represents a threshold for the earth beyond which irreversible and possibly catastrophic changes are likely. If the projections of global warming this century are met, most living things on Earth will likely face severe consequences.

What will predicted changes in climate mean for natural stands of wild rice in Minnesota?

Although climatologists agree that temperatures in this region will increase, predictions of precipitation vary (Figure 3, Kling et al. 2003). Some climate models predict that increasing temperatures will lead to increasing frequency and duration of droughts in the Dakotas and

western Minnesota. Hot, dry conditions can negatively impact the pollination of wild rice and thereby reduce its seed production.

Warmer temperatures will also reduce the severity of winters. The required cold temperature (35° F or less) dormancy of three to four months for wild rice seeds could be reduced, particularly in the southern portions of its range. In addition, warmer conditions often favor non-native species. In particular, warmer waters may increase the survival and spread of carp across Minnesota. Because wild rice lakes, rivers, and wetlands are interconnected, protection of wild rice habitat from carp could become very difficult.

Invasive species such as the non-native phragmites may also benefit from warmer temperatures. Many exotics, such as hydrilla *[Hydrilla verticillata* (L. f.) Royle] and water hyacinth *[Eichhornia crassipes* (Martius) Solms-Laub.] are limited by cold climates (Holm et al. 1977; Langeland 1996). Increased average temperatures may enable these extremely invasive non-native species to migrate and gain footholds in Minnesota. Species such as these could have severe impacts on wild rice waters.

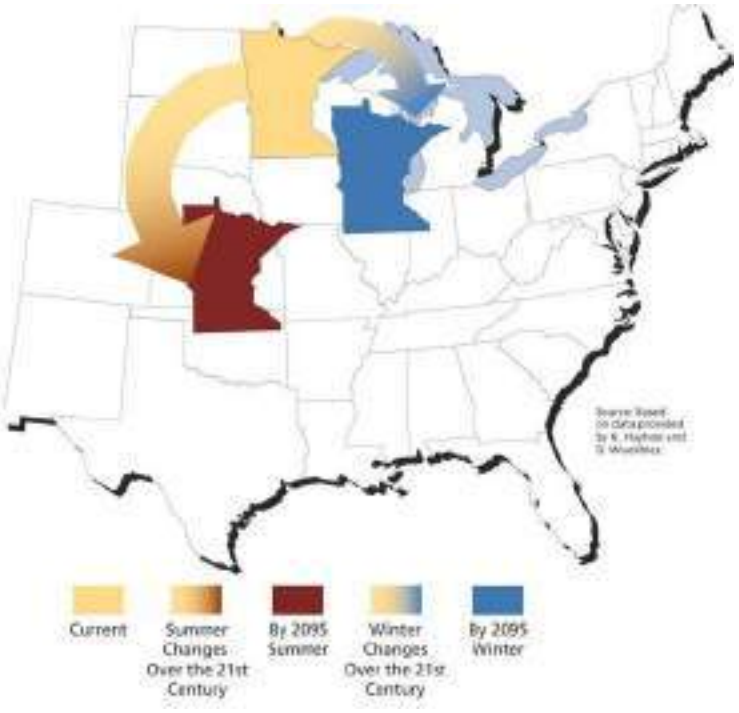

Figure 3. Predicted climate change will effectively alter Minnesota to reflect the climate of states to the south.

The frequency of dewpoints above 70° F is already trending upward in Minnesota (Seeley 2007a). Warm, humid conditions support diseases of wild rice such as brown spot (*Bipolaris oryzae* Luttrel and *Bipolaris sorokiniana* Luttrell) and other pathogens. For example, high humidity and sustained warm overnight temperatures in early August 2007 promoted the development of brown spot in many natural wild rice stands in Minnesota. Estimated crop losses in some stands were 70 to 90% (R. Ustipak, personal communication).

There is strong agreement that global warming will result in increased severity of individual weather events (Seeley 2006). According to Dr. Mark Seeley, University of Minnesota climatologist, 2007 may be representative of the future conditions in Minnesota. In August 2007, the U.S. Department of Agriculture declared 24 Minnesota counties to be in severe drought and eligible for federal assistance. Also in August 2007, the Federal Emergency Management Agency declared seven counties in southeastern Minnesota to be flood disasters, also eligible for federal assistance (Seeley 2007b).

In nearly two hundred years of weather history, there are no records of such extremes occurring in the same month of the same year in Minnesota. Increasing severity of storm events will cause more flooding and hence more abrupt changes in lake levels during the growing seasons of wild rice and other aquatic vegetation. Natural wild rice will be particularly susceptible to damage while in the floating-leaf stage.

The southern edge of the range for natural wild rice may already be receding northward. While many factors have likely contributed to a decline in range of natural wild rice, climate may well be involved.

Lack of Recruitment and Retention of Harvesters

As Minnesotans have fewer positive experiences with natural wild rice through harvesting, hunting, trapping, or wildlife watching, they are less likely to recognize or have concerns about its potential loss. They are also less likely to appreciate the severe impacts that the previously noted threats could have on wild rice, and thus on the historic and culturally rich quality of life in Minnesota. This loss of appreciation, while not a direct threat to rice in itself, nevertheless increases the risks for wild rice because the level of resource protection and management is often based on its perceived value.

The protection and management of natural wild rice relies not only on tribes and agencies, but on the users of the resource, as well. Harvesters support management activities through the purchase of annual licenses. Because they have a personal stake in the future of natural wild rice in Minnesota, they are the ones most likely to report activities that are damaging the resource. Harvesters are also great advocates for natural wild rice. They promote its value within the ricing community and to the state as a whole.

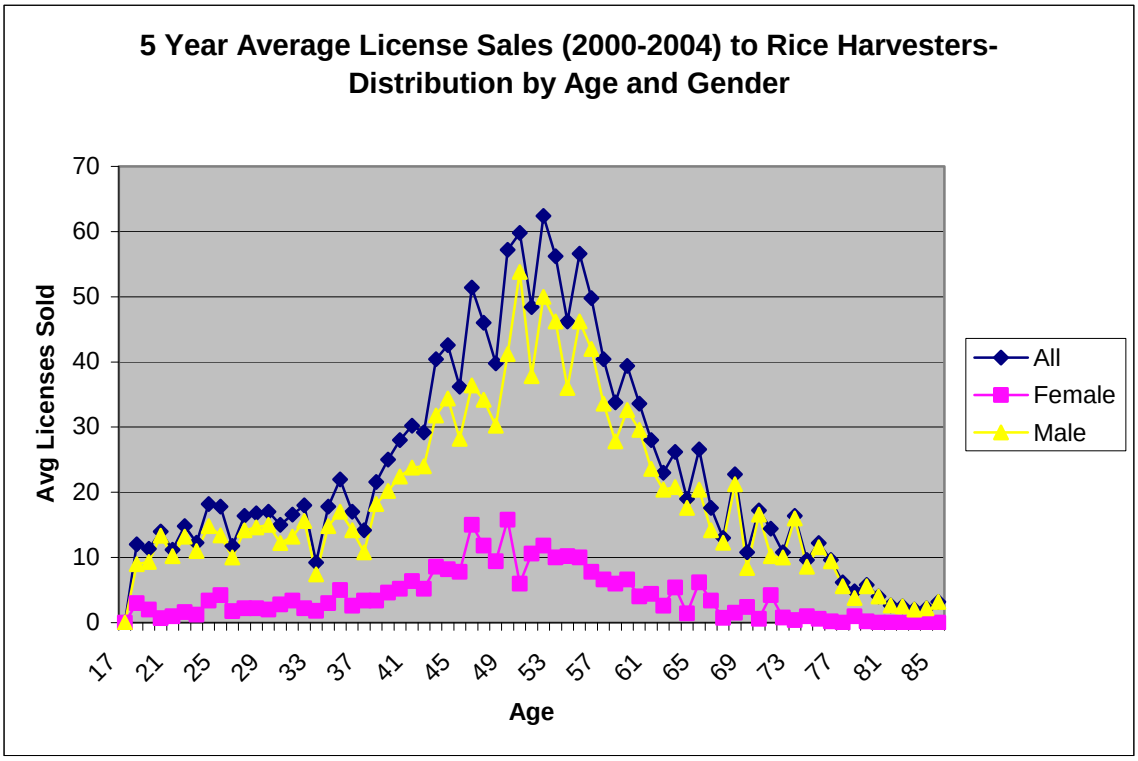

Figure 4. Age distribution of state licensed wild rice harvesters.

Wild rice harvesters are relatively few in numbers, though, and these numbers have declined over the last fifty years. During the 1960s, sales of state licenses in Minnesota averaged over 10,000 per year. Since 2000, these sales have averaged fewer than 1,500 annually. Harvesters under tribal regulations are not required to purchase a state license. Their numbers are estmated to exceed 3000 (R. Norrgard personal communication) and have likely experienced moderate increases in recent years (J. Persell, personal communication).

The MNDNR surveyed wild rice harvesters who purchased licenses from 2004 to 2006 to gather information on harvester characteristics and potential barriers to participation. This survey found that the majority of harvesters were male and at least 40 years old (82% and 81%, respectively). Figure 5 illustrates a similar age distribution from 2000 to 2004. Nearly all of the harvesters who responded had been introduced to wild rice harvesting by a friend or family member (87%).

Although most were satisfied with their harvest experience (82.3%), those surveyed identified several barriers to continuing this tradition. The most important barriers were time, knowing when to harvest, knowing where to harvest, and finding a wild rice processor. Other barriers included finding a ricing partner, physical challenges, financial expenses, finding a buyer, and having proper equipment.

Even for experienced harvesters, the difficulty of finding information on where and when to harvest can limit participation. For those living outside of natural wild rice areas, finding this information can be particularly difficult. For new harvesters, even finding a processor to finish the rice is a significant challenge.

Difficulty in acquiring harvest-related information may influence the distribution of harvesters and harvesting pressure on individual stands. The MNDNR 2006 survey revealed that only 25 lakes accounted for half of all harvesting trips. By contrast, the inventory of wild rice stands compiled for this document indicates that 119 lakes (100+ acres in size) account for more than half of the acreage of natural wild rice in Minnesota.

Addressing the educational or informational needs of Minnesotans interested in natural wild rice has been largely ignored. As with other natural resources in Minnesota, the lack of recruitment and retention of harvesters threatens the sustainability of natural wild rice in the state. Without readily available information and inspiring programs of education, public support of protection and management of the very resources that define Minnesota will likely decline.

Management Challenges

The future of natural wild rice in Minnesota will depend in large part on its protection and management by state and tribal natural resource agencies. The most important management issues relate to those threats identified in the previous section. The challenges that managers of natural wild rice face are further complicated because of limitations to their authority, inherent variability of wild rice production, and the need for additional information concerning wild rice in Minnesota.

Multiple Jurisdictions

Minnesota state statutes provide that ownership of wild rice and other aquatic vegetation is vested in the state (MS 84.091). State statutes also establish regulatory control over wild rice removal and harvest (MS 84.10, 84.15, 84.027, 84.28). Exceptions to state harvest regulations apply in geographic locations that are described by treaties and subsequent agreements, statutes, and rules (MS 84.10, MR 6284.0600 and 6284.0700). State and tribal enforcement officers often operate under temporary agreements until formal agreements are finalized.

The enforcement of harvest regulations in Minnesota is mainly stable and without major controversy. One issue still being discussed, however, is the posting of lakes as "closed" to wild rice harvest until it is determined that the grain is ripe. Both state and tribal governments have done this in the past on lakes that are popular with harvesters. In 1996, a new state law was passed that opened the ricing season on July 15 each year and made it illegal to pick rice that is not ripe (MS 84.105). Because wild rice usually ripens in Minnesota between the third week of August and the second week of September, the new law was intended to encourage a "pick when ripe" philosophy.

Most tribal governments have continued to post popular wild rice lakes within their jurisdictions. For many tribes, this practice is part of a long-standing tradition that relies on counsel provided by tribal committees. Tribes have urged the state to work cooperatively to post additional lakes. The position of the state, however, is that posting is unnecessary for the long-term health of the wild rice resource and the MNDNR currently has statutory authority only to post lakes as "closed" to "protect against undue depletion of the crop so as to retard reseeding or restocking of such area or so as to endanger its effective use as a natural food for waterfowl" (MS 84.15). In some cases, productive wild rice lakes are within both tribal and state jurisdictions. For these lakes, the differences in management philosophy have created conflicts between tribal and state agencies and with some harvesters.

Jurisdictional issues also arise over management of lake resources in general. Although the state of Minnesota has the responsibility of ownership of natural wild rice, the state includes many agencies, and each has its own mission and interest groups. No single agency or governmental entity in Minnesota assumes all of the responsibility for protecting natural wild rice. In public waters, the MNDNR takes the lead to regulate harvest and damage or removal of wild rice plants. Counties take the lead, within state statutory guidelines, to regulate shoreline development and most local recreational surface-water use. The Minnesota Pollution Control Agency regulates discharges to waters throughout the state; the Minnesota Department of

Agriculture assumes the lead for issues involving cultivated wild rice; and the state Environmental Quality Board has the lead responsibility to coordinate, notify, and evaluate any potential release of genetically engineered wild rice.

Within the MNDNR, the Division of Waters assumes the lead on shoreline regulations; the Division of Ecological Resources leads on aquatic plant management and invasive species; and the Division of Fish and Wildlife leads on habitat management for fisheries and wildlife values. The MNDNR Division of Enforcement is responsible for enforcement of natural resource regulations including the harvest of natural wild rice except when tribal regulations apply.

A formal, interdisciplinary planning process for Minnesota lakes does not exist. Lake management plans typically reflect the specific goals of the sponsoring entity. The plans often focus on aspects of either fisheries, wildlife, water quality, or vegetation without considering a comprehensive approach that addresses all of these components of a lake ecosystem.

Within Minnesota state statutes, there is no unifying policy of wild rice management that provides integration of these various agencies. By contrast, a unifying policy is clear regarding wetlands. Under public water laws, state statutes declare that it is in the public interest to increase the quantity, quality, and biological diversity of Minnesota's wetlands (MS 103A.201 subd. 2). A similar policy statement would help insure the sustainability of the natural wild rice resource in Minnesota.

Annual Crop Variability

Management by MNDNR and its conservation partners to maintain water levels beneficial to natural wild rice stands has never been greater. Water level monitoring, beaver control, debris removal, and invasive species management has annually taken place on more than 200 lakes and impoundments with significant wild rice stands. This management is based on the combined efforts of the Minnesota Department of Natural Resources, U. S. Fish and Wildlife Service, Ducks Unlimited, Tribal governments, and at least three lake associations. Much of the funding for these management efforts comes from the revenue generated by wild rice license sales.

Nevertheless, the expectations of those who value natural wild rice often exceed the capabilities of those responsible for protecting and managing this resource in Minnesota. A particularly difficult challenge for managers is the critical role that weather plays in wild rice development. Even when growing conditions have been exceptionally favorable, a single storm can reduce or even devastate the local harvest. At best, wild rice managers can “set the table” by maintaining free-flowing outlets or by setting appropriate runout elevations on water control structures. These management actions improve the harvest potential in good years and lessen the impact of poor conditions in less favorable years.

It can be easy for both user groups and managers to overlook the reality that natural wild rice has adapted to changing weather patterns through strategies that promote long-term survival rather than consistent annual abundance. The boom and bust cycle of natural wild rice has been recognized for centuries. This variation in annual productivity may be driven as much by seed dormancy and nutrient cycling as it is by variable weather. Resource managers, wild rice

harvesters, and other stakeholders must remember that productivity of natural wild rice is highly variable, both by stand and by year. Responsible management of this unique resource should strive to maximize its long-term sustainability in the Great Lakes region.

Information Needs

To effectively manage natural wild rice for future generations, resource managers need a better understanding of its natural ecology; its historical losses and patterns of abundance and distribution; threats to its sustainability; and the needs of harvesters.

While much has been learned about the ecology of wild rice over the last several decades, adequate information is still lacking on environmental tolerances and limiting factors such as water and sediment chemistry, seasonal water levels, and disturbance. This information will help create a better understanding of the historical reductions in wild rice distribution and provide much needed guidance for restoration of wild rice habitat.

