

Sarah Kompas

Clean energy is perfect for our area of the Eastern US. To our south of Nantucket are some of the strongest offshore breezes in New England. Wind energy produces zero emissions of greenhouse gases such as carbon dioxide and methane. More and more scientific evidence points to fossil fuel burning as being responsible for major damage to the atmosphere by the release of carbon dioxide and methane.

With a power rating at completion of all of its phases of 2,000 to 2,300 megawatts, Vineyard Wind South would displace over 2 million tons of CO₂ per year and power about a million homes and businesses annually. This would be like taking almost 1 million cars off the road annually.