In addition, a better understanding of ecological relationships in wild rice waters could guide strategies to counter threats such as mining and climate change. Improved ecological understanding would also provide much needed insight into the issues of invasive species. Of particular concern is the potential spread of carp, flowering rush, and exotic phragmites. Better assessments of the damage caused by rusty crayfish are needed as well.

Another concern is that basic information concerning the natural genetic makeup of native stands of wild rice is lacking. An understanding of the natural genetic variability of natural wild rice in the Great Lakes region and genetic drift between stands is critical. This information is needed to guide restoration efforts, particularly in the face of changing climate, and to help detect changes in diversity. We also need to better understand reproduction and its role in population genetics of natural wild rice.

More thorough information is needed on the distribution and overall acreage of natural wild rice in Minnesota. For this study, the MNDNR and the Wild Rice Study Technical Team revised and updated an earlier database of this information (Appendix B). While the recent revision is the most complete and detailed information of its kind for Minnesota, it still represents a gross estimate because information for many lakes, wetlands, rivers, and streams is incomplete or totally lacking. Further refinements and updates to this database are needed. In addition, refined methods are needed to improve the monitoring of annual productivity and the effects of management actions. This information would also help identify new opportunities for harvesters and better distribute harvesting pressure. With improved methods of monitoring and more complete databases, the overall health of the wild rice resource will be better managed.

Managers also need to better understand the harvesters of natural wild rice. What are annual trends? How can agencies and the wild rice community encourage retention of existing harvesters and recruit new people to continue this tradition? Who are the potential harvesters and what do they need in terms of ricing information, education, and support to be successful? The future of the wild rice resource in Minnesota may very well depend on the level of interest in its harvest and traditions.

Department of Natural Resources Recommendations

Introduction

This section is in response to the legislative request to include recommendations "on protecting and increasing natural wild rice stands in the state". The following recommendations were developed with valuable input and discussion from the members of the Wild Rice Study Technical Team and Partnership Team. However, the Minnesota Department of Natural Resources assumes sole responsibility for these recommendations as written and presented here.

MNDNR recognizes the importance of protecting natural wild rice beds from genetic modification and agrees with wild rice stakeholders that this protection is critical to the future of this resource. We strongly support the Environmental Quality Board in adopting rules that require an environmental impact statement for a proposed release of genetically engineered wild rice (MS 116C.94 Subd.1b).

Recommendation 1

Recodify current wild rice harvest statutes and rules to remove duplication and inconsistencies.
Rationale: The state's wild rice statutes and rules have been developed and modified piecemeal over a long period of time. As a result they contain a number of inconsistencies and duplication. Most of these changes relate to the harvest regulations (MS 84.27 – 84.91) although statutory recognition of wild rice as the state grain (MS 1.148) is also out of date in its nomenclature.

Recommendation 2

Establish statutory policy guidance on wild rice and its management.
Rationale: Within state statutes there is no unifying policy that provides direction to agencies responsible for some aspect of wild rice management. In contrast, the policy of the state is clear when it comes to wetlands. State statutes declare that it is in the public interest to increase the quantity, quality, and biological diversity of Minnesota's wetlands (MS 103A.201 subd. 2). A similar policy statement concerning natural wild rice would be useful guidance for state and local agencies. Suggested language includes "The legislature finds that natural wild rice in Minnesota provides public value by its contributions to fish and wildlife habitat, ecological diversity, environmental quality, recreational opportunities, cultural traditions, human sustenance, and economic well-being, and that it is in the public interest to protect existing natural wild rice stands, including their inherent genetic diversity, and restore wild rice to its historic range and abundance for its ecological, economic, and cultural values."

Recommendation 3

The DNR will convene an interagency workgroup in 2008 to identify desired statutory updates in harvest regulations.
Rationale: Harvest regulations and license fee structure should be reviewed by an interagency work group for suggested changes that would work towards resolution of posting lakes closed to harvest and regulating reservation border lakes, as well as encouraging recruitment and retention of wild rice harvesters. Possible changes include broadening the use of funds deposited in the wild rice account to allow for information and education, removal of the season framework, adding a combination (spouse) license, extending special one-day license, providing special one-day mentored license for resident and nonresident participants in formal education programs, and establishing a special youth day when mentors are not required to have a license.

Recommendation 4

The DNR will designate and publish a list of important natural wild rice areas.
Rationale: Recognizing important wild rice areas and publishing the list would call attention to the importance of these areas, indicate management priorities, and provide a formal list that may prove useful for local units of government that are considering zoning and surface use restrictions.

Recommendation 5

The DNR will convene a standing interagency wild rice workgroup to share information and develop recommendations for inventory methodology and trend assessments, education and information outreach, lake planning and management, harvester recruitment and retention, and other management issues as they arise.
Rationale: Comprehensive protection and management of wild rice involves multiple agencies. Management needs include better inventory information including consistent methodology for trend analysis, documenting natural genetic diversity, and establishing long-term case studies on identified lakes. This information will encourage sound restoration strategies and help foster the development of interdisciplinary lake management plans. In addition, the workgroup should focus on developing outreach information for harvesters, shoreline owners, realtors, boaters, and outdoor educators.

Recommendation 6

Increase intensive natural wild rice lake management efforts and accelerate the restoration of wild rice stands within its historic range.
Rationale: Protecting and managing natural wild rice resources on many lakes requires active annual management activities to maintain free flowing outlets. The MNDNR works cooperatively with other agencies and nonprofit organizations such as Ducks Unlimited to accomplish this management. Tribal agencies also conduct independent management efforts on specific lakes. In recent years these efforts have improved wild

rice habitat on approximately 200 lakes and impoundments annually. Additional funding could expand accomplishments beyond current efforts.

The MNDNR has also been involved to a lesser extent in restoring wild rice to wildlife habitat areas within the historic range of natural wild rice. These efforts should be accelerated as funding, time, and opportunity permit.

Appendix A

Natural Wild Rice Study Development Process

Scope: This study provided an information document on natural wild rice developed with conservation partner input, review, and possible endorsement. The document included the current location and estimated acreage and area of natural stands; potential threats to natural stands, including, but not limited to, development pressure, water levels, pollution, invasive species, and genetically engineered strains; and recommendations to the house and senate committees with jurisdiction over natural resources on protecting and increasing natural wild rice stands in the state.

Format: The final document was formatted to include an Executive Summary, Introduction, Background, Threats, Management Challenges, Recommendations, and Appendices.

Process: A Partnership Team was organized to review, comment, and consider endorsement of the planning process, interim draft of the document, and the final draft to be released for public review. DNR Assistant Commissioner Bob Meier chaired the Partnership Team. Invited members of the Partnership Team included representatives from other agencies and organizations including DNR Tribal Liaison Paul Swenson, the DNR Divisions of Ecological Services, Enforcement and Waters, MN Department of Agriculture, Board of Water and Soil Resources, Minnesota legislature (Representatives Frank Moe and Sondra Erickson), U. S. Bureau of Indian Affairs, U. S. Fish and Wildlife Service, U. S. Natural Resources and Conservation Service, Minnesota Chippewa Tribe, Tribal representatives, Ducks Unlimited, MN Wild Rice Council, Minnesota Waterfowl Association, Save Our Rice Alliance, Minnesota Waters, and the Association of Minnesota Counties. The Partnership Team was offered the opportunity to submit dissenting reports to be included in the appendices.

A Technical Team was organized to propose the document development process, develop the draft document and incorporate revisions as the process proceeded. DNR Wetland Wildlife Program Leader Ray Norrgard chaired the team and assumed the role of lead writer. Invited members of the Technical Team will include DNR wildlife field staff Gary Drotts, Ann Geisen, Shelley Gorham, Beau Liddell, Rob Naplin and Regional Enforcement Supervisor Ken Soring, along with Michelle McDowell (Fish and Wildlife Service), Becky Knowles (Leech Lake Department of Resource Management), Rod Ustipak (Consultant), Jon Schneider (Ducks Unlimited), MN Wild Rice Council (Beth Nelson and Jon Dokter), Rachel Walker (University of Minnesota – St. Paul), Dr. Ron Phillips (University of Minnesota – St. Paul), Dr. Raymie Porter (University of Minnesota- Grand Rapids), Annette Drewes (University of Wisconsin), Thomas Howes (Fond du Lac Reservation), Darren Vogt (1854 Authority), Steve Smith and John Persell (Minnesota Chippewa Tribe), Mike Swan (White Earth Reservation), Andrea Hanks (White Earth Land Recovery Project), and Peter David (Great Lakes Indian Fish and Wildlife Commission).

Timelines: The process began with the passage of the 2007 legislative request and will end with a completed report to the legislature by February 15, 2008. The Technical Team met on August 14, 2007 to develop the final draft of the proposed document development process, and a draft outline of the final document. The Technical Team communicated by email and followed up with meetings on November 13, 2007 and January 7, 2008. The draft study document underwent 10 revisions in all. The Partnership Team met on September 19 and December 3, 2007 to review

the Technical Team's proposals. Review of the final working draft of the study document was conducted by mail. The final document will be presented to the legislature by February 15, 2008. Copies of the final document will be posted on the MNDNR website and available upon request through DNR regions and central office.

Partnership Team Roster

Organization	Name	Title
Association of Minnesota Counties	Anna Lee Garletz	Policy Analyst
Bois Forte DNR	Cory Strong	Commissioner
Bureau of Indian Affairs	Bob Jackson	
Clearwater County	Tom Anderson	County Commissioner
DNR Commissioner's Office	Bob Meier	Asst Commissioner/Policy
DNR Division of Ecological Resources	Lee Pfannmuller (Donna Perleberg)	Director
DNR Division of Enforcement	Mike, Hamm	Director
DNR Division of Waters	Kent, Lokkesmoe	Director
DNR Northwest Region Office	Paul Swenson	Tribal Liaison
Ducks Unlimited	Ryan Heiniger	Director, Cons Programs

Rachel Walker	Ph.D Candidate Water Resources	University of Minnesota

Appendix B

Wild Rice Distribution and Abundance in Minnesota

EXECUTIVE SUMMARY

Project Leader
Gary Drotts
Minnesota Department of Natural Resources
Area Wildlife Supervisor - Brainerd

Purpose

To further the understanding of natural wild rice distribution and abundance in Minnesota, Minnesota Department of Natural Resources (MNDNR) staff and other Technical Team members of the Natural Wild Rice in Minnesota Legislative Study undertook an effort to consolidate and update existing natural wild rice inventory information. The following objectives guided inventory design and development.

1. Consolidate various data/information on the location (i.e. lake, wetland, or river segment) of natural wild rice stands in Minnesota.
2. Determine size and natural wild coverage for each location.
3. Determine type of water level management structure (if present) on each location and primary management authority.
4. Document Tribal, Treaty and/or State authority for each location.
5. Determine natural wild rice harvest potential, harvest pressure, and access for each location.
6. Provide a starting point for a useable data framework/information system for the long-term protection, management and monitoring of natural wild rice in Minnesota.

Methods

An existing dataset (Microsoft Access) maintained by the MNDNR Shallow Lake Program provided the starting point for this effort. This dataset originated in the late 1980's based on a review and consolidation of the best existing data sources at that time (i.e. MNDNR Enforcement wild rice lists, tribal rice camps, etc.) followed up with field interviews to MNDNR Area Wildlife and Tribal offices in the primary natural wild rice range. This initial assessment found over 700 lakes in 31 counties totaling 1.5 million basin acres contained approximately 61,000 acres of natural wild rice.

Since this initial dataset was formed, various MNDNR, federal, treaty and tribal authorities have accomplished a significant amount of additional inventory work. This information was reviewed, consolidated and added to the initial dataset and sent out for review to MNDNR Area Wildlife and Treaty/Tribal authorities for their comments and input. Return information was entered into a finalized dataset.

Primary information collected consisted of a location (i.e county, basin name), basin area and estimated natural wild rice coverage. For basins having a significant stand of natural wild rice, additional information was requested as to: water level management restrictions (i.e. dam at outlet); general wild rice location within the basin; treaty/tribal authority; and harvest potential, pressure and access.

Information sources

Information sources included the following:

- Minnesota DNR – initial survey data, 2006 Wild Rice Harvesters Survey, Fisheries lake surveys, Wildlife/shallow lake surveys, aquatic plant management permits, and aquatic plant survey data from Ecological Resources.
- Treaty/Tribal - 1854 Treaty Authority, Great Lakes Indian Fish and Wildlife Commission, Fond Du Lac Indian Reservation, Mille Lacs Indian Reservation, Leech Lake Indian Reservation, and, White Earth Indian Reservation.
- U.S. Fish and Wildlife Service, National Wildlife Refuge System

Results

Inventory results note that stands of natural wild rice were present or occurred in recent history on 1,292 lakes or river/stream segments in Minnesota. Of these 1,286 locations, 777 have information on natural wild rice coverage, which totals approximately 64,328 acres. The remaining 509 locations that currently do not have coverage information are primarily small lakes/wetlands on the edge of the current natural wild rice range (southern and western Minnesota) or river/stream segments.

On a county basis, the greatest concentration of natural wild rice locations is in St. Louis (8,939 acres), Itasca (8,448 acres), Cass (8,323 acres), Aitkin (4,859 acres), and Crow Wing (3,751 acres). These five counties contain over 60% of the inventoried natural wild rice acreage in Minnesota.

Recommendations

- This inventory should be considered a work in progress. Further edits and review are needed, especially for small lakes/wetlands on the edge of current natural wild rice range and the numerous river/stream segments that may been missed in this inventory.
- A procedure to review and update this inventory on a regular basis (every 5-10 years) should be undertaken.
- Information gathered on harvest potential, pressure and access to these natural wild rice locations should be listed/posted on appropriate web sites (i.e. MNDNR web site).

Wild Rice Harvest Survey

The full report will be posted on the MNDNR website www.dnr.state.mn.us prior to March 1, 2008

Executive Summary

Introduction

The following objectives guided the study design, survey instrument and final report for this effort.

- To determine the characteristics of wild rice harvesters in Minnesota.
- To assess current harvest levels and harvester satisfaction.
- To assess current natural wild rice harvest use of Minnesota lakes and rivers.
- To obtain wild rice harvester opinions of current state regulations and proposed revisions.
- To determine factors that limit wild rice harvesting.
- Identify information needs of wild rice harvesters, and the best means to deliver information to harvesters.
- To determine support for natural wild rice management priorities.

In November of 2006 the Minnesota Department of Natural Resources initiated a self-administered, mail questionnaire of all 2006 wild rice license holders (n=1,625) to gather information on the objectives listed above, and all 2004 and 2005 license holders who did not purchase a license in 2006 (n=945) to gather information on why they did not harvest wild rice in 2006. Completed questionnaires were returned by 53 percent (n=1,365) of the 2,574-license holder sample.

Characteristics

The 2004 to 2006 wild rice license holder respondents were predominately male (82%), Minnesota residents (98%), and averaged 51 years of age. A large majority (81%) are 40 years of age or older. A majority harvested wild rice under only a state license (86%). The average age that harvesters began gathering wild rice was 31. Friends and parents were the primary means of introduction to the activity, and 69 percent of harvesters reported introducing others to gathering wild rice. The average harvester has 13 seasons of experience.

Harvest Levels

Based on responses, an estimated average of 430 pounds of unprocessed natural wild rice was gathered per harvester in 2006. Based on state issued license sales of 1,625 in 2006, this creates a total harvest estimate of approximately 700,000 pounds of natural wild rice. Approximately two percent of 2006 respondents harvested more than 2,000 pounds of rice, while 79 percent harvested less than 500 pounds. When comparing these groups (those harvesting > 500 lbs and those harvesting < 500 lbs) there is a difference in both the average age they began harvesting (20 and 33 years old, respectively) and the average number of seasons participated (25 and 12 years, respectively). A large majority (85%) of harvesters harvest for personal use.

Harvester Satisfaction

A large majority (82%) of 2006 harvesters were satisfied with their overall wild rice harvesting experience, with only one in ten expressing dissatisfaction. Harvesters were neutral on the existing wild rice season opening date (July 15th) and slightly in favor of the current wild rice season hours (9 a.m. to 3 p.m.). Other comment topics included: high licensing fees, less than ideal water levels, lack of processor information, lack of enforcement, weather, shoreline degradation, motor boats in wild rice stands, beaver control, and a need for more regulation of genetically modified wild rice.

Use of Minnesota Lake and Rivers to Harvest Wild Rice

A total of 3,151 trips were reported by 845 harvesters, resulting in an average of 4 trips per person to gather wild rice. Sixty percent (60%) of 2006 harvesters took three or fewer trips, while 12 harvesters (1%) managed 20 or more trips. One half (50%) of the respondents reported harvesting on only one lake, indicating that multiple trips were made to the same lakes. An additional 28 percent reported harvesting on two lakes. The average number of lakes visited for harvesting wild rice was 1.8 across all harvesters. The maximum number of lakes visited was six.

During 2006, over two-thirds (70%) of all wild rice harvesting trips were in Aitkin, St. Louis, Itasca, Crow Wing or Cass counties. The next five counties with the highest number of trips were Becker, Clearwater, Beltrami, Lake and Hubbard counties. The above ten counties had 91 percent of all wild rice harvesting trips. A total of 28 counties were identified as being visited for wild rice gathering.

While 407 locations were identified from the survey results to at least the county level, only 313 noted a specific name (i.e. lake name or river segment). Of these 313 locations, the top ten harvest locations based on harvest pressure (number of trips) account for 27.4 percent of the statewide total. Further review notes that 50 percent of total trips are represented by the top 32 locations and that the top 68 locations represent 66.6 percent of total trips.

State Regulations

About half (53%) of the respondents supported a change in harvesting hours from 9 a.m. - 3 p.m. to 10 a.m. - sunset, and three-fourths (77%) supported changing the wild rice season opening from July 15 to August 14. More than half (62% and 66% respectively) of the respondents opposed use of watercraft up to 38 inches wide or establishing a 7-day nonresident license.

Participation, Information Needs

The most important factors identified by respondents that limit participation in harvesting were personal time, and knowing when and where to harvest wild rice. For respondents that did not harvest is 2006, finding a rice processor ranked highest after personal time. Where and when to harvest are again ranked high for information helpful to 2006 ricers. In order of preference, the preferred method for delivery of information is through web sites, pamphlets or as a section of the DNR Hunting Regulation Handbook. Other limiting factors identified in comments include the cost of the license, fuel and transportation costs, and access (to private and reservation lakes).

Management Priorities

A large majority of respondents ranked water level management as the highest management priority, followed by availability of information. Seeding ranked third, while enforcement of regulations, access site improvement, and wild rice research were ranked fourth, fifth and sixth,

respectively. Other comments included protection from genetically modified rice, increased habitat protection, and excessive license fees. Specific habitat protection comments included more restrictions on shoreline development, protection from motorized watercraft, prevention of the removal of wild rice through aquatic plant management permits, and more management of specific lakes that are historical wild rice lakes.

Appendix D

The Life History of Natural Wild Rice

Growth and Development

The following description of the growth of wild rice plants is adapted primarily from the work of Dr. Ervin Oelke and others at the University of Minnesota unless noted otherwise (Oelke et al. 2000, Oelke 2007).

As an annual plant, wild rice develops each spring from seeds that fell into the water and settled into sediment the previous fall or before. Germination requires three to four months of cold, nearly freezing water (35° F or colder). Seeds exposed to drying die. Seed dormancy is regulated through hormonal growth promoters and inhibitors and by an impermeable, tough, wax-covered pericarp. Low oxygen levels can also inhibit germination.

Seed germination typically occurs when the substrate and surrounding water temperatures reach about 40° F. Depending on water depth, latitude, and the progression of spring weather, wild rice germinates in Minnesota sometime in April, well ahead of most but not all perennial plants. Within three weeks, rooted wild rice seedlings develop three submerged leaves. These leaves usually remain submerged and decay as the plant matures. Adventitious roots arise at the first leaf node and occasionally at the second and third nodes. Most, but not all, roots are shallow, often rust-tinged due to iron deposits, and may spread 8 to 12 inches. Natural mortality can be relatively high during the submerged leaf stage (Meeker 2000).

The emergent stage begins with the development of one or two floating leaves and continues with the development of several aerial leaves two to three weeks later. The floating leaves are apparent in late May to mid June in Minnesota, again dependent on water depth, latitude, and weather. It is at this stage of growth that wild rice is most susceptible to uprooting by rapidly changing water levels due to the natural buoyancy of the plant. Rising water levels can significantly stress the plant even if it remains rooted.

The upper portion of the wild rice stem is hollow, with thin evenly spaced partitions. The number of tillers, or additional flowering stems, can vary with plant density and water depth. In deep water there may only be one stem per plant while in shallow water the number can exceed 30. Tillers typically mature 7 to 14 days later than the main stem (Meeker 2000).

Wild rice begins to flower in mid to late July in Minnesota. Flowering times are dependent on both day length and temperature. Short day lengths trigger earlier flowering but a reduction in kernel number. Longer day lengths delay flowering while increasing kernel number. Warmer temperatures will accelerate development, and cooler temperatures will slow growth. Wild rice flowers are produced in a branching panicle with female flowers (pistillate or seed-producing) at the top of the panicle on appressed branches. Female florets typically number about 130 per plant. Male flowers (staminate or pollen-producing) are produced on nearly horizontal branches on the lower portion of the panicle. Natural wild rice is primarily pollinated by wind. High temperatures and low humidity can negatively affect fertilization rates.

There are several variations of the typical wild rice panicle. One is the bottlebrush variant, often associated with male sterility, in which the male flowering branches remain appressed and give the panicle a compact bottlebrush appearance. Another variant is the crowsfoot panicle, in which the female flowering branches spread in the same manner as the male branches. In another variant, the male florets are replaced by female florets, resulting in a gynoecious or entirely female panicle.

Cross-pollination is typical for natural wild rice because the female flowers develop, become receptive, and are pollinated before the male flowers on the same plant shed pollen. The female florets are receptive over a period of about ten days (Moyle 1944b). Cross-pollination is enhanced by plant-to-plant variation for flowering within the same stand due to the effects of water depth, non-synchronous tillering, and genetic differences among plants (Moyle 1944b, Meeker 2000).

Cross-pollination within and among wild rice populations helps maintain genetic variability and the biologic potential for wild rice to adapt to changing conditions. Some changes may be seasonal or annual in nature; others, such as changing climate in the Great Lakes region, will likely be long term. The variability in natural wild rice genetics that exists today may be a critical determinant of whether natural wild rice can adapt to changes in regional weather. Studies in northern Wisconsin found sufficient genetic diversity among geographically distinct stands of natural wild rice to identify four regional populations. The degree of diversity within stands varied widely, however, with larger and denser stands having higher levels (Waller et al. 2000).

When viable pollen grains land on the female stigma, they germinate within one hour and reach the embryo sac within two. Seeds are visible two weeks after fertilization, and they mature in four to five weeks. Immature seeds have a green outer layer that turns purplish black as the seed reaches physiologic maturity.

Seeds ripen over several days on an individual stem, starting at the top. Primary stems ripen earlier than secondary tillers, plants in rivers ripen earlier than those in lakes, plants in shallow water earlier than those in deeper water, and plants in northern Minnesota earlier than those in more southerly stands.

This staggered maturation process means that ripe seeds may be available within individual stands for several weeks, and across the entire range of natural wild rice in Minnesota for a month or longer. This extended period of “shattering”, or dropping of ripened seed, is an important mechanism that insures at least some seeds will survive to perpetuate the natural wild rice stand. The entire process, from germination of a new plant to the dropping of mature seeds, takes about 110 to 130 days (or about 2600 growing-degree days) depending on temperature and other environmental factors.

Not all wild rice seed germinates the following year. Under some conditions, natural wild rice seeds can remain dormant in the bottom sediment for many years to several decades if conditions are not suitable for germination. This allows wild rice to survive years when high water levels or

storms reduce or eliminate productivity. Wild rice can germinate and colonize habitats after other plants have been removed by environmental disturbance if a seed bank is present (Meeker, 1999).

Even under ideal growing conditions, wild rice populations follow approximately three to five year cycles (Jenks 1900, Moyle 1944b, Pastor and Durkee Walker 2006, Walker et al. 2006). Highly productive years are followed by unproductive ones followed by a gradual recovery (Moyle 1944b, Grava and Raisanen 1978, Atkins 1986, Lee 1986, Archibold et al. 1989). Recent study suggests that oscillations in wild rice may be caused by delays in nutrient recycling to plant uptake. Wild rice litter accumulation may inhibit plant growth and production (Pastor and Durkee Walker 2006, Walker et al. 2006). In particular, the amount of wild rice straw, stage of decay, and tissue chemistry (root litter) may affect available nutrients, influence production, and result in population cycling (Walker, Ph.D. thesis 2008).

Habitat Requirements

While the historical range of wild rice illustrates its broad distribution, its specific occurrence and abundance is in large part dependent on local environmental conditions. The following descriptions are a capsulation of the historical and current literature (Moyle 1944a, Rogosin 1951, Lee 2000, Meeker 2000, Oelke 2007). For more detailed information be sure to check the original sources.

Hydrology

Wild rice generally requires some moving water, with rivers, flowages, and lakes with inlets and outlets being optimal areas. Water basins with intermittent or seasonal flow may sustain beds, but annual production will fluctuate more widely. Seasonal water depth is critical. Wild rice grows well in about 0.5 - 3 feet of water, although plants may be found deeper. Shallower sites support strong competition from perennial emergent plants and deeper water stresses the plant to the point that seed production is limited or nonexistent. At Rice Lake National Wildlife Refuge from 2002 to 2005, production and growth parameters were highest at water depths of 1- 30 inches (McDowell, personal communication).

Water levels that are relatively stable or decline gradually during the growing season are preferred. Abrupt water level increases during the growing season can uproot plants. Wild rice is particularly sensitive to this disturbance during the floating leaf stage. However, some observers feel that water levels kept stable over the long term (multiple years) tend to favor perennial aquatic vegetation over wild rice (David and Vogt, personal communication).

Water characteristics

Clear to moderately stained water is preferred, as darkly stained water may limit sunlight penetration and hinder early plant development.

Wild rice grows over a wide range of alkalinity, pH, iron, and salinity. It does best in water that has a pH range of 6.0 - 8.0 and alkalinity greater than 40 ppm. Some of the measured chemistry

parameters are alkalinity (5-250 ppm), pH (6.4-10.1 SU), Iron (0.1-3.0 ppm) and True Color (50-300 Pt-Co) (Andryk 1986, Persell and Swan 1986).

The state of Minnesota instituted a water quality criterion for sulfate in wild rice waters of 10 mg/liter. The level was established based on observations by Moyle (1944a), however, other field observations and research show that wild rice can grow in waters with significantly higher sulfate concentrations (Grava 1981, Lee and Stewart 1983, Peden 1982). This research also indicates that factors such as oxygen levels and potential sediment anoxia are involved in the wild rice-sulfate connection.

While researchers have observed that natural wild rice ecosystems are relatively nutrient rich, excess levels of nutrients, especially phosphorus, can have significant adverse effects on natural wild rice productivity (Persell and Swan 1986).

Sediment

Although wild rice may be found growing in a variety of bottom types, the most consistently productive are lakes with soft, organic sediments (Lee 1986). The high organic matter content with a rather low carbon/nitrogen ratio is necessary to meet the rather high nitrogen needs of wild rice (Carson 2002). Nitrogen and phosphorus are major limiting nutrients for wild rice (Carson 2002). Flocculent sediments with nitrogen and phosphorus concentrations less than one gram per square meter are typically incapable of supporting sustained production (Lee 1986).

Competing Vegetation

As an annual plant sprouting each year from seed, wild rice can have difficulty competing with aggressive perennial vegetation, particularly where natural hydrologic variation has been reduced. Cattail (*Typha* spp.), particularly hybrid cattail (*Typha x glauca*), yellow water lily (*Nuphar variegata*), and pickerelweed (*Pontederia cordata*) are examples of plants that have been cited as competing with wild rice (Norrgard, David, and Vogt, personal communication).

Re: The report "Natural Wild Rice in Minnesota" submitted by the DNR

In this statement I do not speak on behalf of the University of Minnesota, but rather as a scientist who has been engaged in research on cultivated wildrice breeding at the University of Minnesota for almost 20 years.

I would like to commend the Technical Team convened by the DNR to pull together the information that contributed to this report. Although the participants represent diverse interests when it comes to wildrice, our meetings have been characterized by a vigorous interchange of ideas with mutual respect, while focusing on what is actually known about wildrice. I hope that future efforts to deal with the issues identified by this report will be as positive and fruitful as what I have experienced in the meetings of the Technical Team. I would like to add the following comments to the report for emphasis.

The loss of genetic diversity should be viewed *not* as a primary *cause*, but rather as an *effect* resulting from other causes. Granted, addressing the loss of genetic diversity is crucial for the species to flourish in state waters. Loss of genetic diversity means loss of the alleles (or variant forms) of genes across the many natural populations of wildrice, which also means that there are fewer genotypes (genetic types) for a given trait within a given population. Having fewer genotypes may limit a population's ability to respond to seasonal, yearly, or long-term changes in the local environment of that population. This is especially true if the genotypes lost are ones needed for adaptation to conditions that prevail at that site. But, since loss of genetic diversity is usually caused by factors that reduce the number of individuals in populations to low numbers, alleviating the problems that reduce wildrice stands will help maintain the genetic diversity of wildrice. The report does a good job of characterizing the primary threats that limit wildrice stands and that could therefore reduce genetic diversity.

But how will we know whether or how genetic diversity is being affected? Only through knowledge about the genetics of wildrice. Sound scientific knowledge about the genetic make-up of natural stands, coupled with knowledge about how different genes respond to various environmental factors, should prove useful in guiding restoration efforts. If seeds need to be brought in from other natural stands in order to restore a site, knowing the genetics of the potential donor stands could help identify those that might be most similar to the population that remains at, or that once existed at, the site.

What about cultivated wildrice? Is the breeding of wildrice really a threat to natural stands from a genetic perspective? The consensus of the Technical Team is that it is not. I agree with this perspective. In fact, I believe that cultivated wildrice should not be made a scapegoat for problems in natural stands. I have heard speculations that cultivated wildrice causes this or that problem observed in a natural stand– speculations without evidence. What I know about population genetics leads me to the conclusion that such speculations will never find evidence to support them. Some basic facts about population genetics and wildrice should shed light on this.

Cultivated varieties (cultivars) of wildrice in Minnesota are not genetically uniform—they are heterogeneous, or made up of many different genotypes. The wildrice breeding project at the University of Minnesota has endeavored to maintain as much genetic diversity as possible in the cultivars released. Also, since all the genes in cultivars ultimately originated in the natural wildrice gene pool, they are a subset of the total genetic variability of wildrice. No new alleles or genes have been artificially added (i.e., no genetic engineering has been done, nor is it being pursued). Therefore, it seems reasonable to assume that cultivated wildrice has less total genetic diversity than natural wildrice. But this is the norm for any cultivated crop species, since breeders would tend to select only those alleles (variant forms) of genes that make the crop better adapted under the narrower range of cultivated conditions. Conversely, breeding a crop for adaptation to cultivated conditions tends to make it less fit for survival in the wild.

But even if a wildrice cultivar were genetically uniform, that uniformity should not impact the vast diversity of natural wildrice. There are many more acres of natural stands than cultivated stands, and they are rarely in close proximity to each other. That wildrice pollen travels over long distances has *not* been established. But even if pollen should travel between cultivars and natural stands, it could just as easily travel from one natural stand to another. And pollen moving from one natural stand to another natural stand nearby would likely be so few in number compared to the pollen produced locally that it would be diluted to insignificant amounts. Also, the viability of that pollen once it arrives is in doubt, given the short life of wildrice pollen.

"Migration" is the term used by population geneticists to describe gene movement between populations. But what would happen in those cases of successful migration of alleles of genes into a population? If the allele of that gene is *already* present in the population, the migration doesn't add anything new. If the allele is *not* already present, it would *add* to the genetic diversity of the population where it has found its home. This new allele, along with all the other alleles already present in the population, are then subjected to the forces of natural selection. If the allele increases the fitness of the plant to survive under the conditions of that population, natural selection favors it, and it will increase in its frequency in the population according to how much fitness it adds. If it decreases the fitness of the plant, natural selection will not favor it, and other plants with more favorable alleles will out-compete it. In this manner, natural selection will determine the genetic make-up of the population.

The heterogeneous nature of wild populations is the response of those populations to ever-changing local conditions. Any given year, some genotypes will do well, others will do poorly. In a different season, other different genotypes may prevail. In short, those plants with alleles that enable the plant to grow well and produce more seed under the local environmental conditions will contribute those genes to the next generation. Natural selection will enable the best plants to survive. This will be the case as long as there is enough genetic variability to allow adaptation to that environment.

Therefore, those factors that are known to adversely impact natural stands should be the focus of efforts to protect and enhance natural wildrice. This would accomplish the most to prevent loss of genetic diversity. It has been stated in the report that the threat of transgenic wildrice doesn't exist—no one knows of anyone who is pursuing it, and it seems unlikely that they would. Traditional (or conventional) breeding of wildrice is not a threat, by consensus of the Technical Team, for the reasons that I have just given. Other threats have been identified as important. Those threats should be addressed.

Ray Norrgard
Wetland Wildlife Program Leader
MN DNR
500 Lafayette Rd.
St. Paul, MN 55155-4020

Dear Mr. Norrgard:

As President of the Minnesota Cultivated Wild Rice Council (MCWRC), I appreciate the opportunity to comment on the Natural Wild Rice in Minnesota Study you were required to complete and are submitting to the Minnesota Legislature. The protection of natural stands of wild rice is an extremely important issue and is supported strongly by the MCWRC.

As I'm sure you know, cultivated wild rice plays an important role in Minnesota's rural economy. It is grown on marginal crop lands, providing income to some of the poorest counties in Minnesota. As forestry, mining, and other industries have lost jobs in the region, alternative opportunities for employment have become more important to the region. The cultivated wild rice industry has provided much-needed economic activity in these northern Minnesota counties. More than 500 people derive full or part-time employment directly from the cultivated wild rice industry in Minnesota, many of them on farms that have been in the family for four generations. On a full-time equivalent basis, these jobs equal more than 200 positions.

Additionally, the wild rice industry generates about $3.1 million in employee compensation annually. It also contributes a total of $8.7 million in total employee payroll and over $21 million in revenues to Minnesota's economy. Other industries share in about $20 million in revenues directly related to the wild rice industry. So you can see how important the cultivated wild rice industry is to northern Minnesota. *(The economic information cited herein is taken from a 1992 study of the economic impact of wild rice in Minnesota. Therefore, these figures understate the contributions of wild rice to Minnesota's economy in today's dollars.)*

With regard to the legislation passed in 2007 which requires an environmental impact statement for any proposed release of genetically modified wild rice and a study of potential threats to natural stands of wild rice, the MCWRC remained neutral. However, we feel it is very important to address a couple of specific issues as they relate to cultivated wild rice in Minnesota.

First, we would like to bring attention to the fact that, as noted in the wild rice study, traditional wild rice breeding programs do not pose a threat to natural stands. Wild rice grown in paddies is the same genus and species as that found in natural stands. Evidence to support this fact can be found by analyzing the 2007 harvest.

In 2007, hand harvesters enjoyed their most productive harvest in more than 40 years - at the same time cultivated wild rice producers recorded their highest production ever, a virtual impossibility if cultivated wild rice truly had a negative impact on natural stands. An article by Rod Ustipak, coordinator of a wild rice management program in Minnesota for Ducks Unlimited (DU) and the Minnesota Department of Natural Resources (DNR), which appeared in the September 16, 2007 edition of the St. Paul Pioneer Press (an article still available online at http://www.ducks.org/news/1359/DroughtimprovesMinne.html), explains how drought conditions over the past few years have actually conspired to create an environment in which natural stands thrived and produced a bumper harvest, conditions completely unrelated to cultivated wild rice production.

Secondly, although it is mentioned in the Natural Wild Rice In Minnesota Study as a concern, we feel it is extremely important to explicitly state the following: ***genetically engineered wild rice does not exist.***

There is a widely held belief, though completely inaccurate, that wild rice is somehow, somewhere being genetically modified or engineered. It is not. The MCWRC is neither developing, nor does it have plans to develop genetically engineered wild rice. We are not aware of any entity that is developing GE wild rice. The federal and state regulatory processes currently in place, coupled with the enormous investment (in the millions of dollars) necessary to develop GE wild rice, renders any effort to do so cost prohibitive. These facts, coupled with the recently passed legislation which requires an environmental impact study prior to the release of any genetically modified varieties of wild rice provide ample safeguards to the environment to ensure food safety and environmental integrity.

Since natural wild rice stands gave birth to the cultivated wild rice industry in Minnesota growers are keenly aware of the importance of protecting them. In fact, the MCWRC board of directors went on record with its support of protecting natural stands when it passed the following resolution at its July 27, 2005, board meeting, *"The MCWRC fully supports the protection of native stands of wild rice in Minnesota. There is no genetic engineering of wild rice occurring. The biosafety requirements in place through the coordinated framework of the USDA, EPA, FDA, the State of Minnesota, and the University of Minnesota are working well to assure a safe environment and food supply."*

Many threats may exist to natural stands of wild rice – shoreline development, climate change, wildlife activity, and recreational water use just to name a few. If we are to be successful in maintaining the vigor and existence of natural stands it is imperative that we analyze and focus our efforts on current threats - those that exist now - rather than perceived threats which are likely never to exist.

Sincerely,

Beth Nelson,
President

Tribal Statement Regarding MNDNR Wild Rice Study
Submitted To the State Legislature February 15, 2008

We appreciate the opportunity to provide input into the development of this *Natural Wild Rice in Minnesota* report. Manoomin (wild rice) is a remarkable and valuable component of the Minnesota landscape, and it is commendable that the State is concerned with its future. We concur with most of the wild rice history, ecology and proposed management recommendations contained therein and offer our statements below as points for emphasis and clarity to the Legislature and State DNR.

Manoomin is an inherent part of being Ojibwe. Our lifestyles and cultural identity are intimately bound to manoomin, spiritually, physically and economically. The importance of manoomin to the Ojibwe people cannot be overstated as it holds a central position in the lives and rich history of the Ojibwe people. It is more than just another grain or crop; it is a cultural resource of indescribable importance. It is a sacred gift from the creator to our people and is used for sustenance, ceremonial and commercial purposes.

The right of the Ojibwe to harvest and use manoomin was reserved and guaranteed in treaties signed between the Chippewa Bands of the region and the federal government that predate Minnesota statehood. Recent Supreme Court rulings have upheld the existence of these treaty reserved rights along with the federal trust responsibility to uphold these rights, and resources they are built upon.[1] Today, Tribal members continue to harvest manoomin, as they have for many years, in numbers greater than the rest of the state population. The very existence of the Ojibwe people depends on the vitality of their environment, their resource use and their culture which is intricately connected to natural wild rice.

Science and technology in the world is rapidly changing and challenging the environment of our daily lives. Threats to the existence and integrity of natural stands of wild rice are of immense concern to the Ojibwe. Today, the thought of genetic modification of wild rice poses an alarming threat into the possibility of irreversible genetic contamination of our natural stands of wild rice. This would have a profound negative impact on the Ojibwe people. The connection between Ojibwe culture and wild rice is not a static concept and should not be viewed as such. Rather, our relationship to wild rice should be acknowledged as a respectful, living force that guides the growth and development of our Ojibwe communities, as it has for centuries.

We feel strongly that manoomin must be protected from genetic engineering. From the beginning of the genetic engineering debate in Minnesota, the tribes have wanted GE wild rice banned. For the Ojibwe, no level of contamination is acceptable. Once genetic contamination occurs, there is likely no way to reverse it. There are published documents and reports demonstrating that genetically engineered plants can escape test plots and intermingle with native populations at distances greater than was previously thought. These same studies have shown that the range of impacts on native populations is significantly greater than currently recognized.[2] Thus, if GE wild rice were to be grown in Minnesota, it is not a question of whether contamination will occur rather, it is a question of how quickly and to what extent contamination will occur.

We recognize and appreciate that the current statute requiring an Environmental Impact Statement prior to any proposed release of GE wild rice represents progress. However, we desire complete and permanent protection for manoomin. There are currently no proven safe guards that could effectively isolate GE strains of wild rice from natural stands. The only way to prevent genetic contamination is to ensure that no GE wild rice is released into the environment. A ban on genetically engineered rice in Minnesota would be the best way to achieve this.

We recommend that the State Legislature require the Environmental Quality Board to specifically include Tribal cultural impacts as part of any GE wild rice Environmental Impact Statement process. Statements should include effects on the cultural practices of the Tribal community and State and address effects on Ojibwe culture, and traditional and customary rights.

We can not afford to hesitate when it comes to protecting natural stands of wild rice. We must conserve the biodiversity of natural wild rice stands. The rapid development of new technology and science combined with corporate exploitation of resources adds to the urgency. We must not allow Minnesota manoomin to be genetically contaminated by genetically engineered varieties that may be developed. This resource is far too precious, far too significant ecologically, economically and culturally, and far too sacred to allow this to occur. The protection and preservation of natural bed wild rice needs to be the concern of all Minnesotans. We desire to work with the State of Minnesota to ensure that wild rice is protected fully and permanently.

RE: Wild Rice Study Report

Dear Commissioner Holsten:

I am writing to express Ducks Unlimited's support for the recently completed wild rice report. Thanks to you and your staff for developing such a thorough document and set of recommendations. In particular, we are especially pleased with recommendations in the report that call for increased management, inventory, and stewardship of Minnesota's wild rice lakes and wetlands. Ducks Unlimited looks forward to helping your staff and other partners implement those recommendations in the coming years through our Living Lakes Initiative.

As with many of Minnesota's natural resources, wild rice habitat for waterfowl and other wildlife has been impacted and degraded due to changes to our land and waters. Due to the biological, cultural and economical values of wild rice, it is incumbent upon the state of Minnesota in collaboration with local stakeholders to invest new financial resources to protect and enhance the precious wild rice habitat that remains. Wild rice is one of the most important aquatic plants to migratory waterfowl and it is also critically important to other game and non-game wildlife species.

Since 2001, Ducks Unlimited has worked in partnership with the Minnesota Department of Natural Resources to assess, enhance, manage, and protect over 100 wild rice lakes annually throughout northern Minnesota. Grants from the Minnesota Environment & Natural Resource Trust Fund as recommended by the Legislative-Citizen Commission on Minnesota Resources have also provided important funding to both improve wild rice lakes and protect their shoreline through conservation easements.

DU was pleased provide input during the development of the wild rice study and we support the final report the DNR developed for the legislature. Please advise us of any opportunities to provide further support regarding this important wetland and shallow lake conservation issue.

Sincerely,

Ryan Heiniger
Director of Conservation Programs – MN/IA

Subject: **Wild Rice Study document "Natural Wild Rice in Minnesota."**

Dear Mr Norrgard:

This is a letter of endorsement for the above mentioned document and for the document development process. The U.S. Fish and Wildlife Service (Service) has long recognized the ecological importance of natural wild rice stands and associated wetlands. The establishment of National Wildlife Refuges, such as Tamarac and Rice Lake, for the purpose of managing these wetland habitats for the benefit of migrating and resident wildlife is evidence of this appreciation. This study, which provides exceptional background information on the importance of natural wild rice as well as identifies potential threats and management challenges, will be extremely useful in the continued management of this critical resource. Additionally, the process fostered a close working relationship between State, Tribal and Federal governments, university researchers, non-government organizations and well as interested citizens. This collaborative effort is essential to insuring the abundance of natural wild rice for future generations.

Thank you for the opportunity to participate in this process and provide comments.

Sincerely,

Barbara Boyle

This article is a companion to Myrbo et al. (2017), https://doi.org/10.1002/2017JG003788 and Pollman et al. (2017), https://doi.org/10.1002/2017JG003785.

Key Points:
- Sulfate loading to freshwater ecosystems may alter aquatic plant communities when sulfate is reduced to sulfide in the anoxic rooting zone
- The occurrence of self-sustaining wild rice populations is mainly controlled by pore water sulfide concentrations
- Even if pore water sulfide is low, wild rice is less likely to be found if the surface water is turbid or warm

Abstract Field observations suggest that surface water sulfate concentrations control the distribution of wild rice, an aquatic grass (*Zizania palustris*). However, hydroponic studies show that sulfate is not toxic to wild rice at even unrealistically high concentrations. To determine how sulfate might directly or indirectly affect wild rice, potential wild rice habitat was characterized for 64 chemical and physical variables in over 100 sites spanning a relatively steep climatic and geological gradient in Minnesota. Habitat suitability was assessed by comparing the occurrence of wild rice with the field variables, through binary logistic regression. This analysis demonstrated that sulfide in sediment pore water, generated by the microbial reduction of sulfate that diffuses or advects into the sediment, is the primary control of wild rice occurrence. Water temperature and water transparency independently control the suitability of habitat for wild rice. In addition to generating phytotoxic sulfide, sulfate reduction also supports anaerobic decomposition of organic matter, releasing nutrients that can compound the harm of direct sulfide toxicity. These results are important because they show that increases in sulfate loading to surface water can have multiple negative consequences for ecosystems, even though sulfate itself is relatively benign.

Plain Language Summary Research in the 1940s and 1950s found that wild rice grew best in low-sulfate Minnesota lakes, but it was not known why. The correlation was a puzzle, since sulfate is not very toxic to plants or animals. This study found that the problem is sulfide, not sulfate. Sulfate can be converted into toxic levels of sulfide in the soil in which wild rice germinates and roots. Wild rice is an annual plant that must sprout each spring from seed that was dropped the previous fall into wet soil. Anaerobic microbes in the soil make sulfide from sulfate in the overlying water. Lakes, streams, and wetlands that have high concentrations of dissolved sulfide in the sediment therefore have a low probability of hosting wild rice. The study also found that wild rice prefers high-transparency water and cold winters.

1. Introduction

Minnesota is unique among U.S. states and Canadian provinces in having a water quality standard that regulates sulfate (SO_4) to protect wild rice, *Zizania palustris* and *Zizania aquatica*. The more common wild rice species in Minnesota, *Z. palustris* (northern wild rice), is an annual emergent aquatic grass that forms monocultures in shallow freshwaters (wetlands, lakes, and rivers) in the area of the Laurentian Great Lakes (Minnesota, Wisconsin, Michigan, Ontario, and Manitoba). Wild rice is culturally important to multiple groups in Minnesota, especially Ojibwe, Dakota, and other Native Americans, and also provides habitat and food for waterfowl and other wildlife (Vennum, 1988). In 1977, the Minnesota legislature voted to make wild rice the Minnesota state grain. Minnesota Rule 7050.0224, promulgated in 1973, seeks to limit the exposure of wild rice to SO_4 concentrations exceeding 10 mg L^{-1} (0.1 mmol L^{-1}). This value was based on empirical research that correlated water chemistry to aquatic plant assemblages and included the observations that no large populations of *Z. palustris* occur in waters exceeding 10 mg L^{-1} SO_4 and that stands are uncommon where SO_4 concentrations exceed 50 mg L^{-1} (Moyle, 1944, 1945). In addition, Moyle (1956) noted that plantings of wild rice seed in high-SO_4 regions generally failed. A larger unpublished Minnesota Department of Natural Resources data set also shows that sites with reported wild rice

presence (DNR, 2008) are generally correlated with surface water SO_4 below 10 mg L^{-1} (Figure S1 in the supporting information).

We report here on a multiyear field survey that was part of a larger study (Myrbo et al., 2017; Pastor et al., 2017; Pollman et al., 2017) designed to reevaluate the 10 mg L^{-1} SO_4 standard by testing potential mechanisms by which SO_4 might be harmful to wild rice. SO_4 is a relatively nontoxic and unreactive compound under aerobic conditions. Pastor et al. (2017) and Fort et al. (2014) have shown that SO_4 is not directly toxic to wild rice at concentrations up to 1,600 mg L^{-1}, which exceeds concentrations in virtually all natural surface waters of the upper Midwest (Gorham, Dean, & Sanger, 1983). The U.S. Environmental Protection Agency's nonmandatory drinking water standard of 250 mg L^{-1} SO_4 (2.6 mmol L^{-1}) is based on taste rather than toxicity (EPA, 2010).

1.1. Potential Effects of Elevated Sulfate and Sulfide in Freshwater Systems

SO_4 concentrations in most freshwaters are less than a few percent of the mean concentration in seawater (2,800 mg L^{-1} (29.1 mmol L^{-1})). We surveyed 108 different lakes, streams, and wetlands across Minnesota, where the median SO_4 concentration in lakes is 10 mg L^{-1} (10th and 90th percentiles of 0.2 and 285 mg L^{-1} (MPCA, 2016)). In the much higher SO_4 concentrations of marine waters, it is well established that SO_4 can diffuse into sediment and be converted by microbial sulfate reduction (MSR) to potentially toxic sulfide that influences the presence and absence of rooted macrophytes, such as seagrasses (Borum et al., 2005; Ingold & Havill, 1984; Koch & Erskine, 2001; Lamers et al., 2013).

Despite a long-standing assumption that SO_4 is benign (Pester et al., 2012; Schindler, 1986; Urban et al., 1994) and plays a negligible role in freshwater biogeochemistry (e.g., Capone & Kiene, 1988), there is evidence that SO_4 availability in freshwaters can control the concentration and therefore the toxicity of hydrogen sulfide (H_2S) in sediment pore water to plants and animals (Bagarinao, 1992; Kinsman-Costello, O'Brien, & Hamilton, 2015; Lamers et al., 2013; Wang & Chapman, 1999). The chemical species of H_2S varies with pH; below pH 7, H_2S dominates, and above pH 7, the bisulfide ion (HS^-) dominates. For simplicity in this discussion we refer to the sum of the two species as sulfide.

1.1.1. Sulfide Toxicity to Freshwater Plants

Remarkably little attention has been given to the potential toxicity of sulfide in sediment pore water, even after Bagarinao (1992) concluded in a major review that sulfide had been "largely overlooked as an environmental factor for aquatic organisms." In a discussion of sediment toxicity testing, Wang and Chapman (1999) also observed that the biological implications of sulfide in sediments are poorly understood and "all too often ignored." They suggested that sulfide may be more important than ammonia in determining sediment toxicity to organisms and made a suite of recommendations to fill the knowledge gap, including the measurement of sulfide in undisturbed sediments. Kinsman-Costello et al. (2015) measured sulfide in undisturbed sediments and concluded that the potential toxicity of pore water sulfide is likely shaping the plant and animal communities of freshwater ecosystems. Lamers et al. (2013), in a review of sulfide toxicity to aquatic plants, pointed out that traditional toxicity testing generally neglects the chemistry of the rooting zone. Simkin, Bedford, and Weathers (2013) showed that pore water sulfide in a wetland controlled the distribution of plants more than did nutrients.

The toxicity of elevated sulfide to freshwater plants was first recognized in paddy-grown white rice (*Oryza sativa*) in the 1950s (Lamers et al., 2013; Pearsall, 1950). Rice paddies and other water-saturated soils present a profound challenge for rooted plants because of the chemical changes caused by the absence of oxygen and resulting potential toxicity of the pore water (Ponnamperuma, 1972). Anaerobic decomposition of organic matter results in elevated pore water concentrations of ammonia, organic acids, and variable concentrations of sulfide and ferrous Fe, depending on the availability of SO_4 and Fe. The interaction of Fe and the S cycle is complicated (Hansel et al., 2015), but because under anoxic conditions sulfide forms an insoluble precipitate with Fe, elevated pore water sulfide concentrations occur when Fe availability is relatively low (Ponnamperuma, 1972; van der Welle et al., 2006). It is thought that the iron sulfide precipitates are relatively inert and that only sulfide dissolved in pore water is potentially toxic. The concentration of sulfide in pore water is the balance between production and competing fates of sulfide, including precipitation with metals such as Fe, oxidation by oxygen introduced by bioturbation or by release from the roots of macrophytes (Armstrong & Armstrong, 2005), and by downward advection of surface water due to groundwater movement or transpiration by dense macrophyte stands (Bachand et al., 2014).

1.1.2. Geochemical Consequences of Enhanced Microbial Sulfate Reduction

Increased SO_4 availability can allow increased anaerobic decomposition of organic matter, releasing the inorganic nutrients that generally limit growth of higher plants (N, P, and K) (Lamers, Tomassen, & Roelofs, 1998; Myrbo et al., 2017; Weston et al., 2006, 2011). Enhanced decomposition breaks down particulate and dissolved organic carbon (DOC) in the sediment, which can increase DOC and dissolved inorganic carbon (DIC) in the overlying water (Myrbo et al., 2017).

In addition to supporting organic matter mineralization, MSR production of sulfide causes a cascade of reactions that can alter ecosystem functioning independent of any toxicity to plants and animals. First, sulfide can participate in redox reactions, chemically reducing Fe, which converts Fe from solid phase Fe(III) oxyhydroxides to water-soluble Fe(II) (Hansel et al., 2015). The dissolution of the Fe oxyhydroxides releases sorbed ions into solution, including phosphate and trace metals (Caraco, Cole, & Likens, 1993; Davranche & Bollinger, 2000; Søndergaard, Jensen, & Jeppesen, 2003). Second, sulfide can precipitate dissolved metals, including essential plant nutrients Fe, Cu, and Zn, decreasing their bioavailability and leading to nutrient deficiency (Kirk, 2004; Lamers et al., 1998; Neue & Bloom, 1989; Neue & Lantin, 1994). In systems unpolluted with heavy metals, the sulfide precipitate is overwhelmingly dominated by iron sulfide compounds, consisting of a range of stoichiometries and minerals (Schoonen, 2004), which we here term "FeS compounds." Third, the conversion of SO_4 to sulfide entails the production of DIC, or alkalinity, an effect not fully appreciated in freshwater systems until the mechanistic consequences of acid rain were investigated in the 1980s (Baker, Brezonik, & Pollman, 1986; Cook et al., 1986; Schindler, 1986). Alkalinity is thought to be a major factor influencing the distribution of aquatic species, including macrophyte species (Moyle, 1945; Vestergaard & Sand-Jensen, 2000). In addition, elevated alkalinity may further enhance decomposition, producing a positive feedback to the effects of SO_4-driven mineralization (Geurts et al., 2009; Roelofs, 1991).

1.2. Multiple Plausible Negative Effects of Elevated Sulfate and Sulfide Production on Wild Rice

The purpose of this study was to examine the multiple ways that increases in SO_4 concentration and sulfide production can change the biogeochemical functioning of freshwater ecosystems and potentially negatively affect the growth and reproduction of wild rice populations. Before any field data were collected for this study, alternative hypotheses regarding the most likely negative effects were identified (MPCA, 2011), so that appropriate data would be available to test them. The primary hypotheses of how increases in surface water concentrations of SO_4 could harm wild rice populations include direct toxicity by elevated pore water sulfide; reduced bioavailability of Fe, Cu, or Zn; and increased P bioavailability promoting the growth of phytoplankton and macrophytes that compete for light and space. Additional variables were quantified so that exploratory data analysis could be pursued in addition to evaluation of the primary hypotheses. Surface water, pore water, and sediment physical and chemical properties were collected from 108 different sites, both with and without wild rice present, to inform evaluation of these multiple interrelated hypotheses.

2. Methods

2.1. Study Area

2.1.1. Physical Environment

SO_4 concentrations in surface water vary with geology and climate (Gorham et al., 1983) in a northeast-southwest gradient across Minnesota. Bedrock and bedrock-derived glacial deposits of northeastern Minnesota (the "arrowhead") comprise slowly weathered crystalline materials, generally low in S, and surface waters are dilute (specific conductance of $<$140 and often $<$30 μmho cm^{-1}; Gorham et al., 1983). Within this area of naturally low SO_4, iron-mining activities in the "Iron Range" district of northeastern Minnesota have created an "island" of lakes and streams elevated in SO_4 (Figure 1), a result of the weathering of sulfide minerals in waste rock piles and tailing basins. The surficial geology of southwestern Minnesota, in contrast, is derived from marine shales and carbonates that are relatively S-rich and readily weathered: surface waters often exceed 500 μmho cm^{-1} and may exceed 7,000 μmho cm^{-1} (Gorham et al., 1983). SO_4 concentration is positively correlated with conductivity above about 200 μmho cm^{-1} and 10 mg L^{-1} or 0.1 mmol L^{-1} SO_4 (Figure 7B in Gorham et al., 1983). Overprinting this geological pattern is a strong climatic gradient with warmer, drier conditions toward the southwest (toward the northern Great Plains) and colder, more humid conditions to the northeast (toward the Laurentian Great Lakes), which enhances the conductivity gradient: more evaporative conditions in the southwest serve to concentrate surface waters and further increase ionic

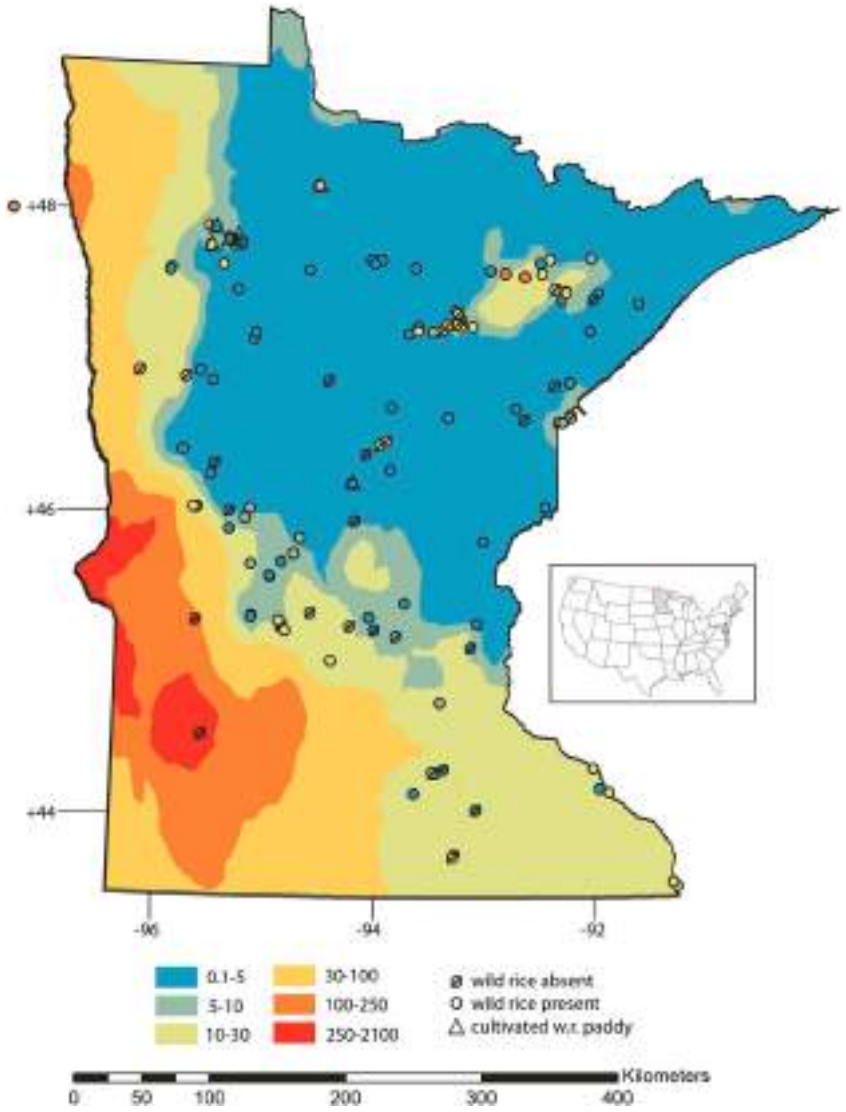

Figure 1. Map of Minnesota showing field sites overlain on kriged contours of average surface water SO_4 concentrations from 4,998 waterbodies (data from MPCA and DNR databases). The symbols are filled with the color corresponding to the site's surface water sulfate concentration. Site to the northwest of the Minnesota map is within the state of North Dakota, 40 km west of the border with Minnesota (see text). Sites where wild rice was not found have a diagonal line through the symbol.

strength, while moister conditions in the northeast maintain low ionic strength in surface waters (Gorham et al., 1983).

2.1.2. Habitat Preferences of Wild Rice

Although the scientific literature contains many assertions concerning the environmental preferences of wild rice regarding water and sediment quality (e.g., DNR, 2008, 2016; Lee, 2002; Moyle, 1944; Moyle & Krueger, 1964; Pillsbury & McGuire, 2009), sometimes little evidence was presented to support the putative preferences. The shallow freshwaters in which wild rice is found are usually relatively transparent because wild rice and other rooted macrophytes do best if they can photosynthesize as they grow each spring from the sediment to the water surface (Scheffer, 1998). Otherwise, any particular habitat preference of wild rice, such as specific chemical ranges of the sediment or surface water, is challenging to identify. Since wild rice is an opportunistic annual plant, a primary habitat requirement is periodic environmental disturbance (Grime, 1977) that keeps perennial plants such as water lilies from controlling the space and light of the shallow waters in which these species cooccur (Pillsbury & McGuire, 2009). Wild rice does not seem to have specific sediment requirements, as it has been observed growing in a variety of substrates (Aiken et al., 1988; Lee,

1986) within its range. Annual plants are adapted to exploit environments intermittently favorable for rapid plant growth and to maximize seed production (Grime, 1977). Wild rice produces between 25 and 150 relatively large seeds per stem (Eule-Nashoba, Biesboer, & Newman, 2012). Seeds buried in the sediment can survive for up to several decades until conditions are again favorable for germination and growth (DNR, 2008). *Zizania palustris* seeds germinate at low rates unless they have been exposed to near-freezing temperatures for at least 3 months (Kovach & Bradford, 1992), although the environmental cues for subsequent germination are poorly understood, aside from elevated temperature.

Because *Z. palustris* does not normally self-pollinate and is wind-pollinated (which implies that the pollen source must be relatively nearby; Friedman & Barrett, 2009), does not reproduce asexually, and has an annual life cycle (Aiken et al., 1988), in this analysis the presence of wild rice plants is taken to mean that the waterbody hosts a successfully reproducing and self-sustaining population. A few of the sites in this study may have experienced recent watershed changes such that steady state has not yet been reached among environmental variables and wild rice reproduction, but the balance of the 108 sites should have been in steady state at the time of sampling. The population of wild rice in a given lake can exhibit large fluctuations from year to year, which has been attributed to disturbances such as abrupt increases in water level (DNR, 2008) and to cyclical changes in N availability (Walker et al., 2010). Wild rice fills a unique ecological niche, in that there are virtually no other annual aquatic macrophytes across the Great Lakes region (Eggers & Reed, 2011).

2.1.3. Site Selection

The goal of the field survey was to identify and sample potential wild rice habitat across a gradient of SO_4 concentrations. Potential wild rice habitat was defined simply as shallow water (30–120 cm deep, though some sampled sites had water as shallow as 5 cm) that was sufficiently transparent to support rooted aquatic macrophytes. Turbidity from dense phytoplankton blooms or suspended solids may effectively exclude rooted macrophytes due to light limitation (Scheffer, 1998).

Most Minnesota lakes that host wild rice populations have low SO_4 concentrations; the median concentration of wild rice lakes is 1.8 mg L^{-1}, and the 75th percentile is 3.6 mg L^{-1} (MPCA, 2014). If only those waters hosting abundant wild rice were sampled, most of those would be low in SO_4, and little would be learned about how elevated SO_4 concentrations (or other important variables) might affect wild rice. Conservation biologists commonly identify important habitat variables through binary (i.e., is the species present or absent at a given site?) logistic regression, which requires the sampling of sites that do not support the species of interest (e.g., Carroll, Zielinski, & Noss, 1999; Peeters & Gardeniers, 1998; van der Heide et al., 2009). Consequently, potential wild rice habitats with a range in SO_4 concentrations were sampled without regard to whether the waterbody hosted or was known to host wild rice. An effort was made to sample waterbodies that covered the range of SO_4 concentrations across Minnesota and especially to sample sites in high-SO_4 regions that had reports of recent or historical presence of wild rice. This strategy also resulted in the sampling of a high-SO_4 wild rice site in the North Branch of the Turtle River (198 mg SO_4 L^{-1}), 40 km into North Dakota from northwestern Minnesota (Figure 1). A gradient of SO_4 concentrations was sampled by identifying potential wild rice habitat in two areas of elevated SO_4, the "island" of elevated SO_4 in the Iron Range region of northeastern Minnesota and waters naturally elevated in SO_4 to the west and south of the known range of wild rice (Figures 1 and S1). Nutrient (N and P) availability (reflecting natural soil fertility as well as agricultural runoff) also increases to the west and south, potentially supporting phytoplankton growth sufficient to exclude macrophytes, including wild rice. Consequently, in western and southern Minnesota, DNR lake databases were screened for the presence of water lilies (*Nuphar variegata* or *Nymphaea odorata*), the occurrence of which indicates transparency sufficient to support rooted macrophytes that also often cooccur with wild rice. In an analysis of DNR aquatic plant surveys from 1,753 shallow lakes, we found that the odds of finding wild rice where there are water lilies are 26 times the odds of finding wild rice where there are no water lilies, with a 95% confidence interval of 20–36 times (neither wild rice nor water lilies = 968; wild rice but not water lilies = 60; no wild rice but water lilies = 272; both wild rice and water lilies = 453).

With these considerations, water bodies were selected for sampling based on preliminary data including average water depth, presence of water lilies, conductivity or SO_4 concentration, and geographic distribution (i.e., to sample widely across the state). Both rivers and lakes were sampled, as were seven different cultivated wild rice paddies. Within a given water body, the field team chose a location for sampling based on a decision tree (Table S1 in the supporting information).

2.2. Field Methods

Sampling occurred in August–September 2011 and June–September 2012 and 2013. Sampling efforts were focused in late summer to capture physical and chemical conditions when wild rice plants were maturing and when identification of wild rice is most certain; voucher specimens of wild rice were always taken. Samples were collected from an anchored canoe or small boat, except in the cultivated wild rice paddies when the water was too shallow to float a canoe, and samples were collected on foot. A Hach model HQ40d or Hydrolab Quanta sonde, calibrated daily, was used to measure temperature, specific conductance, dissolved oxygen, and pH in the surface water. Water transparency was determined with a 1 m long Secchi-tube (Water Monitoring Equipment & Supply, USA), and apparent color was measured using a Hach model CO-1 color test kit. Surface water samples (later split into separate subsamples; see below) were collected by a technician wearing long nitrile gloves in two 2 L amber Nalgene bottles that had been previously triple rinsed with deionized water and rinsed 3 times with water from the site before filling. Water samples were stored on ice.

Short (~50 cm) sediment cores with ~10–20 cm of overlying water were collected at eight undisturbed locations at least 1 m apart around the boat using an HTH corer (Pylonex, Sweden) with a 7 cm diameter polycarbonate barrel. A piston was inserted in the bottom end of each core as it was retrieved. Cores were kept upright and shaded prior to sample processing.

Aquatic macrophytes were identified and percent cover estimated within a plastic hoop 1 m in diameter placed at 4 locations around the boat. In 2012 and 2013, the number of stems of wild rice inside each hoop was also quantified.

Pore water samples were obtained from cores processed on shore using 10 cm Rhizon™ filters (pore size 0.12–0.18 μm) (Rhizosphere.com, Netherlands; Shotbolt, 2010) inserted vertically into the core tops, following extrusion of overlying water, and connected to evacuated serum bottles with PVC/polyethylene tubing and a stainless steel needle. Three separate cores were sampled, one for nutrients (nitrate + nitrite, TP, and TN) and DOC (70 mL), a second for metals (50 mL), and a third for dissolved silica, Cl, and SO_4 (30 mL). A fourth core was sampled for pore water sulfide, but in this case, the serum bottle was preloaded with 0.2 mL of 2.0 N zinc acetate, 0.5 mL of 15 M sodium hydroxide, and a stir bar, flushed with a nitrogen atmosphere, evacuated, and preweighed. Air was flushed from the Rhizon-tubing assembly with sample pore water using a second evacuated bottle before the needle was inserted into the sulfide sample bottle. In 2011 only pore water samples for sulfide and metals were collected. Pore water pH was measured on a fifth core by inserting the probe of a Hach model HQ40d pH meter into the sediment to a depth of 5 cm and allowing the reading to stabilize.

A composite sediment sample was collected from the uppermost 10 cm of the sixth, seventh, and eighth cores, placed into a stainless steel bowl, and stirred under nitrogen atmosphere to homogenize. A 50-mL subsample was placed in a polypropylene sample bottle along with 1.0 mL of 1.0 N zinc acetate for analysis of acid-volatile sulfide (AVS). The headspace of the AVS sample bottle was flushed with N_2 and the bottle capped; that bottle was placed in a larger glass jar and that jar flushed with N_2 and tightly sealed. The sample was immediately placed in a cooler with dry ice to freeze. The remaining composited sediment was placed into a polycarbonate container and stored on ice for later analysis.

Water subsamples were taken from the large amber Nalgene bottles by a technician wearing nitrile gloves. Sulfuric acid (5 mL of 10%) was immediately added to subsamples for the analysis of P, TKN (total Kjeldahl nitrogen), ammonia, and nitrate + nitrite in 250 mL polyethylene bottles. Nitric acid (2.5 mL of 20%, to acidify to pH < 2) was immediately added to subsamples for the analysis of total metals in 250 mL polyethylene bottles. Samples for dissolved metals were subsampled in 250 polyethylene bottles and subsequently filtered using a 0.45 μm filter and preserved with nitric acid in the laboratory. Samples were stored on ice.

2.3. Laboratory Methods

Surface water, pore water, and most sediment analyses were conducted by the Minnesota Department of Health Environmental Laboratory (MDHEL) in 2012 and 2013, following standard methods. In 2011 other laboratories conducted the analyses (University of Minnesota Soils Laboratory (UMNSL), St. Croix Watershed Research Station (SCWRS), and Gustavus Adolphus College (GAC)); methodological differences are noted, and the laboratory is identified where relevant.

Surface and pore water samples were analyzed for anions (Cl and SO_4) by ion chromatography on a Dionex ICS-3000 (MDHEL), Fe, Ca, Na, Mg, and K by inductively coupled optical emission spectrometry on a Varian 715-ES (MDHEL), Mn, Cu, Zn, Co, Ni, Al, As, and Se by inductively coupled mass spectrometry on a Perkin Elmer Elan DRCE (MDHEL), and DOC by UV-persulfate oxidation on a Tekmar-Dohrmann Phoenix 8000 (SCWRS and MDHEL). N and P were measured by colorimetric methods (on a Lachat Quikchem Flow-Injection Autoanalyzer) at SCWRS and MDHEL following cadmium-reduction (nitrate and ammonia) or dual alkaline-persulfate digestions (TP and TN). Silica was measured colorimetrically at SCWRS on the Lachat Autoanalyzer and at MDHEL on a Beckman Coulter DU 800 UV/VIS spectrophotometer. Pore water sulfide was analyzed colorimetrically on each lab's Lachat Autoanalyzer following in-line acid distillation and NaOH trapping (SM 4500-S2). Alkalinity was measured by potentiometric acid titration (MDHEL) or as DIC by acid digestion and IR detection (SCWRS). DIC was converted to alkalinity using pH, temperature, and specific conductance of the surface water.

Sediment samples from 2011 were analyzed by combustion for total carbon (TC), total nitrogen (TN), and total sulfur (TS) using, respectively, a Tekmar Phoenix 8000 CO_2 analyzer, an Elementar Vario Max N analyzer, and a LECO sulfur analyzer (UMNSL). Samples from 2012 and 2013 were analyzed for CHN on a Costech 4010 Elemental Analyzer (UMN Stable Isotope Laboratory). Total inorganic carbon (carbonate) was analyzed by coulometric titration on a UIC CM5015 CO_2 coulometer, while water and organic matter content were determined by loss-on-ignition methods (Heiri, Lotter, & Lemcke, 2001) in the UMN LacCore facilities. Sediment AVS was analyzed colorimetrically, as above for pore water sulfide, following acid-distillation and in-line alkaline trapping (SM 4500-S2; Hsieh & Shieh, 1997).

Sediment phosphorus was extracted from freeze-dried sediments following methods of Engstrom and Wright (1984) for total-P and Hieltjes and Lijklema (1980) for P fractions (NH_4Cl-extractable, NaOH-extractable, HCl-extractable, and residual (organic)-P). The P extracts were measured colorimetrically by flow-injection autoanalyzer (SCWRS). Extractable iron and trace metals were quantified from a 0.25 g homogenized freeze-dried sediment subsample incubated in 0.5 M HCl for 30 min at 80°C. The samples were centrifuged, decanted, and analyzed by ICP-MS at GAC. This extraction releases metal oxyhydroxides, sulfides, and loosely bound phases from the sediment without appreciably attacking the silicate matrix (Balogh et al., 2009).

2.4. Data Subsets and Statistical Analysis

From 2011 to 2013, 260 site visits were conducted in 108 different natural waterbodies, including lakes, small streams, backwaters of the Mississippi River, and wetlands, plus 7 different cultivated wild rice paddies. For a variety of logistical reasons, the full suite of samples could not be collected on some site visits. Three subsets of the field data were identified for the analyses reported here. A subset that consists of all of the samples from natural waterbodies (excluding the cultivated paddies) with virtually complete analyses (surface water, pore water, and bulk sediment; $n = 194$) was termed for internal purposes Class D. Pollman et al. (2017) used Class D to develop a structural equation model to elucidate key variables that govern the concentration of sulfide in sediment pore water. A second subset, Class S, of 51 samples from 7 stream and 8 lake sites was each sampled 3 to 5 times from 27 May to 19 September 2013, to provide a data set to assess seasonality in variables. A third subset, Class B, was used for conducting probabilistic analyses to identify the most likely parameters controlling the presence and absence of wild rice and to examine Spearman nonparametric correlations among field variables. Class B consists of one sample from each site ($n = 108$) and excludes samples collected in 2011, which were analyzed with slightly different lab methods. Although Class B was not created as a random sample of Minnesota waterbodies, the frequency distribution of SO_4 concentrations is intermediate between a probability-based survey conducted by USEPA (MPCA, 2016) and a list of known wild rice water bodies, which are overwhelmingly low-SO_4 lakes (MPCA, 2014). Therefore, the Class B data set is reasonably representative of potential wild rice habitat, and binary logistic regressions can be used to approximate the probability of wild rice occurrence as a function of field variables such as pore water sulfide. The Class B data set is used in all analyses presented here, with two exceptions: (1) Figures 3a–3c present the full Class D data set, plus for comparison, data from the cultivated wild rice paddies; (2) Statistical analysis was performed with the software package R version 3.2.3.

To identify variables associated with the presence and absence of wild rice, we relied on binary logistic regressions (BLR), using the glm function in R. BLR does not require normally distributed data, but

Table 1
Field Variable Correlation With the Presence-Absence of Wild Rice, Assessed Through Binary Logistic Regression (BLR), Plus Spearman Correlations Between Variables[a]

[a]Note. The variables are ordered by the significance of the BLR. The first 12 variables have BLR significance of $p < 0.05$. The additional 14 variables are listed because of their correlation with pore water sulfide, sediment AVS, or surface water transparency or temperature—or their notable lack of correlation with wild rice presence-absence (pw = pore water; sw = surface water; sed = sediment).
*$p < 0.05$. **$p < 0.01$. ***$p < 0.001$.

nevertheless, we transformed some variables (Table 1) to achieve approximately normal distributions. BLR also yields the probability of occurrence at a given value of the variable. Spearman nonparametric correlations (rho) between field variables in Class B were examined as part of the effort to identify the major biogeochemical interactions in these shallow-water systems. Seasonality in a variable was assessed using linear mixed effects models, with time (fraction of a year) as a fixed variable and site as a random factor (to account for multiple samples per site). In the model developed for each field variable, we accounted for the seasonal cycle using the following equation (Crawley, 2007), where *A*, *B*, and *C* are fitted model coefficients:

$$y = A + B\ \sin\ (2\pi\ \text{time}) + C\ \cos\ (2\pi\ \text{time}) \quad (1)$$

3. Results and Discussion

3.1. Field Variables Associated With Wild Rice Presence and Absence

Of the 64 field quantified variables, BLR identified 12 that are associated with the presence/absence of wild rice at the 0.05 probability level or better (Table 1): pore water sulfide, K, and Fe (Figures 2a, 2b, and 2f); surface water temperature, TP, TN, and pH (Figures 2d, 2m, 2n, and 2o); sediment Se and TS (Figures 2c and 2p); water depth and transparency (not shown; Figure 2e); and latitude of the site (Figure 2g). These variables may be important in controlling the presence or absence of wild rice or may merely be correlated with one or more actual causative factors. Because we are primarily interested in factors that control presence or absence of wild rice, in contrast to the density of wild rice, we place primacy on the BLR results and use the Spearman

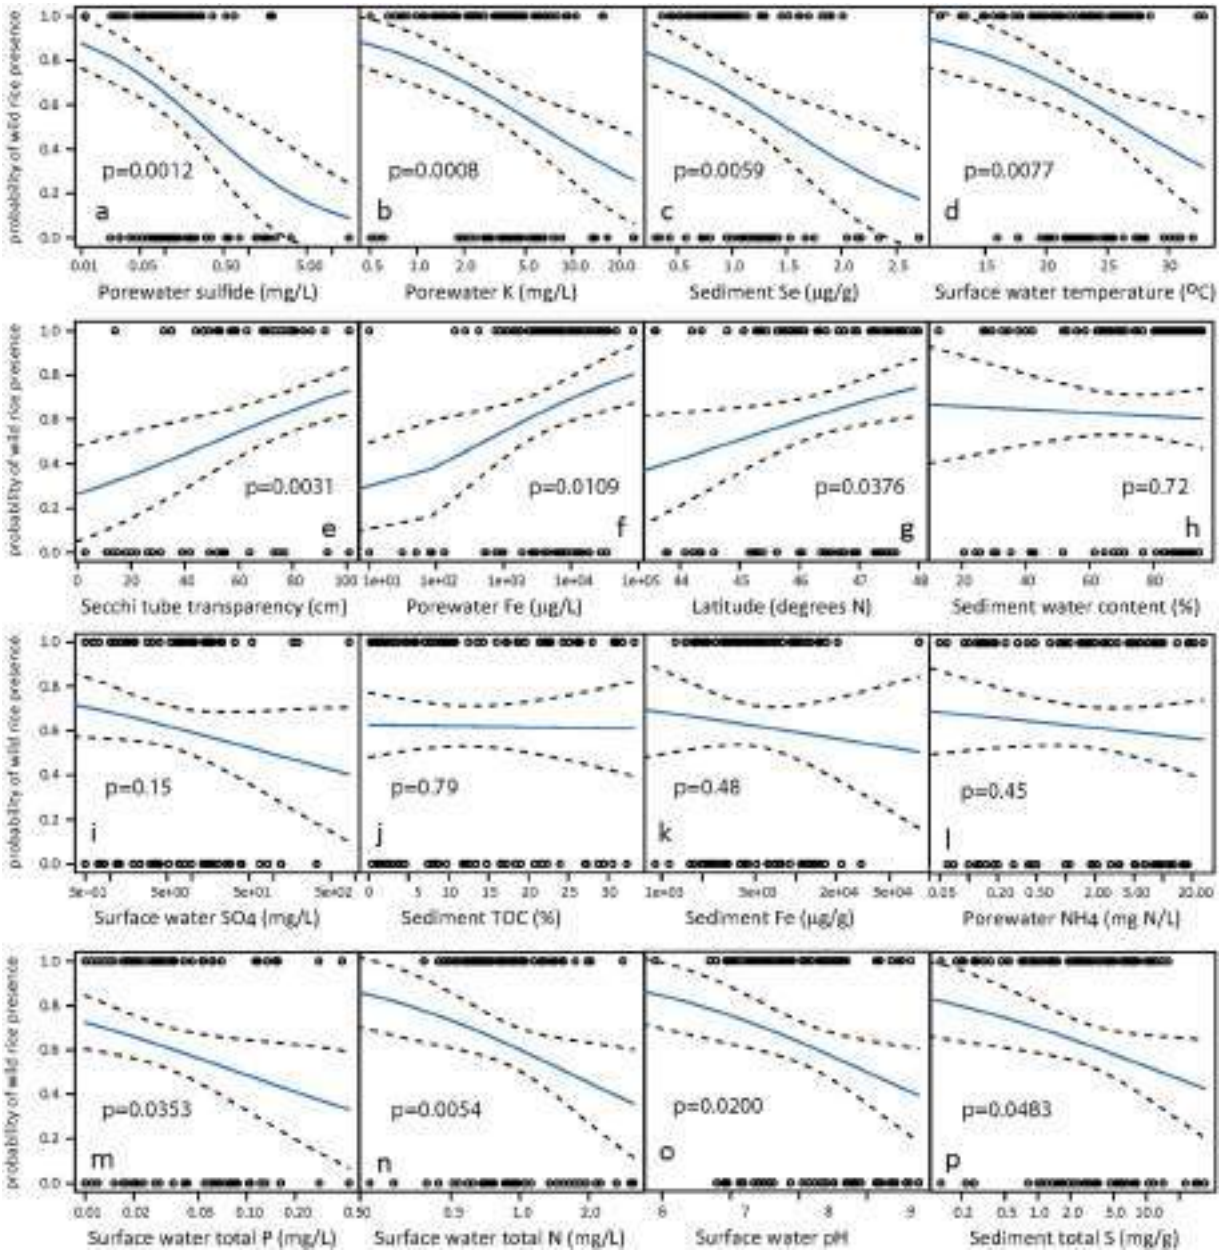

Figure 2. Binary logistic regressions for 16 variables found to be statistically significant in this study or indicated in the literature as important for wild rice habitat. The open circles indicate the value for a given parameter of each site used in the analysis; the circles at the top of a plot indicate sites with wild rice present; the circles at the bottom of a plot indicate sites with wild rice absent. The span of the dashed lines around the solid line indicates the 95% confidence interval.

correlations to help understand the relationships between environmental factors of interest. Wild rice density is negatively correlated with pore water sulfide, potassium (K), and NH_4 and positively correlated with surface water alkalinity (Table 1). There are likely factors controlling the density of wild rice at any particular location in addition to the variables measured, such as herbivory and hydrological disturbances.

One should be cautious in the interpretation of statistically significant associations between wild rice and field variables, in that true cause and effect are not necessarily obvious. For instance, is the toxic quality of pore water sulfide sufficient explanation for its negative associations with both the presence and density of wild rice? Do sites with greater density of wild rice have lower pore water sulfide because low sulfide allows wild rice to grow, or because plants release oxygen from their roots, oxidizing sulfide? The true explanation is likely a combination of the two mechanisms: elevated pore water sulfide can eventually extirpate a wild rice

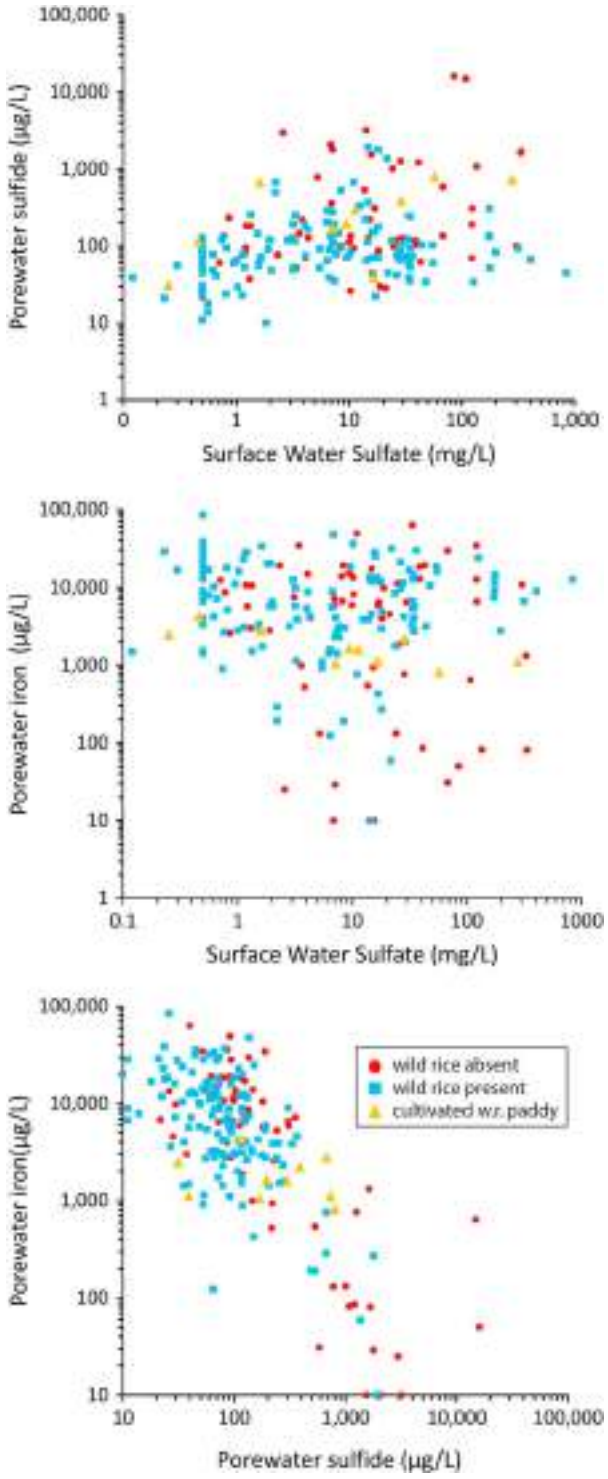

Figure 3. Class D data plus cultivated wild rice paddies (yellow triangles) showing sites with wild rice present (blue squares) and absent (red circles). Note that (a) pore water sulfide is not linearly related to surface water SO_4, indicating that additional factors besides SO_4 concentration contribute to the sulfide concentration in pore water; (b) wild rice can occur in sites over a wide range of surface water SO_4 values as long as pore water Fe is relatively high; and (c) pore water Fe and sulfide have a strong negative relationship, due to the energetically favorable formation of FeS compounds, and that wild rice mainly occurs where pore water sulfide is $<1{,}000\ \mu g\ L^{-1}$.

population by reducing seedling survival and seed production, weight, and viability (Pastor et al., 2017), but oxygen release from roots when sulfide concentrations are low enough to allow wild rice to successfully reproduce drives sulfide to even lower concentrations than would have occurred without the plants (Myrbo et al., 2017). Although the negative correlation between pore water sulfide and wild rice density (rho = -0.31, $p < 0.01$, Table 1) could be interpreted to mean that lower sulfide allows a larger population to grow, it is also possible the correlation is partly caused by oxygen release from the wild rice roots, decreasing sulfide concentrations. This hypothesis is supported by the observation from a controlled experiment that acid-volatile sulfide (AVS) sediment concentrations were 30% lower when wild rice was present (Myrbo et al., 2017).

Of the 12 variables significantly associated with the occurrence of wild rice, we propose that nine are noncausal and merely related to one or more of three truly causative factors: (1) pore water sulfide, (2) water transparency, and (3) water temperature. These three variables are not significantly correlated with one another (Table 1), and there are plausible mechanisms for each to independently exclude wild rice from otherwise suitable habitat: (1) elevated sulfide reduces the growth of wild rice (Pastor et al., 2017); (2) low water transparency plausibly constrains the ability of a germinated wild rice seed to reach sufficient light before it runs out of endosperm energy (Aiken et al., 1988; DNR, 2008); and (3) warmer winter water temperature at lower latitudes may limit seed germination, as the seeds of *Z. palustris* must experience at least 3 months in cold water to break seed dormancy (Kovach & Bradford, 1992) (although summer temperatures were measured in this study, winter and summer temperatures would be correlated).

3.2. Pore Water Sulfide as a Causal Variable and Associated Correlated Variables

Our primary a priori hypothesis was that elevated surface water SO_4 can produce elevated pore water sulfide concentrations which, in turn, negatively affect potential wild rice habitat. A plot of pore water sulfide against SO_4, with wild rice presence noted (Figure 3a), suggests that wild rice is generally not found at sites with elevated sulfide. Of the sites with pore water sulfide greater than 1,000 $\mu g\ L^{-1}$, wild rice was present in 23% (3 of 13, with only a few plants found at 2 of those 3 sites). In contrast, wild rice was present at 74% of the sites where sulfide was less than 1,000 $\mu g\ L^{-1}$. Despite historical reports of *Zizania aquatica* in Minnesota, inspection of voucher specimens, following the taxonomy of Terrell et al. (1997), found only *Z. palustris* at all sites sampled. *Zizania aquatica* (Southern wild rice) is rare in Minnesota, but its range extends east through Wisconsin and the southern part of the Great Lakes region to New England and occurs in freshwater tidal marshes south to Florida and west to Louisiana (Terrell et al., 1997). The findings of this study, especially those related to temperature, may not apply to *Z. aquatica*.

Despite a strong relationship between sulfide and wild rice, the relationship between SO_4 and pore water sulfide among the 108 field sites was not a simple linear function. High surface water SO_4 did not always result in high pore water sulfide (above 1,000 $\mu g\ L^{-1}$), and some samples with surface water SO_4 less than 10 $mg\ L^{-1}$ had pore water sulfide greater

than 1,000 μg L^{-1} (Figure 3a). The 33 samples with surface water SO_4 below 1.0 mg L^{-1} all had pore water sulfide less than 200 μg L^{-1}, suggesting that surface water SO_4 might limit maximum sulfide production.

Wild rice was present at high and low SO_4 concentrations as long as pore water Fe was high and sulfide was low (Figures 3b and 3c): pore water Fe and sulfide each exert antipathetic control over the concentration of the other (Figure 3c; Pollman et al., 2017), and wild rice mainly persists in sites where pore waters are low in sulfide and high in Fe. Pollman et al. (2017) developed a structural equation model showing that variations in three variables (SO_4, sediment TOC, and sediment extractable Fe) contribute nearly equally to the observed variations in pore water sulfide among the sites in this study. Sulfate-reducing bacteria are simultaneously limited in their production of pore water sulfide by surface water SO_4 and sediment TOC (which are roughly proportional to available SO_4 and labile organic matter, respectively). Concentrations of sulfide in pore water are then constrained by the availability of pore water Fe, which is in turn controlled by the overall supply of Fe in the sediment (Pollman et al., 2017).

If pore water sulfide concentration is a causative factor controlling the presence of wild rice, as hypothesized, then other variables may be statistically significant because they either vary with the process of SO_4 reduction or with the sulfide itself. Pastor et al. (2017) showed that wild rice growth declines in proportion to sulfide concentrations in both hydroponic and outdoor mesocosm experiments. In a study of the Pastor et al. mesocosms, Myrbo et al. (2017) showed that the enhanced mineralization of plant litter associated with SO_4 reduction produced increases in surface water P and N, and increases in pore water sulfide caused decreases in pore water Fe. These effects from the controlled mesocosm experiment are consistent with correlations observed among sites in the field data between pore water sulfide and surface water N and pore water Fe (Table 1). Surface water P is not significantly correlated with pore water sulfide in the field data, despite dual mechanisms of P mobilization from sediment, (1) the interaction between sulfide and Fe (Caraco et al., 1993; Maynard, Dahlgren, & O'Geen, 2011; Smolders & Roelofs, 1993) and (2) mineralization of organic matter. The lack of correlation of surface water P with pore water sulfide in this field study is not surprising because given the wide variety of landscapes sampled, there is no reason that pore water sulfide would be proportional to the mass of Fe that has reacted with sulfide and released sorbed P. In SO_4 addition experiments where the P and Fe content of the sediment is held constant, there is often a significant correlation between pore water sulfide and mobilized P (Myrbo et al., 2017). In contrast to the lack of correlation of pore water sulfide with surface water P in this field study, AVS is significantly correlated with surface water P (rho = 0.30, $p < 0.01$, Table 1), presumably because AVS is proportional to the iron that has reacted with sulfide.

Elevated pore water sulfide is a product of SO_4 reduction-driven mineralization of sediment organic matter, which also releases the constituents of the decaying plant material, N, P, K, silica, and C (either as DIC, which increases alkalinity, or DOC) into sediment pore water and the overlying surface water (Myrbo et al., 2017). Consequently, the occurrence of wild rice is negatively associated not only with pore water sulfide ($p = 0.001$) but also with elevated pore water K ($p = 0.0008$) and surface water TN ($p = 0.005$, Table 1). Median concentrations of these variables are lower in wild rice waters compared to waters with no observed wild rice (88 versus 126 μg L^{-1} sulfide, 2.4 versus 4.3 mg L^{-1} pore water K, and 0.74 versus 0.95 mg L^{-1} TN, Table S3). Pore water sulfide is itself positively correlated with pore water K, TN, NH_4, and silica, surface water K, alkalinity, and pH, and sediment TS and AVS (Tables 1 and S4).

The strong evidence for the association of elevated pore water K with the absence of wild rice (Table 1) is interesting, as K is an essential plant nutrient, and therefore, it is unlikely that the association is based on toxicity to wild rice. Rather, it is likely that the association is a result of the simultaneous mobilization of K with the production of sulfide as plant matter is mineralized. Potassium does not bond covalently with organic compounds and is readily leached out of dead organic matter (Troeh & Thompson, 2005). Silica phytoliths dissolve as plant matter is mineralized, allowing additional K that had been trapped within the phytoliths to be released into sediment pore water (Nguyen et al., 2015). Wild rice and other wetland macrophytes develop abundant phytoliths that release dissolved silica upon decomposition (Struyf & Conley, 2009). Additional dissolved silica is likely released to pore water as epiphytic diatoms are mineralized. Pore water silica, K, and sulfide are all significantly correlated with each other (Tables 1 and S5). The negative correlation of pore water K with wild rice may be magnified by its additional positive correlation with elevated water temperature (Table 1), which plausibly accelerates dissolution of silica in organic matter (Gudasz et al., 2010; Kamatani, 1982).

AVS largely consists of solid-phase sulfide, which is not available to plants and therefore is not significantly associated with wild rice presence/absence ($p > 0.10$, Table 1). AVS is a measure of cumulative sulfide production, which is proportional to past mineralization of organic matter, consistent with significant positive correlations between AVS and pore water TP and NH_4, and surface water TP and alkalinity ($p < 0.01$, 0.05, 0.01, and 0.01, respectively, Table 1).

The negative association of sediment total-S (TS) with wild rice presence (BLR $p = 0.048$, Table 1) is likely the result of both TS and wild rice being controlled by sulfide production; the median TS concentration at sites with wild rice is 2.6 mg g^{-1}, compared to 4.1 mg g^{-1} at sites without wild rice (Table S3). Sediment TS is correlated with both pore water sulfide and AVS. The negative association of sediment Se with wild rice (BLR $p = 0.006$) is surprising, given that median Se concentrations are very low (0.9 and 1.2 μg g^{-1} in sites with and without wild rice, respectively). The slightly higher Se at sites without wild rice may be caused by the coprecipitation of Se and S by SRB, as shown by Hockin and Gadd (2003). Selenium is correlated with sediment total S (rho = 0.35; $p < 0.001$).

3.3. Water Transparency as a Causal Variable and Associated Correlated Variables

Lower water transparency is associated with a lower probability of wild rice occurrence (BLR $p = 0.003$). Transparency is not related to wild rice density (rho = 0.11, $p > 0.20$, Table 1); however, low transparency can apparently exclude wild rice (11 of the 12 sites with transparency <30 cm had no wild rice), but above that threshold, other variables control wild rice density. Low water transparency decreases photosynthesis of wild rice seedlings while growing to the water surface, which (a) decreases oxygen production that could otherwise be used to detoxify sulfide internally (Krüssel et al., 2014), or externally if released into pore water from the roots (Colmer, 2003); and (b) decreases the energy available for root development, enhancing vulnerability to a sudden increase in water depth, which can uproot an entire year's cohort (DNR, 2008). Wild rice is unusual among grasses in that the stem develops before the root, probably because the seedling may have to grow over 50 cm before reaching the water surface, at which time floating leaves are developed that can supply energy for root development (Aiken, 1986). If transparency is too low, or the water too deep, the energy stored in the seed can be insufficient for the seedling to reach the water surface.

Water transparency can be controlled by the density of phytoplankton, which was not measured in this study. However, transparency is highly correlated with the nutrient concentrations that control phytoplankton growth, total phosphorus (rho = −0.58, $p < 0.001$), and total nitrogen (rho = −0.61, $p < 0.001$). Transparency can also be controlled by colored dissolved organic matter, consistent with the observed significant correlation between transparency and water color (rho = −0.68, $p < 0.001$, Table S4).

3.4. Temperature as a Causal Variable and Associated Correlated Variables

Wild rice germinates at higher rates following longer exposure at temperatures closer to freezing (Kovach & Bradford, 1992), consistent with the significant association of wild rice absence with lower latitudes (BLR $p = 0.04$) and warmer summer water temperature (BLR $p = 0.008$; medians of 21.9° and 23.7°C with and without wild rice, respectively). Sites with warmer summer water temperatures generally also have warmer winter temperatures. Warmer and shorter winters would cause lower germination rates, ultimately reducing the probability that a population could persist over the long term. For this reason, the Minnesota Department of Natural Resources hypothesizes that climate change may push the range of wild rice farther north (DNR, 2008, 2016). However, the temperature control of wild rice germination has not been adequately investigated to rigorously assess this hypothesis. The observed association of wild rice with lower pH surface waters (BLR $p = 0.04$; median pH values of 7.8 and 8.5 at sites with and without wild rice, respectively) may be due simply to the correlation of wild rice with cooler surface waters: the solubility of CO_2 is higher in colder water, leading to lower pH (Spearman correlation between temperature and pH = 0.35, $p < 0.0001$).

Lower latitude sites are negatively associated with wild rice presence and density (Table 1). Lower latitude sites are correlated with higher water temperature (rho = −0.51, $p < 0.001$). Geological and land use gradients also correlate with latitude, producing correlations with surface water N and P (rho = −0.25 and −0.31, $p < 0.01$). Despite these correlations with nutrients, latitude is not significantly correlated with water transparency (rho = 0.13), so the general unsuitability of lower latitudes for wild rice may be a combination of warmer winters and some reduced transparency as a result of nutrient enrichment. Latitude is not significantly correlated with pore water sulfide (rho = −0.06).

3.5. Synergy Among the Three Causal Variables of Sulfide, Temperature, and Transparency

While temperature may control wild rice presence/absence through winter temperatures too warm to achieve high rates of seed germination in the spring, higher summer temperatures may act synergistically on variables correlated with pore water sulfide. Elevated summer temperatures likely enhance microbial activity, no matter which electron acceptor is respired by the dominant microbes (Gudasz et al., 2010). Water temperature is indeed correlated with pore water concentrations of the plant nutrients N, P, and K released by decomposition, which are also significantly correlated with either pore water sulfide or AVS (Table 1). Although sulfide production may be enhanced by elevated temperature, the correlation between sulfide and temperature is weak (rho = 0.17; $p > 0.05$).

The production of sulfide plausibly contributes to the significant correlation of six of the nine variables with wild rice occurrence: P and N in surface water, Fe and K in pore water, and S and Se in sediment. Water temperature is significantly correlated with three of these variables (P, N, and K), and therefore, synergistically reinforces their associations with the absence of wild rice. Elevated surface water P and N are further synergistically associated with the absence of wild rice because their release via MSR-driven mineralization also enhances phytoplankton growth, reducing light available to wild rice seedlings; P and N are highly correlated with reduced transparency ($p < 0.001$, Table 1).

In this data set greater water depth is negatively associated with the occurrence of wild rice, not because wild rice grows better in shallower water, which it may, but because of where field crews took samples when wild rice was not present. Following a decision tree (Table S1), when wild rice was not present, field crews usually sampled among water lilies, which, on average, were observed in slightly deeper water than wild rice (67 cm compared to 52 cm).

Finally, *multiple* BLR was employed to investigate the question of whether any of the correlated variables provided additional explanatory power for the occurrence of wild rice beyond the models with sulfide, transparency, or temperature as base predictors. Surface water temperature is predictive of wild rice presence independent of sulfide ($p = 0.03$). Pore water K improves models based on sulfide ($p = 0.02$) or temperature ($p = 0.004$) alone but provides no significant additional explanatory power beyond a model built on both sulfide and temperature ($p = 0.07$). Overall, multiple BLR analysis confirms that other variables provide no additional explanatory power and that the three base predictors are independent of each other.

Multiple BLR was used to model the probability of wild rice occurrence (WR presence) as a function of pore water sulfide (pw sulfide, in mg L^{-1}), water transparency as measured by the Secchi tube (trans, in cm), and water temperature (Temp, in °C):

$$\text{Logit}\,(\text{WR presence}) = 0.532 + 0.0183\,(\text{trans}) - 1.169\,(\,\text{log10 pw sulfide}) - 0.107\,(\text{Temp}) \quad (2)$$

where odds = exp(logit) and probability = (odds/(1 + odds)).

Pore water sulfide and water transparency are significant variables in the multiple BLR ($p = 0.012$ and $p = 0.016$, respectively), whereas water temperature is only marginally significant ($p = 0.056$). To visualize the interaction of the variables, a 3-D plot was constructed that predicts the probability of wild rice occurrence as a function of sulfide and transparency, while holding constant the marginally significant variable, temperature, at the median value of the Class B data set (23.2 C; Figure 4). Within the range of variables in Class B, modeled probabilities of wild rice occurrence range from a high of 89.8% (trans = 100 cm, which was the maximum of the measurement device, and pw sulfide = 11 $\mu g\ L^{-1}$, which was the reporting limit) to a low of 9.6% (trans = 3 cm, which was the minimum observed, and pw sulfide = 2,000 $\mu g\ L^{-1}$). Modeling was cut off at a sulfide concentration of 2,000 $\mu g\ L^{-1}$ because only three Class B sites had pore water sulfide greater than 2,000 $\mu g\ L^{-1}$ and none of the three hosted wild rice.

3.6. Field Variables not Evidently Associated With Wild Rice Presence and Absence

Some variables included among the initial hypotheses, or in the past cited as important attributes of wild rice habitat, were not found to be significantly associated with wild rice presence and absence. These include sediment TOC ($p = 0.79$, Figure 2j; DNR, 2008; Lee, 1986; Moyle & Krueger, 1964), flocculent sediment (quantified here as the sediment water content; $p = 0.72$, Figure 2h; DNR, 2008; Lee, 1986; Moyle & Krueger, 1964), sediment N ($p = 0.68$, Table 1; Carson, 2002; Walker et al., 2010), sediment P ($p = 0.27$, Table 1; Carson, 2002; DNR, 2008), and surface water alkalinity ($p = 0.28$, Table 1; Moyle, 1944).

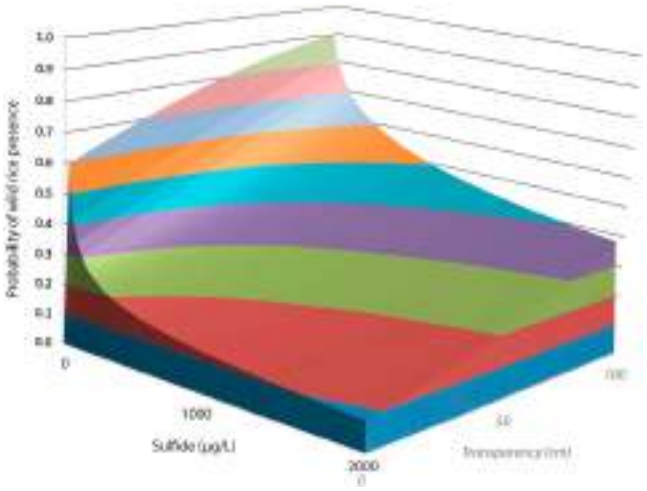

Figure 4. Visualization of the relationship, determined by multiple binary logistic regression, between water transparency and pore water sulfide in controlling the probability of wild rice occurrence at 23.2°C, the median temperature for all sites in the class B data set.

Reduced sediments are generally regarded as producing pore water constituents that are potentially toxic to rooted plants; potentially toxic agents, in addition to sulfide, include ammonia and Fe (Pezeshki & DeLaune, 2012). Analysis of the binary logistic regressions showed no evidence for ammonia toxicity (BLR $p = 0.45$, Figure 2l) or Fe toxicity (wild rice presence is positively correlated with pore water Fe, BLR $p = 0.01$, Figure 2f). As a product of decomposition, ammonia is correlated with pore water sulfide, K, and silica (Spearman correlations $p < 0.001$, Table S4).

The field data provide little evidence that elevated sulfide production excludes wild rice by producing Fe, Cu, or Zn deficiency (Table S3). The possibility that *low* pore water Fe limits wild rice growth is difficult to distinguish from sulfide toxicity because of the strong negative correlation between pore water Fe and pore water sulfide (rho = −0.58, $p < 0.0001$, Table 1). Hydroponic studies using chelated Fe in combination with elevated sulfide (Pastor et al., 2017) show reduced growth, implying that the mechanism is sulfide toxicity, rather than Fe limitation, assuming that the chelated Fe remains bioavailable in the presence of sulfide (Li et al., 2009). The median pore water Fe levels at sites with and without wild rice are similar, 5.7 and 5.9 mg L^{-1}, respectively; average levels are 11.0 and 7.0 mg L^{-1}, respectively, which produced the significant BLR positive correlation between pore water Fe and wild rice presence. On balance, there is little evidence to support the hypothesis that elevated sulfide reduces wild rice growth through Fe deficiency rather than by direct sulfide toxicity. Pore water Cu concentrations were often below the detection limit in the field sites sampled, precluding analysis of their correlation with wild rice presence and absence. The BLR for pore water Zn concentrations with wild rice presence and absence was not statistically significant (data not shown). Neither Cu nor Zn had a significant Spearman correlation with pore water sulfide (data not shown), unlike Fe.

3.7. Seasonality in Field Variables

Fifteen natural wild rice sites were sampled 3 to 5 times in 2013 to determine which field variables exhibit statistically significant seasonal trends that might be important to consider in the overall analysis, given that different sites were sampled in different months. Some variables conformed to expected seasonal trends, such as water temperature ($p = 0.001$), which increased in early summer, peaked about 1 August, and then declined. Some of the surface water variables exhibited monotonic increased concentrations over the summer (alkalinity, Na, Mg, and SO_4; $p = 0.0009$, 0.008, 0.021, and 0.05, respectively). One hypothesis that explains this observation is that waterbodies in Minnesota, after being diluted by spring snowmelt, in general become more concentrated as the summer progresses due to evaporation and, for waterbodies with shorter residence times, greater influence of groundwater flux. Cl and Ca had nonsignificant positive slopes ($p = 0.29$ and 0.37, respectively), whereas K exhibited no trend ($p = 0.48$). As expected, none of the solid-phase variables of the homogenized 10 cm long sediment cores showed any significant seasonal trends (e.g., sediment extractable Fe $p = 0.93$, sediment TOC $p = 0.96$). Among the pore water variables, only K and pH exhibited significant trends. Pore water K values decreased over the summer ($p = 0.006$), likely as a result of diffusion into surface water or uptake by growing rooted macrophytes. Pore water pH generally increased over the summer ($p = 0.003$), which may reflect loss of CO_2 as the sediment warmed over the summer, reducing the solubility of gases. The lack of seasonality in pore water sulfide ($p = 0.62$) indicates that sulfide concentrations were in steady state with the variables that exert primary control over its concentration, surface water SO_4, extractable Fe, and sediment TOC (Pollman et al., 2017). Of the variables controlling pore water sulfide, only SO_4 exhibited even marginally significant seasonal trends ($p = 0.05$, 0.93, and 0.97, for SO_4, extractable Fe, and sediment TOC, respectively). Despite the finding of seasonal variation in SO_4, Pollman et al. (2017) found that SO_4 is one of the primary variables that control pore water sulfide concentrations. Seasonal variation in SO_4 concentrations undoubtedly contributes to noise in the statistical relationship documented by Pollman et al. (2017). Myrbo et al. (2017) found that the microbial production of pore water sulfide in a wild rice sediment is proportional to the long-term average SO_4 surface water concentration.

3.8. Cultivated Wild Rice Paddies

Commercial wild rice paddies have been reported with healthy stands of wild rice growing under surface water SO_4 levels as high as 170 mg L^{-1} (Aiken et al., 1988). Our limited measurements in seven different paddies ranged from 0.3 mg L^{-1} to 279 mg L^{-1} SO_4, with a median of 8.3 mg L^{-1} (n = 7, Table S3). Natural wild rice waters in our study had a median SO_4 concentration of 4.1 mg L^{-1}. Surprisingly, median pore water sulfide in paddies was 182 μg L^{-1}, greater than the medians of natural wild rice waters (88 μg L^{-1}; n = 67) and waters without wild rice (126 μg L^{-1}; n = 41). The median sediment extractable Fe concentration of paddies (4.5 mg g^{-1}) is similar to that of natural wild rice waters (4.8 mg g^{-1}). In contrast, median sediment TOC is much higher in paddies (25.2%) than natural wild rice waters (9.1%). It thus appears that the greater TOC driving enhanced SO_4 reduction (Pollman et al., 2017) and driving median pore water Fe lower than in natural wild rice sediments (1.6 and 5.7 mg L^{-1}, respectively), despite the similar reservoirs of Fe in the sediment. Elevated production of sulfide coupled with the consumption of the available Fe may put some paddies on the brink of sulfide toxicity to wild rice.

However, the physical setting of cultivated wild rice paddies differs from that of natural lakes and streams in a number of important ways. Often paddies and their surface sediments are dewatered during the growing season through use of buried drainage tiles, allowing tillage after harvesting and enhanced aerobic decomposition of rice straw and roots, and possibly reoxidation of sulfide and reduced Fe. Prior to drainage tile installation in the 1980s, failure of wild rice crops was sometimes attributed to elevated sulfide (Grava & Rose, 1975; Gunvalson, personal communication, 2016). Water depth in paddies is also typically shallower (median of 30 cm) than wild rice habitat in natural lakes and rivers (median of 52 cm), allowing seedlings to emerge above water with less energy expended, photosynthesize sooner, and release oxygen from roots to oxidize sulfide. The use of nitrogen fertilizers may further enable seedlings to elongate more quickly through the water and into the air. Fertilized plants have been shown to be more resistant to sulfide toxicity than are control plants (Geurts et al., 2009). The production of sulfide would be inhibited if N fertilizers were applied as nitrate—but N fertilizers are applied as ammonia or urea (Oelke et al., 1997).

3.9. Conclusions and Implications

Analysis of an extensive suite of physical and chemical parameters from 108 different sites with potential wild rice habitat shows that pore water sulfide toxicity is a primary biogeochemical factor controlling the occurrence of wild rice populations in otherwise favorable habitat. High concentrations of pore water sulfide greatly decrease the probability that a wild rice population will be found in a waterbody. When pore water sulfide is low enough to support reproducing wild rice populations, however, it is likely that the relationship between sulfide and wild rice becomes more complicated and analysis of cause and effect more ambiguous. The variation in sulfide concentration is correlated to the density of wild rice, at least partially as a result of oxygen release from roots, and thus, not only does sulfide affect wild rice but wild rice affects sulfide.

Aside from low pore water sulfide, favorable wild rice habitat has long, cold winters and transparent surface water in the ice-free season. *Zizania palustris* seeds germinate at low rates if the winter is too warm or too short. The probability that wild rice seedlings successfully grow to maturity is reduced if photosynthesis is inhibited by low water clarity. Thus, pore water sulfide (itself a function of surface water SO_4, sediment Fe, and sediment organic matter (Pollman et al., 2017)), water temperature, and water transparency together largely determine wild rice presence and absence. These three factors are independent of one another but may act synergistically on other related processes.

In addition to generating sulfide, SO_4 reduction supports organic matter mineralization that releases nutrients and alkalinity to the surface water, which has the potential to change plant community structure even if Fe is high enough to keep pore water sulfide from reaching phytotoxic levels (Myrbo et al., 2017). Natural and anthropogenic SO_4 loading to freshwaters may thus strongly affect ecosystem composition and function, despite the low direct toxicity of SO_4 under oxic conditions.
